Welcome to the EANM Congress 2016 in Barcelona

With great pleasure the European Association of Nuclear Medicine welcomes you to its 29th Annual Congress in Barcelona, Spain.

The Annual EANM Congress 2016 offers attendees from all over the world the broad perspective on basic, translational and clinical science that makes nuclear medicine such an exciting and vibrant profession. The EANM Committees have made a tremendous effort to put together a high-quality program for you to attend. You will not only recognize the traditional elements that make our meeting stand out, but also some novelties to further enhance your experience during the meeting. Next to the clinicians, scientists and technologist in nuclear medicine, we are especially proud to extend a special welcome to the numerous guests from outside our community, who will deliver lectures and discuss multimodality molecular imaging, therapy, physics, basic science, technology from their perspective.

The 2016 plenary sessions will traditionally open on Sunday, October 16 with Clinical Molecular Imaging (including the Marie Curie Lecture by Prof. Sally Barrington from London, UK on the role of nuclear medicine in malignant lymphoma), followed by "Radiation – facts and figures" on Monday, October 17. As part of the M2M - Molecule to Man track, which has rapidly expanded to a track running over the full duration of the meeting, the plenary session on Tuesday, October 18 will focus on New Developments in Cancer Imaging and Therapy. We are honored that Prof. Maria Blasco, one of leading scientists in cancer research, will give a lecture based on her world-class research. The traditional conclusion of the meeting on Wednesday, October 19 will be the Highlights Lecture, presented by Prof. Francoise Kraeber-Bodéré and Prof. Eric Aboagye.

The joint efforts of the EANM Committees will be visible throughout the congress. Multi-committee collaborations are reflected in the Molecule to Man (M2M) track which addresses basic and translational research and in the Dosimetry and Molecular Radiotherapy (Do.MoRe) tracks. Both tracks will run throughout the Congress. To highlight the best proffered papers in M2M and Do.MoRe tracks, both tracks will feature a Rapid Fire session chaired by distinguished experts in the field, in which the authors of the very best papers in these tracks are invited to give a short plenary pitch of their work, followed by discussions with you while gathering around posters detailing the work. The third Rapid Fire session will again summarize the best presentations in field of clinical oncology.

You will experience the best that clinical, translational and fundamental nuclear medicine has to offer in an open, truly multidisciplinary setting that is characterized our profession. The Scientific Program Committee, representing all EANM Committees, received a total of 2201 abstracts, of which 1881 were accepted for oral sessions (509 presentations) or poster sessions (1372 presentations). For the first time the EANM Congress will feature the Presidential session, a one-of-a-kind session during the meeting presenting you works of excellence and late-breaking science.

In the pre-congress and the joint symposia, a large number of experts from disciplines outside nuclear medicine together with experts from the EANM Committees will provide new data and will share with you how nuclear medicine contributes to better science and enhanced patient care throughout the areas in which nuclear medicine is active. A special symposium on radionuclide therapy has been organized by Dr. Savvas Frangos, commemorating the pioneering work of Prof. Saul Hertz, who performed the first radioiodine treatment of thyroid disease 75 years ago.

In collaboration with the European School of Nuclear Medicine, the EANM Committees organized a full track of CME sessions, again featuring many interactive sessions. As hybrid imaging is one of the core contributions of nuclear medicine to today's patient care, educational lectures on cross-sectional imaging to support interpretation of molecular imaging are an important part of the educational program. The EANM Technologist Committee contributes to a successful meeting with a full parallel program of oral and poster sessions as well as Continuing Technologist Education (CTE) sessions and courses.

It has been a true privilege for me to be allowed to act as your Congress Chair for the EANM'16 Congress. The content of the meeting reflects the team work of many professionals in our field who have devoted time and effort to deliver the program in all its diversity. I am very grateful to all members of the EANM Committees, the staff of the EANM Executive Office, all speakers and session chairs and everyone involved in putting this meeting together.

On behalf of the EANM community, I welcome you to the 29th EANM Congress Barelona'16. I sincerely hope that you will enjoy, discuss, learn and get inspired for the bright future of our profession and that you will appreciate the many wonderful features that Barcelona has to offer.

Prof. Dr. Wim J. G. Oyen
EANM Congress Chair 2014-2016

Saturday, October 15, 2016

Oral Sessions

PS1 – Saturday, October 15, 2016, 09:00 - 16:00, Hall 115
Pre-Congress Symposium 1: Imaging for Therapy with Statistical SPECT/PET Reconstruction

PS01
General Introduction on Pre-Therapy Imaging for Predicting Biodistribution under Therapy
G. Glatting; Medizinische Fakultät Mannheim der Universität Heidelberg, Medizinische Strahlenphysik/Strahlenschutz, Mannheim, GERMANY.

PS02
Introduction to Problems Related to Quantitative Imaging of SPECT and PET
M. Ljungberg; Lund University, Dept Medical Radiation Physics, Lund, SWEDEN.

PS03
Statistical Reconstruction Methods
M. Defrise; UZ Brussel, Department Nuclear Medicine, Brussels, BELGIUM.

PS04
Compensation Methods in Statistical Reconstruction Methods
H. de Jong; UMC Utrecht, Utrecht, NETHERLANDS.

PS05
Quantitative Y-90 PET Imaging
H. de Jong; UMC Utrecht, Utrecht, NETHERLANDS.

PS06
Quantitative Y-90 SPECT Bremsstrahlung Imaging
M. Ljungberg; Lund University, Dept Medical Radiation Physics, Lund, SWEDEN.

PS07
Quantitative Lu-177 SPECT Imaging
K. Sjögreen Gleisner; Lund University Hospital, Clinical Sciences, Lund, Medical Radiation Physics, Lund, SWEDEN.

PS08
Quantitative I-124 SPECT Imaging
W. Jentzen; Klinik für Nuklearmedizin, Essen, GERMANY.

PS09
Quantitative I-131 SPECT Imaging
Y. K. Dewaraja; University of Michigan, Department of Radiology, Ann Arbor, UNITED STATES OF AMERICA.

PS10
Developments in New Hardware
S. Walrand; Saint-Luc, Université Catholique de Louvain, Nuclear Medicine Center, Brussels, BELGIUM.

PS2 – Saturday, October 15, 2016, 09:00 - 12:00, Hall 111
Pre-Congress Symposium 2: Radionuclide Therapies of Brain Tumours

PS12
WHO 2016 Classification of CNS Tumours; Incorporation of Diagnostic and Prognostic Molecular Markers
P. Wesserling; Radboud UMC, Nijmegen, NETHERLANDS.

PS13
Challenges in Imaging for Diagnosis and Management of Brain Tumours
A. Waldman; Charing Cross Hospital, Department of Imaging, London, UNITED KINGDOM.

PS14
The Potential of PET for Guiding Therapy in Brain Tumours
K. Herholz; University Of Manchester, Wolfson Molecular Imaging Centre, Manchester, UNITED KINGDOM.

PS16
Surgical Management with Standard Techniques and New Approaches
J. Barcia; Hospital Clínico San Carlos, Department of Neurosurgery, Madrid, SPAIN.

PS17
Treatment Management in Adults and Children with Brain Tumours - Insight on Clinical Trials
A. Salmaggi; Ospedale di Lecco, Lecco, ITALY.

PS18
Radiotherapy and Brain Tumours - How and When?
A. L. Grosu; University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, GERMANY.

PS19
Radionuclide Therapy in Brain Tumours
F. Forrer; Kantonsspital St. Gallen, Department of Radiology and Nuclear Medicine, St. Gallen, SWITZERLAND.

PS4 – Saturday, October 15, 2016, 09:00 - 12:00, Hall 116
Pre-Congress Symposium 4: Myocardial Perfusion Imaging in Clinical Routine - From SPECT/PET to Hybrid Imaging

PS20
How to Speak Cardiology - Risk Factors, Medications, the ECG, Stress Testing
H. Verberne; Academic Medical Center, Department of Nuclear Medicine, Amsterdam, NETHERLANDS.

PS21
Clinical Indications for SPECT and PET MPI - Patient Selection delete etc.
D. Wolinsky; Cleveland Clinic Florida, Weston, UNITED STATES OF AMERICA.

PS22
SPECT/CT and PET/CT Hybrid Imaging - How and When?
S. Dorbala; Brigham and Women's Hospital, Department of Radiology, Boston, UNITED STATES OF AMERICA.

PS23
Patient-Centered Imaging and Radiation Dose Reduction Strategies
E. Depuey; Mount Sinai Hospital, New York, UNITED STATES OF AMERICA.

PS24
Case Review - A Systematic Approach to Interpreting and Reporting MPI SPECT(/CT)
A. Todica; Klinikum Großhadern, University of Munich, Departement of Nuclear Medicine, Munich, GERMANY.

PS25
Case Review - A Systematic Approach to Interpreting and Reporting MPI PET(/CT)
R. Sciagra; University of Florence, Department of Nuclear Medicine, Florence, ITALY.

PS26
Effective Reporting for Patient Risk Stratification and Management
B. Abbott; Rhode Island Hospital, East Greenwich, UNITED STATES OF AMERICA.

PS6 – Saturday, October 15, 2016, 09:00 - 12:00, Hall 113
Pre-Congress Symposium 6: Advances in Hybrid Imaging in Musculoskeletal Infections

PS28
What do Clinicians Wants to Know from the Imaging Specialists?
P. Jutte; Orthopaedic Surgery, University Medical Center Groningen, Groningen, NETHERLANDS.

PS29
New Available Tests to Diagnose Musculoskeletal Infections
A. Cataldo; National Institute for Infectious Diseases, Clinical Department, Rome, ITALY.

PS30
Radiologic Imaging of Musculoskeletal Infections
V. Cassar-Pullicino; The Robert Jones and Agnes Hunt Orthopaedic Hospital, Department of Diagnotic Imaging, Oswestry, UNITED KINGDOM.

PS31
Hybrid Imaging of the Painful Joint
W. van der Bruggen; Slingeland Ziekenhuis, Dept. Radiology and Nuclear Medicine, Doetinchem, NETHERLANDS.

PS32
Imaging the Painful Spine (Including the New Joint Society Endorsed Guidelines for Imaging Spondylodiscitis)
E. Lazzeri; Centro Regionale Medicina Nucleare, Azienda Ospedaliero Universitaria Pisana, Pisa, ITALY.

PS33
Imaging Peripheral Bone Infection (Including the New Joint Society Endorsed Guidelines)
A. Glaudemans; University Medical Center Groningen, Nuclear Medicine and Molecular Imaging, Groningen, NETHERLANDS.

PS34
Imaging Prosthetic Joint Infection (Including the New Joint Society Endorsed Guidelines)
O. Gheysens; KU Leuven, Leuven, BELGIUM.

PS8 – Saturday, October 15, 2016, 09:00 - 16:00, Hall 114
Pre-Congress Symposium 8: Challenging the Brain: Imaging Neurotransmitter Release

PS36
Radiotracers for Measuring Endogenous Neurotransmitter Release
C. Halldin; Psychiatry Section, Department of Clinical Neuroscience, Stockholm, SWEDEN.

PS37
Methodological Considerations for Measuring in Vivo Neurotransmitter Release
A. Lammertsma; VU University medical center, Department of Nuclear Medicine & PET Research, Amsterdam, NETHERLANDS.

PS39
Striatal Dopamine Release - From Pharmacologic to Non-Pharmacologic Challenges
J. Booij; Academic Medical Center, Nuclear Medicine, Amsterdam, NETHERLANDS.

PS40
Extrastriatal Dopamine Release
E. van de Giessen; Academic Medical Center, University of Amsterdam, Nuclear Medicine, Amsterdam, NETHERLANDS.

PS42
Serotonin Release - Promises and Pitfalls
G. Knudsen; Copenhagen University Hospital Rigshospitalet, Neurobiology Research Unit 9201, Copenhagen, DENMARK.

PS43
New Ways to Image Noradrenaline
S. Finnema; Yale University, PET Center, New Haven, UNITED STATES OF AMERICA.

PS45
Measuring Endogenous GABA Release
J. Myers; Imperial College London, Division of Brain Sciences, Centre for Neuropsychopharmacology, London, UNITED KINGDOM.

PS46
Effects of Psychotropic Medications on the Developing Brain (ePOD) - A Case for Pharmacological MRI
L. Reneman; Academic Medical Center, Department of Radiology, Amsterdam, NETHERLANDS.

PS3 – Saturday, October 15, 2016, 13:00 - 16:00, Hall 111
Pre-Congress Symposium 3: Strategies in Endocrine Tumours

PS49
Novel Developments in Adrenocortical Carcinoma
C. Bluemel; University of Wuerzburg, Wuerzburg, GERMANY.

PS50
F-18-Choline-PET/CT vs MIBI-Scintigraphy in Parathyroid Adenomas
W. Langsteger; St Vincent's Hospital, PET - CT Center LINZ, Nuclear Medicine & Endocrinology, Linz, AUSTRIA.

PS51
Renaissance of Redifferentiation in Thyroid Cancer
J. Nagarajah; University Hospital Essen, Nuclear Medicine, Essen, GERMANY.

PS52
New MTC Guidelines and Role of Nuclear Medicine
G. Treglia; Oncology Institute of Southern Switzerland, Bellinzona, SWITZERLAND.

PS53
Low versus High Activities in Ablation - Open Discussion
U. Mallick; FREEMAN HOSPITAL, NCCC, ONCOLOGY, Newcastle Upon Tyne, UNITED KINGDOM.

PS54
Low versus High Activities in Ablation - Open Discussion
F. A. Verburg; University Hospital Aachen, Dept. of Nuclear Medicine, Aachen, GERMANY.

PS5 – Saturday, October 15, 2016, 13:00 - 16:00, Hall 116
Pre-Congress Symposium 5: Multimodality Imaging – Opportunities and Challenges

PS56
Multimodality Imaging – Opportunities and Challenges – General Aspects
G. van Dam; University of Groningen, Groningen, NETHERLANDS.

PS57
Opportunities and Challenges of Compounds for Multimodality Imaging

PS58
In Vivo Imaging of Tumor Metabolism and Acidosis by Combining PET and MRI-CEST pH Imaging
S. Aime; Molecular Imaging Center, Torino, ITALY.

PS59
Combined Optical and Nuclear Medicine Imaging
W. Cai; University of Wisconsin-Madison, Department of Radiology and Medical Physics, Madison, UNITED STATES OF AMERICA.

PS7 – Saturday, October 15, 2016, 13:00 - 16:00, Hall 113
Pre-Congress Symposium 7: Radionuclide Support Crisis – An Update: what will happen?

PS61
Global Update on Mo-99
S. Schwarz; Washington University School of Medicine, Washington, UNITED STATES OF AMERICA.

PS62
Overview from the European Industrial Perspective
J. VANDERHOFSTADT; I.R.E., Fleurus, BELGIUM.

PS63
Cyclotron-Produced Tc-99m
R. Harper; Centre for Probe Development and Commercialization Hamilton Health Sciences, Hamilton, CANADA.

PS64
Alternative Cyclotron-Produced Radionuclides
L. Perk; Radboud university medical center, Radboud Translational Medicine, Nijmegen, NETHERLANDS.

101 – Sunday, October 16, 2016, 08:00 - 09:30, Auditorium
CME 1 - Paediatrics/Oncology/ELI: PET in Lymphoma: What are the New Fields in Adult and Paediatric Practice?

OP001
Early Response PET in Paediatric Lymphoma - Qualitative Criteria or qPET?
R. Kluge; Universität Leipzig, Klinik und Poliklinik für Nuklearmedizin, Leipzig, GERMANY.

OP002
PET in Peripheral T Cell Lymphoma
A. Cottereau; Henri Mondor, Nuclear Medicine, Paris, FRANCE.

OP003
PET Combined with Biological Data in Lymphoma
A. Gallamini; A. Lacassagne Cancer Center, Research, Innovation and statistics department, Nice, FRANCE.

Personalized treatment planning in radioembolization of Hepatocarcinoma with 90 Y glass microspheres: update of clinical outcomes in the Milan experience

M. Maccauro[1], C. Spreafico[2], C. Chiesa[1], M. Mira[1], M. De Nila[1], R. Romito[3], C. Morosi[2], C. Sposito[3], S. Bhoori[3], G. Aliberti[1], E. Seregni[1], G. Tagliabue[4], F. Crippa[1], A. Marchianò[2], V. Mazzaferro[3]; [1]Department of Nuclear Medicine, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Milan, ITALY, [2]Department of Radiology, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Milan, ITALY, [3]Department of Surgery, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Milan, ITALY, [4]Department of Epidemiology, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Milan, ITALY.

Aim: to compare the clinical outcome of radioebolization (TARE) with ^{90}Y glass microspheres in Hepatocarcinoma (HCC), after ^{99m}Tc-MAA SPECT personalized treatment planning with respect to the standard "120 Gy to lobe" glass microspheres indication. **Methods:** two sequential cohorts of intermediate/advanced HCC patients were treated. 52 patients (cohort 1) were enrolled in a phase II prospective study (Mazzaferro Hepatology 2013) with tight exclusion criteria: tumor burden >50%, anti-tumor therapy including drug treatment within 30 days before TARE, previous TACE, complete PVT. Therapeutic activity was chosen according to the standard indications (120 Gy to lobe). 166 sequential "real life" patients were enrolled in cohort 2. Child A of this cohort were treated according to a ^{99m}Tc-MAA SPECT personalized treatment planning. This aimed to the maximal tumor dose with a dose limit to whole parenchyma of 75 Gy, in order to keep the liver decompensation rate below 15%, as obtained in cohort 1. Further dose reduction for Child B cases was applied. For a meaningful comparison, we tried to identify a subcohort 2 of 110 patients, homogeneous to cohort 1, applying retrospectively most of the exclusion criteria of cohort 1: complete PVT, tumor burden >50%, concomitant sorafenib. Patients with previous TACE were included. Liver decompensation within 6 months was considered excluding cases clearly attributable to progression. **Results:** Treatment related liver decompensation rate in Child A patients of subcohort 2 (15/106=14%) was maintained as in cohort 1 (6/43=14%), as programmed.The median overall survival of subcohort 2 was identical to cohort 1: 15 months, 13 months for PVT and 17 months for non PVT patients. **Discussion:** The absence of the expected gain in survival is attributed to tumor volumes of subcohort 2 of double size than in cohort 1. Lesion volume in subcohort 2 versus cohort 1 were average 186 cc vs 93 cc, median 70 cc versus 22 cc ($p<0.001$); for non PVT median 49 cc versus 9 cc ($p=0.001$) and for PVT, median 83 cc vs 31 cc ($p=0.02$). **Conclusion:** Personalized treatment planning was able to maintain the same overall survival and toxicity rate previously obtained with standard method, despite patient of subcohort 2 were less selected, representing the real life, and with twice larger lesion volumes. In order to validate the impact of personalized treatment planning on patient outcome, we recommend a new setting of a randomized study, with deep attention to many clinical details.

OP012

Subjective vs Objective Y90 dosimetry based on MAA

M. Tann[1], P. Haste[1], V. Aaron[1], T. Laroche[1], T. Mauxion[2], M. R. Dreher[2], S. Persohn[1], M. S. Johnson[1]; [1]Indiana University Health, indianapolis, IN, UNITED STATES, [2]BTG, London, UNITED KINGDOM.

Distribution of ^{99m}Tc-MAA and ^{90}Y Glass Microspheres in Hepatocellular Carcinoma: A Subjective Versus Objective Analysis

Aim: The ideal radioembolization treatment provides optimal therapeutic dose to the tumor without exceeding the tolerable dose to normal liver tissue. Pre-treatment personalized dosimetry, based on the absorbed dose distribution calculated from ^{99m}Tc-MAA, shows potential for improving radioembolization treatment. Currently, most pre-treatment absorbed dose (AD) calculations assume that ^{99m}Tc-MAA and ^{90}Y have the same distribution. These assumptions are mainly based off subjective similarities in appearance. Our goal was to compare subjective analysis of the distribution of ^{99m}Tc-MAA and ^{90}Y, in both tumor and whole liver normal tissue (WLNT), with objective absorbed doses calculated from 99mTc-MAA/SPECT and ^{90}Y PET/CT. Material/Methods: From 2013-2014, 84 patients with HCC underwent ^{90}Y glass microsphere radioembolization with pre-treatment ^{99m}Tc-MAA SPECT and post-treatment ^{90}Y PET/CT. SPECT, PET, and CT images were fused (3 blinded reviewers) and the WLNT and the largest lesions (5 lesions maximum) were segmented (MIM software Inc.). The AD was calculated using the MIRD methodology. Two Nuclear Medicine radiologists then subjectively evaluated the SPECT and PET images and graded tumor to background uptake (4 point scale) for all tumors on both SPECT and PET. Direct subjective comparison between ^{99m}Tc-MAA and ^{90}Y, in both tumors and WLNT, was performed using a 3 point scale (complete/near complete, moderate, poor/no agreement). Objective and subjective agreements between reviewers and between ^{99m}Tc-MAA and ^{m}Y (Bland Altman - 95% limit of agreement [LoA], Non parametric Kruskal-Wallis, Mann-Whitney and Wilcoxon tests) were analyzed. Results: Objective analysis demonstrated a clinically acceptable LoA between ^{99m}Tc-MAA and ^{90}Y for WLNT AD (LoA= [-15;15] Gy; Bias=0 Gy). However, the LoA for tumor AD was deemed clinically unacceptable

(LoA= [-355;327] Gy; Bias=-14Gy). Subjectively, 87%±3% of patients show either moderate to complete agreement between 99Tc-MAA and 90Y distribution for WLNT and 90%±5% of patients show moderate to complete agreement in distribution within tumors. Agreement between reviewers was found clinically acceptable but non-statistically significant ($p>0.05$). We also found a significant correlation between AD and subjective tumor to background uptake for both agents ($p<0.05$), particularly for one reviewer ($p<0.001$). Conclusion: ^{99m}Tc-MAA and ^{90}Y demonstrate a subjectively similar distribution, in both tumors and WLNT, for the majority of the cases. However, this subjective similarity does not match the poor objective agreement between ^{99m}Tc-MAA and ^{90}Y in tumors. Importantly, the objective correlation between ^{99m}Tc-MAA and ^{90}Y in WLNT is clinically acceptable, agreeing with the subjective impressions.

OP013

Downstaging intermediate and advanced HCC using radioembolization therapy, a difficult but achievable strategy

M. Manfredi[1,2], P. Carbonatto[1], A. Codegone[1], E. Richetta[1], M. Tabone[1], R. E. Pellerito[1]; [1]Azienda Ospedaliera Ordine Mauriziano, Torino, ITALY, [2]Azienda Ospedaliero-Universitaria Città della Salute e della Scienza, Torino, ITALY.

In patients with unresecable hepatocarcinoma (HCC) due to portal venous thrombosis, large or multifocal tumour, or vascular proximity, Y-90 radioembolization (TARE) results in a good benefit in overall survival (OS). This approach also raises the possibility of patient downstaging, showing promising results in allowing salvage surgery for large HCCs, as evaluated in this prospective pilot study. Between 2011 and 2014, 22 patients with HCC unsuitable for chemoembolization, showing conserved liver function and good performance status, were enlisted to receive TARE with downstaging purpose. According to hepatic angiography and Tc-99M scintigraphy, due to technical reasons, TARE was not feasible for 5 patients, that received the best possible care. The remaining 17 patients underwent one or more TARE treatments and were re-evaluated for restaging. The downstaging was possible in 5 out of 17 cases: 4 patients underwent resection surgery and 1 underwent transplantation. On the opposite, surgery was not possible for the other 12 patients, in 11 cases for insufficient tumor regression, unsuitable tumor localization or pathology progression, while in the remaining patient the transplantation was feasible, but no liver was available leading the patient to suffering from pathology progression. All the patients were followed until death or until March 2016. This prospective pilot study defines three subgroups of patients with significant differences in OS (Log-rank test P= 0,03): (1) the ones that are not suitable for TARE, with no other possible therapy than Sorafenib or palliative treatments, probably due to a more aggressive pathology, as suggested by significantly higher Alpha-fetoprotein and tumor dimension compared with the other groups (median survival: 11 months); (2) the ones that, despite TARE treatment, did not achieve surgical requirements, showing better survival rates, comparable to chemioembolization treatment (median survival: 17 months); and (3) a group that following TARE had access to surgery, that showed the better OS with more than 50% patients alive at the end of the study. In conclusion, downstaging was possible in a small subgroup of patients, moreover TARE treatment alone was sufficient to increase survival. This study suggests a new possible approach for the treatment of intermediate and advanced HCC that, although not validated by extensive studies, can be safely applied in centers where TARE is available, following accurate selection of patients. However, further investigation is needed, to better define the HCC population in which TARE could lead to surgery.

OP014

Dose-Response Relationship Evaluation in Selective Intraarterial Radionuclide Therapy

N. Alan Selcuk[1], T. Toklu[1], S. Karaaslan[2], A. Ozgen[3], O. Eren[4], L. Kabasakal[5]; [1]Yeditepe University Hospital, Dept. of Nuclear Medicine, Istanbul, TURKEY, [2]Yeditepe University, Dept. of Physics, Istanbul, TURKEY, [3]Yeditepe University Hospital, Dept. of Radiology, Istanbul, TURKEY, [4]Yeditepe University Hospital, Dept. of Oncology, Istanbul, TURKEY, [5]Istanbul University, Cerrahpasa Medical School, Dept. of Nuclear Medicine, Istanbul, TURKEY.

Aim: To evaluate dose-response relationship in transarterial radioembolization (TARE) using microspheres loaded with Yttrium-90 in the treatment of primary and metastatic tumors of the liver. Methods: A retrospective analysis were performed on 25 adult patients with primary (4 patients) and secondary (21 patients) tumors of the liver who underwent 39 course of treatment. Twenty-nine of them were standard TARE and 10 were superselective TARE. Four patients had primer liver cancer, 8 patients had metastasis of colorectal carcinoma, 4 patients had metastatic breast carcinoma, 3 patients had gastric cancer and 6 patients had other cancer with liver metastases. Tumor, healthy injected liver dose (HILD) and total healthy whole liver doses (HWLD) were evaluated. Doses were calculated using Medical Internal Radiation Dosimetry (MIRD) with partition model. Treatment results were grouped as complete or partial response, and progression of disease in the targeted area. Dose values were compared in these two groups. Follow-up of the patients were made by using PET-CT and contrast enhanced magnetic resonance imaging and/or computed tomography. Results: Mean follow-up time was 7.8 months. Progression was observed in 7 patients, while complete or partial response were detected in the rest of the patients. Four patients were died because of extrahepatic disease while one was died due to liver failure during follow-up. Mean tumor dose, HILD and HWLD were 204.7±77.2 Gy, 72.2±20.3 Gy and 25.4±13.0 Gy, respectively. Radiation induced liver disease (RILD) was not observed in any patient. Mean tumor dose was 183.3±65.5 Gy in progressive group while 207.1±79.2 Gy in responsive group. Conclusion: According to our results, minimum of 200 Gy tumor dose seems to be necessary for a successful treatment, although statistically significant difference in tumor doses was not observed. HILD of up to 110 Gy is generally tolerated by liver.

OP015

Correlation Between Pre-Treatment ^{99m}Tc-MAA SPECT and Post-Radioembolization ^{90}Y PET

N. M. Maughan, K. J. Fowler, R. Laforest, A. Sharma, J. Olsen, C. K. Speirs, T. DeWees, S. Markovina, P. J. Parikh, N. E. Saad; Washington University in St. Louis, Saint Louis, MO, UNITED STATES.

Aim: In this study, we investigated the role of pre-treatment ^{99m}Tc-MAA SPECT to predict individual lesion response, as well as its correlation with post-treatment PET. Materials and Methods: 22 patients who received standard-of-care pre-treatment ^{99m}Tc-MAA SPECT/CT, ^{90}Y radioembolization, and follow-up imaging at our institution were included in this retrospective analysis. Patients received a PET/MRI after radioembolization according to an IRB-approved protocol. Regions of interest were drawn and approved by a board-certified radiologist on the contrast-enhanced MRI from PET/MRI and on 3-6 month follow-up imaging. We classified response based on vRECIST criteria. Both ^{90}Y PET and ^{99m}Tc-MAA SPECT images were rigidly registered and fused to the contrast-enhanced MRI. Dose from ^{90}Y PET was calculated by convolving the activity with a dose point kernel (DPK), with dose from the lower resolution ^{99m}Tc-MAA SPECT calculated using the local deposition method. Dose was normalized and scaled according the amount of

delivered ^{99m}Tc-MAA and ^{90}Y activities, respectively. Dose metrics previously shown to be predictive of response—D70 and $D_{average}$—were compared between ^{99m}Tc-MAA SPECT and ^{90}Y PET using Spearman's Correlation test. D70 and $D_{average}$ from ^{99m}Tc-MAA SPECT and ^{90}Y PET were also assessed for their ability to predict response using Logistic Regression. Results: A total of 83 lesions were identified in both PET/MRI and follow-up imaging: 41 metastatic colorectal cancer (mCRC), 39 hypervascular lesions (hepatocellular carcinoma, neuroendocrine tumor, and thymic carcinoid), and 3 metastatic esophageal cancer. D70 and $D_{average}$ were correlated between SPECT and PET for hypervascular lesions ($r=0.53$ and 0.57, $p<0.05$) and for mCRC ($r=0.31$ and 0.36, $p<0.05$). While D70 and $D_{average}$ from ^{90}Y PET were predictive of response in mCRC ($p<0.05$), neither of these dose parameters from ^{99}Tc-MAA SPECT were predictive of response in any group ($p>0.05$). There was a strong and significant correlation for $D_{average}$ in the treated lobe of the liver between ^{99m}Tc-MAA and ^{90}Y ($r=0.89$, $p<0.0001$). Conclusion: The strong correlation for $D_{average}$ in the treated lobe of the liver between ^{99m}Tc-MAA and ^{90}Y may be useful for estimating possible toxicity levels. The weaker correlation between tumor dose measured on the two modalities suggests that the pre-treatment ^{99m}Tc-MAA SPECT may be useful for qualitative predictions of microsphere distribution but not for quantitative predictions of lesion response. This may be due to changes in liver blood flow or catheter position. This study further emphasizes the unique role of post-treatment dosimetry in ^{90}Y radioembolization.

OP016

Usefulness of ^{99m}Tc-MAA scan for ^{90}Y-Radioembolization planning in 532 patients

L. Sancho, M. Rodríguez-Fraile, E. Prieto, V. Morán, D. Martinez-Urbistondo, D. Martinez-Urbistondo, M. Iñarrairaegui, J. Martí-Climent, J. Arbizu, J. Bilbao, B. Sangro; Clínica Universidad de Navarra, Pamplona, SPAIN.

AIM: To determine whether ^{99m}Tc-MAA scan results that will contraindicate ^{90}Y-Radioembolization as it was initially designed can be predicted from baseline patient and tumor characteristics. *MATERIALS AND METHODS*: A single-centre retrospective study of patients that underwent ^{99m}Tc-MAA scan planning for radioembolization using ^{90}Y resin microspheres was conducted between 2006 and 2015. Baseline tumor and patient characteristics were compared between the group of patients in which the results of ^{99m}Tc-MAA scan led to contraindication of ^{90}Y-Radioembolization and the group that was treated as initially planned. Patients were dismissed as the result of the ^{99m}Tc-MAA for three main causes, two objective ones [high lung shunt fraction (HLSF) and extrahepatic uptake (EU)] and a single subjective one [mismatch between ^{99m}Tc-MAA and intrahepatic tumor distribution (MM)]. Variables that carried an independent risk of resulting in contraindication were identified by logistic regression analysis. The ability of these variables to predict contraindication was obtained. *RESULTS:* A total of 532 patients (365 males) with hepatocellular carcinoma (n=217), cholangiocarcinoma (n=31) and liver metastases from colorectal cancer (n=142), neuroendocrine tumors (n=49), or other tumors (n=93) were identified. ^{90}Y-Radioembolization was contraindicated in 48 patients as the result of the ^{99m}Tc-MAA scan findings due to objective causes [HLSF (n=29) or EU (n=19)] and in 73 patients as a result of subjective causes (MM). For objective dismissal, an association was found between HLSF and vascular invasion (VI) (OR 5,58[95%CI:2,56-12,2] p<0,01) and for EU the association was found with the presence of secondary tumors (ST) (OR 3,6 [95%CI:1,75-7,39] p<0,01) and prior intraarterial chemotherapy (OR 2,3 [95%CI:1,06-4,9] p<0,01). The negative predictive value (NPV) for VI and high LSF was 97%, for ST and EU was 99% and for both of them versus contraindication was 92%. Variables significantly related with the subjective cause of dismissal (MM) were the presence of uninodular tumors (OR 0,839 [95%CI: 1,227-4,367] p<0,01) and prior antiangiogenic drugs (OR 1,036 [95%CI:1,583-5,018] p<0,01), both of them with a NPV of 89%. *CONCLUSION:* The presence of vascular invasion, secondary tumors, uninodular tumors and antiangiogenic drugs independently predicted ^{90}Y-Radioembolization contraindication based on the results of the ^{99m}Tc-MAA scan. Nevertheless, the lack of strong discrimination power emphasizes the value of ^{99m}Tc-MAA scan in the workup of ^{90}Y-Radioembolization. The absence of either of them identifies a group of patients with very low risk of contraindication. However, the severity of complications encourage the use of ^{99m}Tc-MAA scan.

OP017

Advancing Post-Radioembolization Yttrium-90 Imaging: The Clinical Impact of Time-of-Flight in Next-Generation Digital PET/CT versus Conventional PET/CT Systems

C. L. Wright[1], K. Binzel[1], J. Zhang[1], E. Wuthrick[1], P. Maniawski[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Philips Healthcare, Cleveland, OH, UNITED STATES.

Aim: Yttrium-90 (^{90}Y) microspheres are used to selectively embolize tumor-associated neovasculature as well as deliver therapeutic doses of radioactivity to unresectable malignant/metastatic liver lesions (radioembolization). Bremsstrahlung is currently used for post-therapy detection of ^{90}Y microsphere radioactivity, but is limited by poor ^{90}Y-to-background contrast and quantitative dosimetry. ^{90}Y produces a small fraction of annihilation photons which can be imaged using conventional photomultiplier tube-based PET (cPET). New, solid-state, digital photon counting PET (dPET) detectors produce best-in-class time of flight (ToF) timing resolution, ~325 ps. This study evaluates the clinical impact of ToF on image quality and post-therapy volumetric assessment of ^{90}Y radioactivity following radioembolization using both cPET/CT and dPET/CT. **Materials and Methods:** Standard bremsstrahlung (bSPECT, Symbia T16, Siemens) was performed for 15 patients within a few hours following interventional radioembolization with ^{90}Y microspheres, with an acquisition time of 22m. Pre-commercial release dPET/CT (Vereos, Philips) and cPET (Gemini TF 64, Philips) imaging was performed. Both were performed 4 - 50 h following radioembolization with an acquisition time of 21m each. PET data were reconstructed with and without ToF. ^{90}Y image characteristics and isocontoured activity volumes were evaluated by matched comparison using the Intellispace Portal workstation including comparison with bSPECT/CT. **Results:** When compared with bSPECT/CT, dPET detection of ^{90}Y radioactivity provided markedly improved image quality, exceptional ^{90}Y-to-background contrast and more precise volumetric assessment of intrahepatic ^{90}Y activity when ToF enabled reconstructions were utilized. On the other hand, non-ToF dPET reconstructions demonstrated ^{90}Y-to-background contrast and image quality which was poorer than ToF dPET but better than bSPECT. For dPET, no significant differences in the intrahepatic ^{90}Y activity volumes were noted for ToF and non-ToF reconstructed data sets when using 1% isocontours. ^{90}Y activity volumes were consistently larger on cPET. Non-ToF cPET volumes were even more greatly skewed. **Conclusion:** Currently ^{90}Y imaging is arduous due to long image acquisition times necessary for cPET imaging or the low image quality/limited quantitative capability of bremsstrahlung imaging. These results demonstrate that ToF dPET image quality is superior to non-ToF dPET as well as cPET and bSPECT. The faster timing resolution of ToF dPET likely contributes to more precise localization of ^{90}Y internal pair production events and less partial volume effect. It is expected that dPET technology will enable new strategies for ^{90}Y image acquisition and reconstruction, contributing to faster imaging with better image quality, dose quantification and predictive response assessment in patients treated with existing and new ^{90}Y-based theranostics.

OP018

Differences Between Free-Breathing and Breath-Hold CT for Application in SIRT Dosimetry

A. Thyroff[1], J. C. Sanders[1,2], T. Kuwert[1], M. Beck[1], **P. Ritt**[1]; [1]Clinic of Nuclear Medicine - University Hospital Erlangen, Erlangen, GERMANY, [2]Pattern Recognition Lab - University of Erlangen-Nuremberg, Erlangen, GERMANY.

Aim In Selective Intra-arterial Radio Therapy (SIRT) of liver tumors with Y-90 loaded microspheres, prevailing compartment models for dosimetry assume that the deposited energy dose due to treatment is proportional to the injected Y-90 dose and inversely proportional to the liver volume. For the pre-therapeutic SPECT/CT-based dosimetry, a wide range of SPECT/CT systems is used, including numerous devices which are not suited for achieving the necessary scanning speed for breath-hold CT imaging of the abdomen. Respiratory artifacts in these slow CT acquisitions could result in an erroneous CT-based volume determination, which would lead to incorrect dosimetry. The aim of this study was to assess the differences in liver volume determination between slow, free-breathing and fast, breath-hold CT acquisitions. ***Material and Methods*** In 14 patients, breath-hold (Siemens Biograph mCT, 40 CT detector slices) as well as free-breathing (Siemens Symbia T2, 2 detector slices) CTs were acquired. The time difference between the two acquisitions was 8.7±3.8 (1-15) days. The liver volume was determined by manual segmentation of the transaxial CT slices by one experienced reader. The breath-hold CT was considered as ground-truth. Additionally, the intra-reader variability was measured by segmenting 10 acquisitions for a second time after sufficient temporal distance. ***Results*** The average volume difference between breath-hold and free-breathing CT was 5.8±4.6% ($p<0.001$), ranging 0.1-14.1%. This corresponds to a volume difference of 101±82 (1-271) ml. The intra-reader variability was 0.4±0.3% (0.1-1.3%). 5 and 8 datasets had lower and higher volumes, respectively, in the free-breathing versus the breath-hold acquisitions, with one dataset having an equal volume. ***Conclusion*** Determination of liver volume based on free-breathing CT examinations results in significant volume inaccuracies. These errors directly affect SIRT dosimetry, and, depending on the respiratory movement relative to the patient table motion during the CT acquisition, the volume may be either over- or under-estimated.

Synthesis and comparative evaluation of three ^{18}F-AmBF$_3$ derivatives of Glu-ureido-Lys for imaging PSMA expression in prostate cancer with positron emission tomography

H. Kuo[1], J. Pan[1], H. Merkens[1], J. Lau[1], C. Zhang[1], Z. Liu[2], D. M. Perrin[2], F. Benard[1], **K. Lin**[1]; [1]BC Cancer Agency, Vancouver, BC, CANADA, [2]University of British Columbia, Vancouver, BC, CANADA.

OBJECTIVES: Expressed in most prostate cancers (PCa), the membrane-bound glycoprotein prostate specific membrane antigen (PSMA) is an attractive diagnostic and therapeutic target. In recent years, several PSMA-targeting radiotracers have successfully entered the clinic for imaging PCa. Among them, ^{18}F-DCFPyL is one of the most sensitive tracers for the identification of PSMA-positive PCa. However, the reported radiosynthesis of ^{18}F-DCFPyL involves multiple steps, and is challenging for automation using GMP-compliant synthesis modules. In this study, three ^{18}F-labeled PSMA-targeting Glu-ureido-Lys derivatives (HTK01069, HTK01070 and HTK01130) that could be radiolabeled via a one-step ^{18}F-^{19}F isotope exchange reaction on the ammoniomethyltrifluoroborate (AmBF$_3$) motif were synthesized and evaluated for PSMA imaging. **METHODS:** HTK01069 was synthesized by coupling succinimido 4-(*N*-trifluoroborylmethyl-*N*,*N*-dimethylammonio) methylbenzoate to Glu-ureido-Lys. HTK01070 and HTK01130 were prepared by coupling 2,3,5,6-tetrafluorophenyl 4-(azidemethyl)benzoate and 2,3,5,6-tetrafluorophenyl 6-(azidomethyl)nicotinate, respectively, to *t*-butyl protected Glu-ureido-Lys, followed by deprotection and click reaction with *N*-propargyl-*N*,*N*-dimethyl-ammoniomethyltrifluoroborate. Radiolabeling was conducted via ^{18}F-^{19}F isotope exchange reactions and tracers were purified by HPLC. The stability of the tracers was assessed in mouse plasma. PET imaging and biodistribution studies were performed in mice bearing PSMA-expressing LNCap PCa xenografts. For blocking studies, mice were co-injected with 0.5 mg of DCFPyL. **RESULTS:** ^{18}F-HTK01069, ^{18}F-HTK01070 and ^{18}F-HTK01130 were obtained in 3 - 9% average decay-corrected radiochemical yields with > 99% radiochemical purity and ≥ 29.6 GBq/μmol average specific activity. All tracers were stable (>99% intact) after 2 h incubation in plasma. From PET images,all three tracers successfully delineated PSMA-expressing LNCap xenografts at 1 h post-injection (p.i.) with excellent tumour-to-background contrast. The clearance of these tracers was predominantly renal with minor involvement of the hepatobiliary pathway. At 1 h p.i., ^{18}F-HTK01070 exhibited higher tumour uptake (8.28 ± 1.25 %ID/g) than ^{18}F-HTK01069 (5.82 ± 1.09 %ID/g) and ^{18}F-HTK01130 (4.22 ± 0.44 %ID/g). ^{18}F-HTK01070 was also superior to ^{18}F-HTK01069 and HTK01130 in terms of tumour-to-muscle ratio (37.7 ± 9.53 vs. 18.9 ± 6.05 and 21.6 ± 5.46) and tumour-to-blood ratio (16.0 ± 1.37 vs. 11.9 ± 4.60 and 7.89 ± 3.13). With PSMA blockade, uptake in tumours reduced by > 90% for all tracers. **CONCLUSION:** Three AmBF$_3$-conjugated Glu-ureido-Lys derivatives were successfully radiolabeled with ^{18}F-fluoride and evaluated for imaging PSMA expression with PET. With high tumour uptake, excellent tumour-to-background contrast, and ease of synthesis, ^{18}F-HTK01070 warrants further investigation as a PSMA imaging agent.

OP021

High Affinity F-18 Labeled PSMA Inhibitors: Preclinical Evaluation and Comparison to 68GaDKFZ-PSMA-11

J. M. Kelly, A. Amor-Coarasa, A. Nikolopoulou, D. Kim, C. Williams, Jr., S. Ponnala, J. W. Babich; Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, USA, New York, NY, UNITED STATES.

Aim*:* Current clinical imaging of PSMA-positive prostate cancer (PCa) by positron emission tomography (PET) mainly feature ^{68}Ga-labeled tracers, notably DKFZ-PSMA-11. The longer half-life of ^{18}F offers significant advantages over ^{68}Ga in both clinical and production environments. Therefore we aimed to develop high affinity PSMA inhibitors labeled with ^{18}F as alternatives to ^{68}GaDKFZ-PSMA-11 for imaging PCa. *Methods:* Six Glutamate-urea-Lysine (EuK) based triazoles and their alkyne precursors were synthesized starting from H-Glu(OtBu)-OtBu. 2-Azidoethyltosylate was synthesized from 2-bromoethanol. PSMA binding affinities were determined in a competitive binding assay on LNCaP cells. Radiofluorination was achieved using Cu(I)-catalyzed click chemistry after preparation and distillation of [^{18}F]fluoroethylazide. [^{18}F]fluorinated triazoles were isolated using prep-HPLC. [^{18}F] labeled compounds were evaluated in nude mice bearing LNCaP tumors (n=2-5), with imaging at 1, 2, 4 and 6hrs p.i. The same mice were imaged with ^{68}GaDKFZ-PSMA-11 within 24 hours. Biodistribution studies were performed on the two tracers with the highest imaged-derived tumor uptake

(5 mice/time point) at 1, 2 and 4hrs post-injection. PSMA specific uptake was confirmed by co-administration of PMPA. *Results:* [^{18}F]Fluoroethyl-triazoles were prepared with an overall decay corrected RCY of 21-43% and >98% radiochemical and chemical purity. PSMA binding was in the range 8-25 nM (IC_{50}). Preference for substitution on the phenyl ring was in the order 3 > 4 > 2, and direct conjugation of the triazole with the phenyl alkyne moiety was preferred to insertion of a spacer group. Image-derived tumor uptake was calculated for each of the injected mice and ranged from 6 to 14% ID/g (at 2 hrs). By the same calculation, uptake of ^{68}GaDKFZ-PSMA-11 in the tumor was 5% ID/g. Biodistribution studies of the compounds displaying the highest imaged-derived tumor uptake (also highest PSMA affinity) gave tumor uptakes of 8.3±2.5%, 10.9 ±1.0%, and 10.3±1.9%, and 12.7±1.6%, 14.3±2.5%, and 13.9±2.1% at 1, 2 and 4hrs p.i., respectively. The biodistribution of ^{68}GaDKFZ-PSMA-11 was determined at 1hr post-injection and tumor uptake was found to be 5.32 ± 1.56%. *Conclusions:* Six urea-based triazoles were [^{18}F]fluorinated by click chemistry in good radiochemical yield. The compounds showed PSMA-specific uptake in LNCaP tumors as high as 14% ID/g, nearly a 3-fold increase over ^{68}GaDKFZ-PSMA-11. The facile and high yielding radiosynthesis of these F-18 labeled urea-based triazoles as well as their promising in vitro and in vivo characteristics make them worthy of clinical development for PET imaging of PCa.

OP022

^{18}F-PSMA-1007: The Optimal Variant of Radiofluorinated PSMA Ligands Derived from PSMA-617

J. Cardinale[1], M. Schäfer[1], M. Geerlings[1], M. Benešová[1], M. Eder[1], U. Bauder-Wüst[1], A. Baranski[1], O. Neels[1], K. Leotta[1], U. Haberkorn[2], F. Giesel[2], K. Kopka[1]; [1]German Cancer Research Center, Heidelberg, GERMANY, [2]University Hospital, Heidelberg, GERMANY.

Aim: Urea-based inhibitors of the prostate-specific membrane antigen (PSMA) show promising results for the diagnosis (1,2) and endoradiotherapy (3) of prostate cancer. The aim of the project was the development of F-18 labeled PSMA ligands derived from PSMA-617. So far, the compound PSMA-1007 offered the most promising characteristics in preclinical experiments. To further investigate the structure activity relationships, a variety of PSMA inhibitors with altered linker modifications have been developed. Therefore, we especially aimed at high internalization ratios. **Materials and Methods:** The PSMA binding-motif Glu-NH-CO-NH-Lys was synthesized on a solid phase (chlorotrityl-resin) (4), and subsequently amino acid linkers were built up by fmoc-based solid phase synthesis (SPPS). After separation from the resin and deprotection, the peptidomimetics were conjugated using the prosthetic group 6-fluoronicotinic acid TFP-ester. The non-radioactive reference compounds were also prepared by SPPS. The K_i-values of all compounds were determined by competitive a binding assay on LNCaP cells against ^{68}Ga-PSMA-10 using the respective cold reference compounds. Additionally, the internalization of the radiofluorinated ligands was analyzed. **Results:** The no-carrier-added radiofluorination of the new PSMA inhibitors with 6-fluoronicotinic acid TFP-ester was accomplished with good radiochemical yields. With one exception the K_i-values of all compounds were in between 1.0-15.0 nM while internalization ratios up to 65 % of the total bound activity were observed. Within the novel series PSMA-1007 still shows the best characteristics for clinical translation (6.7±1.7 nM, 65% int. ratio). Thus, PSMA-1007 was selected as the leading candidate for the translation into the clinic. **Conclusions:** Based on PSMA-617, a series of promising radiofluorinated PSMA ligands was developed and evaluated *in vitro* and (partly) *in vivo*. Amongst those, PSMA-1007, showed the most promising characteristics *in vitro*. Since a further improvement of the binding characteristics could not be achieved, PSMA-1007 was selected as candidate for clinical translation. **Literature:** (1) A. OP023

^{44}Sc-labeling of PSMA-617 for dosimetry of prostate cancer

E. Eppard[1], A. de la Fuente[2], M. Benesova[3], S. Kürpig[1], K. Kopka[3], F. Rösch[2], M. Essler[1]; [1]University Hospital Bonn, Bonn, GERMANY, [2]Johannes Gutenberg University, Mainz, GERMANY, [3]German Cancer Research Center, Heidelberg, GERMANY.

OBJECTIVES By conjugation the prostate-specific membrane antigen (PSMA) inhibitor Glu-NH-CO-NH-Lys(Ahx) with the complexing agent DOTA a broad pool of radionuclides becomes available for its radiolabeling. This allows the visualization of the biological behavior over different periods of time depending on the half-life of the respective radionuclide (^{68}Ga $t_{1/2}$ = 68 min; ^{44}Sc $t_{1/2}$= 3.9 h). Additionally, different imaging modalities and peptidomimetic mediated radionuclide therapy (i.e. targeted endoradiotherapy) can be applied depending on the employed radionuclide (e.g. ^{44}Sc (PET); ^{111}In (SPECT); Gd (MRT); ^{90}Y/^{177}Lu (Therapy)). METHODS PSMA-617 was obtained from ABX (Radeberg, Germany). ^{44}Sc was obtained from a ^{44}Ti/^{44}Sc generator in Mainz, where ^{44}Ti decays with a half-life of 60 years to no-carrier-added (n.c.a) ^{44}Sc. Radiolabeling with ^{44}Sc was performed in 3 mL 0.25 M ammonium acetate buffer at 95°C. Stability studies and cell studies (internalization and binding assay) were performed. Quality control was performed using radioHPLC and radioTLC. A PTW torso phantom with ^{44}Sc and ^{68}Ga was measured 5 min every 30 min over 2.5 h. RESULTS ^{44}Sc-PSMA-617 was effectively labeled at 95 °C. Subsequent cartridge-based solid-phase-extraction (C-18) resulting in a radiochemical purity of the final tracer of ≥98%. Stability studies with ^{44}Sc-PSMA-617 showed the high stability against transchelation and transmetallation of the compound. In cell studies ^{44}Sc-PSMA-617 showed similar behavior like ^{68}Ga-PSMA-617 and ^{177}Lu-PSMA-617. Radiochemical purity could be analyzed effectively using radioHPLC and radioTLC. Measurement of a torso phantom applying ^{44}Sc into the spheres and ^{68}Ga into the surrounding was done. CONCLUSIONS The radiolabeling of PSMA-617 with the new generator-derived PET radionuclide ^{44}Sc was investigated in detail. ^{44}Sc-PSMA-617 was investigated *in vitro*. Also a radiolabeling and quality control protocol along the lines of the monograph of the European Pharmacopoeia for ^{68}Ga-DOTATOC was developed and validated to produce ^{44}Sc-PSMA-617 suitable for clinical investigations.

Guiding the Arrow: A Dual Targeted Approach to Prostate Cancer Therapy

J. M. Kelly[1], A. Amor-Coarasa[1], T. Wuestemann[1], A. Nikolopoulou[1], P. Barelli[2], C. Williams, Jr.[1], D. Kim[1], B. Hu[3], S. DiMagno[3], D. Hage[4], D. Warren[2], X. Zheng[5], J. W. Babich[1]; [1]Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, USA, New York, NY, UNITED STATES, [2]Milstein Chemistry Core Facility, Department of Biochemistry, Weill Cornell Medicine, New York, NY, USA, New York, NY, UNITED STATES, [3]Department of Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL USA, Chicago, IL, UNITED STATES, [4]Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE, USA., Lincoln, NE, UNITED STATES, [5]epartment of Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL USA, chicago, IL, UNITED STATES.

Aim*:* Several prostate specific membrane antigen (PSMA) targeted radiotherapeutics based on the Glu-urea-Lys (EuK) pharmacophore are currently under clinical investigation and showing anti-tumor activity in

mCRPC. However, these compounds localize to the salivary and parotid glands, as well as kidney, which may present dose-limiting organs or lead to related long term adverse events effecting quality of life. We therefore sought to modulate pharmacokinetics through interaction with serum albumin (HSA) which might limit normal tissue uptake without affecting tumor targeting. *Methods:* A series of small molecules (< 600 Da) possessing the *EuK* moiety and an albumin-binding moiety were synthesized and evaluated in vitro and in vivo. HSA binding affinity was determined by high-performance affinity chromatography. PSMA affinity was determined using a competitive binding assay in LNCaP cells, and uptake and internalization of the radiolabeled compounds were measured both in the presence and absence of HSA. Radiolabeling with I-131 or I-124 proceeded via iodo-destannylation. Four compounds were labeled with I-131 and biodistributions determined in nude mice bearing LNCaP tumors at 1, 6, 12, 24 and 48h post-injection (n=4). The compound with the most promising pharmacokinetics was labeled with I-124 for PET imaging at 1, 3, 6, 24 and 48h post-injection. *Results:* Calculated IC_{50}s for PSMA were 8-15 nM and K_d for HSA 1-53 μM. For all compounds in vitro cell uptake was lower in the presence of HSA with uptake inversely related to HSA affinity. Compounds with K_d <2 μM had extended blood residence over 48h and decreased tumor uptake while those compounds with K_d >20 μM were rapidly cleared from the blood and elevated kidney uptake. One compound was identified to show dramatically improved pharmacokinetics, with prolonged tumor retention (9% ID/g at 1h vs. 5.5% ID/g at 48h) leading to high tumor:kidney and tumor:blood ratios after 24h. Imaging with a ^{124}I-labeled analogue confirmed the excellent targeting and contrast. *Conclusions:* The improved pharmacokinetics of a dual targeting ligand by tailoring HSA binding represents a potentially valuable development in the design of targeted radiotherapeutics for prostate cancer. Preliminary pre-clinical data suggest that the compound has lower uptake in non-target tissue and consequently presents a greater therapeutic index. The ligand may be suitable for treatment of prostate cancer in man when labeled with therapeutic doses of I-131 or the alpha emitter At-211.

OP025

Protecting salivary glands: Displacement of off-target bound prostate-specific membrane antigen ligands

T. Wüstemann[1], A. Nikolopoulou[1], A. Amor-Coarasa[1], D. Kim[1], J. M. Kelly[1], C. Williams, Jr.[1], U. Haberkorn[2], J. W. Babich[1]; [1]Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, USA, New York, NY, UNITED STATES, [2]Department of Nuclear Medicine, University Hospital Heidelberg, Germany, Heidelberg, GERMANY.

Aim: Prostate-specific membrane antigen (PSMA)-targeted endoradiotherapy has recently shown significant promise in metastatic castrate resistant prostate cancer. Radiolabeled small molecule inhibitors of PSMA developed to date show high specificity to its molecular target in vivo and promising results in the clinic. However, as PSMA is also expressed in several normal tissues, radiation doses especially to kidneys and salivary and parotid glands may limit therapeutic dosing. Developing ligands with less binding to normal tissues remains challenging and until such compounds are found alternative approaches to protect normal tissues are needed. A promising pharmacological approach has been explored by us to displace off-target PSMA-associated renal radioactivity (J Nucl Med. 2015 Feb;56(2):293-8). We now apply this approach to protection of the salivary glands with the intent of minimizing xerostomia. Methods: 2-(Phosphonomethyl)pentane-1,5-dioic acid (PMPA) was used to selectively displace the PSMA PET tracer, ^{68}Ga-labeled HBED-CC-(Ahx)Lys-NH-CO-NH-Glu (68Ga-HBED-CC), localized to the salivary glands of healthy male Sprague-Dawley rats. The salivary glands were first localized by ^{99m}Tc-pertechnetate imaging using μSPECT/CT (Inveon^{R}, Siemens). Rats were then injected with ^{68}Ga-HBED-CC followed by μPET/CT imaging of the head, at 2 h pi, to define baseline uptake in the salivary glands. After acquisition of baseline images rats were administered PMPA (1-10 mg/Kg), or saline, either by tail vein injection or as a mouth rinse imitating a gargle. μPET/CT imaging was then repeated 30 min post PMPA or saline administration to assess displacement. Results: Localization of the salivary glands was achieved by μSPECT/CT imaging. ^{68}Ga-HBED-CC μPET/CT showed co-localization to the glands. Intravenous injection of PMPA led to a near complete displacement of ^{68}Ga-HBED-CC at 10mg/Kg and 80% reduction at 1mg/Kg. PMPA gargle also achieved significant, but lower reduction, with 80% displacement at 10mg/Kg and 50% at 1mg/Kg. Saline infusion or gargle showed no reduction in ^{68}Ga-HBED-CC retention in salivary glands. Conclusions: This study indicates that gargling a PMPA solution 2h after injection of PSMA radiopharmaceuticals can reduce PSMA-specific localized activity in the salivary glands. The low toxicity of PMPA and the simplicity of administration suggest this finding could easily be implemented in the clinic and should be investigated to improve PSMA-based therapy and preserve the quality of life of the prostate cancer patient.

Metabolic tumor volume in FDG PET/CT is a useful predictor for survival in patients with unresectable esophageal squamous cell carcinoma treated by definitive chemoradiotherapy

S. Watanabe[1], M. Myoujin[2], K. Itoh[2], K. Hirata[1], O. Manabe[1], K. Kobayashi[1], Y. Onodera[2], K. Kanegae[3], H. Takahashi[3], M. Hosokawa[2], N. Tamaki[1]; [1]Hokkaido University Graduate School of Medicine, Sapporo, JAPAN, [2]Keiyukai Sapporo Hospital, Sapporo, JAPAN, [3]Keiyukai 2nd Hospital, Sapporo, JAPAN.

Objective FDG PET/CT has predictive values in the prognosis of esophageal carcinoma. Identification of additional prognostic factors could improve risk-adapted treatment strategies to select patients who would benefit from intensified treatment. Since usefulness of volumetric analysis of FDG PET/CT in relation to patient prognosis has not been fully known, we aimed to investigate the prognostic value of pretreatment metabolic tumor volume (MTV) in a population of patients with unresectable

esophageal squamous cell carcinoma (ESCC). **Methods** We retrospectively reviewed 98 (aged 65 ± 9 years; 87 men) patients with pathologically proven ESCC who underwent pretreatment FDG PET/CT in Keiyukai Sapporo Hospital. All of them were clinically diagnosed as T4 stage without distant metastasis based on endoscopy, endoscopic ultrasound, CT, MRI, esophagography, endobronchial ultrasound and FDG PET/CT. MTV and maximum standardized uptake value (SUVmax) for the primary tumor were measured on FDG PET/CT. A fixed-threshold-based analysis, using an SUV of 2.5, was chosen for the measurement of MTV. The prognostic significance of MTV, SUVmax, clinical parameters and overall survival (OS) was assessed by univariate and multivariate Cox proportional hazards regression analysis. To further evaluate and compare the predictive performance of MTV and SUVmax, time-dependent receiver operating characteristic curve (ROC) analysis was used. **Results** At the time of analysis, 61 (62.2%) patients had died and 37 (37.8%) were alive. Median follow-up period for surviving patients was 24 months (range, 15-37 months). Median overall survival time was 15 months [95%CI, 13-17 months], with 2-year cumulative survival of 39%. MTV ranged between 7.9 cm^3 and 196.0 cm^3, with median of 65.7 cm^3 and mean of 72.2 cm^3. SUVmax ranged between 6.2 and 35.5, with median of 16.8 and mean of 17.0. In the univariate analysis, MTV (HR 1.008, P = 0.013) of the primary tumor was a significant predictor of survival. Age, sex, SUVmax and the location of the primary tumor, presence of clinical lymph metastasis, and radiation dose did not correlate with the OS. On multivariate analysis, MTV (HR 1.011, P = 0.005) was the only independent predictive factor associated with short OS. SUVmax was not a significant factor (HR 0.974, P = 0.357). On time-dependent ROC analysis, MTV (AUC = 0.647) achieved better predictive performance for OS than SUVmax (AUC = 0.549). **Conclusion** MTV of the primary lesion before definitive chemoradiotherapy is an important independent prognostic factor for survival in patients with unresectable ESCC.

Introduction: Conventional imaging allows staging of hepatocellular carcinoma (HCC) according to the BCLC classification, which links staging to therapeutic modalities. The aim of our study was to assess the impact of dual tracer 18F-Fluorocholine and 18F-FDG PET/CT on tumor staging and treatment allocation. **Methods:** 154 dual-tracer PET/CT were performed in 138 patients with HCC between 2012 and 2015 in two institutions. Diagnosis of HCC was based on histological (n=108) and/or radiological findings. For these patients, we retrospectively reviewed HCC staging according to the BCLC classification based on the conventional imaging and treatment proposition. Then, we collected any new lesion detected, as well as any change in BCLC classification and treatment allocation based on the dual-tracer PET/CT. Modification of BCLC classification and treatment allocation according to the dual tracer PET/CT were defined in a multidisciplinary meeting. **Results:** Patients were mostly men (n=122; 88%) with cirrhosis in 106 patients (77%). BCLC staging was 0 or A in 52 patients (34%), B in 32 patients (23%), C in 25 patients (16%). No typical active tumor was identified with conventional imaging in the remaining 45 patients (29%). 18F-FDG PET/CT detected new lesions in 21 patients (14%), upgraded BCLC staging in 15 patients (10%) and modified the treatment in 17 patients (11%). Dual-tracer 18F-Fluorocholine and 18F-FDG PET/CT detected new lesions in 30 patients (19.4%). BCLC staging was upgraded in 22 patients (14%), and dual tracer PET/CT had an impact on treatment decision in 23 patients (15%). New intrahepatic lesions were detected in 7 patients, extrahepatic lesions in 16 patients and both intra and extrahepatic lesions in 7 patients. Ten patients had new bone lesions, 6 vascular invasion, 8 tumoral nodes, 3 lung metastasis and 1 adrenal metastasis. In patients waiting liver transplantation, staging was modified in 9% of the patients with active lesion (n=34) and in 4% of patients without tumor remaining after curative treatment (n=26). BCLC staging was modified in 19% of the patients assessed before percutaneous treatment or resection (n=36), in 10% of the patients assessed before palliative treatment (n=30). Staging was modified in 23% of the patients with doubtful extra-hepatic lesions (n=17) and in 36% of the patients with increased AFP without typical lesions at conventional imaging (n=11). **Conclusion:** In our population, dual-tracer 18F-Fluorocholine and 18F-FDG PET/CT allowed the upstaging in the BCLC classification in 13.6 % of the patients with HCC and treatment modification in 14.9% of the cases.

OP031

FDG-PET/CT in Primary Staging of Cholangiocarcinoma

A. Sabaté-Llobera[1], L. Gràcia-Sánchez[1], J. Mestres-Martí[1], I. Puig-Povedano[1], J. L. Vercher-Conejero[1], E. Llinares-Tello[1], L. Rodríguez-Bel[1], J. J. Robles-Barba[1], M. Cortés-Romera[1], L. Lladó-Garriga[2], T. Serrano-Piñol[3], E. Ramos-Rubio[2], C. Gámez-Cenzano[1]; [1]PET Unit. Department of Nuclear Medicine - IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN, [2]Department of Surgery. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN, [3]Department of Pathology. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN.

AIM: To assess the role of FDG-PET/CT in cholangiocarcinomas, identifying the primary tumor and staging, both in intrahepatic (IHC) and extrahepatic (EHC) lesions. **MATERIAL AND METHODS:** Between 2012 and 2015, 50 patients (27 men, mean age 68 years) with confirmed or suspected cholangiocarcinoma were studied with FDG-PET/CT at initial staging, as well as diagnostic CT and MRI. Thirty-one patients (62%) had an IHC and 19 (38%) an EHC. Metabolic parameters of primary lesions (SUVmax and lesion-to-normal-hepatic-activity ratio (L/NHA)) as well as performance of FDG-PET/CT for detection of regional lymph node metastasis and distant disease were compared between EHC and IHC. **RESULTS:** All IHC (31/31 patients-100%) showed an increased FDG uptake with a median SUVmax of 8.7 (3.6-19.5) and a median L/NHA ratio of 2.86 (1.06-7.22). By contrast, only 13/19 EHC (68%) showed an increased FDG uptake with a of median SUVmax of 4.5 (2.6-9.6) and a median L/NHA ratio of 1.45 (1-1.96). SUVmax and ratio L/NHA were significantly higher in primary lesions of IHC compared to EHC (p<0,01). In 14/31 (44%) patients with IHC FDG-PET/CT detected regional/distant disease: isolated regional lymph node metastases in 7 (22%) (not biopsy-proven), and both regional and distant metastases in 7 (22%), located in peritoneum (3), bone (2), liver and mediastinum, with biopsy-proven disease in peritoneal and mediastinal sites. Additionally, a syncronous colorectal cancer was diagnosed. In patients

with EHC, 6/19 (32%) primary tumors did not show increased FDG uptake. Histhologically there were one mucosecretor adenocarcinoma, one poorly-differenciated adenocarcinoma, three moderately-differentiated, and one well-differentiated adenocarcinoma. In these 6 patients with non-FDG avid tumors surgery discovered non-FDG avid metastases: regional lymph nodes in 3 and peritoneal metastases in 1. In 1/13 FDG-avid primary EHC, FDG-avid regional and distant metastases (supraclavicular nodes) were confirmed. **CONCLUSION:** FDG-PET/CT appears to be a useful technique in primary staging of cholangiocarcinoma, with better results in intrahepatic compared to extrahepatic lesions. IHC and its metastases seem more FDG-avid, whereas EHC are more heterogeneous, limiting the assessment of disease extension. These results must be confirmed by larger number of patients and biopsy-proven lesions.

OP032

Prognoctic value of combined [^{99m}]Tc-MAA-SPECT/CT and [^{18}F]Fluorethylcholine-PET/CT in patients suffering from advanced hepatocellular carcinoma prior to radioembolization

M. Hartenbach[1], S. Weber[2], S. Hartenbach[3], M. Zacherl[4], P. M. Papprottka[5], R. Tiling[6], P. Bartenstein[4], M. Hacker[1], N. L. Albert[4], A. Haug[1]; [1]Medical University of Vienna, Dep. of biomed. imaging and image guided therapy, Vienna, AUSTRIA, [2]Medical University of Vienna, Vienna, AUSTRIA, [3]German Armed Forces Hospital, Institute of Pathology, Vienna, AUSTRIA, [4]Univ. of Munich, Department of Nuclear Medicine, Munich, GERMANY, [5]University of Munich, Clinical Institute of Radiology, Munich, GERMANY, [6]University of Munich, Dept. of Nuclear Medicine, Vienna, GERMANY.

Hepatocellular carcinomas (HCC) are increasingly treated with radioembolization (RE). However, prognostic factors with regard to survival are needed for better patient selection. ***Methods*** 24 patients with advanced HCC underwent MAA-SPECT/CT und FEC-PET/CT prior to RE. We evaluated various uptake parameters, tumor-to-spleen-ratio and volumetric overlap of uptake on MAA-SPECT/CT and FEC-PET/CT using Hermes Hybrid 3D viewer. This data was analyzed with regard to survival. We used ROC analysis, Youden-index, multiple logistic regression analysis and Kaplan-Meier analysis for statistical analysis. ***Results*** All patients died with a median survival of 437±71 days. A high overlap of MAA SPECT/CT and FEC PET/CT was significantly associated with a shorter survival (AUC=0,75; P<0,05). A combination of SUV values, tumor-to-spleen-ratio and volumetric data using multiple logistic regression had an AUC of 0.87 (P=0.004) with a sensitivity of 100%, specificity of 75%, accuracy of 92%, a NPV of 89% and a PPV of 100% (P<0.001). Regression analysis was able to separate patients with regard to prognosis (median survival 531±68 days versus 840±96 days; log rank: 5.7; P=0.017) ***Conclusion*** Patients suffering from advanced HCC and a combination of high overlap of MAA-uptake (as a parameter for high tumor vascularization) and FEC-uptake have a significantly shorter survival as the remaining patients. This finding may aid to enhanced patient selection for RE.

OP033

Evaluation of the predictive role of ^{18}F-FDG PET/CT in patients with locally advanced rectal cancer submitted to neoadjuvant therapy: correlation with tumour characteristics and treatment response

E. Puta[1], F. Orsini[1], L. M. Leva[1], L. Deantonio[2], L. Turri[2], R. Grasso[2], S. Torrente[2], A. Caroli[2], F. Apicella[2], D. Ferrante[3], M. Krengli[2], G. M. Sacchetti[1]; [1]Nuclear Medicine Department, University Hospital "Maggiore della Carità",, Novara, ITALY, [2]Radiotherapy Dept., University Hospital "Maggiore della Carità",, Novara, ITALY, [3]Biostatistics & Clinical Epidemiology, University Hospital "Maggiore della Carità", Novara, Italy, Novara, ITALY.

Aim [^{18}F]FDG PET/CT has an important role in staging and treatment planning of rectal cancers. Neo-adjuvant chemo-radiotherapy (CT-RT) in locally advanced rectal cancer (LARC) helps to obtain tumour downsizing/downstaging. According to the literature data about 20% of these patients reach pathological complete response (pCR) after neo-adjuvant CT-RT leading to the concept of non-surgical approach aiming at organ preservation. The aim of our study was to evaluate whether baseline [^{18}F]FDG PET/CT could help to predict histopathological response in LARC in patients treated with neoadjuvant CT-RT. Materials and Methods Fifty-six patients (37 males, 19 females; median age 69yrs) with LARC underwent a baseline [^{18}F]FDG PET/CT study within 5 days from CT simulation scan. All patients had neoadjuvant CT-RT followed by radical surgery. For each patient we calculated the pre-treatment PET/CT values of SUVmax, SUVmean, Metabolic Tumour Volume (MTV) and Total Lesion Glycolysis (TLG) and we analysed their correlation with clinical parameters (cT3 and cT4) and histopathological data (Tumour Regression Grade TRG1 vs TRG2-5). Results According to TRG classification, 10/56 patients (17.9%), were classified as TRG1 (ypT0N0) corresponding to pCR and 46/56 patients (82.1%) as TRG2-5 (ypT1-4N0-2). SUVmax and TLG were significantly different between T-stage classes (p=0.05; p=0.002) and histopathological response (p=0.05; p=0.03). MTV was significantly different only between T-stage groups (p=0.008). SUVmean was not significantly different between T-stage (p=0.07) or histopathological response groups (p=0.18). We fit all the SUV variables in a logistic regression model and considered as a cut-off the median value of each SUV parameter. Values of SUVmax and SUVmean higher than the median resulted in a significant prediction of T4 primary tumour (p= 0.01 and p= 0.05). Higher SUVmax was associated with TRG2-5 (OR 5.2; CI95% 1.0-27.2), and SUVmax, SUVmean, MTV and TLG with T-stage (OR 5.3; CI95% 1.0-27.7).Conclusions Our data suggest that pre-treatment [^{18}F]FDG PET/CT SUVmax and TLG are significantly lower in patients with pCR and SUVmax, MTV and TLG are significantly lower in patients with less extended primary disease (cT3). This study suggests that the baseline [^{18}F]FDG PET/CT could predict treatment response; however the present results require validation in larger cohort.

OP034

Value of PET/CT in the characterization of extra-hepatic lesions in patients with hepatocellular carcinoma before liver transplantation

M. Houseni[1], **L. zidan**[2]; [1]National Liver Institute, Menoufia University, Menoufia, EGYPT, [2]Faculty of Medicine, Cairo University, cairo, EGYPT.

Aim: Evaluate the role of FDG-PET/CT in the differentiation between neoplastic and benign extra-hepatic lesions in patients with hepatocellular carcinoma before liver transplantation. **Methods:** A total of 106 patients (89 male, 17 female with mean age 57 y) diagnosed with hepatocellular carcinoma and have extra-hepatic lesions detected during their assessment before liver transplantation enrolled in this study. FDG-PET/CT with multiphase CT was performed at same time. All finding were confirmed with histopathology or clinical and imaging follow-up for at least 24 months. **Results:** Thirty-seven patients have extra-hepatic metastases. The extra-hepatic findings were benign in 69 patients. The prevalence of extra-hepatic metastases was 34.9%. The sensitivity, specificity, accuracy, positive predictive value and negative predictive value for FDG-PET/CT were 83.8%, 85.5%, 84.9%, 75.6% and 90.8%, respectively. **Conclusion:** FDG-PET/CT can be of value in the assessment of patients with hepatocellular carcinoma before liver transplantation. PET/CT imaging play an important role in the characterization of extra-hepatic disease and expedite the transplantation process especially when the test is negative due to high negative predictive value.

OP035

18F-FDG PET/CT for restaging gastric cancer after surgical resection: is there a role in the assessment of local relapse?

G. Polverari[1], F. Ceci[1], V. Ambrosini[1], P. Castellucci[1], P. Guidalotti[1], D. Campana[2], A. Matti[1], G. M. Lima[1], S. Fanti[1]; [1]Service of Nuclear Medicine, S.Orsola-Malpighi University Hospital, University of Bologna, Bologna, ITALY, [2]Department of Internal Medicine and Surgery, S.Orsola-Malpighi University Hospital, University of Bologna, Bologna, ITALY.

Aim: to investigate the performance of 18F-FDG-PET/CT in the evaluation of local recurrence in resected gastric cancer (GCa) patients, presenting 18F-FDG uptake in remnant stomach or anastomotic site. Secondary aim was to assess if clinical and diagnostic features might have an influence on the images reading process. **Materials and methods**: inclusion criteria were: 1) proven GCa treated with surgery with curative intent; 2) 18F-FDG-PET/CT performed during follow-up to restage the disease; 3) 18F-FDG uptake observed in remnant stomach or anastomotic site; 4) validation of PET/CT results obtained by histology and/or clinical/radiological follow-up. Exclusion criteria were: 1) no 18F-FDG uptake in remnant stomach or anastomotic site; 2) no validation of PET/CT results. 58 patients were retrospectively enrolled (35 male and 23 female). The 22.4% (13/58) performed total gastrectomy, while the 77.6% (45/58) performed subtotal gastrectomy. The mean time between surgery and 18F-FDG-PET/CT was 22 months (median 11 months). The overall performance of 18F-FDG-PET/CT (sensitivity, specificity, positive predicting value (PPV), negative predictive value (NPV) and accuracy) was calculated in accordance with an informed reading performed by two experienced readers aware of all the clinical and diagnostic data. A blind reading was performed in order to assess if clinical and diagnostic features might have an influence on the images reading process. A lesion suspected for malignancy was considered with focal and intense uptake with/without pathologic lesions in CT. A non-malignant lesion was suspected with faint and diffused uptake without pathologic lesions in CT. **Results**: at the informed reading, aware of the type of surgery (radical vs. partial) and the time from surgery to 18F-FDG-PET/CT, the 46.5% of scans (27/58) were considered suspected for local GCa relapse, while the 53.5% (31/58) were considered as not suspected for local relapse. Histological confirmation was obtained in the 48.3% of patients (28/58), while in the 51.7% (30/58) were validated with follow-up. Local GCa recurrence was proved in the 41.4% (24/58) of patients. 18F-FDG-PET/CT sensitivity, specificity, PPV, NPV and accuracy were 96%, 88%, 85%, 97% and 91%, respectively. Considering a blind reading of the images 18F-FDG-PET/CT sensitivity, specificity, PPV, NPV and accuracy were 58%, 76%, 64%, 72% and 69%, respectively. **Conclusion**: in our patient-series, 18F-FDG-PET/CT showed good performance for the assessment of local recurrence in resected GCa patients. An informed reading of the images could help physicians, with type of surgery and time from surgery to 18F-FDG-PET/CT as the main criteria for differentiating malignant vs. non-malignant lesions.

OP036

Visual scoring system for the assessment of treatment response in patients with oesophageal and gastro-oesophageal junction carcinoma

E. Cong[1], M. Lee[1,2,3], A. Chicco[4], M. Lin[1,4,3], J. Yap[4], P. Lin[1,4,3], T. Tran[2], I. Ho-Shon[1,4,3]; [1]University of New South Wales, Sydney, AUSTRALIA, [2]Cancer Therapy centre, Liverpool Hospital, Sydney, AUSTRALIA, [3]Western Sydney University, Sydney, AUSTRALIA, [4]Department of Nuclear Medicine and PET, Liverpool Hospital, Sydney, AUSTRALIA.

Aim*:* To evaluate the prognostic value of a 5 point FDG-PET/CT visual scoring system in patients with newly diagnosed oesophageal or gastro-oesophageal junction (GOJ) cancer that have received neoadjuvant or definitive radiotherapy and/or chemotherapy. *Methods:* Ninety seven patients with endoscopically confirmed oesophageal or gastro-oesophageal junction carcinoma treated with definitive or neoadjuvant therapy received pre-treatment PET-CT scans, and of these, sixty seven received post-treatment PET/CT scans. Primary tumours were assessed using a 5 point visual scoring system (visual score of the primary tumour: PVS) for both the pre and post-treatment scans. The score is derived from comparisons between tumour uptake and background references adapted from the Deauville score used to assessment treatment response in lymphoma. Cox regression was used to analyse the relationship between pre-treatment PVS (prePVS), post-treatment PVS (postPVS), change in PVS (deltaPVS) and survival (overall survival: OS, progression free survival: PFS). Log-rank tests were used to separate PVS into two prognostic categories with the greatest survival separation. Tumours were independently scored by 4 experienced observers blinded to all other information. Agreement was assessed using Cohen's kappa for individual scores and for two categories of scores (postPVS 1-3 vs 4-5 and deltaPVS (-4)-(-2) vs (-1)-1). *Results:* On multivariate analysis postPVS and deltaPVS were significant predictors of survival. Patients with postPVS of 1 to 3 had significantly greater median OS (ranging from 53.3-56 months between all observers) compared to patients with postPVS 4-5 (15.2-23.6 months; all observers). Patients with primary tumours experiencing a reduction of 2 or more points had much greater median OS (56 months - not reached in study; all observers) compared to patients whose tumours only experienced a point reduction of 1, had no change, or increased in points by 1 (15.1-21.8 months; all observers). Agreement for high uptake at site of primary tumour in the post-treatment scan (postPVS = 4-5) versus low uptake at site of primary tumour (postPVS = 1-3) was good with kappa ranging from 0.70 to 0.88 for paired combinations of all four readers. *Conclusion:* A visual assessment based on tumour uptake relative to reference background structures has the potential to provide valid and reproducible prognostic information following neoadjuvant or definitive radiotherapy +/- chemotherapy for oesophageal or GOJ carcinoma. These scores also have the potential to stratify treatment responders and non-responders, thus influencing management.

The reliability of estimated glomerular filtration rate in South African oncology patients

J. Holness, H. Simonds, P. Barnardt, J. Warwick; Stellenbosch University, Cape Town, SOUTH AFRICA.

Aim: Due to the nephrotoxicity of platinum-based chemotherapy, it is essential that patients' kidney function is measured accurately prior to commencing treatment, and monitored closely during therapy. Although glomerular filtration rate (GFR) is widely accepted as the best measure of kidney function, it is not feasible to measure in all patients. Consequently, GFR is usually estimated from the serum creatinine concentration using one of a variety of equations. However, these equations have been shown to perform poorly in many non-Caucasian populations around the world, including South Africans, and it is hypothesized that they will be even less accurate in cancer patients. The aim of this study is to determine whether estimated GFR can be used routinely for the measurement of kidney function in South African cancer patients. **Materials and methods:** This was a retrospective review of 233 cancer patients who had a GFR study to determine renal function prior to or during treatment with platinum-based chemotherapy, between January 2011 and May 2015. For GFR determination (mGFR), 40 MBq of ^{99m}Tc-diethylenetriamine pentaacetic acid (^{99m}Tc-DTPA) was administered

intravenously. Venous blood samples were taken at 2, 3 and 4 hours after injection. GFR was calculated using the slope-intercept method. The mean Brochner-Mortensen correction was applied after correction for body surface area. Serum creatinine was measured within seven days of the GFR study with patients receiving no treatment between the two measurements. Estimated GFR (eGFR) was calculated using the Cockgroft-Gault, Modification of Diet in Renal Disease (MDRD), and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations. The correlation, bias, accuracy, and impact on patient management of the estimated GFR was determined for each equation. **Results:** The correlation between eGFR and mGFR was poor with R^2 = 0.25-0.5. All three equations generally over-estimated GFR with a mean bias of 12-20 ml/min/1.73m^2. The precision of the three equations, expressed as the percentage of estimated GFR values within 30% of mGFR (P_{30}), was 53-69%. Use of eGFR would have led to inappropriate management in 11-13% of cervix cancer patients, with 5-8% receiving too high a dose or the incorrect drug, and 4-7% having the drug withheld or the dose reduced unnecessarily. **Conclusion:** Estimated GFR using Cockgroft-Gault, MDRD or CKD-EPI equations cannot be used as replacement for measured GFR in South African cancer patients requiring nephrotoxic chemotherapy.

OP038

Assessing four kidney function parameters with dynamic FDG-PET/MR: a feasibility study

B. K. Geist, S. Rasul, A. Staudenherz, M. Hacker; Medical University of Vienna, Vienna, AUSTRIA.

Aim: The routinely used sugar-like PET tracer FDG participates in several crucial kidney processes: it is filtrated, reabsorbed and extracted. The renal time activity curves (TACs) of FDG therefore might contain information about certain kidney functions. The aim was, to extract four kidney parameters (clearance, split Function, transit time, renal blood flow) from one dynamic FDG-PET/MR scan and to compare the results to standard methods. Method: In a current study in the General Hospital in Vienna, kidneys of 20 healthy volunteers are examined with a PET/MR scan (Siemens Biograph mMR), including two MR pictures of the abdomen, in which the regions of interest in both kidneys were drawn; and one 30 minutes dynamic PET scan directly after injection (2 Mbq/kg) with FDG, from which TACs were extracted after image fusion. From renal cortex TAC, the slope of the Patlak-Rutland-Plot and the integral over the first 3 minutes were calculated. Maximum transit time and renal blood flow were calculated with the - from the image derived aorta input function - deconvoluted renal cortex TAC. Kidney volume was determined solely from the according MR pictures. As reference method, volunteers undergo a renography with Tc-MAG3 for determination of split function and transit times. Additionally, blood samples were drawn for determination of glomerular filtration rate and renal blood flow (methods by Cockcroft-Gault and Bubeck, respectively). Results: So far, 11 healthy volunteers have been evaluated (estimated study end: June 2016), between 25 and 59 years. The slope of the Patlak-Rutland-Plot, reflecting the initial filtration process, multiplied with the kidney volume correlates with the glomerular filtration rate significantly ($r = 0.86$, $p < 0.001$). Split function from renography varies between 45 % and 57 % (left kidney) and correlates well with cortex FDG-TAC split function ($r = 0.8$, $p < 0.001$). Maximum transit times and renal blood flow also correlate well with reference methods ($p < 0.0001$ and $p < 0.0005$, respectively).Conclusion: The kidney parameters extracted from a dynamic FDG-PET/MR scan show promising preliminary results compared to routinely used methods in nuclear medicine. Four crucial parameters can be estimated from FDG-TACs if the cortex region and the kidney volume can be determined accurately from MR scans. As a consequence, kidney function might be assessed simultaneously to a routine PET/MR scan. The results of the finished study will be presented in detail.

OP039

The effect of measurement errors on glomerular filtration rate: a comparison of the slope-intercept, single-sample and slope-only methods

J. Holness[1], J. Fleming[2], J. Warwick[1]; [1]Stellenbosch University, Cape Town, SOUTH AFRICA, [2]University Hospital Southampton NHS Foundation Trust, Southampton, UNITED KINGDOM.

Aim: Glomerular filtration rate (GFR) is conventionally measured using the slope-intercept method (SI-GFR), which has acceptable accuracy provided strict attention is paid to avoid technical errors at a number of stages. Single-sample GFR estimates (SS-GFR) have recently been shown to be as accurate as SI-GFR, while having the advantage of taking less time to perform. A third method, slope-only GFR (SO-GFR), based exclusively on the slope of the terminal exponential of the plasma clearance curve, obviates the need for a standard or measurement of the doses, height or weight. The aim of this paper is to use patient data to model GFR measurement error resulting from the SI-GFR, SS-GFR and SO-GFR methods. Materials and methods: Departmental records were reviewed to identify all GFR studies that were performed using Tc-99m DTPA between Jan 2008 and March 2016, in which at least 3 blood samples were taken (2h, 3h and 4h after injection). Using the original data, GFR was calculated using 8 methods: SI-GFR:3-sample (2h 3h 4h); SI-GFR:2-sample (2h 3h); SI-GFR:2-sample (2h 4h); SI-GFR:2-sample (3h 4h); SS-GFR:2h (Fleming's method); SS-GFR:3h; SS-GFR:4h; SO-GFR. These values were regarded as the reference GFR values. Realistic, normally distributed, random errors were subsequently introduced to all measurements: height (2.5cm), weight (2kg), syringe masses (0.005g), standard flask volume (1%), pipetting volumes (2%), sampling times (2 min) and count rates (√counts), to generate 30 GFR realisations per study. The mean errors in GFR were then compared, and correlated with GFR. Results: A total of 780 GFR studies were included. GFR ranged from 15 to 158 ml/min/1.73m^2 (median 85 ml/min/1.73m^2). Mean measurement error in GFR was highest using SI-GFR:2 sample (3h 4h) (95% CI 3.27-3.45 ml/min/1.73m^2) and lowest using SS-GFR:4h (95% CI 1.84-1.87 ml/min/1.73m^2). However, none of the methods differed significantly. Mean error increased with GFR for all methods ($p<0.001$). Conclusion: Using all GFR calculation methods, the measurement errors that can be expected in a busy clinical Nuclear Medicine department are small compared to intra-patient variation of repeat measurements. These findings support emerging evidence in favour of using the shorter SS-GFR over SI-GFR or SO-GFR in busy clinics with high patient throughput.

OP040

Clinical usefulness of advanced quantitative analysis of diuresis renogram in patients with equivocally obstructed upper urinary tract

S. BEATOVIC[1], M. Jankovic[2], D. Sobic Saranovic[1], E. Jaksic[1], V. Antic[3], M. Blagic[3], V. Artiko[1]; [1]University of Belgrade Faculty of Medicine, Center for Nuclear Medicine, Clinical Center of Serbia, BELGRADE, SERBIA, [2]University of Belgrade Faculty of Electrical Engineering, BELGRADE, SERBIA, [3]Center for Nuclear Medicine, Clinical Center of Serbia, BELGRADE, SERBIA.

Introduction: Advanced parameters of diuretic renography - output efficiency (OE) and normalized residual activity (NORA) help to distinguish between obstructed and non-obstructed kidneys. Unfortunately, algorithm for their calculation is not widely available. Non-commercial software developed by International Atomic Energy Agency (IAEA) enables this comprehensive analysis, but till now, it has not been widely implemented in the nuclear medicine institutions in developing countries. The aims of this study were: a) to calculate, by means of the International Atomic Energy Agency (IAEA) software, the values of ^{99m}TcDTPA renogram parameters in obstructed kidneys and hypotonic unobstructed

kidneys and to determine significance of OE and NORA in the assessment of equivocally obstructed urinary tract. Subjects and methods: 153 patients with suspected obstruction (age range: 18-83 years; mean: 51.8 years) underwent ^{99m}Tc DTPA dynamic scintigraphy with furosemide stimulation at 20 minute. 164 kidneys were investigated. 40-minutes acquisition with 240 10-sec images was applied. Post-void static image was acquired at 50 minute. Studies were analyzed by two observers and, according to assessment of images and renograms, kidneys were classified as obstructed (56), hypotonic unobstructed (63) and equivocal (45). IAEA software was applied to each study. Parameters analyzed were: OE at 20 minute (OE_{20}) and 20 minutes after injection of furosemide (OE_{F+20}), NORA at 20 minute ($NORA_{20}$), NORA on the post-micturition acquisition ($NORA_{PM}$) and residual kidney counts on post-micturition acquisition normalized to maximum kidney counts (PM/max). Results for obstructed kidneys were: OE_{20}: 56.8±10.1%; OE_{F+20}: 69.5±7.1%; $NORA_{20}$: 2.28±0.52; $NORA_{PM}$: 0.40±0.12; PM/max: 0.21±0.05. Results for hypotonic unobstructed kidneys were: OE_{20}: 52.8±10.1%; OE_{F+20}: 87.9±3.7%; $NORA_{20}$: 2.38±0.52; $NORA_{PM}$: 0.12±0.04; PM/max: 0.061±0.02. Difference between obstruction/dilatation was significant for OE_{F+20}, $NORA_{PM}$ and PM/max *($p<0.001$)*. Linear regression analysis between OE_{20} and $NORA_{20}$ was significant *($r = -0.975$; $p<0.001$)*. Among 45 kidneys with equivocal findings according to standard parameters, calculation of OE_{F+20} revealed 26 kidneys to be non-obstructed. In 2 kidneys obstructive pattern was converted into non-obstructive according to $NORA_{PM}$ and PM/max value. In remaining 17 kidneys both parameters were in obstructive range. Conclusion: Results of OE_{20}, OE_{F+20}, $NORA_{20}$ and $NORA_{PM}$ for obstructed and unobstructed kidneys, calculated by the use of IAEA software showed excellent agreement with previously reported values of these parameters for ^{99m}Tc DTPA. High correspondence between OE and NORA gives the opportunity of replacing OE with NORA, when algorithm for OE could not be applied. OE_{F+20}, $NORA_{PM}$ and PM/max contribute to clarify equivocal findings of diuresis renography.

OP041

Blood-Pool Compensation Method Revisited: Similarity and Difference in Comparison with Patlak-Rutland Plot

M. Samal[1], A. Brink[2], V. Ptacnik[1], H. Jiskrova[1], D. Skibova[1], J. Kubinyi[1]; [1]Charles University Prague @ General University Hospital in Prague, Prague, CZECH REPUBLIC, [2]Red Cross War Memorial Children's Hospital, Cape Town, SOUTH AFRICA.

A slope of Patlak-Rutland plot (PRP) has been used to calculate differential kidney function not affected by vascular background in the kidney ROI. Blood-pool compensation method (BPC) claims that it further corrects for extravascular (interstitial) background [EJNMMI 2016;43:550]. The aim of this study was to examine the assertion in more detail. Method: Performance of PRP and BPC has been compared with simulated and patient data (107 MAG3 dynamic renal studies in adults and 173 in children). Renal curves were simulated as "zero-output curves" (without outflow) - scaled integrals of a monoexponential plasma clearance curve. Vascular backgrounds were simulated as scaled plasma curves, extravascular backgrounds as weak kidneys. In the patient data, PRP and BPC were applied to a fixed interval between 1 - 2 minutes. Both the heart and the liver ROIs have been used to generate input functions and a circumferential kidney ROI was chosen to represent kidney background. Differential kidney functions calculated by PRP and BPC under various conditions were compared using Passing-Bablok regression. Results: Using the same time-activity curves, PRP and BPC provided almost identical results. PRP has been found more robust with better linear relationship between the plotted variables. In all simulated experiments, the ratio of PRP slopes was identical to the ratio of BPC intercepts. Differential function was not affected by vascular background in the kidney ROI and by extravascular background in the heart or the liver ROI. However, it was affected by extravascular background in the kidney ROI. Despite this fact, an independent analysis has confirmed the main result of the EJNMMI paper above: BPC with the liver ROI input curve (without additional background subtraction) provides the same result as PRP with the heart ROI input curve and circumferential background subtraction from the kidney ROI. Whether this is the result of renal extravascular background compensation by BPC or another effect (related to the liver ROI curve rather than kidney curve) still remains to be established. Conclusion: BPC method definitely extends a tool kit for calculation of differnetial kidney function. It has also been shown that in case of absence of the heart in the field of view, the liver can be used as an excellent substitution in either BPC or PRP. It is interesting that such a possibility has already been proposed 30 yrs ago by C.S.Patlak [JCBFM 1985;5:584] but remained overlooked in renal nuclear medicine by now.

OP042

Clinical validation of comprehensive non-commercial software for renogram analysis: values of washout parameters in healthy individuals

S. BEATOVIC[1], M. Jankovic[2], D. Sobic Saranovic[1], E. Jaksic[1], V. Artiko[1]; [1]University of Belgrade Faculty of Medicine, Center for Nuclear Medicine, Clinical Center of Serbia, BELGRADE, SERBIA, [2]University of Belgrade Faculty of Electrical Engineering, BELGRADE, SERBIA.

A decade ago IAEA initiated the work on comprehensive non-commercial software for processing of renogram on a simple p-computer, but the software hasn't been completed and only the draft version was available. Furthermore, the accuracy of numerical outputs of the software has not been assessed in comparison with commercial software. Purpose: The aims of this study in healthy individuals were: to implement IAEA software into analysis of Tc-99m DTPA and Tc-99m MAG_3 dynamic scintigraphy and to validate results of obtained renogram parameters against their reference values. Patients and Methods: Study population consisted of 104 healthy subjects who were evaluated by dynamic scintigraphy for kidney donation. 54 of them underwent Tc-99m DTPA scintigraphy and 50 ^{99m}Tc MAG_3 scintigraphy. 208 kidneys were analyzed in total. IAEA software was applied to process the studies. Parameters analyzed were: time to maximum activity (T_{max}), time to half maximum ($T_{1/2}$), output efficiency at 20 minutes (OE_{20}), residual kidney counts at 20min normalized to the 1-2min counts ($NORA_{20}$), residual kidney counts on post-micturition acquisition normalized to the 1-2min counts ($NORA_{PM}$), residual kidney counts on post-micturition acquisition normalized to maximum kidney counts (PM/max), whole kidney mean transit time (MTT) and mean parenchymal transit time (MPTT). Correspondence between OE_{20} and $NORA_{20}$, was evaluated by Pearson correlation coefficient and linear regression analysis. The results for Tc-99m DTPA were: T_{max}: 3.6 ± 0.9 min; $T_{1/2}$: 9.1 ± 3.5 min; OE_{20}: 88.1 ± 2.3%; $NORA_{20}$: 0.66 ± 0.1; $NORA_{PM}$: 0.07 ± 0.02; PM/max: 0.06 ± 0.01; MTT: 2.08 ± 0.54 min and MPTT: 1.77 ± 0.37 min. Results for ^{99m}Tc MAG_3: T_{max}: 3.8 ± 0.7 min; $T_{1/2}$: 6.9 ± 1.9 min; OE_{20}: 92.0 ± 2.4%; $NORA_{20}$: 0.38 ± 0.1; $NORA_{PM}$: 0.03 ± 0.01; PM/max: 0.02 ± 0.01; MTT: 2.44 ± 0.61 min and MPTT: 1.80 ± 0.33 min. The excellent agreement was observed between obtained values of renogram parameters and their reference values in the literature. Significant linear correlation between $NORA_{20}$ and OE_{20} was observed ($r = -0.936$, $p< 0.01$). Conclusion: IAEA software gives reliable numerical indices of kidney excretion. The values for normal kidneys were almost identical with previously reported reference values for DTPA and MAG_3 parameters. $NORA_{20}$ highly corresponds with OE_{20} and could replace the former parameter in the evaluation of kidney drainage. The obtained results should be an incentive for IAEA to continue its work on completion of software in order to standardize technique of dynamic renal scintigraphy.

OP043

Evaluation of interobserver agreement in interpretation of indirect radionuclide cystography

B. Caliskan, A. N. Korkmaz; Abant Izzet Baysal University, Department of Nuclear Medicine, Bolu, TURKEY.

Aim: Indirect radionuclide cystography (IRC) offers chance to investigate vesico-ureteric reflux (VUR) without bladder catheterization and it has an advantage of lower radiation burden compared with radiological micturating cystogram. We aimed to investigate the interobserver agreement in interpretation of IRC. **Material and metods:** Indirect radionuclide cystograms of 47 patients were retrospectively evaluated independently by 2 experienced nuclear medicine physicians. The mean age of the patients was 8.25±3.75 and 37 of the patients were females (79%). All patients had routine dynamic renal scintigraphy. Subsequently IRC's were performed by collecting 3-second frames during voiding. Curves were generated by drawing region of interests over bladder and two kidneys. IRC's were interpreted in a stepwise fashion involving visual images, compressed images and curves, respectively. The diagnosis of VUR was recorded as a result of the final decision of physician. The interobserver agreement between the two physicians in determining the VUR was investigated using the Kappa statistics. A Kappa-value >0.80 was considered as "excellent", 0.61-0.80 as "good", 0.41-0.60 as "moderate" and 0.40 or less as "poor". **Results:** The interobserver agreement was found to be poor when the physicians made their decision with only visual images (k=0.242, p=0.102). There was a moderate interobserver agreement in assessment of VUR with the evaluation of compressed images of IRC (k=0.564, p<0.001) and there was no difference between the observers in determining the VUR by curves. When a final diagnosis of VUR was made with taking of all three kind of processes into consideration, there was a moderate agreement between the two observers to assess the VUR in IRC (k=0.589, p<0.001). **Conclusions:** The diagnosis of VUR in IRC is more reliable when all of the visual images, compressed images and curves are taken into consideration. Interpretation of only the visual images decreases the interobserver agreement in IRC.

OP044

Non-infectious complications of peritoneal dialysis detected by Peritoneal scintigraphy - our experience

A. Fernandes, T. Faria, A. Oliveira, V. Alves, M. Perez, A. Pinto, J. Pereira; Hospital São João, Porto, PORTUGAL.

Introduction/Aim: The use of Continuous Ambulatory Peritoneal Dialysis (CAPD) is increasing. Despite its confirmed advantages (compared with haemodialysis), several complications have been recognized - including infectious and pressure-related ones. The infusion into the peritoneal cavity leads to increased intra-abdominal pressure with potential leakage. Dialysate leakage occurs in more than 5% of patients in the first year of CAPD. Leaks may present as pericatheter drainage, but more often present as subcutaneous swelling and oedema, weight gain, peripheral or genital oedema, and apparent ultrafiltration failure. When dialysate leakage occurs into subcutaneous tissues, it is sometimes difficult to evaluate. Available diagnostic methods include radiography, CT with contrast material, and peritoneal scintigraphy. Our aim was to analyse our results and ascertain the diagnostic value of peritoneal scintigraphy. **Materials/Methods:** We reviewed data from all patients who underwent peritoneal scintigraphy at our department from 2008 to March 2016 (n=81), and used indirect follow-up criteria to verify leakage: surgical intervention to the catheter/CAPD suspension - "confirmation"; maintenance of CAPD with no further surgical interventions - "non-confirmation". Peritoneal scintigraphy protocol: the abdominal cavity was drained of all dialysate, and 185 MBq of Tc-99m-MAA (in 1 L of dialysate solution) were instilled via the peritoneal catheter. Images were acquired 5 hours after instillation: planar images of the peritoneal cavity (anterior/lateral projections), obtained both with the patient in a supine position and standing-up, before and after drainage of the dialysate. When necessary, SPECT/CT was performed. **Results:** Scintigraphies were performed because of abdominal wall swelling, inguinal/genital swelling, poor drainage/ultrafiltration, or pleural effusion. We detected leaks in 57 patients (70%), some with multiple sites, resulting in 62 leaks (48.4% in the umbilical region, 17.7% in the hypogastric region, 16.1% in the iliac region, 6.5% in the lumbar region, 4.8% in the pleural cavity, 3.2% in the genital region, and 3.2% in other locations). Of these 57, we confirmed leakage in 41; 6 patients maintained CAPD with no further surgical interventions; we couldn't assess the follow-up of 10 patients. Of the 24 negative studies, 21 maintained CAPD with no further surgical interventions; two patients had otherwise diagnosed leakage; we couldn't assess the follow-up of 1 patient. The positive predictive value (PPV) was 87,2% and the negative predictive value (NPV) was 91,0%. **Conclusion:** Peritoneal scintigraphy is a simple, safe, low-radiation-exposing, non-invasive method of determining the site of dialysate leak, allowing diagnosis, post-surgery evaluation and follow-up. In our series we found high PPV and NPV.

M2M: New Radiotracers - Brain

OP058
Evaluation of two new radiotracers for alpha synuclein PET imaging

E. Levigoureux[1,2], W. ZEINYEH[3], T. BILLARD[3], F. CHAUVEAU[1], M. VERDURAND[1], L. ZIMMER[1,2,4], S. LANCELOT[1,2]; [1]Université Claude Bernard Lyon 1, Lyon Neuroscience Research Center, INSERM, CNRS, Lyon, FRANCE, [2]Hospices Civils de Lyon, Lyon, FRANCE, [3]Université Claude Bernard Lyon 1, Institute of Chemestry and Biochemestry, CNRS, Villeurbanne, FRANCE, [4]CERMEP-Imaging Platform, Bron, FRANCE.

Aim Alpha-synuclein (α-syn) aggregation is a neuropathological hallmark of neurodegenerative diseases called synucleinopathies, including Parkinson's disease, dementia with Lewy bodies and multiple system atrophy. The purpose of this study was to evaluate two new radiotracers, the N-{4-[(E)-2- (1,3-benzoxazol-2yl)ethenyl]phenyl}-4-fluoro-N-methylbenzene-1-sulfonamide or [^{18}F]ZW27 and N-{4 [(E)-2-(1,3-benzoxazol-2-yl)ethenyl]phenyl}-2-fluoro-N methylbenzene-1-sulfonamide or [^{18}F]ZW31, as possible probes for PET imaging of cerebral α-syn plaques. **Material and methods** To investigate the selectivity of the two radiotracers, we tested the ability of [^{18}F]ZW27 and [^{18}F]ZW31 to bind to synthetic α-syn and Aβ1-42 fibrils. Synthetic fibrils were obtained by incubating human recombinant proteins at 200 μM, 37 °C. The quality of the fibril formation was determined by ThT fluorescence and transmission electron microscopy, before the binding assays. Fibrils (400 nM) were incubated with increasing concentrations of [^{18}F]ZW27 and [^{18}F]ZW31 (0.5-200 nM). These reactions were duplicated in the presence of unlabeled molecules at a concentration of 50 μM to evaluate the non-specific binding. Binding data were analyzed with a curve fitting software that calculates the Kd and Bmax using nonlinear regression. **Results** Analyses indicated that [^{18}F]ZW27 bound on α-syn fibrils with a low affinity (Kd = 155.4 nM and Bmax = 2.073 pmol/nmol of fibrils) and with a better affinity on Aβ1 42 fibrils (Kd = 7.74 nM and Bmax = 0.802 pmol/nmol of fibrils). In contrast, [^{18}F]ZW31 bound on α-syn fibrils with a high affinity (Kd = 3.291 nM and Bmax = 0.128 pmol/nmol of fibrils) and with a lower affinity on Aβ 1- 42 fibrils (Kd = 145.3 nM and Bmax = 0.592 pmol/nmol of fibrils). **Conclusion** These preliminary results suggest that [^{18}F]ZW31 is potentially a radiotracer for α-syn imaging while [^{18}F]ZW27 is more interesting for amyloid imaging studies. These molecules have now to be evaluated in postmortem studies in synucleinopathies and Alzheimer' disease patients in order to confirm this trend and to envisage a possible first-in-man study.

OP059
Novel compounds for specific visualization of α-synucleinopathies by PET

B. Hooshyar Yousefi[1], M. Mohring[1], T. Arzberger[2], G. Höglinger[3], H. Wester[4], M. Schwaiger[1]; [1]Klinikum rechts der Isar, Technical University Munich, Nuclear med. Dept., Munich, GERMANY, [2]Neurobiobank München, Center for Neuropathology and Prion Research, Department of Psychiatry and Psychotherapy, Ludwig-Maximilians-Universität München, Munich, GERMANY, [3]Klinikum rechts der Isar, Technical University Munich, Department of Neurology and German centre of neurodegenrative diseases (DZNE), Munich, GERMANY, [4]Technical university Munich, LS Pharm. Radiochemistry, Garching, GERMANY.

PET is increasingly applied for diagnosis of neurodegenerative diseases such as Alzheimer's disease by targeting neuroproteopathies like cerebral amyloid (Aβ), PHF-tau and NFTs. Tracer delineating α-synuclein protein expression would be invaluable for early diagnosis of α-synucleinopathies (α-syn) and clinical trials testing of therapeutic strategies aimed at lowering α-synuclein protein levels in the brain. Hence, the objective of this study was to find chemical entities that can be transformed into radiolabeled tracers for selective imaging of α-synuclein depositions. **Methods:** Among the compounds screened in our lab, a promising series of candidates based on 4,4'-diaryl-2,2'-bithiazole (DABTA) was identified as specific markers for α-syn as opposed to other proteopathies (eg. Aβ and tau). Pharmacokinetics of these radioligands were investigated using biodistribution and in-vivo stability studies. Furthermore, blood-brain-barrier penetration and specific binding

have been studied with longitudinal PET, ex vivo/ in vitro autoradiography and IHC using transgenic E46K rats. **Results:** The search for α-syn tracers revealed several compounds with nanomolar affinity for α-syn suitable for ^{11}C- or ^{18}F-labeling. The first biological evaluation of [^{18}F]DABTA-11, 4-(benzo[d][1,3]dioxol-5-yl)-4'-(4-([^{18}F] fluoroethoxy)phenyl)-2,2'-bithiazole, indicated a high intial brain uptake (> 5 %ID/g at 5 min, log D=2.9) and fast brain clearance (5/30 min brain uptake ratio > 5.7, n=5) with high binding (Ki<10nM), and high selectivity (>120-fold) over Aβ and tau. Moreover, [^{18}F]DABTA-11 PET in 2 month old E46K rats showed accumulation in medulla oblongata which became more prominent after 6 months of age and a detectable uptake in substantia nigra. **Conclusion:** A library of DABTAs was screened and preclinically evaluated as α-syn imaging agents. [^{18}F]DABTA-11 PET showed excellent accumulation in medulla oblongata followed by substantia nigra (known α-syn rich regions) in E46K rats at 6 month. These findings suggest that DABTA-11 is the first promising and selective α-synuclein tracer that may allow early diagnosis of α-synucleinopathies such as Parkinson's disease and dementia with Lewy bodies or multiple system atrophy.

OP060

Evaluation of the Ligand [^{18}F]IMA201 as a Novel Radiotracer for Aggregated Alpha-Synuclein in Parkinson's Disease

E. J. Smyth[1], S. Tang[1], I. Ahmed[2], L. A. Wells[1], C. Plisson[1], J. Passchier[1]; [1]Imanova Ltd, London, UNITED KINGDOM, [2]Parkinson's UK Brain Bank, Imperial College London, London, UNITED KINGDOM.

Alpha-synuclein is found in an aggregated state in many neurodegenerative diseases such as Parkinson's disease (PD). The availability of a PET ligand selective for α-synuclein would greatly help in drug development for PD in addition to the diagnosis and prognosis of α -synuclein associated diseases. The aim of this study was to evaluate [^{18}F]IMA201 as a potential PET ligand for delineation of α-synuclein in patients with PD. Animal experiments were conducted in accordance with the UK Animals (Scientific Procedures) Act 1986. [^{18}F]IMA201 was prepared following the recently developed copper II-mediated ^{18}F-fluorination methodology.[1] Human tissue was ethically sourced from the Parkinson's UK Brain Bank. Anatomically adjacent fresh frozen tissue sections (10μm) from the grey matter area of the midbrain or cortical region of three individual PD patients were cut and fixed in 4% paraformaldehyde. Sections were incubated with increasing concentrations of [^{18}F]IMA201 (0.3, 1, 10nM) for 45 minutes, washed twice and opposed to phosphor-imager plates. Specific binding (SB) was identified by homologous block (10μM) and ligand binding was quantified using a standard curve. The presence of α-synuclein was confirmed with immunohistochemistry in anatomically adjacent slides. Dynamic PET scans were conducted under baseline conditions and following pre-treatment with unlabelled IMA201 (2 mg/kg *i.v.*) to determine *in vivo* regional brain uptake of [^{18}F]IMA201 in a healthy male rat. IMA201 was successfully labelled with ^{18}F with a radiochemical yield of 150-400MBq and mean specific activity of 10 ±11 GBq/μmol (n=3). [^{18}F]IMA201 demonstrated a heterogenous SB signal in brain tissue of three patients at three different concentrations (**0.3nM:** 6.2, 22 and 6.5 DLU/mm^2/Bq; **1nM:** 0, 120 and 40 DLU/mm^2/Bq;**10nM:** 390, 370 and 100 DLU/mm^2/Bq). Percentage SB ranged from 0 - 87%, which was consistent with the heterogenous expression of α-synuclein between patients as determined by immunohistochemistry. [^{18}F]IMA201 demonstrated good brain penetration in a healthy rodent with reversible kinetics during the time of the scanning period. The successful labelling, SB characteristics and good *in vivo* kinetic profile of [^{18}F]IMA201 suggest that this is a potential candidate for monitoring α-synuclein in the CNS. Radiosynthesis optimisation to allow clinical translation and further studies investigating the selectivity of [^{18}F]IMA201 for α-synuclein over other misfolded proteins in patient brains, including the evaluation of a SB signal in a rodent model of PD, are required to confirm the potential of [^{18}F]IMA201 in clinical applications and neurodegenerative drug development. **Reference: 1. OP061

Identification of PF-06684511 as a novel β-secretase (BACE) selective radioligand lead for PET imaging

L. Zhang[1], M. A. Brodney[1], E. M. Beck[1], J. K. Dutra[2], B. T. O'Neill[2], L. M. Buzon[2], T. J. McCarthy[1], C. E. Nolan[1], A. Villalobos[1], L. Chen[2]; [1]Pfizer Inc., Cambridge, MA, UNITED STATES, [2]Pfizer Inc., Groton, CT, UNITED STATES.

Aim Amyloid β (Aβ) plaque accumulation in brain is a hallmark of Alzheimer's disease (AD) pathology. Aβ production occurs by consecutive cleavage of amyloid precursor protein by β- and γ-secretase. Limiting Aβ production via inhibition of β-secretase (BACE) is an attractive strategy to develop a disease-modifying AD therapy. We are interested in developing a BACE-specific PET ligand to facilitate clinical characterization and assessment of BACE inhibitors. Herein, we report PF-06684511 as a potent and selective PET radioligand lead that demonstrated high specific binding in vivo. **Materials and methods** The existing chemical matter was prioritized based on potency/selectivity, physicochemical, and in vitro pharmacokinetic properties. Specifically, we targeted central nervous system PET multi-parameter optimization (CNS PET MPO >3); passive permeability (RRCK > 10 x 10^{-6} cm/s) and multi-drug resistance efflux (MDR BA/AB ≤ 2.5); and brain fraction unbound (Fu_b > 0.05). The in vivo specific binding was assessed in a LC-MS/MS based "cold-tracer" method in mice. PF-06684511 was dosed in tracer amount (10 μg/kg, iv). Concentrations were quantified in cerebellum, frontal cortex, hippocampus and striatum at 45 minutes post administration. The specific binding was defined by comparison between a wild-type (WT) group and a BACE-knockout (KO) group (n=5 per group). Vehicle and three doses of a selective BACE inhibitor (1, 10 and 80 mg/kg, sc) were tested in male 129/sve mice to determine target occupancy (TO). **Results** Prioritization of existing chemical matter (~800 compounds) led to rapid identification of PF-06684511 as a promising radioligand lead. Structurally PF-06684511 is amenable to either [^{11}C] or [^{18}F] labeling. It showed high BACE potency (IC_{50}= 0.7 nM), high RRCK (17.5 x 10^{-6} cm/s), low MDR BA/AB (1.6) and favorable Fu_b (0.06). In the LC-MS/MS "cold-tracer" study, PF-06684511 showed high brain uptake and bio-distribution consistent with BACE expression.A significant reduction of PF-06684511 binding was observed in KO mice (e.g. 0.7% ID/g vs. 2.3% ID/g WT in hippocampus), indicating high specific binding. Furthermore, binding of PF-06684511 in these brain regions was reduced by a selective BACE inhibitor in a dose-dependent manner, confirming its potential for TO determination. **Conclusions** Using a set of PET ligand design parameters, PF-06684511 was rapidly identified with favorable in vitro attributes and structural handles for PET radiolabeling. Further evaluation in a LC-MS/MS "cold-tracer" study revealed high specific binding to BACE in vivo. Taken together, these data suggested PF-06684511 is a promising radioligand lead for BACE PET imaging.

OP062

Fluorinated Derivatives of Puromycin for PET Imaging of Protein Synthesis

H. M. Betts[1], S. Milicevic Sephton[2], C. Tong[3], R. O. Awais[3], P. J. Hill[3], A. C. Perkins[3], F. I. Aigbirhio[2]; [1]Nottingham University Hospitals NHS Trust, Nottingham, UNITED KINGDOM, [2]University of Cambridge, Cambridge, UNITED KINGDOM, [3]University of Nottingham, Nottingham, UNITED KINGDOM.

Introduction and Aims: Disruption of cellular protein synthesis (PS) is a hallmark of numerous diseases including cancer and neurodegeneration. The ability to visualise and quantify PS is an important goal in diagnosis, treatment and monitoring of these conditions. Radiolabelled amino acids have been investigated widely for this purpose, but their application suffers from several key limitations, including the inability to distinguish between active transport and PS.[1] At present, there is no ideal radiotracer for imaging PS by PET. The aim of this project was to develop a radiotracer which is not an amino acid but enables measurement of PS *in vivo,* and can be radiolabelled with fluorine-18, via [^{18}F]fluoride. Puromycin (PURO) is an antibiotic that inhibits PS in both bacteria and eukaryotes by mimicking aminoacyl-tRNA at the ribosome.[2] We hypothesised that a fluorine-18 labelled PURO analogue could be used for PS imaging, and previously reported a single derivative as a potential candidate.[3] We now describe the synthesis and PS inhibitory potency of a series of PURO analogues containing a fluorine substituent. **Materials and Methods**: A previously reported common intermediate was employed for further derivatisation.[4] The novel PURO analogues were analysed in a PS assay using Gaussia Luciferase as a bioluminescent reporter, and their potency compared with that of commercially available PURO. The radiosynthesis of the most potent candidate was achieved by direct nucleophilic [^{18}F]fluorination of a tosylate precursor followed by deprotection. **Results**: Fifteen novel PURO analogues were prepared from the common intermediate in 20-90% yields. Fluoroethylpuromycin (FEPURO) proved the most potent PS inhibitor of the class, exceeding the inhibitory activity of PURO itself in the assay. Three-step radiosynthesis of [^{18}F]FEPURO was achieved in 140 min in 2±1% radiochemical yield (not corrected for decay) and with radiochemical purity >99%. **Conclusions**: From the series of novel PURO analogues, FEPURO was identified as a potential candidate for PET imaging of PS. Radiosynthesis of [^{18}F]FEPURO was successfully accomplished in modest yield and excellent radiochemical purity. Characterisation of [^{18}F]FEPURO *in vivo* is underway in our laboratories. [1]P. OP063

[18F]F13640 preclinical evaluation as a 5-HT1A receptor agonist for PET neuroimaging, from rodent to non-human primate

B. Vidal[1], S. Fieux[1], T. Billard[2], O. Barret[3], G. Tamagnan[3], A. Newman-Tancredi[4], L. Zimmer[1,5,6]; [1]Université Claude Bernard Lyon 1, Lyon Neuroscience Research Center, INSERM, CNRS, Lyon, FRANCE, [2]Université Claude Bernard Lyon 1, Institute of Chemistry and Biochemistry, CNRS, Villeurbanne, FRANCE, [3]Molecular NeuroImaging, New Haven, CT, UNITED STATES, [4]Neurolixis Inc., Dana Point, CA, UNITED STATES, [5]Hospices Civils de Lyon, Lyon, FRANCE, [6]CERMEP - Imaging Platform, Bron, FRANCE.

Aim: Serotonin 1A receptors are known to play an important role in many psychiatric and neurodegenerative disorders. Currently, all available 5-HT1A fluorinated PET radiopharmaceuticals are antagonists. As agonists bind preferentially to the high-affinity (G-protein-coupled) state of receptors, it would be of great interest to develop agonist radioligands which could provide a measure of the functional 5-HT1A receptors in pathophysiological processes. The agonist 5-HT1A radiotracer candidates we proposed recently had interesting in vitro properties but were not optimal in terms of in vivo imaging (Eur J Nucl Med 2010, 37(3): 594-605; J Nucl Med 2012, 53(6): 934-41). We propose now a new selective agonist with a suitable affinity for 5-HT1A receptors. Materials and methods: F13640 is a ligand with a high affinity (1nM) and a high selectivity for 5-HT1A receptors. Its nitro-precursor was synthesized and radiolabeled via a fluoro-nucleophilic substitution. Its radiopharmacological characterization included autoradiographic studies, biodistribution and metabolic studies, PET scans in rats, cats and non-human primates. Several of these results were compared with studies using the antagonist [18F]MPPF, a validated 5-HT1A radiopharmaceutical. Results: The radiochemical purity of [18F]F13640 was > 98%. [18F]F13640 in vitro binding was consistent with the 5-HT1A receptors distribution. Biodistribution studies revealed that 1% of the radiotracer rapidly entered the brain and led to few brain radiometabolites. [18F]F13640 binding was decreased by co-injection of WAY-100635, a 5-HT1A antagonist, or blocked by pre-injection of 8-OH-DPAT, a 5-HT1A agonist (-40% and -85% in the rat, respectively). [18F]F13640 in vivo distribution differed from the classical distribution observed with [18F]MPPF. As an example, in the three studied species, [18F]F13640 binding was high in the dorsal raphe nucleus and the cingular cortex, but moderate in the hippocampus. Finally, ex vivo and microPET studies in rat revealed a high sensitivity of [18F]F13640 to endogenous serotonin, with a binding decrease after low doses of fenfluramine (a serotonin releaser). Conclusions: [18F]F13640 has suitable characteristics for probing in vitro and in vivo the high-affinity states of the 5-HT1A receptors. Interestingly, this study reveals that the binding pattern of a selective agonist radiotracer can differ significantly from the binding of a selective antagonist radiotracer. Quantification analyses with kinetic modelling are in progress to prepare the first-in-man study of [18F]F13640.

OP064

In vivo characterization of a novel [18F]-labelled radiotracer for PET Imaging of multidrug resistance or drug toxicity

P. Kannan[1], J. Collins[2], T. Falls[2], W. Ladno[2], S. Dizdarevic[3], M. van Dam[2], J. Lee[2], D. Maheshwari[1]; [1]Avaant Pharmaceuticals Inc, Woburn, MA, UNITED STATES, [2]Crump Institute for Molecular Imaging, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine at UCLA, Los Angeles, CA, UNITED STATES, [3]Avaant Pharmaceuticals Inc, Brighton and Sussex University Hospitals NHS Trust and Brighton and Sussex Medical School, Brighton, UNITED KINGDOM.

Background: Multidrug resistance (MDR) is a major impediment in the treatment of cancer and various neurological disorders. Two efflux transporters from the ATP-binding cassette (ABC) family, ABCB1 (P-gp) and ABCG2 (BCRP), commonly contribute to MDR by restricting the entry of therapeutic drugs into target organs, including into brain across the blood brain barrier and tumours. Contrary, constitutionally low expression of ABC transporter proteins is linked with drug toxicity and susceptibility to ABC-mediated disease. **Aim:** The goal of this work was to characterize the specificity, brain uptake, and metabolism of the new tracer, AVT-011, with an ultimate aim for detecting and investigating the function of ABC-transporter proteins, MDR or drug toxicity in vivo. **Methods:** To enhance clinical utility, AVT-011 was radiolabelled with [^{18}F]. The specificity of the radiotracer [^{18}F]-AVT-011 for ABCB1 and/or ABCG2 was measured using three groups of mice (FVB background strain, females): wild-type (n = 5), those genetically lacking *abcb1a/1b* (n = 5), and those genetically lacking *abcg2* (n = 5). Brain uptake was assessed quantitatively and reported as standardized uptake value (SUV) from dynamic PET scans performed over 120 mins following intravenous injection of approximately 3-4 MBq [^{18}F]-AVT-011. The plasma protein binding of the radiotracer was determined using human plasma proteins, while the metabolism of the radiotracer was determined using human microsomes. **Results:** AVT-011 was successfully radiolabelled with [^{18}F], resulting in a decay-corrected yield of 3.7 ± 1.0% (n=4) and specific activity of 143 ± 31 (n=4) GBq/μmol. At 120 min, brain uptake of [18F]-AVT-011 was 2 times higher in mice lacking ABCB1 (0.15 ± 0.04 SUV) and 1.4 times higher in mice lacking ABCG2 (0.10 ± 0.02 SUV) than in wild-type mice (0.075 ± 0.013 SUV). Brain

uptake remained stable out to 120 mins, with peak uptake occurring within the first minute. Plasma protein binding of the radiotracer was 43.6 ± 4.0%, and 91% of the radiotracer remained in its unchanged form at 30 min. **Conclusions:** AVT-011 can be readily labelled with [^{18}F] at sufficiently high specific activity and yield for in-vivo imaging. The radiotracer [^{18}F]-AVT-011 is a substrate for ABCB1 and ABCG2 at the mouse blood brain barrier, is stable metabolically, and has good bioavailability. Since many drugs are dual substrates for ABCB1 and ABCG2, and these transporters are often co-expressed in causing MDR in multiple disease, [^{18}F]-AVT-011 seems to be a promising new radiotracer for dual ABC/MDR imaging.

OP065

Supervised Cluster Analysis for Automatic Extraction of Reference Region in Dynamic [^{18}F]THK5317 PET

M. Jonasson[1,2], A. Wall[2], K. Chiotis[3], K. Heurling[1], L. Saint-Aubert[3], G. Antoni[1,2], A. Nordberg[3], M. Lubberink[1,2]; [1]Uppsala University, Uppsala, SWEDEN, [2]Uppsala University Hospital, Uppsala, SWEDEN, [3]Karolinska Institutet, Stockholm, SWEDEN.

Objectives: [^{18}F]THK5317 is a PET tracer for in-vivo imaging of tau pathology which is associated with neurodegeneration and cognitive impairment. Research investigation on tau pathology imaging with PET is facilitated by the availability of simplified analysis methods such as standardized uptake value ratios (SUVr). However, previous work has shown modest correlation between SUVr and binding potential (BP), with the latter assumed to be better representation of tau accumulation. Parametric images based on dynamic [^{18}F]THK5317, showing BP at voxel level, are preferred for investigation of tau distribution in the brain. Reference tissue models, used to compute these images, require a reference region time-activity curve (TAC). The aim of this study was to evaluate a supervised clustering analysis method (SVCA) for automatic extraction of a reference region and compare with parametric images computed using MRI-based cerebellum volume of interest (VOI) as reference input. **Methods:** Sixteen subjects (5 healthy controls, 8 AD and 3 MCI) received a 60 min dynamic [^{18}F]THK5317 PET scan and a T1-weighted MRI scan. A set of four predefined kinetic classes was defined based either on the five healthy subjects (cerebellum reference class) or five randomly selected AD subjects (white matter, grey matter and blood pool class). The SVCA algorithm segments voxels in the dynamic PET volume based on the shape of their TACs with no spatial constraint. Voxels with TACs most resembling the kinetic behavior of the proposed reference region are selected and a reference TAC can be obtained. Reference Logan DVR-1 and SUVr-1 (40-60 min p.i.) images were computed for the remaining AD and MCI subjects using both MRI-based and SVCA-based reference. Nine representative regions were used for the evaluation. Correlation and agreement of DVR-1 and SUVr-1 values of the two methods were assessed by linear regression. **Results:** Correlation and agreement between DVR-1 values of all nine regions, based on MRI and SVCA reference regions, were high: R^2=0.92 and 0.87, slope=1.09 and 1.05 for DVR-1 and SUVr-1 values respectively. When evaluating single regions, correlation was somewhat lower; e.g. R^2=0.76 and 0.74, slope=0.94 and 1.21, for DVR-1 and SUVr-1 values in hippocampus, respectively. **Conclusion:** The results indicate that supervised clustering may be used to obtain a reference TAC from a dynamic [^{18}F]THK5317 PET scan. This would allow for automated computation of parametric images without the need for an MRI scan. The presented method needs to be evaluated in a larger number of subjects.

OP066

[11C]flumazenil kinetics in the rat brain: model preference and the impact of non-specific and non-selective binding in reference region modeling

I. Lopes Alves[1], D. Vállez García[1], A. Parente[1], J. Doorduin[1], A. Marques da Silva[2], M. Koole[3], A. T. M. Willemsen[1], R. Dierckx[1], R. Boellaard[1]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, BRAZIL, [3]KU Leuven, Leuven, BELGIUM.

Aim: The analysis of [^{11}C]flumazenil pre-clinical studies currently follows the quantitative models validated in the clinical setting. Since tracer kinetics can differ between species, [^{11}C]flumazenil kinetic modeling was evaluated for the rat brain. Material and Methods: 60min [^{11}C]flumazenil brain PET scans with arterial sampling were performed in two groups of male Wistar rats (n=10, tracer dose only; n=2, pre-saturated with 330nM of flumazenil). Time-activity curves (TACs) were generated for frontal cortex, hippocampus, cerebellum, medulla and pons (reference). Next, noiseless TACs (n=10) were simulated using an average input function and representative rate constants from animal data. A three-tissue compartment model including a compartment for non-selective binding was simulated with different levels of specific-binding (k_3 ranging from 0.2 to 2.6min^{-1}). For animal and simulated data, distribution volume (V_T) and distribution volume ratios (DVR) were calculated using one and two-tissue compartment models (1TCM and 2TCM) and spectral analysis (SA). Binding potential (BP_{ND}) was determined from full and simplified reference tissue models with one or two-tissue compartments for the reference (FRTM, SRTM and SRTM-2Ref). Parameter agreement was assessed by Spearman's correlation and Bland-Altman plots. Akaike information criterion (AIC) was used to determine model preference. Results: 1TCM and 2TCM V_T of regions with high specific-binding (frontal cortex, hippocampus and cerebellum) showed similar AIC (143±7 and 148±10 respectively), strong correlation (r_s=0.99) and good agreement (0.1% difference). In contrast, low specific-binding regions (pons and medulla) showed worse correlation (r_s=0.77) and agreement (17.6% difference), while AIC were lower for 2TCM (134±10) than for 1TCM (161±8). The pre-saturated group displayed similar results to those of low specific-binding regions. High levels of non-specific and/or non-selective binding (2TCM V_T=2.5±0.4) was observed in pons and affected BP_{ND} estimation by all tested reference tissue models. Simulations showed a similar pattern: 2TCM V_T demonstrated better agreement (<8.0% bias) than 1TCM for all levels of specific-binding, while 1TCM V_T demonstrated smaller bias with increasing specific-binding (from -55.1% to 3.1%). SA generated accurate V_T (<0.9% bias) for all specific-binding levels. 1TCM DVRs resulted in the largest BP_{ND} overestimation (up to 58% bias), while SRTM-2Ref showed an overall smaller bias (<1.5%). Conclusion: [^{11}C]flumazenil kinetics in rats was substantially different from that in humans, especially in low specific-binding regions. In those, the 2TCM is preferred and the standard 1TCM and SRTM can lead to major errors in parameter estimation. Instead, models which can better account for non-specific and/or non-selective binding should be used, such as 2TCM or SA.

OP067

Quantitative Assessment of Osteoblastic Tumor Burden with Threshold-based Volumetric Na^{18}F PET/CT Methodologies - Challenges and Opportunities

C. I. Odom, C. L. Wright, P. Subramanian, J. Zhang, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

Aim: Although routinely used for ^{18}F-FDG PET, maximum lesion SUVs for Na^{18}F-avid lesions demonstrate very high values even in benign areas of increased bone turnover. Total lesion fluoride (TLF) and fluoride tumor volume (FTV) are recently described metrics that may enable better prognostic information for ^{18}F-avid malignant/metastatic osteoblastic lesions.

These metrics can be rapidly established using whole-body threshold-based isocontouring but are confounded by the inadvertent inclusion of benign regions of increased bone turnover. This study assessed methodologies for evaluating and quantifying osteoblastic tumor burden in oncologic patients. **Materials and Methods:** 20 patients who underwent routine $Na^{18}F$ PET/CT studies for prostate, breast, thyroid, and head/neck cancers were retrospectively evaluated. Visual assessment of ^{18}F-avid osteoblastic lesions was performed by a reader panel. Quantitative isocontour assessment of ^{18}F-avid osteoblastic tumor burden was performed using either automated threshold-based whole body contouring or manual contouring of individual lesions. Using a MIM workstation, the following parameters were assessed: highest SUV_{max} for all osteoblastic lesion ($hSUV_{max}$), average of SUV_{max} values over all ^{18}F-avid osteoblastic lesions, fluoride tumor volume (FTV) for all isocontoured lesions, and the whole-body total lesion fluoride (TLF) uptake. **Results:** Qualitative assessment demonstrated a spectrum of ^{18}F-avid osteoblastic tumor burden ranging from no lesions to extensive multifocal osteoblastic disease. In addition, there was a wide spectrum of osteoblastic degenerative disease burden. Quantitative whole-body isocontour assessment of ^{18}F-avid osteoblastic activity using a minimum threshold SUV of 10 were sufficient to capture osteoblastic metastatic lesions but it also captured benign degenerative disease which confounded the automated whole-body results (Automated analysis: $hSUV_{max} = 56 \pm 43$, average $SUV_{max} = 15 \pm 6$, FTV = 153 ± 111 mL, and TLF = 2371 ± 1956 SUV*mL). Although labor-intensive, manual lesion-by-lesion isocontouring of ^{18}F-avid osteoblastic metastatic lesions (Manual analysis: $hSUV_{max} = 48 \pm 48$, average $SUV_{max} = 16 \pm 10$, FTV = 33 ± 58 mL, and TLF = 884 ± 1777 SUV*mL) minimizes false-positive tumor activity from underlying benign osteoblastic disease and provides more accurate quantification of tumor-specific osteoblastic disease burden. **Conclusion:** Confounding factors like degenerative disease limits the clinical utility of automated or semi-automated whole body threshold-based methodologies for quantifying tumor-specific osteoblastic disease burden. The alternative approach of using manual lesion-by-lesion quantitative assessment produces more robust and more accurate metrics for quantifying osteoblastic disease burden.

OP068

Investigation into the optimal model for whole tumour and voxel FMISO kinetics analysis

D. R. McGowan[1,2], R. E. Macpherson[2], S. L. Hackett[1], F. V. Gleeson[2], G. S. Higgins[1], J. D. Fenwick[1,3]; [1]University of Oxford, Oxford, UNITED KINGDOM, [2]Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM, [3]University of Liverpool, Liverpool, UNITED KINGDOM.

Purpose A study is presented of the relative abilities of different kinetics compartmental models to describe whole tumour and voxel FMISO uptake time-activity-curves (TACs). **Methods** Two-, three- and four-compartment models were fitted to 28 TACs obtained for 14 tumour structures in 8 patients with advanced stage lung cancer, each imaged twice as part of an ongoing clinical trial. Descriptions of the TACs provided by fits of the models were compared using the Wald-Wolfowitz runs test, Akaike and Bayesian information criteria (AIC/BIC), and leave-one-out cross-validation. The accuracy and precision with which fitted model parameters estimated the uptake kinetics were calculated using statistical simulation procedures carried out for several different ground-truths. These analyses were performed both for whole tumour volumes as well as for individual voxels. **Results** An irreversible three-compartment model, 3C5K, provided the best overall description of the FMISO uptake time-courses of whole tumours according to AIC, BIC and cross-validation scores totalled across TACs. Fits of the 3C5K model and a more complex four-compartment model, 4C7K, passed the runs test for 23/28 and 28/28 TACs respectively. However, the simulation studies indicate that 3C5K fits provided the most accurate and precise estimates of FMISO uptake kinetics (10% precision for tumour fractional blood volumes and FMISO binding rate-constants), even for TACs described better by the 4C7K model. The 3C5K model also provided the best overall description of time-courses of FMISO uptake in individual voxels according to AIC and BIC measures. However, simulation studies indicated that 2C3K model fits provide the most accurate and precise estimates of voxel FMISO uptake kinetics (39% precision for tumour fractional blood volumes and 37% for FMISO binding rate-constants): the higher noise-levels within single voxel uptake time-courses means that the greater stability of this simpler model outweighs its less accurate descriptions of their time-courses. **Conclusion** Fits of an irreversible three-compartment model provide the best descriptions of uptake time-courses of whole tumours, and the most precise and accurate estimates of their uptake kinetics. For single voxels the three-compartment model also provides the best descriptions of uptake time-courses, however fits of a simpler irreversible two-compartment model provide more precise and accurate estimated of uptake kinetics in single voxels.

OP069

A comparative analysis between SVM and PCA plus Logistic Regression for the construction of a discriminative glucose metabolic brain pattern in ALS

M. Devrome, J. Ceccarini, D. Van Weehaeghe, P. Van Damme, K. Van Laere, M. Koole; KU Leuven, Leuven, BELGIUM.

Introduction The differential diagnosis of neurodegenerative disorders may be difficult on clinical grounds only, especially at an early stage. [^{18}F]FDG brain PET imaging allows the identification of several disease-specific metabolic patterns such that a differential diagnosis is facilitated. Two different machine learning methods, Support Vector Machine (SVM) and regularized Logistic Regression (LR) combined with Principal Component Analysis for feature extraction (PCA-LR), were used for the construction of a discriminative brain pattern in Amyotrophic Lateral Sclerosis (ALS) and were evaluated in terms of classification performance. **Methods** PCA-LR is based on the method of Spetsieris et al. [1]. First, PCA is performed by selecting a limited number of eigenvectors of the data covariance matrix. Regularized LR is then applied to find the weights discriminating the most between the ALS and healthy controls PCA features, where the weighted sum of the selected eigenvectors corresponds to a discriminative brain pattern for ALS. SVM is a sparse kernel technique obviating the feature selection prior to training of the classifier. A linear kernel is considered, because this leads to a straightforward construction of the ALS specific discriminative pattern. Static [^{18}F]FDG-PET scans were selected from a prospective cohort of 175 patients with a clinical diagnosis of ALS [2]. 20 ALS scans were randomly selected and combined with the 20 scans of age matched healthy controls to generate a realistic training set. Performance was tested using a leave-one-out cross-validation. **Results** The PCA-LR approach resulted in a sensitivity of 91%, a specificity of 96%, an accuracy of 93.5% and an Area Under Curve (AUC) of 96.1% for the Receiver Operating Characteristic (ROC) curve. For SVM, a sensitivity of 90.5%, a specificity of 97.5%, an accuracy of 94% and an AUC of 96.6% for the ROC curve was found. Both methods generated a discriminative metabolic brain pattern for ALS where known regions of relative hypo-and hyper-metabolism could be clearly identified. **Conclusion** A discriminative voxel-wise metabolic brain pattern for ALS was constructed, based on both a SVM and PCA-LR approach. In terms of discriminative performance, similar results were obtained for both methods for a relatively small but realistic sample size, with a comparable discriminative brain pattern. Partial Volume Effect correction (PVC) improves the sensitivity of SPM for the detection of focal cordial dysplasia on refractory epilepsy

J. Silva-Rodríguez[1], J. Cortés[2], X. Rodríguez-Osorio[3], Á. Ruibal[2], P. Aguiar[1]; [1]Fundación Ramón Domínguez, Santiago de Compostela, SPAIN, [2]Nuclear Medicine Department, University Hospital, Santiago de Compostela, SPAIN, [3]Neurology Department, University Hospital, Santiago de Compostela, SPAIN.

Introduction: In latter years, PET has gained a leading role in the presurgical evaluation of refractory epilepsy. The availability of co-registered PET/MRI images has improved the interpretation of images of both modalities, while the use of quantification techniques, such as Statistical Parametric Mapping (SPM), has improved the interpretation of PET images. SPM is a well-known quantification technique in PET neuroimaging, but its sensitivity in epilepsy is still relatively low when compared with other applications such as dementia. This might be related with the Partial Volume Effect (PVE) and the low resolution of PET images when dealing with small focal hypometabolisms, such as those observed in epilepsies associated with focal cortical dysplasias (FCDs). Due to this, techniques that can provide an improvements on PET resolution are promising in order to improve the localization of these focal hypometabolisms. On a previous work, our group has shown how PVE correction improves the sensitivity of both quantification and visual inspection on temporal lobe epilepsy, which was associated to an improved visualization of the hippocampal region. **Aim:** In this work, we investigate the impact of PVE correction on the sensitivity of SPM for the localization of small focal hypometabolisms associated with FCD on refractory epilepsy. **Methods:** This study was performed on 14 patients diagnosed with refractory epilepsy caused by a FCD reported on the MRI examination (11 FCD-I, 2 FCD-II and 1 FCD-III). All of them underwent surgery with positive outcome. PET images were visually evaluated using PET/MR co-registered images. The analysis was complemented by with a SPM statistical analysis comparing the patient to 87 controls. PET images were corrected using a novel PVE correction method. The quantification results with and without PVE correction were compared. Co-registered images and quantitative analysis were provided by IQ-Brain (QubioTech Health Intelligence S.L). **Results:** On the original evaluation, the visual inspection of PET/MR co-registered images reported hypometabolism associated with the FCD on 85.7% (12/14) of the patients, while SPM performed very poorly, being positive only for 57.1% (8/14) of the patients. After the correction, the SPM statistical analysis showed a sensitivity of 85.7% (12/14), which implies an improvement of a 28.6% and is comparable to the sensitivity of the visual inspection. These results are in good agreement with the ones previously obtained on TLE patients. **Conclusions:** PVE correction showed potential to improve the sensitivity of SPM on the detection of the hypometabolisms associated with FCD in refractory epilepsy.

Value of ^{111}In-PSMA-radioguided surgery for salvage lymphadenectomy in recurrent prostate cancer: correlation with histopathology and clinical follow-up

I. Rauscher, T. Maurer, M. Wirth, M. Schottelius, H. Wester, J. E. Gschwend, M. Schwaiger, M. Eiber; Klinikum rechts der Isar, Munich, GERMANY.

Aim: With the advent of ^{68}Ga-HBED-PSMA PET hybrid imaging techniques even small and atypical localized metastatic lesions of prostate cancer (PCa) can be visualized. Previously, the novel technique of PSMA-radioguided surgery (PSMA-RGS) to localize those metastatic lesions using a γ-probe after injection of a radiolabelled PSMA-ligand has been described. However, follow-up of these salvage surgery cases is necessary to determine its possible role in clinical routine. Thus, the aim of this study was to evaluate the feasibility of preoperative injection of ^{111}In-labeled PSMA-I&T SPECT/CT for facilitated intraoperative identification of PSMA-positive lesions using a γ-probe in recurrent PC and to correlate these results with postoperative histopathological results of the resected lymph nodes. Further, the impact of PSMA-RGS was tested using postoperative prostate-specific antigen (PSA) values and clinical recurrence-free survival. **Material and Methods**: 22 consecutive patients with localized recurrent prostate cancer (PCa) underwent PSMA-RGS with ^{111}In-labeled PSMA ligand during April 2014 to March 2015. Preoperative median PSA was 1.38ng/ml (range: 0.19 - 13.90ng/ml). Results of ex vivo radioactive rating (positive vs. negative) of resected tissue were compared to findings of postoperative histological analysis. Best PSA response without additional treatment was determined 8-16 weeks following PSMA-RGS and PCa-specific additional treatments were recorded. **Results**: In 21/22 patients PSMA-RGS could identify the lesions intraoperatively. One patient without identification of the metastatic lesion in the deep internal region exhibited a PSA of 0.45ng/ml. On follow-up PSMA-PET imaging lesion was still present. In total, 85 surgical specimens were removed and 34 showed metastatic involvement at histological analysis. 32 were correctly classified as metastatic and 47 as cancer-free, 2 specimens were false negative and 4 false positive compared to standard histological evaluation. Follow-up information was available for 21/22 patients. PSA reduction >50% were observed in 16/21 patients and >90% in 10/21 patients. In 11/21 patients a PSA drop below 0.2ng/ml could be observed. 9/21 patients received further PCa-specific treatment after median 4 months after PSMA-RGS (range: 3 - 13 months), the remaining 12 patients remained treatment free at a median follow-up of 10 months (range: 7 - 17 months). **Conclusion**: PSMA-radioguided surgery proved to be of high value for intraoperative detection of even small metastatic lesions in PCa patients scheduled for salvage lymphadenectomy and might have a beneficial influence on further disease progression. However, identification of suitable patients on the basis of PSMA-PET imaging is critical to obtain satisfactory results.

Predictive and prognostic potential of volume-based metabolic variables with 18F-FDG PET/CT in locally advanced breast cancer

A. Garcia Vicente[1], J. Pérez-Beteta[2], M. Tello Galán[1], D. Molina-García[2], G. Jiménez Londoño[1], V. Pérez-García[2], A. Martínez-González[2], F. Pena Pardo[1], A. Soriano Castrejón[1]; [1]Nuclear Medicine Department. Hospital General Universitario de Ciudad Real, CIUDAD

REAL, SPAIN, [2]Instituto de Matemática Aplicada a la Ciencia y a la Ingeniería. UCLM., CIUDAD REAL, SPAIN.

Aim: To investigate the usefulness of metabolic variables of breast lesions obtained in 18F-FDG PET/CT in the prediction of neoadjuvant chemotherapy (NC) response and prognosis in locally advanced breast cancer (LABC). ***Material and methods:*** Prospective study including 67 patients with LABC and NC indication and a baseline 18F-FDG PET/CT. After breast tumor segmentation, SUV variables (SUVmax, SUVmean and SUVpeak) and volume-based variables as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were obtained. Breast specimens were grouped into molecular phenotypes and classified as responders or no responders after completion of NC. Univariate analysis was performed with the use of Kaplan-Meier and Cox proportional hazards models to study the potential of metabolic variables, molecular phenotypes and histologic response to predict: disease-free status (DFs), disease-free survival (DFS) and overall survival (OS). ***Results:*** Sixty patients underwent NC. 14 were classified as responders. 56 patients had a DFs during the follow-up. Median±SD of DFS and OS was 43 ±15 and 46±13 months respectively. SUV and volume-based variables showed significant relations ($p<0.005$) with the histological response with higher values in responders compared to no responders (median, mean and SD of SUVmax, SUVmean, SUVpeak, MTV and TLG of 13.77,13.34 and 5.79; 8.85, 8.35 and 3.73; 11.33, 10.7 and 4.88; 13.44, 26.60 and 34.58 and 96.39, 258.12 and 384.63 for responders vs 6.04, 7.84 and 5.26; 3.42, 4.77 and 3.20; 4.79, 6.06 and 4.08; 9.88, 13.63 and 12.48 and 33.78, 70.17 and 97.94 for non responders respectively).MTV and TLG showed significant association with DFs ($p=0.015$ and $p=0.038$ respectively). Median, mean and SD of MTV and TLG for patients with DFs were: 8.90, 13.72 and 15.12 and 33.78. 90.54 and 144.64 respectively. Median, mean and SD of MTV and TLG for patients with a non-DFs were: 16.72, 29.70 and 31.09 and 90.89, 210.98 and 382.80 respectively. No significant relations were observed with SUV variables and DFs. No significant relations were obtained for none metabolic variable with DFS and OS. ***Conclusion:*** Volume-based metabolic variables obtained with 18F-FDG PET/CT, differently to SUV based variables, were good predictors of neoadjuvant chemotherapy response and disease free status in patients with locally advanced breast cancer.

OP076

Ga68 RM2 PET/MRI Evaluation of Gastrin-Releasing Peptide Receptor Status in Patients with Biochemically Recurrent Prostate Cancer and Negative Conventional Imaging

A. Iagaru, I. Sonni, R. Minamimoto, A. Loening, S. Vasanawala; Stanford University, STANFORD, CA, UNITED STATES.

Background: ^{68}Ga-labeled DOTA-4-amino-1-carboxymethyl-piperidine-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH2 (^{68}Ga-RM2, formerly known as ^{68}Ga-Bombesin or BAY86-7548) is a novel synthetic bombesin receptor antagonist that targets gastrin-releasing peptide receptors (GRPr). GRPr are highly overexpressed in several human tumors, including prostate cancer (PC). Because of their low expression in BPH and inflammatory prostatic tissues, imaging GRPr has potential advantages over current choline- and acetate-based radiotracers. We now present data on the use of ^{68}Ga-RM2 PET/MRI in patients with biochemically recurrent prostate cancer (BCR PC) and non-contributory conventional imaging (CI). **Methods:** We enrolled 28 men with BCR PC, 59-83 year-old (mean±SD: 68.4±6.7) in an IRB-approved prospective study. Imaging started at 40-69 minutes (mean±SD: 50.1±7.2) after injection of 3.6-4.1 mCi (mean±SD: 3.8±0.2) of ^{68}Ga-RM2 using a time-of-flight enabled simultaneous PET/MRI scanner. MRI sequences consisted of T1-weighted, T2-weighted and DWI. SUV_{max} and SUV_{mean} measurements were recorded in normal tissues and areas of uptake outside the expected physiologic biodistribution. **Results:** All patients had rising PSA (range: 0.3-36.4 ng/mL; mean±SD: 6.9±7.9) and non-contributory CI (CT, MRI, ^{99m}Tc MDP bone scan). ^{68}Ga-RM2 uptake had the highest value in the pancreas and bladder, while moderate uptake was noted in the esophagus, kidneys, blood pool, stomach, small bowel and colon. High ^{68}Ga-RM2 uptake (SUV_{max}: 12.7 ± 7.8 [range: 2.6 - 33.5], SUV_{mean}: 5.7 ± 2.5 [range: 1.7 - 10.8]) corresponded to pelvic lymph nodes (7 patients), retroperitoneal lymph nodes (5 patients), prostate bed (3 patients), seminal vesicle (2 patients), supraclavicular lymph node (2 patients), mesenteric lymph nodes (1 patient), mediastinal lymph node (1 patient), liver (1 patient), lung (1 patient) and bone marrow (1 patient). ^{68}Ga-RM2 PET findings were compatible with recurrent prostate cancer in 19 of the 28 participants. MRI identified findings compatible with recurrent prostate cancer in 8 of the 28 patients (lymph nodes in 6 patients, prostate bed in 1 patient, lung in 1 patient and bone marrow in 1 patient). **Conclusions:** ^{68}Ga-RM2 produces high quality PET images for assessment of GRPr expression in patients with BCR PC. High uptake in multiple areas compatible with cancer lesions suggests that ^{68}Ga-RM2 is a promising PET radiopharmaceutical for localization of disease in participants with BCR PC and non-contributory conventional imaging.

OP077

^{68}Ga-PSMA PET/CT for early restaging prostate cancer. Preliminary results of a prospective trial in patients with biochemical failure after radical therapy and PSA levels < 2 ng/mL

F. Ceci, P. Castellucci, T. Graziani, C. Fonti, F. Lodi, S. Boschi, S. Fanti; Service of Nuclear Medicine, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim: the goal of this mono-centric prospective trial was to assess the performance of ^{68}Ga-PSMA-PET/TC in detecting the site of relapse in prostate cancer (PCa) patients who experienced biochemical recurrence (BCR) after primary treatments. **Materials and methods**: this prospective trial was approved by the local ethical committee (protocol "PSMA-PROSTATA"). Inclusion criteria were: 1) histological proven diagnosis of PCa; 2) radical therapy with radical prostatectomy (RP) or primary external-beam radiotherapy (EBRT) (with/without adjuvant therapies); 3) proven BCR with rising PSA values comprised between 0.2-2 ng/mL; 4) Gleason Score (GS) ≥7; 5) Age ≥35 years. The study was designed to enrol a homogenous cohort of 100 consecutive patients, with stringent selection criteria for preventing heterogeneity in our cohort. From March 2016 to April 2016, 50 patients have been so far enrolled and included in the present analysis. 47/50 (94%) patients were treated with RP + pelvic lymph-node (LN) dissection, while 3/50 (6%) received EBRT as primary therapy. 12/50 (24%) patients received salvage radiotherapy during follow-up for BCR. Only 2/50 (4%) patients were receiving androgen deprivation therapy at the time of ^{68}Ga-PSMA-PET/TC. The mean PSA values at the time of scan were 0.89 ng/mL (median=0.77 ng/mL); mean age=69,7 years-old (median=70); median GS=7. Correlative imaging with choline-PET/CT and/or pelvic magnetic resonance (MR) was available in 27/50 (54%) patients. **Results**: ^{68}Ga-PSMA-PET/TC resulted positive in 31/50 patients (positivity rate=62%). Local uptake (prostate bed or prostate gland and/or pelvic LNs) was observed in 15/50 patients (30%); distant uptake (retroperitoneal LNs and/or bone) in 10/50 patients (20%); local and distant uptake in 5/50 patients (10%); lung uptake in 1/50 (2%). The mean PSA values in PET-positive patients was 1.04 ng/mL (median=0.91 ng/mL), while in PET-negative patients was 0.65 ng/mL (median=0.31 ng/mL). In 26/31 PET-positive patients (83.9%) were observed not more than 1 or 2 lesions (oligometastatic disease). In PSA range values comprised between 0.2-0.5 ng/mL ^{68}Ga-PSMA-PET/TC resulted positive in 6/18 patients (positivity rate=30%). Correlative imaging was available in 18 of 31 PET-positive patients and resulted negative/inconclusive in 14/18 (77.8%) of cases. 1/50 (2%) patient had negative ^{68}Ga-PSMA-PET/TC and positive choline-PET/CT. The lung lesion was later confirmed as PCa relapse by histology.

Conclusion: the preliminary results of this prospective trial confirmed the promising performance of ^{68}Ga-PSMA-PET/TC for early restaging PCa patients with BCR. The validation of ^{68}Ga-PSMA-PET/CT in the clinical setting and its comparison with histology and/or other techniques would facilitate the routine implementation of this modality.

F-18-FDG PET/CT in the evaluation of tumour response after neoadjuvant chemoradiation (nCRT) in locally advanced oesophageal cancer

M. J. Valkema[1], B. J. Noordman[1], B. P. L. Wijnhoven[1], J. P. Ruurda[2], G. A. P. Nieuwenhuijzen[3], M. I. Van Berge Henegouwen[4], M. N. Sosef[5], J. J. B. Van Lanschot[1], R. Valkema[1]; [1]Erasmus MC University Hospital, Rotterdam, NETHERLANDS, [2]University Medical Centre, Utrecht, NETHERLANDS, [3]Catharina Hospital, Eindhoven, NETHERLANDS, [4]Academic Medical Centre, Amsterdam, NETHERLANDS, [5]Atrium Medical Centre, Heerlen, NETHERLANDS.

Aim: Neoadjuvant chemoradiotherapy (nCRT) with "CROSS" (NEJM 2012) is effective in reducing tumour load preoperatively. Many patients (92%) had radical resections after nCRT, with pathologically complete response (tumour regression grade = TRG1) in 29%. In future, we aim at postponing surgery using adequate clinical response evaluations (CRE) until residual locoregional disease without distant metastases has been identified. A multicentre feasibility study is underway (preSANO trial, NL41732.078.13) including endoscopy, biopsies, ultrasound and FDG-PET/CT with surgery 12 weeks after nCRT. The current preliminary analysis focuses on FDG-PET/CT to predict residual vital tumour (minimal: ≤10% vital cells = TRG1+2, substantial: >10% = TRG3+4) after nCRT. **Methods:** FDG-PET/CT at baseline and CRE was performed according to EANM guidelines 1.0 (2.3MBq/kg F-18-FDG; scanning 60±5min.). Visual assessment: presence of residual tumour and/or metastases. SUV and SUV/lean body mass (SUL) measurements at tumour, lymph nodes, oesophagus, liver and bloodpool were recorded and compared with pathology (resection specimen). **Results:** Of 75 patients analysed, 7 withdrew before CRE. Ten patients had no surgery (1 died, 1 metastases before CRE, 5 FDG-positive metastases, 3 surgery postponed). Eight patients had surgery without FDG-PET/CT at CRE. In the remaining 50 operated patients FDG-PET/CT at CRE was positive in 36 (72%). In 3/36 patients tumours appeared irresectable, 33/36 patients had radical resections. In 18/33 TRG3 or TRG4 residual tumour was found. SUL-max in these tumours was 3.67±0.97 and SUL-max-ratio tumour/oesophagus (SULR) 1.83±0.41. In 8/33 patients TRG2 residual tumour was present; SUL-max 4.35 ±2.52 and SULR 2.24±1.41. In 1/33 patients TRG score was missing. In total, FDG-PET/CT was true positive in 29/36 patients (81%). 6/36 patients had no vital tumour (TRG1; 17% false positive); SUL-max 2.84±0.97, SULR 1.60±0.69. In 14/50 operated patients FDG-PET/CT at CRE was negative. No vital tumour (TRG1) was found in 6/14 patients (43% true negative); SUL-max 1.94±0.29, SULR 1.14±0.16. Conversely, 1 patient had minimal (TRG2) and 7/14 patients had substantial residual tumour (TRG3 or TRG4); SUL-max 2.49±0.71, SULR 1.43±0.09. Two patients (1 irradical resection) had non-FDG avid baseline scans, 6 (1 irradical resection) had good FDG-response compared to baseline. **Conclusion:** Positive FDG-PET/CT after nCRT predicts substantial residual tumour in 81% of patients. However, visual and quantitative FDG-PET/CT alone is not sufficiently accurate for detection or exclusion of substantial vital tumour; results of FDG-PET/CT performance combined with endoscopy, biopsies, ultrasound have to be awaited.

OP079

Using dynamic ^{18}F-FDG PET for lung tumour segmentation and quantitative assessment of glucose metabolism for different histological types

T. W. H. van Zon-Meijer[1], L. F. de Geus-Oei[2,3,4], E. P. Visser[3], W. J. G. Oyen[5], M. G. Looijen-Salamon[6], D. Visvikis[7], A. F. T. M. Verhagen[8], J. Bussink[1], **D. Vriens**[2]; [1]Department of Radiation Oncology, Radboud University Nijmegen Medical Centre (Radboudumc), Nijmegen, NETHERLANDS, [2]Department of Radiology, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS, [3]Department of Radiology and Nuclear Medicine, Radboud University Nijmegen Medical Centre (Radboudumc), Nijmegen, NETHERLANDS, [4]Biomedical Photonic Imaging Group, MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, NETHERLANDS, [5]The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, UNITED KINGDOM, [6]Department of Pathology, Radboud University Nijmegen Medical Centre (Radboudumc), Nijmegen, NETHERLANDS, [7]INSERM, UMR 1101, LaTIM, Université de Bretagne Occidentale, Brest, FRANCE, [8]Department of Cardiothoracic Surgery, Radboud University Nijmegen Medical Centre (Radboudumc), Nijmegen, NETHERLANDS.

OBJECTIVES: Combined radiochemotherapy is the standard treatment for irresectable stage III non-small cell lung cancer (NSCLC). The aim of this prospective cohort study was dual. Firstly, to answer whether 4D dynamic is superior to static ^{18}F-FDG PET for tumor delineation using pathology volumes as Gold standard. Secondly, to describe tumor regional variation in pharmacokinetic rate constants of ^{18}F-FDG metabolism (K_1-k_3) and fractional blood volume (V_B) in regions with different levels of glucose metabolic rate (MR_{glc}) and compare these between histologies. METHODS: One-hour dynamic ^{18}F-FDG PET/CT scans were acquired in 38 patients with resectable NSCLC of at least 30mm in diameter. Two datasets were obtained: a static image 50-60min post injection and a parametric image of Patlak MR_{glc} values. Lesions were delineated on both using three strategies: (i) a threshold of 50% of the maximum voxel value, (ii) an adaptive threshold method of 40% of the background subtracted maximum voxel value and (iii) using the fuzzy locally adapted Bayesian (FLAB) algorithm. The pathological volume was calculated from three orthogonal tumor diameters. For the second aim, the tumor was divided in three equal volumes of increasing MR_{glc}, in which, K_1-k_3 and V_B were computed. RESULTS: 35 patients having 36 primary malignancies were available for analysis. These included 20 squamous cell carcinomas (SCC), 12 adenocarcinomas (AC) and 4 lesions with another malignant histology. Pathological volumes were significantly larger than image volumes, except for FLAB volumes in a subset of 23 patients without macroscopic necrosis. Static PET volumes were significantly larger than volumes determined on MR_{glc} images. The volume determined by FLAB on the static PET corresponded best with the pathological volume. In SCC compared to AC, lesion MR_{glc} and k_3 were significantly higher and V_B was significantly lower. AC showed less heterogeneity relative to SCC in terms of mean MR_{glc}, k_3 and V_B. In SCC, a significant higher value for k_3 and lower value for V_B was found in regions with higher values of MR_{glc}. CONCLUSIONS: FLAB delineation on static ^{18}F-FDG PET scans resulted in volumes in best agreement with pathology. There was significant difference in glucose metabolic rate, phosphorylation rate (k_3) and fractional blood volume between the major pathological subtypes of NSCLC. In SCC, tumor regions with higher MR_{glc} showed higher phosphorylation rate and lower fractional blood volumes compared to regions with less intense metabolism. These differences in metabolism between NSCLC histologies might be relevant for targeting therapies and radiotherapy dose escalation.

OP080

Quantification of FDG uptake to detect residual nodal disease in locally advanced head and neck squamous cell carcinoma (LAHNSCC) after chemoradiotherapy (CRT): which threshold is optimal?

N. Helsen[1,2], T. Van den Wyngaert[1,2], L. Carp[1,2], O. Hoekstra[3], F. De Geeter[4], A. Maes[5], K. Spaepen[6], J. Cambier[7], F. Homans[6], D. Van den Weyngaert[8], S. Stroobants[1,2]; [1]University of Antwerp, Antwerp, BELGIUM, [2]Antwerp University Hospital, Wilrijk, BELGIUM, [3]VU university medical center Amsterdam, Amsterdam, NETHERLANDS, [4]Sint-Jan, Brugge, BELGIUM, [5]AZ Groeninge, Kortrijk, BELGIUM, [6]Sint-Augustinus, Wilrijk, BELGIUM, [7]Jessa Hospital, Hasselt, BELGIUM, [8]Middelheim Hospital, Antwerp, BELGIUM.

Background Surveillance of the neck with FDG-PET/CT after CRT in LAHNSCC patients is a valid alternative to routine neck dissection (Mehanna H, et al. N Engl J Med 2016). However, image interpretation remains largely unstandardized and quantification may further improve diagnostic accuracy. **Methods** Different $SUV_{body\ weight}$ thresholds and lesion-to-background ratios were explored in a prospective multicenter study of FDG-PET/CT 12 weeks after CRT in newly diagnosed LAHNSCC patients (ECLYPS). Whole-body (WB) and dedicated head-and-neck (H&N) series were acquired in 5 PET centers with scanner cross-calibration and image reconstruction according to EANM EARL criteria. Reference standard was histology or >1y negative clinical follow-up after imaging. Time-dependent receiver-operator characteristics (ROC) curves were used to determine the optimal cut-off thresholds and ratios at 1 year after CRT. Prognostic value was assessed with Cox regression. Thresholds were validated in an independent retrospective cohort of HNSCC patients referred for suspicion of disease recurrence using non-standardized FDG-PETC/CT scans as performed in routine clinical care (n=127; median interval of imaging after CRT: 13 weeks, mean FU time 29.2 months). **Results** A total of 152 patients were enrolled, with 125 (male 93; median age 59) having primary tumor control and entering clinical follow-up. With a median follow-up of 20.4 months, 23 nodal neck recurrences were observed (prevalence 18.4%; 95% CI: 12.0-26.3%). A threshold of SUV_{50}=2.1 yielded an optimal AUC on both WB series (AUC=0.88, sensitivity=79.7% and specificity=80.8%) and H&N series (AUC=0.84, sensitivity=73.1% and specificity=79.8%), but only the WB series outperformed visual assessment (AUC=0.79; sensitivity=73.1%, specificity=85.0%; p=0.040). lesion-to-background ratios were not superior to visual assessment for WB (SUV_{50}/SUV_{liver}; threshold=0.96; AUC=0.89; p=0.056) and H&N ($SUV_{90}/SUV_{parasp\ muscle}$; threshold=2.7; AUC=0.84; p=0.507) images. Validation of thresholds in an independent cohort yielded similar AUC values: WB SUV_{50}=0.84, WB SUV_{50}/SUV_{liver}=0.90, HN $SUV_{90}/SUV_{parasp\ muscle}$=0.88. WB SUV_{50}/SUV_{liver} had best sensitivity (74.6%) and specificity (94.8%), and outperformed visual read (p=0.011). The SUV_{50}/SUV_{liver} ratio was the most prognostic metric in the prospective and retrospective study for prediction of nodal recurrence (HR 6.98 and 13.2; 95% CI: 3.03-16.09 and 6.94-25.4; p<0.0001) and survival (HR 6.78 and 4.31; 95% CI: 2.46-18.71 and 2.29-8.12; p<0.0001). **Conclusion** FDG uptake quantification improves the diagnostic performance of FDG-PET/CT in LAHNSCC patients 1 year after CRT and contributes clinically meaningful prognostic information. When using EARL standardized PET acquisitions and reconstruction, absolute SUV metrics prove robust, yet ratios may be more useful in routine clinical care with less standardized imaging protocols.

OP081

Feasibility and results of a comprehensive whole-body PET/MR protocol for staging non-small cell lung cancer

M. Soussan, C. Comtat, S. Djelbani, V. Brulon, I. Buvat, B. Helal; IMIV, CEA-Inserm, Univ Paris Sud, CNRS, Université Paris Saclay, Orsay, France, Orsay, FRANCE.

OBJECTIVES: For non-small cell lung cancer (NSCLC) staging, FDG-PET/MR might be superior to PET/CT in the detection of mediastinal invasion and metastatic disease. We evaluated the feasibility of a comprehensive PET/MR protocol for NSCLC staging. **METHODS:** 23 patients underwent a dual-imaging protocol consisting of a PET/CT scan (Biograph, Siemens) followed by PET/MR scan (Signa, GE healthcare) for lung cancer staging. PET/CT scans were performed 63±11 min after injection of 4MBq/kg of 18F-FDG (head to mid-tight, 3 min/bed position (n=7 beds), FORE+OSEM reconstruction, 6 iterations/8 subsets). Subsequently (108±14 min after injection), PET/MR was performed (2-3min/bed position, 5-6 beds) and PET data were reconstructed using TOF- OSEM, 2 iterations/28 subsets. MR sequences included a Dixon sequence for attenuation correction and a 5mm section axial T2- T2W FRFSE, with respiratory triggering (duration ~2-3 min). Axial T1-weighted 3D dual-GE sequence (LAVA-Flex) in the thorax was then performed (duration ~1 minute, n=10/23). Then, MR brain imaging was performed (n=15/23), including a FLAIR and a post contrast 3D-T1-weighted sequences (duration ~8 min). Thoracic lesions were identified visually in PET/CT and PET/MR. The number, location, SUVmax, and largest diameter were compared between both modalities. **RESULTS:** 50 hypermetabolic lesions were identified: 26 lung lesions, 22 lymph nodes (LN), one adrenal and one bone lesions. All lung lesions (mean CT size: 28+/-23 mm [3-81 mm] seen on CT were also identified on T2W images, with an excellent correlation in lesion size (r=0.99) and with no significant difference between MR and CT-estimated size (p=0.4). Mediastinal hypermetabolic LN were measurable in 17/22 and 16/22 of cases in PET/CT and PET/MR, respectively. Correlations in LN size and SUVmax were excellent: r=0.95 and r=0.92, respectively. Pooling all lesions, SUVmax were 79±63 % higher in PET/MR than PET/CT, due to both the ~45 min delay between PET/MR and PET/CT, and the different generation of PET scanners (TOF vs non-TOF).Thoracic T1W sequence, for T staging purpose, was feasible and provided good contrast between tumor with mediastinum or thoracic wall. Brain imaging was feasible and showed brain metastasis in 5/15 patients. **CONCLUSION:** PET/MR including thoracic and brain imaging is feasible for the TNM staging of NSCLC, with scan duration less than 45 min. Lesion-size measurements in PET/MR for lung and mediastinal lesions are comparable to those in PET/CT. PET/MR imaging might thus be considered as a "one-stop shop" modality for the staging of NSCLC.

OP082

Comparison Between LUGANO, EORTC, PERCIST And IHP Criteria At Interim PET In Patients With Follicular Non-Hodgkin's Lymphoma

L. Baratto[1], O. Jegede[2], F. Hong[2], B. Kahl[3], A. M. Evens[4], A. Quon[1]; [1]Division of Nuclear Medicine and Molecular Imaging, Department of Radiology, Stanford University, Stanford, CA, UNITED STATES, [2]Department of Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Harvard Chan School of Public Health, Boston, MA, UNITED STATES, [3]Department of Medicine, Washington University School of Medicine, St. Louis, MO, UNITED STATES, [4]Division of Hematology/Oncology, Tufts University School of Medicine, Tufts Cancer Center, Tufts Medical Center, Boston, MA, UNITED STATES.

OBJECTIVES: FDG PET/CT is a standard clinical tool for response assessment in aggressive lymphoma. The aim of this preliminary study is to compare different PET interpretation criteria at interim therapy (i-PET) to find out which is the best predictor of clinical response. METHODS: This study is part of an Eastern Cooperative Oncology Group (ECOG) randomized phase II multicenter trial, (ECOG protocol E2408), that enrolled 250 patients with a histologically confirmed diagnosis of follicular non-Hodgkin lymphoma.Among these 250, 90 patients were included in our analysis.All patients performed at least two 18F-FDG PET/CT scans: at diagnosis (baseline PET) and after 3 cycles of

chemotherapy (i-PET). Response evaluation at i-PET was retrospectively performed according to LUGANO criteria, EORTC (European Organization for Research and Treatment of Cancer), PERCIST (PET Response Criteria in Solid Tumors) and IHP (International Harmonization Project), classifying the patients into 4 categories: complete metabolic response(CMR), partial metabolic response(PMR), stable metabolic disease(SMD), and progressive metabolic disease(PMD). All criteria were correlated to the best-observed response after 6 cycles of chemotherapy (referred to as "step 1" or end of initial round of treatment). RESULTS: LUGANO, EORTC and IHP were registered in 90 patients; PERCIST was recorded in 81 patients. For the first group(90 patients), the best observed response was CMR in 67/90 patients(74.5%), PMR in 19/90(21.1%), SMD in 2/90(2.2%) and PMD in 2/90(2.2%).In the second group (81 patients), the best observed response was CMR in 62/81(76.5%), PMR in 17/81(21%), SMD in 0% and PMD in 2/81(2.5%).According to LUGANO criteria, the rate of CMR at i-PET was 92,5%(62/67), for EORTC and IHP was 89.5(60/67).For all these three criteria the rate of PMR was 21%(4/19), the rate of SMD and PMD was 50%(1/2).For PERCIST CMR rate at i-PET was 90.3%(56/62), PMR 17.7%(3/17), SMD 0% and PMD 50%(1/2).The overall response rate (defined by i-PET indicating at least stable disease or better) for LUGANO and IHP was 96.5%, for EORTC was 95.3% and for PERCIST was 93.7%; all criteria gave the same percentage for progressive disease. The rate of SMD was higher with LUGANO, EORTC and IHP criteria; no significantly differences between them and PERCIST. The strongest correlation (~ 90% or higher) for all criteria was between CMR and the best-observed response at step 1. CONCLUSION: Our study demonstrated a strong correlation between interim-PET CMR assessed with all the criteria and treatment response after 6 cycles of chemotherapy. We are still evaluating patients to confirm these data.

OP083

Localisation of insulinoma using Glucagon-like Peptide-1 Receptor (GLP-1R) SPECT/CT, GLP-1R PET/CT and MRI: Preliminary results of a prospective clinical study

K. Antwi[1], M. Fani[1], T. Heye[1], G. Nicolas[1], E. Merkle[1], J. Reubi[2], B. Gloor[3], E. Chris[3], D. Wild[1]; [1]University Hospital Basel, Basel, SWITZERLAND, [2]University of Bern, Bern, SWITZERLAND, [3]University Hospital Bern, Bern, SWITZERLAND.

Purpose: We aimed at prospectively comparing the detection rate of GLP-1R PET/CT vs GLP-1R SPECT/CT vs standardized contrast enhanced 3T MRI in patients with endogenous hyperinsulinemic hypoglycemia. Preliminary results of an ongoing study are reported. Methods: Thirty-three consecutive patients with neuroglycopenic symptoms due to endogenous hyperinsulinemic hypoglycemia were enrolled. A standardized contrast enhanced 3T MRI was performed. Afterwards the patients received a SPECT/CT at 4 and 72 hours after injection of ^{111}In-DOTA-exendin-4 and a PET/CT 2,5 hours after injection of ^{68}Ga-DOTA-exendin-4 in a randomized order. Six independent blinded Nuclear Medicine Physicians and Radiologists reviewed the scans. Standard of comparison was the histological diagnosis after surgery. Results: Previously performed cross-sectional imaging (CT/MRI) was negative or not conclusive in 25/33 (76%) of patients. So far 22 patients have been operated. In this collective, the histological diagnosis of a benign insulinoma was confirmed in 19 patients, 1 patient had adult islet cell hyperplasia. In 1 patient both intraoperative palpation as well as the histological diagnosis did not confirm an insulinoma. In 1 patient symptoms of endogenous hypoglycemia ceased postoperative but histological diagnosis did not confirm the diagnosis of a benign insulinoma or nesidioblastosis. Only this patient was excluded from evaluation, as the final diagnosis remained unclear. Two patients refused surgery. Five patients are awaiting surgery. In 4 patients PET/CT, SPECT/CT as well as the previous performed conventional imaging did not find any suspicious lesion and were thus not operated up to date. In this interim analysis overall pooled sensitivity was 95% for PET/CT, 73% for SPECT/CT, and 81% for MRI. PET/CT was the only modality which correctly identified the area of islet cell hyperplasia (adult nesidioblastosis) within the pancreas. Conclusion: Our interims analysis suggests that GLP-1R PET/CT performs better than MRI and GLP-1R SPECT/CT at a lower radiation dose and shorter examination time. GLP-1R PET/CT might be a useful diagnostic tool in patients where cross sectional imaging (CT/MRI) fails to localize the insulinoma.

I-131-meta-iodobenzylguanidine therapy improves survival in high-risk neuroblastoma patients with I-123-mIBG positive residual metastatic disease

M. C. Schmidt[1], B. Hero[1], B. Decarolis[1], A. Eggert[2], F. Berthold[1], A. Drzezga[1], T. Simon[1]; [1]University Hospital of Cologne, Cologne, GERMANY, [2]Charité Berlin, Berlin, GERMANY.

Background: Randomized trials on the first-line treatment of high-risk neuroblastoma are limited. Therefore, we analyzed the national data base on the impact of I-131-meta-iodobenzylguanidine (I-131-mIBG) therapy, local radiotherapy, and single agent ch14.18 immunotherapy in the first-line therapy of high-risk neuroblastoma. Methods: Patients of two consecutive national neuroblastoma trials in Germany were included if they met all key criteria: (1) stage 4 neuroblastoma, (2) age at diagnosis 18 months or older, (3) N5/N6 induction chemotherapy, (4) non-progressing residual I-123-mIBG positive metastatic disease after induction chemotherapy prior to myeloablative chemotherapy and autologous stem cell transplantation, (5) diagnosis between 1997 and 2012. I-131-mIBG therapy was scheduled for non-progressing I-123-mIBG positive lesions. Local radiotherapy 36-40 Gy was scheduled for I-123-mIBG positive residual disease at the primary site. Single agent ch14.18 was stratified according to open trials. Results: A total of 232 patients were analyzed. The median observation time was 8.8 years. I-123-mIBG positive residual metastases were present prior to myeloablative chemotherapy in 92 patients. The median interval between I-131-mIBG therapy and stem cell transplantation was 21 days. The median I-131-mIBG activity applied was 7.4 GBq. Event-free survival was very similar between patients who underwent I-131-mIBG therapy (5yEFS 32.2+/-7.1%) compared to no I-131-mIBG therapy (5yEFS 27.9+/-6.9%, p=0.553). In contrast, a trend for better overall survival was found after I-131-mIBG therapy compared to no I-131-mIBG therapy (5yOS 58.1+/-7.6% vs. 38.9+/-7.5%, p=0.086). Multivariable analysis including MYCN, I-131-mIBG therapy, local radiotherapy, and immunotherapy with ch14.18 revealed an independent impact of MYCN amplification (p=0.028, hr 1.987) and ch14.18 treatment (p=0.004, hr 0.441) on EFS, and MYCN amplification (p<0.001, hr 3.476), ch14.18 treatment (p=0.008, hr 0.560), and I-131-mIBG therapy (p=0.047, hr 0.426) on OS. Conclusions: I-131-mIBG therapy can improve survival in patients with incomplete metastatic response to induction chemotherapy. These results warrant a prospective multicenter trial on I-131-mIBG therapy. Moreover, this analysis confirmed the efficacy of immunotherapy with ch14.18.

Towards an International mIBG Skeletal Score for High Risk Neuroblastoma: A SIOPEN-COG cooperation

U. Pötschger[1], A. Naranjo[2], G. Yanik[3], M. Castellani[4], A. Boubaker[5], B. Lambert[6], V. Lewington[7], A. Kaminska[8], K. Taborska[9], M. Parisi[10], B. Shulkin[11], J. Park[12], S. Kreissman[13], K. Matthay[14], R. Ladenstein[1]; [1]Children's Children's Cancer Research Institute, Vienna, AUSTRIA,

[2]Children's Oncology Group Statistics and Data Center, Gainesville, FL, UNITED STATES, [3]University of Michigan Medical Center, Ann Arbor, MI, UNITED STATES, [4]Instituto Nazionale Tumori di Milano Nuclear Medicin Division, Milan, ITALY, [5]Centre Hospitalier Universitaire Voudois, Lausanne, SWITZERLAND, [6]Ghent University, Department of Nuclear Medicine, Ghent, BELGIUM, [7]Guy's and St. Thomas NHS Foundation Trust, London, UNITED KINGDOM, [8]Children's Memorial Health Institute, Warsaw, POLAND, [9]Motol University Hospital, Prague, CZECH REPUBLIC, [10]Seattle Children's Hospital, University of Washington, Seattle, WA, UNITED STATES, [11]St. Jude Children's Research Hospital, Memphis, TN, UNITED STATES, [12]Seattle Children's Hospital, University of Washington, Seatlle, WA, UNITED STATES, [13]Duke University Medical Center, Durham, NC, UNITED STATES, [14]University of California, San Francisco, FL, UNITED STATES.

PURPOSE: A collaborative effort was undertaken to derive an internationally agreed semi-quantitative meta-iodobenzylguanidine (mIBG) scoring method in neuroblastoma by harmonising previously established scoring systems, which were each found to have prognostic value at the end of induction (Yanik JNM 2013). The aim of this analysis was to investigate the individual effect on event-free-survival (EFS) of the two components of the scoring system: 1) the number of involved anatomic regions and 2) the scoring value within each segment and to evaluate the prognostic value of the new proposed scoring system. PATIENTS AND METHODS: COG and SIOPEN merged data of children with stage 4, mIBG avid, neuroblastoma entered on the COG-A3973 (216pts) and the SIOPEN/HR-NBL1 trial (341 pts) for first line therapy. Two independent nuclear medicine review teams scored mIBG scans pre and post induction according to Curie- and SIOPEN-methodologies. Here, the SIOPEN score evaluating the skeletal (mIBG) uptake on a 0-6 scale in 12 anatomical regions was chosen for the statistical analysis due to the greater range of values. The two study cohorts were investigated separately and a bootstrap-based internal validation was performed. RESULTS In 557 pts the cumulative SIOPEN-score post induction had a significant prognostic impact with 5-years EFS of 41%, 33% and 15% for total scores of 0, 1-3 and greater than 3, respectively. However, no increasing hazards with increasing scores per segment were observed. In contrast, the number of positive segments alone had a highly significant impact with 5-year EFS of 41%, 32% and 14% for patients with 0, 1-2 and greater than 2 positive segments post induction. CONCLUSION The number of positive segments was the most important prognostic factor. Weighting the involvement within segments did not improve the prognostic value of the scoring system. These results suggest a possible simplification of MIBG scoring, facilitating future international collaborations.

OP086

^{18}F-FDG PET-CT scan versus bone marrow biopsy in Pediatric Hodgkin's Lymphoma: A quantitative analysis

M. Siddique, A. Hassan, H. Bashir, S. Riaz, M. Nawaz; Shaukat Khanum Memorial Cancer Hospital & Research Centre, Lahore, PAKISTAN.

Background: The present study investigates whether combined positron emission tomography/computed tomography using Flourine-18 fluorodeoxyglucose(^{18}F-FDG PET-CT scan) predicts clinically important bone marrow involvement(BMI) by Hodgkin's Lymphoma (HL) in pediatric population with sufficient accuracy to replace routine staging iliac bone marrow biopsy(iBMB). We also characterized distribution patterns of BMI in HL as determined by ^{18}F-FDG PET-CT scan in accordance with bone marrow biopsy findings. **Methods:** Retrospectively analysis of scans, histology reports and treatment records of all pediatric patients diagnosed as HL between July 2010 and June 2015 who underwent ^{18}F-FDG PET-CT scan and iBMB as part of staging work up were analyzed. Different patterns of FDG uptake in patients with BMI were reviewed visually as well as quantitatively. BMI was defined as positive iBMB and/or foci of marrow uptake on ^{18}F-FDG PET-CT scan that behaved concomitantly with other sites of lymphomatous involvement on post treatment evaluation scans. Clinical/radiological stage according to the Ann Arbor staging system was recorded. Significant marrow uptake(SUV_{max}) on ^{18}F-FDG PET-CT scan was evaluated by using *Student's t-test.* **Results:** 788 patients were enrolled. 656(83.2%) male, 132(16.8%) females; male to female ratio [5:1]. Age range: 2-18 years (mean 10.3 years). Overall 108 of 788(13.7%) had BMI. The results of iBMB and ^{18}F-FDG PET-CT scan in the detection of BMI were concordant in 734(93%); positive concordance was observed in 60, and negative concordance was observed in 674. Out of disconcordant cases(n=54,6.8%), four were upstaged by iBMB with normal uptake on ^{18}F-FDG PET-CT scan, while 44 with negative iBMB findings were upstaged due to increased focal medullary uptake that normalized after treatment. Based on PET findings, out of 108 cases with BMI, four had no uptake, six had diffuse, 21 had uni/bifocal and 77 multifocal. Overall, visual assessment of BMI on ^{18}F-FDG PET-CT scan had a sensitivity, specificity, positive predictive value (PPV), negative predictive value(NPV) and accuracy of 96%, 99%, 95%, 99%, 98% respectively versus 59%, 100%, 100%, 93%, 94% for iBMB. On a quantitative assessment, BM-SUV_{max} was significantly higher in patients with BM involvement ($p<0.05$). **Conclusion:** ^{18}F-FDG PET-CT scan demonstrated BMI in 13.7% of newly diagnosed pediatric HL. Diagnosis of BMI in HL by ^{18}F-FDG PET-CT scan was more sensitive than iBMB with potential upstaging in 6% of patients. Multifocal FDG uptake(at least three foci) is more indicative of BMI; however, in case of diffuse FDG uptake, iBMB is still an indispensable procedure for staging.

OP087

Prognostic Value Of Different F-18 FDG PET/CT Quantitative Analytical Methodologies In Pediatric Hodgkin's Lymphoma

O. Serry[1], A. A. Kandeel[2], M. A. El-Sayed[2], A. E. M. Hussein[3], W. S. Omar[4]; [1]Children's Cancer Hospital Foundation, Cairo, EGYPT, [2]Nuclear Medicine Department, Faculty of Medicine, Cairo University, Cairo, EGYPT, [3]Nuclear Medicine Department, Faculty of Medicine, Sohag University, Cairo, EGYPT, [4]Nuclear Medicine Department, National Cancer Institute, Cairo University, Cairo, EGYPT.

Introduction and aim of work: Assessment of the individualized SUVs, PET-derived total metabolic tumor volume (TMTV) and the product of both parameters, termed total lesion glycolysis (TLG) in both initial and interim PET if it carries a better PPV in early assessment of response to therapy in pediatric Hodgkin's lymphoma (PHL) patients. Patients and Methods: Retrospective analysis of PET/CT results was performed on 60 patients (42 males and 18 females; mean age 8.7±4.2 years). To assess the prognostic value of initial and interim 18F-FDG PET/CT, different semi-quantitative parameters such as SUVmax, SUVmean, Total lesion glycolysis (TLG) and TMTV of all lesions using SUVmax & mean including SUV2.5 and 40% of SUVmax as cut-off values were calculated. Follow up for 24 months from initial treatment with calculation of Disease Specific Survival (DSS). According to the recommendations of Deauville criteria interim PET (PET2) results were identified into three groups; PET2-negative (PET2-ve), PET2-positive (PET2+ve), and PET2-minimal residual uptake (PET2-MRU), the cut-off between PET2+ve and PET2-MRU was 3-4 in the 5-point scale. Results: Out of the 60 interim-PET scans, 50 scans were considered as PET2-ve (83.3%), 5 scans as PET2+ve (8.3%) and 5 scans as PET2-MRU (8.3%). The risk of the disease and the visual scoring assessment were significantly correlated with patient's outcome (whether Negative or Residual/Relapse) ($p<0.0001$). Different results were obtained; the most important were TLGmax2.5 (cut-off 2.5), TLGmean2.5 (cut-off 2) and TMTV2.5 (cut-off 0.75 ccm) in interim PET showed the highest sensitivity, specificity, PPV and NPV (58.5%, 97.9%, 87.5% and 90.3% respectively for the 3 parameters). Conclusion: LGmax2.5,

TLGmean2.5 and TMTV2.5 are the most relevant parameters for predicting the outcome in patients with PHL, and can add a significant prognostic insight to interim PET response assessment. This may guide clinicians in their choice of therapeutic strategy.

OP088

Differentiated Thyroid Carcinoma in Children, Adolescents and Young Adults- a bicentric Analysis with long-term Follow Up in 354 Patients

A. Thoma[1], A. Todica[2], P. A. Bartenstein[2], K. Scheidhauer[1], M. Schwaiger[1], **M. Mustafa**[1]; [1]Klinikum rechts der Isar, Dept. of Nuclear Medicine, Munich, GERMANY, [2]Klinikum der LMU, Dept. of Nuclear Medicine, Munich, GERMANY.

Aim: Differentiated Thyroid Carcinoma (DTC) has a worldwide peak incidence between 40 and 50 years of age. In children and adolescents it remains a rare disease, presenting with a different and usually more widespread clinical stage, nonetheless prognosis is supposed to be excellent. This bicentric study aimed at investigating a cohort of pediatric and young patients with DTC, who received radioiodine ablation with regards to differences in primary presentation at diagnosis and long-term follow up. Methods: All patients, who underwent radioiodine ablation between 01/2000 and 12/2015 at both university hospitals in Munich, Germany, were retrospectively analyzed for pediatric and young patients under 30yrs: Group A=83 pts ≤20 yrs. and Group B = 271 pts ≤30 yrs were included. The two cohorts were investigated with regards to histological data (maximum size of tumors, multifocality, aggressive subtypes), extent of lymphadenectomy (number of lymphnodes resected, number of lymphnode metastases), initial presentation at post-ablation radioiodine WBS, follow-up WBS (diagnostic or post-therapeutic), clinical and ultrasound follow-up examinations and additional imaging (including MRI and PET/CT where available) to determine progression free survival (PFS). Results: The median follow-up was 4,8 years. The initial presentation of patients in both groups did not differ with regards to gender (78% female A and B), tumor size according to TNM-classification and maximum diameter (1,5cm in A and 1,4cm in B), average dissected lymph nodes (15,0 Gr. A vs. 15,5 Gr. B), lymph node metastases (N1 54% Gr. A vs. 50% Gr.B; fraction of excessive lymph node metastases defined as >5 LNM). There were significant differences in initial M1 stage (12,0% Gr. A vs. 2,6% Gr. B), 90% of M1 metastases being pulmonary. Of all M1 metastases 80% were radioiodine avid in Gr. A and 86% in Gr. B, complete remission was achieved in 40% (A) and 83% (B). In Gr.A 13,3% of pts and Gr. B 6,3% had persistent or progressive disease, PFS was significantly longer in Gr. A (26 vs. 18months). Conclusion: In this large cohort of pediatric patients and yound adults presenting with DTC initial presentation and response to radioiodine ablation and therapy were comparable. Significant differences were to be found in rates of distant metastases at initial presentation, whereas radioiodine avidity was similar and lead to complete remission in a majority of patients.

OP089

Can FDG PET/CT predict the outcome of pediatric rhabdomyosarcoma?

E. El-kholy[1], I. El-Antabily[1], E. El-Nadi[2], M. S. Zaghloul[3], S. Ahmed[3], H. Hafez[4], O. Shawky[4], T. Rafaat[5], N. El-Kilini[6], A. Younis[7], G. Taha[7]; [1]Nuclear Medicine National cancer Institute (NCI) and Children Cancer Hospital Egypt (CCHE), Cairo, EGYPT, [2]Pediatric Oncology, Faculty of Medicine Benisuef Univeristy and Children Cancer Hospital Egypt (CCHE), Cairo, EGYPT, [3]Radiotherapy Department, Children Cancer Hospital Egypt (CCHE), Cairo, EGYPT, [4]Medical Oncology, Children Cancer Hospital Egypt (CCHE), Cairo, EGYPT, [5]Radiology Department, National cancer Institute (NCI), Children Cancer Hospital Egypt (CCHE), Cairo, EGYPT, [6]Pathology Department, Children Cancer Hospital Egypt (CCHE), Cairo, EGYPT, [7]Surgical Oncology, Children Cancer Hospital Egypt (CCHE), Cairo, EGYPT.

Aim: to establish whether initial 18F-FDG SUV can add prognostic information to clinical staging in pediatric rhabdomyosarcoma patients. **Materials and methods:** 98 patients (48 female, 50 male, Age ranged 4 mo-17.5 years, mean age: 5.8±4.5) with pathologically proven RMS underwent PET/CT for initial cancer staging were included in the study. We retrospectively assessed whether or not FDG PET/CT using primary SUVmax and primary/liver ratio, could predict event-free survival (EFS) or overall survival (OS) in patients with pediatric RMS who received specific therapy according to the standard Children Cancer Hospital-Egypt (CCHE) protocol. Correlation with other prognostic factors was also obtained. **Results:** High SUVmax was significantly related to the presence of nodal or distant metastasis. With marked cutoff values of (3.6) and (2.1) by ROC curve for SUV primary and SUV primary/liver ratio respectively, OS (for 36 months) and EFS proved to be higher in patients with SUVmax below these values. Patients with SUVmax primary/liver less than the cutoff of 2.1 had OS 60.8% and EFS 48.1% compared to 44.5% and 14.8% to those above the cutoff, yet, this semi-quantitative evaluation failed to attain statistical significance. (P value 0.92 & 0.16 respectively). Similar results were obtained in assessment of primary SUVmax with (P value 0.76 and 0.62 respectively). There was prevalence of high SUV primary and SUV primary/liver ratio among those patients with less favorable clinico-pathological features (unfavorable primary site, high and intermediate risk & alveolar pathological type), yet was not statistically significant. **Conclusion:** In this preliminary study, FDG PET/CT may be an additional predictor of outcome in pediatric rhabdomyosarcoma, further studies are needed to correlate between assessment of therapy response by PET/CT and final outcome and survival. **Key words:** FDG PET/CT, rhabdomyosarcoma, prognosis.

Sulesomab in Pediatric Musculoskeletal Infection

A. Javaid[1], S. Usmani[2], M. U. Khan[3], I. AlShammari[1]; [1]Farwania Hospital, Farwania, KUWAIT, [2]Faisal Bin Essa Hospital, Saba Area, KUWAIT, [3]Al Jhara Hospital, Jahara, KUWAIT.

Introduction: Bone and joint infections are one of the major causes of morbidity in infants and children. Early diagnosis with prompt treatment, are key to prevent the complications and morbidity. **Objective:** The objective of this study is to evaluate the diagnostic accuracy of Tc-99m labeled anti-granulocyte monoclonal antibody fragment Fab' (Sulesomab, Leukoscan®) for the detection of musculoskeletal infection in pediatric population. **Material and Method:** This is a prospective study of 55 pediatric patients (30 males and 25 females) with a mean age of 6 years and 9 months (range 1 month to 15 years and 8 months). These patients were referred from out-door clinic or admitted cases in Pediatrics and Medical wards to the Nuclear Medicine Department. The monoclonal antibody scan and the three phase bone scan were carried out with a maximum interval of 7 days. The patients was injected with age adjusted dose according to Webstre's rule taking 20 mCi (750 MBq) as adult dose. The minimum injected dose was 3.5 mCi (130 MBq). Imaging was performed after one and 4-hour after injection and in eight cases at 24-hours. Bone scan was acquired according to standard protocols. The sulesomab scan results was compared with final diagnosis, provided by the primary physician on 2-months clinical follow-up along with biochemical tests.**Results:** The accuracy of the Sulesomab scan was 92.7% for the diagnosis of acute musculoskeletal infection. The calculated sensitivity, specificity, negative & positive predicted values were 95.8%, 90.3%, 96.5% and 88.4% respectively. No patient had adverse events. **Conclusion:** Sulesomab was well tolerated with no apparent side effects. It was found highly accurate and had high sensitivity and negative predicted values. So, this agent can be used with confidence to rule out acute musculoskeletal infection in pediatric age group.

OP091

Can we predict definitive or transient hypothyroidism in new born under one month with iodine scintigraphy?

A. LEGENDRE, Jr., G. PETYT, D. BELLEVRE, G. COLLET, C. HOSSEIN FOUCHER, H. LAHOUSSE; CHRU de Lille, LILLE, FRANCE.

AIM: Iodine scintigraphy in diagnostic of congenital hypothyroidism is very specific to determine location of thyroid and dysgenesis. Usually we wait 2 years to know if hypothyroidism is definitive or transient. In our study we tried to determine factors predictive of definitive of transient hypothyroidism in new born with congenital hypothyroidism. MATERIEL and METHOD: We included 114 children under one month, retrospectively between 2004 and 2014 in CHRU of LILLE who had iodine scintigraphy in diagnostic of congenital hypothyroidism with TSH Superior to 12 mUI/ml. 100 of them had definitive hypothyroidism and only 14 transient with a decline of two years when TSH without levothyrox was measured in order to confirm or not definitive hypothyroidism. We evaluated location of thyroid in scintigraphy, thyroid area on scintigraphy, TSH on Guthrie test, sex and percent of decrease fixation rate after perchlorate discharge test when we saw a thyroid. RESULTS: TSH on Guthrie test is predictive of definitive hypothyroidism (p inferior to 0.0001 Wilcoxon Two Sample Test), higher is TSH more hypothyroidism has chance to be definitive. With TSH superior to 58mUI/L sensitivity is of 84% and specificity of 92% either in 44 children with thyroid in orthotopic position (p=0,001), with TSH superior to 60mUI/ml sensitivity of 60% and specificity of 93%. Concerning location of thyroid all 70 dysgenesis became definitive hypothyroidism. Other 44 children with thyroid in orthotopic location had for 30 definitive hypothyroidisms and 14 transient hypothyroidisms. There is more definitive hypothyroidism in dysgenesis group (p inferior to 0.0001). There is no significant difference of area thyroid test between definitive and transient hypothyroidism (respectively p=0.29 student test. Percent of decrease fixation rate after perchlorate discharge test is significantly higher in definitive hypothyroidism p= 0.02(Wilcoxon two sample test). For increase of 10 percent sensitivity of perchlorate discharge test is of 67% and specificity of 87.5%. CONCLUSION: TSH on Guthrie test, location of thyroid on iodine scintigraphy and percent of increase of iodine rate after perchlorate discharge test are significantly predictive of definitive or transient hypothyroidism. They can be useful for improving the therapeutic education depending on the depth of hypothyroidism.

Gallium-68-PSMA-HBED-CC PET/CT in patients with biochemical recurrence after treatment with curative intent: potential impact on patient management

R. Valkema, M. B. Busstra, I. L. Bakker, T. De Vringer, C. H. Bangma, J. F. Verzijlbergen; Erasmus MC University Hospital, Rotterdam, NETHERLANDS.

Aim: Radical prostatectomy (RP) or radiation therapy (RT) are curative options for patients with localized prostate carcinoma (PCa). Local salvage therapy is considered when prostate specific antigen (PSA) becomes detectable after RP at 0.2 - 0.5 ng/mL, or rises >2ng/mL above nadir after RT. However, only half of the patients will benefit of local salvage therapy, which has important side effects. Current imaging methods are not accurate enough to identify patients with only local recurrence. **Methods:** Fifty-three patients (42 post-RP and 11 post-RT) were referred for ^{68}Ga-PSMA-HBED-CC PET/CT to find the substrate for elevated PSA: prostate fossa (PF), locoregional lymph nodes (LN), or more distal metastases (M). PET/CT was performed 60 min after injection of 104 ± 30 MBq ^{68}Ga-PSMA-HBED-CC. Nominal activity was 1.5 MBq/kg for 3 min/bed; time/bed was extended with less administered activity. Most patients had a delayed partial scan at 120 min p.i., after furosemide. Scans were systematically read (positive, equivocal, negative) for the PF, LN and M regions. **Results:** In 26/42 post-RP patients PET/CT was positive, in 3/42 equivocal and in 12/42 negative. Negative scans were found in 10/25 (40%) of patients with PSA 0.2 - 0.5 ng/mL, in 2/8 (25%) with PSA 0.6 - 2.0 ng/mL and in 0/10 with PSA >2.0 ng/mL. In all 11 post-RT patients (PSA 1.3 - 37 ng/mL) PET/CT was positive. In 21/53 patients, positive LN or M lesions, although unconfirmed, suggested that not local salvage, but alternative options should be considered, thus to avoid side effects associated with (futile) salvage therapy. **Conclusion:** ^{68}Ga-PSMA-HBED-CC PET/CT is promising for sensitive detection of PCa lesions in patients with PSA recurrence after initial RP or RT, even at low PSA levels. Prospective studies are warranted to confirm the accuracy of ^{68}Ga-PSMA-HBED-CC PET/CT and its role in patient management and outcome.

OP108

Detection Rates of ^{68}Ga-PSMA PET/CT in Patients with Biochemical Relapse from Prostate Cancer after Radical Prostatectomy and PSA Values < 1 ng/ml: Preliminary Results from a Prospective, Multicenter Trial

J. B. Nielsen, Jr.[1,2], H. D. Zacho[1,2], K. Dettmann[3], N. C. Landkilde[4], J. B. Jensen[3], U. Haberkorn[5], L. J. Petersen[1,2]; [1]Dept. of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, [2]Dept. of Clinical Medicine, Aalborg University, Aalborg, DENMARK, [3]Dept. of Urology, Holstebro Regional Hospital, Holstebro, DENMARK, [4]Dept. of Urology, Aalborg University Hospital, Aalborg, DENMARK, [5]Dept. of Nuclear Medicine, University Hospital of Heidelberg, Heidelberg, DENMARK.

Aim: To evaluate the clinical value of ^{68}Ga-labelled prostate-specific membrane antigen (^{68}Ga-PSMA) used in PET/CT at low PSA levels (PSA < 1 ng/ml) in patients with recurrent prostate cancer. **Materials and Methods**: This study was a prospective, GCP-monitored clinical trial (EudraCT number 2014-005073-37) of ^{68}Ga-PSMA-HBED-CC (^{68}Ga-PSMA) PET/CT in recurrent prostate cancer. This report included twenty-six patients with biochemical relapse of prostate cancer after radical prostatectomy (RP) with PSA < 1 ng/ml. The administered dose was 2 MBq/kg; scan time was 60 ± 15 min. **Results**: The mean age was 67 years. Mean PSA level at the time of ^{68}Ga-PSMA PET/CT was 0.4 (range 0.2-0.9 ng/ml). A total of 20 of 26 patients had a PSA level < 0.5 ng/ml. Biochemical relapse occurred after mean of 40 months (6-128) after RP; 7 did not reach postoperative PSA < 0.1 ng/ml. Mean activity was 175 MBq ^{68}Ga-PSMA (128-223). Definitive pathological uptake of ^{68}Ga-PSMA was observed in 4 patients and equivocal uptake in 2 patients (23.1%, 95% confidence interval 6.9-39.3%). In all patients with pathological ^{68}Ga-PSMA uptake (n=6), mean PSA was 0.6 ng/ml (0.2-0.9) versus 0.3 ng/ml (0.2-0.7) in PSMA-negative patients. Mean PSA doubling time were 7 months (0-24) and 18 (0-89) months in the patients with and without pathological ^{68}Ga-PSMA uptake, respectively. Mean injected dose and time to scan did not differ among these groups. The location of relapse was at lymph node level in three patients and bone in two patients (one patient had both lymph node and bone involvement). Equivocal lesions were located in the prostatic bed and bone. Control scans in 18 patients participating in a staging protocol, confirmed pathological uptake in all patients with a mean target-to-background ratio of 27, indicating satisfactory scan sensitivity. **Conclusion**: Pathological uptake of the ^{68}Ga-PSMA tracer was detected in 6 of 26 patients (23.1%) with biochemical relapse and low PSA values (PSA < 1 ng/ml) after radical prostatectomy. Pathologic ^{68}Ga-PSMA uptake was shown in lymph nodes and bones but no uptake was shown in the prostatic bed. The detection rate of recurrent prostate cancer in this study was far below previous detection rates reported from a number of large retrospective series.

OP109

Pre - (^{177}Lu-PSMA) Therapy Response Prediction by Textural Heterogeneity Parameters in ^{68}Ga-PSMA PET Scans among Patients with Metastatic Prostate Cancer

Z. Khurshid[1], H. Ahmadzadehfar[1], F. Gaertner[1], L. Papp[2], N. Zsótér[2], M. Essler[1], R. Bundschuh[1]; [1]Uniklinikum Bonn, Bonn, GERMANY, [2]Mediso Medical Imaging Systems, Budapest, HUNGARY.

Objective: Prostate cancer is the most common tumor in men and is the cause of significant patient mortality and morbidity globally. In newer diagnostic agents PSMA linked ones are specifically important due to its significant up regulation in tumor cells. In this era of personalized therapy emphasis is being placed on earlier response prediction and risk stratification of patients even before the start of therapy. Analysis of textural heterogeneity parameters has been associated with determination of innately aggressive and therapy resistant cell lines thus emphasizing their importance in therapy planning. In our study, we aimed to determine pre (^{177}Lu-PSMA) therapy response prediction by textural heterogeneity parameters as assessed by pre therapy ^{68}Ga-PSMA PET scan in metastatic prostate cancer patients.

Materials and Methods: Retrospective analysis of 36 patients was performed. All patients had metastatic prostate cancer and were planned to undergo ^{177}Lu-PSMA therapy. Pre therapy ^{68}Ga-PSMA PET scans were used for analysis. Interview Fusion (MEDISO Medical Imaging) was used for entire analysis. 3D volumes (VOIs) for 3 lesions each in bones and lymph nodes were manually delineated in static PET images (also in prostate and liver when applicable). In addition to conventional parameters, 10 PET based textural heterogeneity parameters were determined. Results obtained were then compared with clinical parameters including pre and post therapy PSA, alkaline phosphate, bone alkaline phosphate levels and ECOG criteria. Spearman correlation was used to determine statistical dependence among variables. **Results:** Two heterogeneity parameters entropy (p=0.046) and homogeneity (p=0.034) in pre therapy scans showed statistically significant correlation with the change in pre and post therapy PSA levels. Entropy showed positive correlation with therapy outcome while homogeneity showed negative. Any of the conventional PET parameter did not show any statistical significance. **Conclusions:** Analysis of pre therapy heterogeneity parameters showed the potential for response prediction with the help of baseline scan only instead of waiting for change in clinical parameters determined before and after the therapy. This can help in risk stratification and advanced strategy making for personalized therapy. The predictive values of heterogeneity parameters were also seen to be superior to conventional PET parameters with high value of entropy showing better treatment response and high homogeneity showing decreased response. These results will be verified with time to progress and overall survival in further studies.

OP110

Protection of Normal Tissue in Molecular Radiotherapy with ^{177}Lu-labeled PSMA-Targeting Peptides using Preloading

P. Kletting[1], D. Hardiansyah[2], A. J. Beer[1], G. Glatting[3]; [1]Department of Nuclear Medicine, Ulm University, Ulm, GERMANY, [2]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Ulm, GERMANY.

Purpose: In molecular radiotherapy with ^{177}Lu-labeled prostate specific membrane antigen (PSMA) peptides, the kidneys, salivary and lacrimal glands are considered to be potentially dose limiting. The aim of this simulations study was to determine the effect of cold PSMA specific peptide applied prior to therapy on the time-integrated activity coefficients (TIACs) of critical organs and tumor and thus on the therapeutic index. Methods: A recently developed physiologically based pharmacokinetic (PBPK) model for PSMA-specific peptides was modified and implemented. Model parameter values were taken from the literature. Salivary and lacrimal glands, kidneys and tumor TIACs were determined for different dissociation constants K_D, peptide amounts and injection times used for preloading. The optimal TIACs tumor-to-kidneys, tumor-to-lacrimal and tumor-to-salivary glands ratio were identified for each scenario. Results: The simulations suggest that the application of high affinity ($K_D \leq 0.1$ nM) PSMA specific peptides 5-30 min before therapy has substantial effect on the therapeutic indices. The optimal preload depends on the affinity of the used ligand. For $K_D = 0.1$ nM the model predicts an optimal preload of 128 nmol improving the tumor-to-kidneys, tumor-to-lacrimal and tumor-to-salivary-glands TIAC ratios 1.6 fold. Conclusion: Based on model predictions, preloading using the optimized amount of a high affinity peptide seems to be an interesting option to improve the therapeutic indices in molecular radiotherapy with ^{177}Lu-labeled PSMA-specific peptides.

OP111

Automatic image segmentation for efficient 3D dosimetry with reduced influence of registration-errors and noise in Lu-177 DKFZ-PSMA-617 therapy using a robust cluster algorithm on sequential SPECT data and subsequent voxel-wise re-scaling

L. Vomacka, A. Delker, A. Gosewisch, W. Fendler, F. Gildehaus, A. Brunegraf, P. Bartenstein, G. Böning; University of Munich, Munich, GERMANY.

Objectives: In Lu-177 DKFZ-PSMA-617 therapy the estimation of 3D-dose distributions in tumours and radiation-sensitive organs such as the kidneys supports individualized therapies. However, common methods which provide 1D-organ- or lesion-doses based on a manual delineation of volumes-of-interest are time-consuming and observer dependent. Therefore we have studied a method for automatic and efficient determination of 3D-dose distributions with reduced influence of image-registration artefacts in sequential SPECT data. Methods: Ten patients with mCRPC received multiple therapy-cycles with the administration of either 3.6GBq or 6GBq Lu-177 DKFZ-PSMA-617 per cycle. In each cycle quantitative 3D-SPECT images were measured 24, 48 and 72h p.i., of which one was performed in SPECT/CT mode. Robust k-means based dynamic-cluster-segmentation (DCS) was established to automatically segment eight clusters containing voxels with similar dynamics and activity values in quantitative 4D-SPECT studies, followed by a labeller to segment each individual connected VOI. For comparison 78 tumour and 36 kidney-cortex VOIs were defined by manual-threshold-segmentation (MTS, th=40% of maximum). For each volume the accumulated activity was derived from a mono-exponential fit on the mean time-activity-curve and re-scaled voxel-wise based on the activity values measured 24h p.i.. Finally the 3D-map filled with accumulated activities was convolved with an S-value kernel obtained from Monte Carlo simulation in soft tissue in combination with a CT-based mass-scaling. Results: DCS successfully found all considered tumours and 32 kidneys. DCS of the kidneys failed in two studies due to overlap with high-uptake lesions or marginal uptake in the kidneys. The mean tumour dose estimate was 1.9+/-1.6Gy/GBq with DCS and 1.8+/-1.7Gy/GBq with MTS. The estimated dose to the kidney cortex was 0.6+/-0.2Gy/GBq for DCS and 0.7+/-0.2Gy/GBq for MTS. We found a strong correlation of dose estimates from both methods for tumours and kidneys (Pearson, p<0.001). However, dose estimates of both methods were significantly different in tumours and kidneys (paired T-Test, p<0.01). This observation may be linked to slightly larger tumour volumes delineated by MTS compared to DCS and to fitting inaccuracies due to a lack of late measurement points. Conclusion: This preliminary study showed that automatic dynamic-cluster-segmentation is a promising approach for the efficient estimation of 3D-tissue dose in radionuclide therapy. Further enhancements such as an organ- or lesion-based co-registration, advanced fit-models, or the inclusion of anatomical information into a multi-dimensional and multi-modal automated dose estimation approach are conceivable.

OP112

PSMA Radioligand Therapy of Metastasized Prostate Cancer Using Lu-177 PSMA I&T and Lu-177 PSMA-617: First comparative Dosimetric Results

C. Schuchardt, H. R. Kulkarni, S. Wiessalla, M. Shahinfar, A. Singh, R. P. Baum; THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, BAD BERKA, GERMANY.

Aim: The prostate-specific membrane antigen (PSMA) is significantly over expressed in prostate cancer cells compared to normal prostate tissue. The aim of our study was to determine and compare the kinetics and dosimetry in patients undergoing PSMA radioligand therapy (PRLT) of castrate resistant metastasized prostate cancer (mCRPC) using Lu-177 labeled PSMA I&T and PSMA-617. **Methods:** Fiftysix patients with progressive mCRPC (aged 71+/-8 years) were included in the analysis.

High PSMA expression was verified before treatment by Ga-68 PSMA PET/CT. 37 patients received 3.4 - 7.6 GBq Lu-177 PSMA I&T and 19 patients were treated with 4.9 - 8 GBq Lu-177 PSMA-617. The time-dependent whole-body, organ and tumor activities were determined based on conjugated planar whole-body scintigraphies and SPECT/CT acquisitions. Dosimetric calculations (MIRD scheme) were performed using OLINDA/EXM software. To analyze the kinetics, we used the following parameters (median values): effective half-life (hours) and uptake (%IA, fraction of injected activity), which were calculated using the fit of the time-dependent activity curve to a mono- or bi-exponential function. **Results:** Relatively intense uptake in the metastases as well as significant uptake in the kidneys, the parotid and lacrimal glands was observed in all patients. A higher uptake of Lu-177 PSMA-617 was found for whole-body as well as parotid and lacrimal glands. The renal uptake was higher for PSMA I&T. Despite the longer half-life of PSMA-617 in kidneys and parotid glands, the renal dose was higher for PSMA I&T (PSMA I&T 0.95 Gy/GBq, PSMA-617 0.78 Gy/GBq); and the dose to parotid glands was comparable for both PSMA ligands (1.1 Gy/GBq). Concerning malignant lesions we distinguished between bone and lymph node metastases. All tumor lesions demonstrated a higher initial uptake for therapy using PSMA I&T followed by a faster wash out at later time points, which was confirmed by a longer half-life of PSMA-617. The longest half-life was determined for bone lesions when using PSMA-617 (PSMA-617 71h, PSMA I&T 44h) but the highest tumor dose was estimated for lymph node metastases in case of PSMA I&T (PSMA I&T 8Gy/GBq, PSMA-617 6 Gy/GBq). No clinically relevant renal or salivary gland toxicity was observed in any or the patients. **Conclusions:** These results demonstrate the different kinetics of both PSMA ligands in mCRPC patients. Additionally, the results revealed a large inter-patient variability of the dosimetric parameters, which leads to the conclusion that individual patient dosimetry is important for the concept of personalized radioligand therapy.

OP113

Differential Response of Bone versus Lymph Node Metastases After Lu-177 Labelled PSMA Radioligand Therapy in Patients with Metastatic Castration-Resistant Prostate Cancer

H. R. Kulkarni, A. Singh, R. P. Baum; THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY.

Aim: The aim of this study was to assess the response of bone and lymph node lesions on Ga-68 PSMA PET/CT after prostate specific membrane antigen (PSMA) targeted radioligand therapy (PRLT).MATERIALS AND METHODS: One hundred and twenty patients with progressive metastatic castration-resistant prostate cancer (mCRPC) underwent PRLT using Lu-177 labeled PSMA inhibitor. A total of 61 skeletal and 73 lymph node metastases, also measurable on CT, were included in the analysis. Response after at least 2 cycles of PRLT was determined applying molecular (EORTC) and morphological (RECIST) imaging criteria, using Ga-68 PSMA PET/CT. RESULTS: Molecular response (reduction in the SUV of the target lesion on PET/CT by > 25%) after 2 or more PRLT cycles was observed in 32/61 (52.4%) bone lesions and 48/73 (65.7%) lymph node lesions, whereas progression (increase of SUV by > 25%) was noted in 5/61 (8.2%) bone and 10/73 (13.7%) lymph node lesions. On the other hand, CT detected decrease in size in only 4/61 (6.6%) skeletal metastases and 29/73 (39.7%) lymph node metastases. All lesions responding on CT revealed a significant decrease in SUV. There was a progression on CT in 10/73 (13.7%) lymph nodes, all of which showed concordant progression on PET/CT. Interestingly, there was an increase in size on CT of 2 osteoblastic lesions in a patient who had a molecular and biochemical complete remission (Ga-68 PSMA PET negative and PSA undetectable, respectively) after 2 PRLT cycles. CONCLUSIONS: Lymph node metastases of mCRPC respond better to PRLT than bone metastases. This may be explained by a higher and more uniform absorbed radiation dose by lymph node metastases as compared to bone lesions, probably due to attenuation of radiation in bone lesions due to the normal surrounding bone tissue. In addition, the biological differences in radiation sensitivity must be considered. Ga-68 PSMA PET/CT is superior in response assessment of skeletal metastases compared to CT alone, in which the actual size of the osteoblastic metastases is difficult to measure and change in size difficult to appreciate. The paradoxical increase in size of the osteoblastic lesions in a patient with complete remission was most probably due to osteosclerosis after therapy (flare phenomenon). Even in lymph node metastases, Ga-68 PSMA PET/CT detects response at an earlier stage than CT (i.e. molecular response precedes morphological changes).

Development and Evaluation of Radiocobalt-labelled Affibody Molecule for Next Day PET Imaging of HER3 Expression

M. Rosestedt[1], B. Mitran[1], K. G. Andersson[2], J. Löfblom[2], S. Ståhl[2], V. Tolmachev[3], A. Orlova[1]; [1]Dept. of Medicinal Chemistry, Div. of Molecular Imaging, Uppsala University, Uppsala, SWEDEN, [2]Div. of Protein Technology, KTH, Royal Institute of Technology, Stockholm, SWEDEN, [3]Dept. of Immunology, Genetics and Pathology, Rudbeck Laboratory, Uppsala University, Uppsala, SWEDEN.

Aim: The human epidermal growth factor receptor type 3 (HER3) recently received attention as a candidate for anti-cancer targeted therapy. HER3 is involved in the development of a variety of cancer types, as well as in the resistance towards tyrosine kinase-targeted therapies. Affibody molecules have in preclinical and clinical studies demonstrated that high contrast imaging is possible a few hours after injection, which is due to the fast blood clearance of the unbound tracer and rapid tumour penetration. Recent preclinical studies have shown that imaging contrast can be improved over time. ^{55}Co is a positron-emitting nuclide with a suitable half-life (17.5h) allowing for imaging at the day of injection as well as the next day. In this study, we evaluated targeting properties of radiocobalt-labelled anti-HER3 affibody in mice bearing HER3-expressing xenografts. **Materials and methods**: ^{57}Co was used as a surrogate for ^{55}Co. An anti-HER3 affibody molecule Z_{08698} with a picomolar affinity, having a HEHEHE-tag on the N-terminus and NOTA chelator on C-terminus was evaluated. The HEHEHE-Z_{08698}-NOTA affibody molecule was labelled with ^{57}Co using ammonium acetate buffer, pH 5.5. Binding specificity and cellular processing were evaluated in vitro. To evaluate the targeting of HER3-expressing tumours in vivo, BALB/C nu/nu mice bearing LS174T colorectal cancer xenografts were used. Mice were injected with 2 μg of ^{57}Co-HEHEHE- Z_{08698}-NOTA and the biodistribution was studied at 3 and 24h post injection (pi). **Results**: HEHEHE-Z_{08698}-NOTA was labelled with ^{57}Co with high stability and >99% purity. The binding of ^{57}Co-HEHEHE-Z08698-NOTA to HER3-expressing cell lines (LS174T, BT474) was specific. Pattern of cellular uptake for LS174T and BT474 cell lines was similar; the internalized fraction did not change over time (3.7% for LS174T; 6.8% for BT474, from cell associated radioactivity). Injected dose of 2 μg resulted in a tumour uptake of 2.6±0.2%ID/g at 3h and 1.9±0.1%ID/g at 24h pi, which significantly ($p<0.05$) exceeded the liver uptake, 1.1±0.7%ID/g. Injection of 70 μg of protein demonstrated a saturation of HER3 in xenografts, indicating on a specific tumour uptake. At 3h pi, the tumour-to-blood, tumour-to-liver, tumour-to-muscle and tumour-to-bone ratios were 5.0 ±0.5, 0.9±0.06, 18.4±3 and 11.6±0.7, respectively. Because of good tumour retention and significant decrease of radioactivity concentration in blood over time, the tumour-to-blood ratio reached the level of 8.2±0.3

and tumour-to-liver was 1.3±0.05 at 24h pi. LS174T xenografts were visualized using microSPECT. **Conclusion**: Radiocobalt-labelled anti-HER3 affibody molecule Z_{08698} is a promising tracer for imaging of HER3 expression in tumours.

OP115

First Real-Time Kinetic in vitro Method for Rapid Prediction of P-glycoprotein Interactions of Newly Developed Radioligands

C. VRAKA[1,2], T. Racz[3], C. Philippe[1], C. Rami-Mark[3], K. Wagner[2], M. Hacker[1], W. Wadsak[1], M. Mitterhauser[1,4]; [1]Division of Nuclear Medicine, Medical University of Vienna (MUW), Vienna, AUSTRIA, [2]Department for Nutritional Science, University of Vienna, Vienna, AUSTRIA, [3]Medical University of Vienna (MUW), Vienna, AUSTRIA, [4]LBI for Applied Diagnostics, Vienna, AUSTRIA.

Aim: The demand of radioligands for cerebral application and tumor diagnostic and therapy (theranostic) is expanding rapidly. One main cause of candidate exclusion and failed tumor theranostics is the efflux mechanism via permeability-glycoprotein (P-gp/MDR1/ABCB1). P-gp is expressed at blood brain barrier, in different peripheral tissue and it is highly expressed on diverse tumors. In detail, pharmaceuticals contact to P-gp can cause drug resistance, poor brain uptake or clinical relevant drug-drug interaction. Aim is to develop an *in vitro* screening method to distinguish between P-gp substrates, inhibitors or radioligands without P-gp interaction in early stage of drug development. **Materials and Methods:** Madin-Darby Canine Kidney cell line, overexpressing human MDR1, (MDCKII-hMDR1) and the MDCKII-wild type (MDCKII-WT) purchased from NKI Amsterdam (Netherlands) were cultivated in DMEM GlutMAX™ (10% FCS & 0.5% Pen/Strep) in the oblique plane of a petri dish. Experiments were carried out with serum free medium to avoid unspecific binding of the tracer to FCS. For P-gp mediated binding or transport *in vivo* kinetics with various PET tracers ((R)-[^{11}C]Verapamil, [^{18}F]FE@SNAP, [^{18}F]FEMeNER-D2 etc.) were performed using LigandTracer®Yellow technology (Ridgeview Instruments AB develops). The half life of each tracer was corrected automatically by LigandTracer® software and the uptake behavior (kinetic) was used for qualitatively interpretation and the slope (k) was calculated for quantitative assessment. **Results:** [^{11}C]Verapamil shows a steep kinetic (k=0.27±0.01, n=3) in the MDCKII-hMDR1 cells, which is replaceable with non labelled verapamil. Whereas on MDCKII wildtype cells uptake is moderate (k=0.12 ±0.01) and not replaceable. The uptake behavior of [^{18}F]FEMeNER-D2 (k= 0.35±0.03, n=3) does not differ in the two cell lines. Additionally, no changes in the kinetics and slopes were observed by replacement with known P-gp inhibitors. No uptake of [^{18}F]FE@SNAP was observed in hMDCKII-MDR1. In contrast, on MDCKII-WT cells and when the P-gp transporter was blocked in hMDCKII-MDR1 cells an uptake of [^{18}F]FE@SNAP was observed (k= 0.06±0.03, n=5). **Conclusion:** A simple and rapid *in vitro* real time kinetic model was developed for prediction of P-gp interaction of radiopharmaceuticals. [^{11}C]Verapamil could be verified as P-gp inhibitor. The missing kinetic of [^{18}F]FE@SNAP on MDCKII-hMDR1 cells in contrast to the uptake in wild type cells proof that [^{18}F]FE@SNAP is a substrate of P-gp and discharged via the transporter. These data correlate with *in vivo* PET quantifications. As a result, newly developed tracer can be distinguished easily into three groups: I. P-gp inhibitors [^{11}C]Verapamil) II. P-gp substrates ([^{18}F]FE@SNAP) III. No P-gp interaction ([^{18}F]FEMeNER-D2)

OP116

Monitoring the effects of combined treatment with EGFR and MET inhibitors in non-small cell lung cancer and synergy quantification by 18F-FLT PET/CT

F. Iommelli[1], V. De Rosa[1], M. Monti[2], M. Panico[1], S. Del Vecchio[2]; [1]Institute of Biostructures and Bioimages, National Research Council, Naples, ITALY, [2]Department of Advanced Biomedical Sciences, University "Federico II", Naples, ITALY.

Aim: In non-small cell lung cancer (NSCLC) patients refractory to treatment with EGFR tyrosine kinase inhibitors (TKIs), mutational and genetic profile of resistant tumors showed that MET amplification may coexist with EGFR bearing T790M mutation or wild type EGFR. Therefore combination therapies simultaneously targeting both receptors may be required to overcome resistance. However, no imaging technique is currently available to detect in vivo drug synergy using a noninvasive approach. Here we tested whether ^{18}F-FLT PET/CT can detect drug synergy between MET and EGFR inhibitors in refractory NSCLC by comparing imaging findings with the rate of proliferation in excised tumors. Materials and Methods: NSCLC cells bearing MET amplification and wild type EGFR (H1993) or EGFR T790M (H820) were selected and tested for the effects of EGFR and MET inhibitors, used alone or in combination, on cell viability and levels of pAKT/AKT, pERK/ERK and cyclin D1. Then, H1993 tumor-bearing mice underwent ^{18}F-FLT PET/CT scan before and after treatment with escalating doses of EGFR and MET inhibitors, alone or in combination, and post-treatment changes of ^{18}F-FLT uptake in tumors were determined. At the end of imaging studies, tumors were removed and tested for cyclin D1 levels by morphodensitometric analysis of western blot signal as well as for Ki67 immunostaining. Synergistic effect was evaluated for in vivo and in vitro data set by determining the combination index (CI) using the CompuSyn software. Results: In the selected cell lines, the highest dose-dependent reduction of cyclin D1 and other signaling mediators levels was obtained by combined treatment with EGFR and MET inhibitors as compared with single agent alone. Imaging studies showed a significant reduction of ^{18}F-FLT uptake in response to combined treatment with escalating doses of EGFR and MET inhibitors ranging between -38.9% and -69.2%. Treatment with EGFR inhibitor alone did not cause any significant change of ^{18}F-FLT uptake whereas a reduction of tracer uptake ranging between -24.5% and -42.5% was obtained in response to MET inhibitor alone. Analysis of imaging data set showed a combination index <1 indicating drug synergism. Furthermore a significant positive correlation was found between reduction of ^{18}F-FLT uptake and percentage decrease in cyclin D1 levels (r=0.94, p= 0.016) and Ki67 positive stained cells (r=0.92, p= 0.022). Conclusion: Our findings indicate that ^{18}F-FLT PET/CT may be used as a surrogate biomarker for synergy quantification in NSCLC patients receiving combined treatment with EGFR and MET inhibitors thus contributing to personalized therapy.

OP117

Experimental study on Multiple Tracers PET/CT in the differention of C6 glioma and different inflammation

L. CAI, S. GAO, Y. WANG, Y. LI, H. YANG; PET/CT Center, General Hospital of Tianjin Medical University, Tianjin, CHINA.

Aim To study the value of ^{18}F-FDG, ^{11}C-MET and ^{11}C-CHO PET/CT in the differention of C6 glioma and different inflammation in experimental rat models. **Materials and Methods** (1)48 male SD rats were randomly divided into 8 groups: group 1 and 2 consisted of 8 rats bearing both C6 glioma and turpentine oil-induce acute inflammation; group 3 and 4 consisted of 8 rats bearing both C6 glioma and turpentine oil-induce chronic inflammation; group 5 and 6 consisted of 8 rats bearing both C6 glioma and BCG-induced granuloma. (2) ^{18}F-FDG and ^{11}C-MET PET/CT were performed on group 1, 3 and 5; ^{18}F-FDG and ^{11}C-CHO PET/CT were performed on group 2, 4 and 6. The lesion-to-muscle(L/M) ratios and a tumor selectivity index, SI=(tumor SUV_{max}-muscle SUV_{max})/(different inflammation SUV_{max}-muscle SUV_{max}), were calculated. (3)After that, the lesions were excised. Immunohistochemical stain were used to demonstrate the situation of glucose transporter-1(GLUT-1),hypoxia inducible factor-1α(HIF-1α), and CD98. (4)A unpaired *t* test and nonparametric Kruskal-Wallis *H* test were used to make statistical analyses. **Results** (1) ^{18}F-FDG and ^{11}C-MET uptake in C6 glioma were higher than that in different inflammatory tissues, and the differences of

two tracers uptake between C6 glioma and acute inflammation, and chronic inflammation, and C6 glioma and granuloma were significant (all P <0.05). The ^{11}C-CHO uptake between different lesions were no significant (all P>0.05). In group 1 models, mean SI_{MET} 4.22 ±2.96 was significantly higher than SI_{FDG} 1.77±0.86(P=0.030); in group 5 models, mean SI_{MET}4.89±2.08 was significantly higher than SI_{FDG}1.72 ±0.769(P=0.042), but in group 3 models, mean SI_{MET}3.84±2.71 was higher than SI_{FDG} 2.28±1.14(P=0.076). (2) Immunohistochemical study showed that there were significant differences of the expression of HIF-1α, CD98 between different lesions (all P <0.05), and no significances of expression of GLUT-1 between different lesions (P=0.061). Nemenyi test showed that there was significant difference between C6 glioma and acute inflammation, C6 glioma and granuloma in CD98 (all P <0.05), and between C6 glioma and chronic inflammation in HIF-1α, CD98 (all P<0.05). **Conclusions** ^{11}C-MET is more tumor selective than ^{18}F-FDG and ^{11}C-CHO, therefore, ^{11}C-MET PET/CT is able to differentiate glioma from different inflammation. ^{11}C-CHO PET/CT is not able to differentiate tumor from different inflammation.

OP118

[^{68}Ga]Pentixafor for CXCR4 Imaging in a PC-3 Prostate Cancer Xenograft Model - comparison with [^{18}F]FDG PET/CT, MRI and ex-vivo receptor expression

S. M. Schwarzenböck[1], J. Stenzel[1], T. Otto[1], J. Kurth[1], S. Polei[1], T. Lindner[1], A. Hohn[1], H. Wester[2], B. Vollmar[1], B. J. Krause[1]; [1]Rostock University Medical Center, Rostock, GERMANY, [2]Pharmaceutical Radiochemistry, Technische Universität München, Garching, GERMANY.

Introduction: Chemokine receptors, i.e. the subtype CXCR4, play a significant role in tumor progression, metastasis, recurrence and angiogenesis. CXCR4 has been demonstrated to be highly overexpressed in prostate cancer. Thus, [^{68}Ga]Pentixafor, targeting CXCR4, might serve as a promising tracer for imaging of aggressive and metastasizing prostate cancer. Aim: The aim of this study was to characterize the properties of [^{68}Ga]Pentixafor as tracer for prostate cancer imaging in an aggressive PC-3 prostate cancer xenograft mouse model by small animal PET/CT and to investigate its correlation with [^{18}F]FDG uptake, functional/morphological MRI and CXCR4 immunohistochemistry (IHC). Methods: A dual tracer small animal PET/CT study was conducted comparing [^{68}Ga]Pentixafor and [^{18}F]FDG. The androgen-independent human prostate cancer cell line PC-3 was implanted subcutaneously in both flanks of NMRI (nu/nu) mice (n= 19). Mice - 4 weeks post xenograft implantation - were injected with 15 MBq [^{68}Ga]Pentixafor and [^{18}F]FDG, respectively, on two separate days. Static PET imaging was performed 60 min p.i. with an Inveon animal PET/CT scanner (Siemens Preclinical Solutions, Knoxville), respectively. VOIs using a threshold of 60% were placed in transaxial slices in tumor, muscle, liver, kidney and blood pool. Diffusion weighted MRI (ADC-Trace, 4 b-values), morphological MRI and ^{1}H MR spectroscopy was performed (7T small animal MRI, Bruker BioSpec 70/30). Uptake of [^{68}Ga]Pentixafor and [^{18}F]FDG was compared to MRI (DWI derived ADC values, T2 weighted MRI derived tumor volume and spectroscopy data). Imaging data were correlated with ex-vivo tumor expression of CXCR4 (assessed via IHC and mRNA). Statistics were performed using SPSS. Ex-vivo biodistribution of [^{68}Ga]Pentixafor in tumor, muscle, liver, kidney and blood was assessed. Results: Tumor uptake of [^{68}Ga]Pentixafor was significantly lower compared to [^{18}F]FDG (mean % ID/g 1.8 / standard deviation (SD) 0.6 and 5.8 / SD 1.2, respectively). No significant correlation was found between the uptake of the two tracers. There was no significant correlation of [^{68}Ga]Pentixafor or [^{18}F]FDG uptake and mean ADC values (mean 1.0 / SD 0.05), respectively. Expression of chemokine receptors on tumor cells was demonstrated qualitatively by IHC as well as quantitatively via mRNA analysis. Conclusion: In a PC-3 prostate cancer xenograft model tumor visualization was feasible using [^{68}Ga]Pentixafor PET/CT; [^{68}Ga]Pentixafor tumor uptake was lower compared to [^{18}F]FDG uptake. No significant correlation was found between tracer uptake and mean ADC values. Expression of chemokine receptors in a model of aggressive and undifferentiated prostate cancer was shown qualitatively and quantitatively as a correlate of [^{68}Ga]Pentixafor uptake.

OP119

Zirconium-89-girentuximab PET/CT imaging in renal cell carcinoma: first in man results

M. Hekman, M. Rijpkema, P. Mulders, E. Oosterwijk, O. Boerman, W. Oyen; Radboudumc, Nijmegen, NETHERLANDS.

Background: More advanced imaging methods are needed to reliably distinguish benign small renal masses (SRM) from renal cell carcinoma (RCC) to prevent invasive biopsies or unnecessary surgeries. Similarly, imaging methods need to be improved for unambiguous detection of lesions suspect for metastatic and relapse RCC during follow-up. Girentuximab is an antibody against Carbonic Anhydrase IX (CAIX), an antigen that is expressed on the cell surface of 95% of clear cell RCC (ccRCC). Zirconium-89-girentuximab PET/CT may be a valuable imaging technique in the diagnosis of patients with RCC. The aim of the present study is to show the impact of the Zirconium-89-girentuximab PET/CT in the clinical management of ccRCC patients. Here we present our first results with Zirconium-89-girentuximab PET/CT for diagnosing patients presenting with either a small renal mass or with a history of ccRCC. **Methods:** Thirty patients suspect of or with a history of ccRCC in whom conventional imaging methods are inconclusive will be included. In these patients a PET/CT will be acquired 4-5 days after injection of 5 mg Zirconium-89-girentuximab (37 MBq). **Results:** So far, 5 patients have been included in this clinical study. One patient presented with a Bosniak 3 lesion in a solitary kidney. Another patient presented with a SRM (31 mm) and a synchronous lung carcinoma. In both patients the SRM showed clear uptake of Zirconium-89-girentuximab and a partial nephrectomy was performed. Histology confirmed ccRCC in the first patient, surgery of the second patient is scheduled. A third patient presented with multiple bilateral growing renal masses. None of the masses showed uptake of Zirconium-89-girentuximab on the PET/CT and repeated biopsies showed the presence of oncocytomas. Two patients with a history of ccRCC and a suspicion of metastases were included. A growing lymph node in the first patient showed no uptake of Zirconium-89-girentuximab on PET/CT. Histology showed that the lymph node contained a CAIX-expressing metastasis of a papillary growing ccRCC. In the second patient clear uptake of Zirconium-89-girentuximab in a large liver lesion and in multiple pulmonary lesions was seen, and therefore a biopsy could be avoided and systemic therapy with pazopanib was initiated. **Conclusion:** These preliminary results suggest that Zirconium-89-girentuximab PET/CT can be a valuable aid in the diagnosis of patients suspected of ccRCC.

OP120

Differential regulation of glucose metabolism by ERK1/2 and AKT pathways in EGFR-driven NSCLC

V. De Rosa[1], F. Iommelli[1], M. Monti[2], S. Del Vecchio[2]; [1]Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY, [2]Department of Advanced Biomedical Sciences, University of Naples "Federico II", Naples, ITALY.

Aim: In a previous study we showed that inhibition of EGFR signaling causes a metabolic switch from aerobic glycolysis to oxidative phosphorylation by reducing hexokinase II (HKII) and phosphorylated form of pyruvate kinase M2 (p-PKM2 Tyr105) and upregulation of mitochondrial complexes (OXPHOS) in NSCLC cells and in vivo in animal models. To test the existence of a cause-effect relationship between the reduced levels of relevant glycolytic enzymes and OXPHOS upregulation, silencing of HKII and

PKM2 mRNAs was performed using targeted or scrambled siRNAs followed by inhibition of EGFR cascade. Furthermore, we tested whether the selective inhibition of AKT and ERK1/2 pathways could differently modulate glycolysis and oxidative phosphorylation. **Materials and Methods**: Erlotinib-resistant H1975 and H1993 NSCLC cells were transfected with 100 nM specific and scrambled siRNAs using Dharmafect reagent and after 24 h they were treated with 1 μM erlotinib, WZ4002, PHA-665,752 or vehicle for additional 48 h. AKT and ERK1/2 pathways were differentially inhibited by treatment with wortmannin (1 μM, 10 μM, 20 μM) or U0126 (1 μM, 10 μM, 20 μM), respectively. Levels of HKI, HKII, PKM1, PKM2 and LDH-A as well as phosphorylation status of PKM2 in the glycolytic cascade along with OXPHOS and PGC-1α were tested in response to each treatment. **Results**: The downregulation of HKII and PKM2 do not cause an increase of OXPHOS levels but enhances the effect of EGFR signaling inhibition on the upregulation of OXPHOS. Furthermore, when cells were exposed to increasing concentration of AKT inhibitor, a dose-dependent increase of OXPHOS levels was obtained whereas no changes of HKII and p-PKM2 Tyr105 levels were observed. Conversely, treatment with ERK1/2 inhibitor caused a dose-dependent decrease of HKII and p-PKM2 Tyr105 levels whereas no changes of OXPHOS levels were observed in treated cells. **Conclusion**: Our findings indicate that aerobic glycolysis and oxidative phosphorylation are differentially regulated by ERK1/2 and AKT pathways, respectively, providing a mechanistic clue for rational combinations of anti-cancer agents targeting EGFR pathways and glucose metabolism.

OP121

MicroRNA-342-3p Suppresses Warburg Effect and Tumor Proliferation by Targeting Insulin-like Growth Factor 1 Receptor in Hepatocellular Carcinoma

L. Kang[1], Y. Huo[1], R. Wang[1], X. Xu[2]; [1]Peking University First Hospital, Beijing, CHINA, [2]Academy of Military Medical Sciences, Beijing, CHINA.

Objective: ^{18}F-FDG PET has been widely used in the detection of malignant tumors based on Warburg effect. Better understanding the regulated factors in Warburg effect can improve the utility of ^{18}F-FDG. miR-342-3p has been proved to play an inhibitory role in some malignant tumors. However, the function of miR-342-3p in Warburg effect remains poor understood. The objective is to investigate the role of miR-342-3p in the regulation of glucose metabolism and potential mechnism in hepatocellular carcinoma (HCC). **Methods:** The HepG2 cells stably overexpressing miRNA and empty vector were constructed by lentiviral vector transfection. Quantitative real-time PCR (qRT-PCR) was used to evaluate the expression level of miRNA-342-3p in HCC cell lines. Then, the role of miR-342-3p was determined on cell proliferation, migration, invasion, and FDG uptake in HCC cell lines. FDG PET imaging and biodistribution study was performed to evaluate the role of miR-342-3p *in vivo*. Finally, a luciferase reporter assay was performed to confirm the target gene of miR-342-3p and the relative proteins are evaluated by Western blotting. **Results:** miR-342-3p is down-regulated in HCC cell lines, and its overexpression induced significant inhibition of HCC cell proliferation and invasion in HCC cell lines, as well as tumor growth and metastasis in xenograft and metastasis mice. In addition, micro PET showed that miR-342-3p repressed FDG uptake in xenograft and metastasis mice. Furthermore, we identified 3'-UTR of insulin-like growth factor 1 receptor (IGF1R) as a target of miR-342-3p and miR-139-5p suppressed FDG uptake via IGF1R/PI3K/AKT/GLUT1 pathway. **Conclusion:** miR-342-3p exhibits a negative role in the regulation of glucose metabolism and FDG uptake via inhibition of IGF1R/PI3K/AKT/GLUT1 pathway.

Sentinel lymph node biopsy using ^{99m}Tc-tilmanocept (Lymphoseek) in patients with oral cavity squamous cell carcinoma: Safety results from Phase III clinical trial

S. Y. Lai[1], F. Civantos[2], A. Agrawal[3]; [1]Department of Head and Neck Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES, [2]Department of Otolaryngology, University of Miami Hospital and Clinics/Sylvester Comprehensive Cancer Center, Miami, FL, UNITED STATES, [3]Department of Otolaryngology—Head and Neck Surgery, Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES.

AIM: In clinically N0 early-stage (T1-2) oral cavity squamous cell carcinoma (OSCC), surgeons presently favour resection of regional lymphatics although up to ~80% of early stage patients are pN0 and may be over-treated, with significant potential morbidity. Sentinel lymph node biopsy (SLNB) has been shown to be a safe and effective alternative to complete elective neck dissection (END) for early-stage OSCC. A recently published multi-centre trial of ^{99m}Tc-tilmanocept (Lymphoseek®), the first and only receptor-targeted (CD206) molecular SLNB agent, was evaluated in head and neck cancer (HNC) patients undergoing SLNB. The study's primary objective was to determine the false negative rate (FNR) of ^{99m}Tc-tilmanocept localized SLNs versus END [published *Agrawal et al, Ann Surg Oncol, 2015; 22(11):3708-3715*]. Here we report safety findings from the study. **MATERIAL AND METHODS:** A Phase III, multicenter, open-label, within-patient trial of ^{99m}Tc-tilmanocept was conducted for detection of SLNs in OSCC and cutaneous SCC patients (T1-4aN0M0). Patients received a single dose (50mcg) of ^{99m}Tc-tilmanocept, radiolabeled with 18MBq (for same-day surgery) or 74MBq (for next-day surgery). Patients underwent preoperative lymphoscintigraphy and SLNB with a handheld gamma detector followed by requisite END. Adverse events, vital signs, electrocardiograms, physical exams, and clinical laboratory parameters were collected. **RESULTS:** 85 patients (79 OSCC, 6 cutaneous SCC) received ^{99m}Tc-tilmanocept and were included in the safety analysis. No deaths occurred in the study, and no serious adverse events (SAEs) were related to the agent. Of the 13 non-drug related SAEs, 11 were considered by the investigators to be related to surgical procedures. Overall, 36 patients (31 OSCC, 5 cutaneous) reported at least 1 AE; most AEs were mild (62%) and unrelated to ^{99m}Tc-tilmanocept (85%), and no event led to discontinuation from the study. There were no reports of injection site pain, and only 1 report of mild injection site irritation. No clinically meaningful changes were noted for laboratory parameters, vital signs, physical examinations, and ECG values. Patient level FNR for SLNB with ^{99m}Tc-tilmanocept was 0.0256 (95% CI=0.0006,0.1349). The mean number of SLNs per evaluable patient was 3.9 (median 4), whereas the mean number of END nodes was 34 (maximum 82). **CONCLUSIONS:** Use of Lymphoseek was well tolerated by the studied population. The strong safety profile in HNC patients and low FNR observed in this trial suggest that ^{99m}Tc-tilmanocept may allow for safe and effective use for SLNB as an alternative to END, with the potential for substantially reduced morbidity.

OP124

Bilateral and contralateral sentinel node identification with ^{99m}Tc-tilmanocept (Lymphoseek®) in oral cavity squamous cell carcinoma patients

S. Y. Lai[1], F. Civantos[2], A. Agrawal[3]; [1]The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES, [2]University of Miami Hospital and Clinics/Sylvester Comprehensive Cancer Center, Miami, FL, UNITED STATES, [3]Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES.

AIM: In clinically N0 early-stage (T1-2) oral cavity squamous cell carcinoma (OSCC), surgeons presently favour resection of regional lymphatics although ~70-80% of early-stage patients are pN0 and may be over-treated, with significant potential morbidity. Sentinel lymph node biopsy (SLNB) has been shown to be a safe and effective alternative to elective neck dissection (END) for early-stage OSCC. ^{99m}Tc-tilmanocept (Lymphoseek®), the first and only receptor-targeted (CD206) molecular SLNB agent, was evaluated in a trial of head and neck cancer patients undergoing SLNB [*Agrawal et al, Ann Surg Oncol, 2015; 22(11):3708-3715*]. The primary objective was to determine the false negative rate (FNR) of ^{99m}Tc-tilmanocept-localized SLNs versus END [2.6%]. Here we report bilateral and contralateral SLN identification from the study. **MATERIAL AND METHODS:** A Phase III, multicenter, open-label, within-patient trial of ^{99m}Tc-tilmanocept was conducted for detection of SLNs in OSCC and cutaneous SCC patients (T1-4aN0M0). Patients received a single dose (50mcg) of ^{99m}Tc-tilmanocept, radiolabeled with 18MBq (for same-day surgery) or 74MBq (for next-day surgery). Patients underwent preoperative lymphoscintigraphy and SLNB with a handheld gamma detector followed by requisite END. **RESULTS:** 85 patients (79 OSCC, 6 cutaneous SCC) received ^{99m}Tc-tilmanocept; 2 did not undergo protocol-defined surgery and are censored from efficacy analyses. Of 83 evaluable patients, 8 had midline tumors (within 1cm; 6 floor-of-mouth [FOM], 1 oral tongue, and 1 mucosal lip); 5 had bilateral SLNs identified in the neck, of which 4 patients had pathology-positive SLNs (1 bilateral positive SLNs, 3 unilateral positive SLNs). The other 3 patients with midline tumors had SLNs identified on one side of the neck, and 2 of the 3 had positive pathology in the SLNs. 24% of patients with single-sided tumors (18 of 75) had contralateral SLNs. Of these, 11 had pathology-positive SLNs: 5 (4 tongue, 1 lower alveolar ridge) had pathology only in the ipsilateral SLN(s); 4 (3 FOM, 1 tongue) had pathology in both ipsilateral and contralateral SLNs; and 2 (both FOM) had pathology only in the contralateral SLN(s). **CONCLUSIONS:** ^{99m}Tc-tilmanocept for SLNB is highly predictive in staging the cN0 neck. In this study, ^{99m}Tc-tilmanocept identified bilateral and contralateral draining nodes that may have not been removed using standard-of-practice END, in some cases identifying the only pathology-positive lymph nodes. In fact, without SLNB, ≥7.2% of the patients treated with standard END would have left behind a positive node. These and other data suggest SLNB with ^{99m}Tc-tilmanocept may be an alternative to END in OSCC.

Real time robotic arm assisted FDG PET/CT-guided percutaneous metabolic biopsy: Initial Experience

R. Kumar, B. R. Mittal, R. K. Radhakrishnan, A. Bhattacharya, A. Sood, A. Sood; PGIMER, Chandigarh, INDIA.

Objective: The aim of this prospective study was to evaluate the feasibility and diagnostic utility of automated robotic arm (ARA) assisted ^{18}F-FDG PET/CT guided real-time metabolic biopsy from various organs during the diagnostic PET scan or with inconclusive prior biopsy results. **Materials and Methods:** In this prospective study we evaluated 31 patients (12 females and 19 males) with median age 54.64 years (20-69 years) who were either directly subjected to a diagnostic ^{18}F-FDG PET/CT scan and per-cutaneous biopsy or had inconclusive prior biopsy results. All the patients underwent whole body FDG PET/CT and site of the biopsy was planned from the most accessible FDG avid lesions. Biopsy was performed after 2 hrs of initial diagnostic study by obtaining one table position PET/CT. The biopsy needle was placed into the lesion with the help of automated robotic arm (ARA) needle navigation technique. The real time tissue sampling was done from the highest metabolically active tissue by confirming the position of the needle tip with a check CT scan. For reviewing the accuracy of the procedures and confirmation of negative results histopathological examination, clinical or imaging follow up results were reviewed. **Results:** Out of the total 31 patients, PET guided biopsy was done from lung (n=17), bone (n= 6), liver (n=2) lymph nodes (n=3), chest wall (n=1), breast (n=1) and abdominal mass (n = 1). Adequate representative tissue sample were retrieved in all the patients and diagnostic results were yielded in all the biopsy procedures; 23 were positive for malignancy (lung -13, liver-1, lymph node-1, breast-1, chest wall -1, bone-5 and abdominal mass-1) and eight had no evidence of malignancy (organising pneumonia-3, tuberculosis-1, reactive lymphoid hyperplasia-2, granulomatous hepatitis-1 and no excess plasma cells-1). All the 15 patients with negative prior CT guided FNAC/biopsy from the lung lesions were found to be positive for malignancy on PET guided biopsy. We noticed complications in four patients only (two had mild pneumothorax while two had hemoptysis) with no life threatening event. The diagnostic yield of real time PET guided metabolic biopsy procedure was 100%. **Conclusion:** We conclude that ARA directed FDG PET/CT guided real time metabolic percutaneous biopsies are technically feasible and are of great help in patients with prior negative lung biopsies. Additionally ARA guided biopsy is a promising tool in targeting the metabolically active site with high accuracy in bone biopsies and help in avoiding unsuccessful and painful blind biopsy procedures.

Lymphoscintigraphic detection of the sentinel lymph node in breast cancer patients: peritumoral injection versus single subareolar injection

P. B. Gouveia, R. Teixeira, R. Brito, R. Castro, I. Amorim; Centro Hospitalar do Porto, Porto, PORTUGAL.

Aim: Preoperative lymphoscintigraphy is without doubt a valid method for the detection of the sentinel lymph node (SLN). However, uncertainty remains regarding the best method of radiotracer injection. The purpose of our study was to evaluate the lymphoscintigraphic identification rate of peritumoral (PT) injection versus a single subdermal subareolar (SA) injection in the detection of SLNs in breast cancer. Material and Methods: A retrospective study was conducted on a cohort of 433 patients with biopsy proven breast cancer that underwent 442 SLN biopsy procedures between January 2008 and February 2016. Nine patients had bilateral breast cancer. Patients with ductal carcinoma in situ diagnosed at needle core biopsy and patients with multifocal breast cancers were included in the study. Patients with cytological positive lymph nodes, with previous ipsilateral axillary surgery, and patients who received neoadjuvant chemotherapy before surgery were excluded from the study. A total of 96 procedures (Group A) were performed using a PT deep injection of radiotracer while 337 procedures (Group B) adopted a single SA injection of radiotracer. Chi-square test was performed to compare the rate between the different groups. $P<0.05$ was considered to be statistically significant. Results: SLNs were identified in the lymphoscintigram in 93/96 cases (96.86%) of Group A (PT injection) and in 322/ 337 cases (95.55%) of Group B (PA injection). Furthermore, in 2/96 patients (2.08%) of Group A, internal mammary lymph nodes were found at lymphoscintigraphy, whereas 4/337 (1.19%) were found in the Group B patients. The intraoperative identification rate of axillary SLNs was 98.95% (95 of 96) in the Group A patients and 99.65% (334 of 337) in the Group B patients. There was no significant difference in the two groups between the incidence of the number of SLNs detected and the incidence of identification of positive SLNs. Conclusion: PT versus single SA injection of radiotracer showed comparable success rates for SLN identification. We

believe that a single SA injection is to be considered the method of choice in the identification of SNLs, since it is less painful for the patient and it is easier to perform. Furthermore, as SA injection requires a single subareolar injection site, the tumor does not have to be located by other techniques, and the "shine-through phenomenon" is avoided, when the tumor is located near the axilla.

OP127

Role of Pleural Pathway in Determining Drug Shunt During Hyperthermic Isolated Lung Perfusion: a Radioisotope Leakage Study

F. Fiz[1], G. Villa[1], E. Ferrari[2], M. Manitto[2], E. Pomposelli[1], S. Morbelli[1], M. Sicignano[1], A. Alloisio[2], D. Pende[3], R. Meazza[3], C. Gereloni[4], G. Ratto[2], C. Marini[5], G. Sambuceti[1]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY, [2]Department of Thoracic Surgery, IRCCS San Martino-IST, Genoa, ITALY, [3]Immunology Laboratory, IRCCS SAn Martino-IST, Genoa, ITALY, [4]TFPCC Foundation, IRCCS Policlinico San Matteo, Pavia, ITALY, [5]National Council of Research, IBFM, Genoa, ITALY.

Rationale**:** Hyperthermic isolated lung perfusion (HILP) is a growing surgical treatment modality, used to deliver supra-maximal chemo- or immunotherapic drug dosage to the lung, while sparing the remaining organism from toxicity. Avoiding shunts from the isolated to the systemic circulation is key. Radioisotopic leakage monitoring has been validated for a long time in the setting of isolated limb perfusion; in the lung, double circulation and pleural re-uptake could complicate the task. In this project, we used a radioisotope technique to test the contribution of pleural shunt in determining drug leakage. Patients and Methods: Eleven patients, with multiple lung metastases, were submitted to a total of 15 HILP, using TNF-α as active agent. Leakage from isolated circuit was monitored by serial blood sampling (from both the isolated and systemic circulation) and by a radio-isotopic method. Briefly, patients' erythrocytes were in-vivo labeled with ^{99m}Tc and stannous agent, using a ten-fold dose fold dose for the isolated circuit. A probe was placed on the temporal artery and real-time counts with respect to baseline were used to compute the percent leakage factor (RLF). TNF-α concentration in the pleural aspirate reservoir (PRC) was measured at the end of the procedure. Results: Average PRC was 429±271ng/ml, not significantly different from mean circuit concentration 700±374 ng/ml (p=ns), but markedly higher than peripheral blood concentration 0,6±1,2 ng/ml (p<0.01). The integral of TNF-α concentration in the perfusion circuit positively correlated with PRC (R=0,64, p<0,05). By contrast, PRC showed a definite negative correlation with RLF (R=0,8, p<0,01), indicating that inefficient removal of pleural fluid could aggravate drug leakage. Accordingly, difference in TNF-α concentration between the isolated circuit and the pleural reservoir showed a positive correlation with RLF (R=0,74, p<0,01). Conclusions: Radioisotopic leakage monitoring is able to correctly TNF-α leakage during HILP. Pleural shunt plays a major role in drug leakage determination: efficient removal of pleural fluids is pivotal in ensuring the patients' safety during the procedure.

Diagnostic value of additional SPECT/CT in sentinel lymph node mapping in breast cancer patients

S. Stanzel[1], B. Pernthaler[1], G. Pregartner[2], T. Schwarz[3], V. Bjelic-Radisic[4], R. M. Aigner[1]; [1]Medical University of Graz, Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA, [2]Medical University of Graz, Institute for Medical Informatics, Statistics and Documentation, Graz, AUSTRIA, [3]Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA, [4]Medical University of Graz, Department of Gynecology and Obstetrics, Graz, AUSTRIA.

Aim: In scientific literature for sentinel lymph node mapping (SLNM) different examination protocols are reported. The objective of the study was to demonstrate the diagnostic value of SPECT/CT in SLNM in patients with invasive breast cancer. **Materials and methods:** One hundred and fourteen patients with invasive breast cancer with clinically negative lymph nodes were included in this study as they were referred for SLNM with ^{99m}Tc-nanocolloid. Planar image acquisition was accomplished in a one-day or two-day protocol depending on the schedule of the surgical procedure. Low-dose SPECT/CT was performed after the delayed planar images. The sentinel lymph node biopsy (SLNB) was considered false negative if a primary recurrence developed within 12 months after SLNB in the axilla from which a tumor-free SLN had been removed. The false-negative rate was determined as the ratio of false-negative results to the total number of positive nodes (false-negative nodes plus true-positive nodes). **Results:** Between December 2009 and December 2011, 114 patients underwent SLNM with SPECT/CT. 139 SLNs were detected with planar scintigraphy alone and 290 SLNs with additional SPECT/CT. In 5 patients, no SLN could be detected with planar scintigraphy. In 4 of the last patients, SLNs were identified with the aid of SPECT/CT. Thus, with SPECT/CT significantly more SLNs were detected than with planar scintigraphy alone (p>0,001). Consequently, 32 patients (28%) had therapy change (axillary lymph node dissection). No patient had lymph node metastasis within 12 months after SLNB in the axilla from which a tumor-free SLN had been removed resulting in a false-negative rate of 0% (0/18). **Conclusion:** Among patients with breast cancer, the use of SPECT/CT-aided SLNM correlated due to a better anatomical localization and identification of planar not visible SLNs with a higher detection rate of SLNs. This led to therapeutic consequences and an excellent false-negative rate.

OP129

Late acquisition with SPECT/CT lymphoscintigraphy improves Sentinel Lymph Nodes detection in vulvar cancer patients

A. Olivier, E. Leblanc, A. Oudoux, E. Tresch, L. Delcroix, C. Leprince, F. Narducci, H. Kolesnikov-Gauthier; Oscar lambret center, lille, FRANCE.

AIM: We assessed the interest of late planar acquisition and single photon emission computed tomography (SPECT/CT) lymphoscintigraphy (LSG) for sentinel lymph node (SLN) detection and dissection in patients with vulvar cancer. **MATERIALS AND METHODS:** 73 consecutive patients underwent a preoperative SLN tracking with 4 intradermal injections of Technetium 99m - nanocolloid (mean total injected dose: 60MBq) and subsequent early planar (mean time after injection: 38.4 minutes), late planar (mean time after injection: 4.2 hours) and SPECT/CT LSG. Directly before radioguided intraoperative detection, 52 of the 73 patients were injected with patent blue dye. We retrospectively analyzed detection rates of early planar (n= 73), late planar (n=59) and SPECT/CT (n=46) LSG, and intraoperative detection. Histologic results for all dissected LN were collected. **RESULTS:** Detection rates of SLN with early planar, late planar , SPECT/CT LSG and patent blue dye were respectively 82.2%, 91.5%, 95.7% and 80.8%. Late planar LSG identified more inguinal and iliac SLN than early planar [respectively per patient: mean value 2.4 (SD 1.7) and 1 (SD 1.1) versus 1.8 (SD 1.5) and 0.6 (SD 0.9)] (p<0.001). SPECT/CT LSG identified more inguinal SLN than late planar [mean value 3 (SD 2) versus 2.4 (SD 1.7)] (p=0.004), and also more iliac SLN than late LSG [mean value 2 (SD 1.8) versus 1 (SD 1.1)] (p<0.001). We analyzed all removed LN who were not radioactive. This could be observed in 3 situations. 1/ Sixteen patients had unilateral isotopic SLN detection(14 patient with midline tumor and 2 with unilateral tumor but positive SLN on the first side). Thirteen patients subsequently had an inguinofemoral lymphadenectomy of the other side. Five of them had metastatic LN in the groin dissection. 2/ Blue dye procedure finds 2 LN who were not detected by isotopic method. None were metastatic in

final histology. 3/ At surgery, 5 not radioactive LN were visually suspect and therefore dissected. Two of them were metastatic. **CONCLUSION:** In vulvar cancer patients, SPECT/CT lymphoscintigraphy leads to a higher identification compared to early or late LSG. Its higher resolution provides better anatomical localization of SLN and improves the detection rate. Systematic SPECT/CT could decrease the number of inguinofemoral lymphadenectomies and so reduce associated comorbidity.

OP130

A pilot study of absolute quantitative SPECT/CT for sentinel lymph node mapping in endometrial cancer

S. Sahbai[1], F. Fiz[1], F. Taran[2], S. Brucker[2], D. Wallwiener[2], C. la Fougère[1], H. Dittmann[1]; [1]Nuclear Medicine, University Hospital Tuebingen, GERMANY, [2]Gynecology and Obstetrics, University Hospital Tuebingen, GERMANY.

Introduction: Our previous study indicated that high venous drainage, as visualized by significant bone marrow uptake, was the most important factor associated with sentinel lymph node (SLN) detection failure in endometrial cancer. Aim of this study was to use absolute quantification in order to further explore actors disturbing successful SLN detection with SPECT/CT after pericervical 99m Tc-Nanocolloide injection. Methods: Fifty-three patients underwent four pericervical injections of 99m Tc-Nanocolloide (200-300 MBq) and preoperative SPECT/CT of abdomen and pelvis (2:30-6:00h p.i.). We compared imaging findings of patients with SLN detection failure (n=14) to a randomized matched cohort of patients (n=14) who showed at least 2 detected SLNs at SPECT/CT. Activity concentration (MBq/ml), percentage of injected dose (%ID) as well as absolute activity (MBq) were assessed by means of a commercial software (GE Healthcare Q.metrics) in volumes of interest: SLN, liver, spleen, injection site and body remainder within the field-of-view. Mann-Whitney U-test was used for statistics. Results: Fifty-four SLN were visualized in the 14 patients with successful detection in SPECT/CT. Mean SLN activity concentration was 0.05 MBq/ml (range 0.003-0.22). In case of successful detection, percentage of injected dose and absolute activity at the injection site were significantly higher than in patients with detection failure (53±25 %ID vs. 29±18 %ID, $p<0.01$ and 73 ±31 MBq vs. 43±37 MBq, $p<0.05$). Failure to detect SLN tended to be associated with higher liver mean uptake through not reaching significance (26±20 vs. 12±7 KBq/ml, $p=0.17$). Moreover, we observed a trend for higher activity fraction in the body remainder in negative SLN scans (15±7% vs. 11±4%; $p=0.13$) and a lower overall %ID (58±27% vs. 75±10%; $p=0.16$) the latter finding indicating a loss of activity after application. Successful SLN detection was not correlated with the amount of injected activity and the time gap between injection and imaging. Conclusion: This pilot study indicates that SLN with a nanocolloide activity concentration as low as 0.003 MBq/ml could be detected on SPECT/CT. Furthermore, SLN detection is associated with a higher persisting activity at the injection site and low venous drainage highlighting the relevance of meticulous injection technique. Further studies, with larger cohorts of patients are needed to confirm these preliminary results.

Penalised Deconvolution of SPECT Images for Tumour Dosimetry

I. Murray[1], M. Gray[1], G. Flux[2]; [1]Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM, [2]Royal Marsden NHS Foundation Trust / Institute of Cancer Research, Sutton, UNITED KINGDOM.

Introduction: The partial volume effect remains a challenge for the quantification of SPECT data for dosimetry. The aim of this work was to develop methods for partial volume correction in the image domain. The Lucy-Richardson (LR) iterative algorithm is used to deconvolve images given the point spread function (psf). It is a particular example of the MLEM algorithm where the system matrix is described by the psf. Penalised MLEM reconstruction techniques use penalty functions that favour a solution reflecting some assumed prior knowledge of the image. However, available anatomical imaging may not always reflect functional boundaries. Methods: An adaption of the LR algorithm was developed to include a Bowsher prior function [1]. The purpose of this function is to favour local smoothness between neighbouring voxels classified as having the same tissue type, whilst maintaining high spatial resolution at the tumour edge. Tissue type was defined by using a fuzzy locally adaptive Bayesian algorithm (FLAB), a segmentation method developed for PET images in the context of radiotherapy planning [2]. The algorithm was applied to OSEM reconstructed SPECT images of a NEMA Image Quality phantom. The phantom was filled with known concentrations of ^{99m}Tc in both the background and spherical insert (10mm - 37mm diameter) compartments. Recovery of the mean counts in each sphere was measured as a function of sphere-size, LR iterations and the β parameter used to describe the weighting given to the Bowsher prior. Results: Without application of the penalised LR algorithm full recovery of the counts within in each sphere was not obtained for any size sphere. Application of the penalised LR algorithm resulted in 100% recovery for the three largest spheres. Recovery was improved from to 47% to 82%; 33% to 60%; and 27% to 48% for the 17mm, 13mm and 10mm spheres respectively. The algorithm was shown to converge as a function of both iterations and β. Further iterations did not increase image noise. Conclusions: An algorithm has been developed for SPECT / PET images demonstrating the potential for substantial partial volume correction in the calculation of absorbed dose to small tumours. 1. Bowsher, J.E., et al. Utilizing MRI information to estimate F18-FDG distributions in rat flank tumors. in Nuclear Science Symposium Conference Record, 2004 IEEE. 2004. 2. Hatt, M., et al., A fuzzy locally adaptive Bayesian segmentation approach for volume determination in PET. IEEE Trans Med Imaging, 2009. 28(6): p. 881-93.

OP132

A fast GPU code for full Monte Carlo based SPECT reconstruction

T. Magnander[1], J. Heydorn Lagerlöf[1], J. Hemmingsson[1], M. Båth[1], J. Svensson[2], P. Gjertsson[3], P. Bernhardt[1]; [1]Department of Radiation physics, Sahlgrenska Academy, Gothenburg, SWEDEN, [2]Department of Oncology, Sahlgrenska Academy, Gothenburg, SWEDEN, [3]Department of Clinical Physiology, Sahlgrenska Academy, Gothenburg, SWEDEN.

To improve image quality in SPECT/CT reconstructions, various approximate recovery resolution techniques have been developed and implemented in clinical practice. However, optimal image reconstruction requires accounting for all physical interactions of the emitted photons in the individual patient. The objectives for this study were to develop a novel Monte Carlo (MC) code for fast simulation of individual image projections, and to implement these projections in ordered subset expectation maximum (OSEM) reconstructions of SPECT/CT images. Method: The MC code was written in Compute Unified Device Architecture language for a computer with four graphic processing units (GeForce GTX Titan X, Nvidia, USA). This enables simulations of parallel photon emission from the voxels matrix (128^3 or 256^3). Each CT number was converted to attenuation coefficients for photo absorption, coherent scattering and incoherent scattering. The type of interaction was determined by the ratio of attenuation coefficients in the CT voxels. For photon scattering the deflection angle was determined by the differential scattering cross sections. The accepted angle for photon interaction with the crystal was determined from the diameter and height of the collimator hole. Predefined energy and spatial resolution kernels for the crystal were used.

The MC code was implemented into OSEM reconstruction of ^{177}Lu, ^{111}In and ^{99m}Tc SPECT/CT images. The National Electrical Manufacturers Association (NEMA) image quality phantom was used to evaluate the performance of the MC reconstruction in comparison with clinical standard OSEM reconstructions and clinical state-of-the-art OSEM reconstructions with recovery resolution corrections. Results and conclusion: The performance of the MC code was 500 millions photons/s. The required number of photons emitted per voxel for obtaining low noise in the simulated image was 400 for a 128^3 voxel matrix. With this number of emitted photons/voxel the MC-based OSEM reconstruction with 10 subsets was performed within 60 s/iteration. The images converged after 2-4 iterations, depending on the sphere sizes in the NEMA phantom. Thereby, the reconstruction time was <4 minutes. The contrast-to-noise level was slightly improved with increased number of emitted photons/voxel, and the reconstruction time was linearly depending on the number of emitted photons/voxel. The signal-to-background for the spheres in the NEMA phantom was clearly improved with MC-based OSEM reconstruction: e.g. for ^{177}Lu the improvement was 37% compared to standard OSEM and 20 % compared to state-of-the-art OSEM. Furthermore, visual inspection of clinical investigations revealed clearly improved resolution and contrast with MC-based reconstruction.

OP133

Optimized Respiratory Gating Strategy for Myocardial Perfusion SPECT

D. Zhang, G. S. P. Mok; University of Macau, Macau, MACAO.

Aim: Different respiratory gating methods are feasible for motion reduction in cardiac SPECT. However, the efficiency of different methods has not been evaluated. This study aims to evaluate three gating methods for respiratory gated SPECT. **Materials and methods:** We used the digital 4D XCAT phantom to model a normal male patient with Tc-99m-MIBI activity distribution. We simulated (i) regular respiratory cycles with 25 mm axial amplitude and 5 s duration; (ii) irregular respiratory cycles with 25, 27.5, 30 mm axial amplitudes and 4, 5 and 6 s respective duration. Each respiratory cycle was divided into 96 frames which were grouped to 6 gates with 3 different methods: (1) equal time gating (TG); (2) equal amplitude gating (AG) and (3) amplitude gating with equal counts (CG). Average of all frames was used to represent static SPECT, while average activity and attenuation maps in each gate represented gated SPECT and CT respectively. Realistic noisy projections were generated using an analytical LEHR projector and reconstructed by OS-EM algorithm using gated CT for AC for up to 30 updates. Reconstructed images of each gate were registered to end-expiration phase using affine+b-spline method and then averaged and reoriented to generate polar plots. Polar plots from static SPECT and end-expiration phase were also obtained. Relative difference (RD) of the average intensity was computed for each segment using end-expiration phase as the reference in 17-segment analysis. Two regions-of-interest (ROIs) were chosen in the basal-anterolateral and mid-septal regions of the polar plots to calculate the intensity ratio (IR). Normalized standard deviation (NSD) of the ROI in mid-septal region was calculated to assess the noise. **Results:** Amplitude-based gating methods (AG and CG) showed less motion artifacts from visual assessment. The TG and CG methods had more uniform NSD distribution among all gates as compared to AG, i.e., their SDs were 0.022, 0.007 and 0.040 respectively. The RDmean for TG, AG and CG were 6.15%, 6.48% and 5.60% for regular breathing cycle and 6.68%, 6.70% and 5.47% for irregular cycle respectively. The IR of static, TG, AG and CG were 51.24%, 88.68%, 91.52% and 86.07% for regular cycle and 48.74%, 75.57%, 82.23% and 85.00% for irregular cycle respectively. **Conclusion:** Out of three respiratory gating approaches, the CG method shows better motion reduction and more uniform noise distribution. Patients with regular respiratory cycles show better gating results. Amplitude-based gating method is preferable for respiratory gated SPECT implementation.

OP134

Navigation of a robot-integrated fluorescence laparoscope in preoperative SPECT/CT and/or intraoperative freehandSPECT data

M. N. van Oosterom[1], **N. S. van den Berg**[1], M. Engelen[1], G. H. KleinJan[1], H. G. van der Poel[2], T. Wendler[3], C. J. van de Velde[1], N. Navab[3], F. W. B. van Leeuwen[1]; [1]LUMC, Leiden, NETHERLANDS, [2]NKI-AVL, Amsterdam, NETHERLANDS, [3]TUM, Munich, GERMANY.

Introduction Robot-assisted laparoscopic surgery is becoming the standard-of-care for prostatectomy and is also increasingly being explored for other types of cancer (e.g. rectal cancer). Preoperative (molecular) imaging can provide the surgeon with three-dimensional insight into the location of lesions and their surrounding anatomy, but it remains a challenge to translate this information to the setting of robotic surgery. Navigation technologies can be a solution, especially when they are directly linked to technologies that provide intraoperative confirmation of the navigation accuracy e.g. fluorescence imaging. In this phantom study, we studied the navigation of a robot-integrated fluorescence laparoscope. **Methods** Both preoperative SPECT/CT and intraoperative freehand SPECT data sets were used to navigate the robot-integrated Firefly laparoscope via an augmented reality overlay provided in the laparoscopic video feed. Errors of the navigation were initially measured in soft-tissue phantoms, followed by studies in a torso phantom. **Results** In both phantom setups, the feasibility of the robotic navigation concept could be successfully demonstrated. Mean navigation accuracy found for SPECT/CT-based navigation was 2.25 mm (coronal) and 2.08 mm (sagittal). For the freehand SPECT-based navigation the respective average accuracy was 1.92 mm (coronal) and 2.83 mm (sagittal). These navigation errors remain well below the < 1 cm detection limit for fluorescence imaging, allowing refinement of the navigation process using fluorescence findings. **Conclusions** The phantom experiments performed suggest that SPECT-based navigation of the robot-integrated laparoscope may aid fluorescence guided surgery procedures.

OP135

Computational-Based Bone Recognition and Tracer Quantification in Patients with Disseminated Prostate Cancer: a SPECT/CT study

F. Fiz[1], S. Sahbai[1], M. Weissinger[1], C. Campi[2], M. Piana[2], G. Sambuceti[3], C. la Fougére[1]; [1]Nuclear Medicine Unit, Department of Radiology, University of Tübingen, Tübingen, GERMANY, [2]Department of Mathematics, University of Genoa, Genoa, ITALY, [3]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY.

Rationale: Evaluating multiple skeletal metastases on hybrid SPECT/CT systems implies significant information flow, which could be simplified by computer-assisted algorithms. The validation of an automated tool is however complex, as it implies the capability to detect and isolate osteoblastic areas within the skeleton and to quantify the morpho-functional data. In this project, a dedicated software application was developed and tested against clinical data. Material and Methods: Seventy-six ^{99m}Tc-DPD SPECT/CT scans, from patients with disseminated bone metastases were analyzed with a dedicated software application. Outputs included volumes, average HU density (HU) as well as blood-pool normalized counts (target-to-background ratio, TBR) in three different bone volumes: total (TBV), compact (CBV) and trabecular (IBV). Volumes and HU values were compared with controls from a published normalcy database. TBV and mean TBR were compared with the corresponding outputs, obtained from a validated commercial quantitative analysis tool. As a measure of osteoblastic reaction, percentage of CBV in TBV (CBV%) and HU in CBV were compared with the number of visible tracer foci at SPETC MIP, with the current PSA values and with the presence of a “superscan” status on NM images. Results: Whole-body

HU was increased in both IBV and CBV with respect to controls (240 ±77 vs. 161±39 and 612±113 vs. 547±45, respectively, p<0,001). Volumetric estimates of TBV and mean TBR provided by our application tightly correlated with the outputs of the commercial application (R=0,93 and 0,96, p<0,001, respectively). The number of visible foci correlated with CBV% (R=0,6, p<0,01) as well as with whole-body HU/TBR in CBV (R= 0,55 and 0,69, respectively, p<0,01). PSA values correlated with TBR in both IBV and CBV (R=0,61, p<0,01 and R=0,49, p<0,05, respectively), as well as with %CBV (R=0,62, p<0,01). Patients with "superscan" status presented increased CBV% (66±5% vs. 61±5%, p<0,001) with respect to the other patients; this difference was even more marked in the axial skeleton (59±6% vs. 51±9%, p<0,001). "Superscan" patients had also increased HU and TBR in both IBV and CBV (p<0,001). Conclusions: These results show that computational-based compact bone identification is able to detect significant changes in patients with osteoblastic metastases, as well as in the patients' subset with scintigraphic signs of advanced disease. Moreover, CT-based segmented volumes and SPECT-based counting rate correlated with an accepted standard for SPECT/CT quantification.

OP136

Standardisation and Optimisation of Quantitative Radioiodine SPECT/CT Imaging for Dosimetry in the Multicentre SEL-I-METRY Trial

R. Gregory[1,2], I. Murray[1,2], J. Gear[1,2], S. Chittenden[1,2], J. Merrett[3,4,5], J. Scuffham[3,5], A. Fenwick[4], M. Stuffins[6], S. Micholopoulou[6], S. Jeans[7], B. Murby[7], J. Tipping[7], G. Flux[1,2]; [1]Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM, [2]Institute of Cancer Research, Sutton, UNITED KINGDOM, [3]Royal Surrey County Hospital, Guildford, UNITED KINGDOM, [4]National Physical Laboratory, Teddington, UNITED KINGDOM, [5]The University of Surrey, Guildford, UNITED KINGDOM, [6]University Hospital Southampton, Southampton, UNITED KINGDOM, [7]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM.

Aims: The aim of this study was to set up the first network of centres to perform standardised quantitative radioiodine imaging for comparable dosimetry measurements in the United-Kingdom for a phase II clinical trial (SEL-I-METRY) . The trial will evaluate the ability of the MEK inhibitor Selumetinib to stimulate radioiodine uptake in iodine refractory thyroid cancer and the subsequent potential benefit from radioiodine therapy. Absorbed doses will be measured on pre-radioiodine therapy ^{123}I and post-therapy ^{131}I NaI SPECT/CT images. Materials and Methods: The SPECT acquisition protocol for the trial was developed to comprise 20% wide energy windows and 72 views, providing high-count projections. Six-percent wide energy windows are are included for triple-energy-window scatter correction. High-energy general-purpose collimators are used for ^{131}I imaging and medium-energy general-purpose collimators for ^{123}I to avoid septal penetration.A standardised calibration protocol was developed for partial-volume effect (PVE) and dead-time correction and used at all centres. A body-shaped phantom with six 0.7 to 196 ml cylindrical inserts filled with 0.25 MBq/ml radioiodine was imaged using the trial protocol, for both ^{123}I and ^{131}I. Volumes of interest (VOI) were defined on the reconstructed images about the internal wall of the cylinders. A sigmoidal fit was applied to the VOI's cps/MBq/ml versus volume. The plateau was set to the average cps/MBq/ml for oversized VOIs defined about the 3 largest cylinders to give a calibration factor in the absence of PVE. Dead-time was also characterised for 20 to 2800 MBq ^{131}I in a 6 L cylindrical phantom. Measured count-rates for activities below 100 MBq were linearly extrapolated to higher activities to determine these rates in the absence of dead time. Paralysable and non-paralysable models were fitted. Results: The PVE correction factors varied between systems for both ^{123}I and ^{131}I. The curves had a plateau ranging from 0.7 to 1.4 cps/MBq/ml for ^{131}I and 1.8 to 3 cps/MBq/ml for ^{123}I. The GE systems need to operate in 'fast' mode for high ^{131}I activities to avoid reaching the peak count rate below 2.8 GBq. Dead-time losses were below 20%. A non-paralysable model fitted these count rates to provide a simple correction. Conclusions: Accurate dosimetry results that are comparable between centres are vital to identify absorbed dose relationships and are reliant on the quantitative accuracy of the SPECT/CT images. The variations in correction factors between these centres demonstrate that this program of standardised calibration measurements is essential for a multicentre dosimetry trial.

OP137

3D Lung quantification using SPECT/CT

D. Gillett, N. Bird, H. Cheow; Addenbrooke's Hospital, Cambridge, UNITED KINGDOM.

Introduction: Functional assessment of lung perfusion using Technetium-99m (Tc-99m) macro aggregated albumin (MAA) has been available for many years. It is commonly used for lung assessment prior to lung volume reduction surgery (LVRS). It is based on dividing a planar perfusion study into three equal portions and calculating the percentage of each portion with respect to the lung. We describe a technique of using SPECT with low dose CT (SPECT/CT). Method: Patients were intravenously administered with 90 MBq (+/- 10%) of Tc-99m-MAA then immediately underwent a SPECT/CT. The CT is used to do attenuation correction of the SPECT and to manually draw regions of interest (ROIs) around each anatomical lung lobe. These ROIs were transferred onto the SPECT images using the size and location information from the DICOM header. The number of counts and area of each 2D ROI are added together to create 3D ROI for each lobe. This data is then used to generate the relative function (RF), approximate volumes and mean counts per voxel (MCV) for each lobe. Validation of the technique was done using a torso phantom with known ratios of activities and concentrations between the lung regions. The imaging protocol used on patients was used with the phantom. Results: Analysis of the phantom experiments (n=3) demonstrated that the RF and MCV calculations were within 1% of the known activities and concentrations that were added to the phantom. Retrospective analysis of patient data (n=19) yielded significantly different RF results for the three lobes of the right lung when the SPECT/CT technique was compared to the planar technique ($p<0.05$). The left lung was excluded from the comparisons because the planar technique divides it into three lobes and the SPECT/CT method divides into two in accordance with the anatomical regions. Conclusion: Using SPECT/CT in combination with manual region drawing of lung lobes generates RF and MCV estimates that closely match known ratios of activity added to a phantom. This result along with comparisons between planar and SPECT/CT lobar analysis in patients suggests that SPECT/CT can be a useful tool in patients undergoing LVRS. The SPECT/CT technique is currently time consuming because of the manual region drawing and would benefit from an automated lung segmentation algorithm.

OP138

Quantitative Optimisation of Triple Energy Windowing and Deconvolution for Artefact Reduction in I-131 Imaging

A. Grimwood[1], F. Barrack[1], L. Livieratos[2], J. Scuffham[1]; [1]Royal Surrey County Hospital, Guildford, UNITED KINGDOM, [2]King's College London, London, UNITED KINGDOM.

Patients undergoing radioiodine treatment for thyroid cancer are given a post-ablation whole body scan to assess therapeutic effectiveness and check for potential metastatic spread or nodal involvement. This is typically indicated by localised regions of activity away from the main tumour/resection site. However, Compton scatter and septal penetration

from high energy gamma emissions introduce noise and imaging artefacts, especially where foci of high activity are present against a low background. Such effects can obscure the presence of involved nodes or distant metastases. Triple energy windowing (TEW) and deconvolution techniques can be used as a means of artefact reduction. In both cases, optimisation is crucial to maximise image correction whilst minimising the effects of over-correction (such as a loss of contrast or the presence of negative counts). Using a Monte Carlo model of the GE Optima 640, the collimator-detector response function was characterised for a range of I-131 scans. By separating list-mode data into contributions from Compton scatter, septal penetration and geometric components, it was possible to quantitatively optimise both TEW and deconvolution methods. A GATE Monte Carlo model of the GE Optima 640 was developed and validated against a real system to ensure clinical relevance. List mode data was recorded from both experimental and simulated systems and used to reconstruct images. Optimisation was performed on simulated data and the resulting image quality was quantified. TEW window widths were selected according to the ratio of scatter fraction to geometric fraction in list-mode. An analytic expression for the point spread function was derived from simulations. This was used for Lucy-Richardson deconvolution with input parameters optimised accordingly. The Optima 640 model accurately represented the clinical system at energies close to the 365 keV primary photopeak, exhibiting a sensitivity and energy resolution of ±15% and ±10% respectively compared to the actual system. Simulated images produced a contrast to noise ratio (CNR) within 1% difference from experimental acquisitions and a similarly close spatial resolution. For a specific acquisition geometry, the optimised TEW images provided a CNR equal to the original image with a negative count ratio of <10%. For deconvolution, CNR was degraded by 28%, however, overall scatter background was reduced by 75% whilst resolution improved 32%. Combining both TEW and deconvolution produced a synergistic effect, effectively removing imaging artefacts.

Normal variability of FDG uptake after prosthetic heart valve implantation

W. E. Vlemmings[1], J. Fanggiday[1], E. Daeter[2], R. Kauling[3], R. Keijsers[1], M. van Buul[1]; [1]St Antonius hospital, Nieuwegein, NETHERLANDS, [2]St Antonius hospital, cardiothoracic surgery, Nieuwegein, NETHERLANDS, [3]St Antonius hospital, cardiology, Nieuwegein, NETHERLANDS.

Introduction: Limited data exist on physiologic FDG uptake in and around artificial heart valves after replacement. In this retrospective study, the metabolic activity in various prosthetic valve types in different valve positions was measured in patients without any suspicion of endocarditis. Data were compared with those of native heart valves. Methods: Thirty-eight FDG PETCT studies in 29 patients in which PET/CT was obtained for noncardiac indications, 2 weeks-260 months (mean 21,5 m) after prosthetic valve implantation, were included. Definite and suspected endocarditis were excluded on basis of the modified Dukes criteria. Maximal standardized uptake values (SUVmax) were measured as well as the ratio between SUVmax around the valves and SUVmean in the descending aorta (SUVmax/SUVmean DA). Statistical analysis was performed to determine differences by Mann-Whitney U testing. Results: 22 M and 7 F, mean age 69,4 y (39-90 y). The aortic valve group contained 5 native aortic valves, 13 trans catheter valve replacements (TAVI), 12 Bentall procedures and 8 aorta valve replacements (AVR). The mitral group contained 9 mitral valve replacements (MVR) and 29 native mitral valves. The tricuspid group contained 34 native valves and 4 replaced tricuspid valves (TVR).All pulmonal valves were native. Compared to native aortic valve, average SUVmax was significantly higher in TAVI, Bentall procedures and AVR (2.1 vs 2.5, 3.8 and 4.1, respectively). Av. SUVmax of TAVI was significantly higher than after AVR, while there was no difference between TAVI and Bentall or between Bentall and AVR. Av. SUVmax/SUVmean DA was only significantly higher in AVR (1.4 vs 2.4). In MVR, both parameters,av, SUVmax and av. SUVmax/SUVmean DA, were significantly higher compared to native mitral valve, av. SUVmax 3.5 vs 2.5 and av. SUVmax/SUVmean DA 1.4 vs 2.0. In the tricuspid group, only the av. SUVmax/SUVmean DA of TVR was significantly higher, 1.3 vs 1.8. Average SUVmax of the pulmonary valve was 2.6 and av. SUVmax/SUVmean DA was 1.5. Conclusion: physiologic FDG uptake in native and artificial heart valves after replacement is given. Compared to native heart valves, average SUVmax increases significantly in all aortic and mitral valve prosthesis. In aortic valve prosthesis, the highest uptake was found after full surgical replacement. In Tricuspid valve prosthesis, only the average SUVmax/SUVmean AD ratio value was significantly higher.

OP140

18F-FDG PET/CT in the Evaluation of Large-Vessel Vasculitis: Comparison Between Visual and Semi-Quantitative Analysis and Their Correlation with Clinical and Biochemical Data

L. M. P. Pires[1], R. Silva[1,2], P. Lapa[1], G. Costa[1], J. P. Lima[1,2]; [1]Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, [2]Instituto de CIências Nucleares Aplicadas à Saude, Coimbra, PORTUGAL.

AIM: Recent scientific evidence has demonstrated the potential use of 18F-FDG PET/CT for the evaluation of large-vessel vasculitis (LVV). It has been postulated that 18F-FDG PET/CT may have superior sensitivity in an early stage, because of its ability to identify metabolism changes that precede structural alterations. However, studies have shown notable variability regarding the diagnostic criteria used for the differentiation between affected and unaffected vessels. In this study we aim to compare two different visual and semi-quantitative quantification methods and their correlation with clinical data in patients with suspected LVV. **MATERIAL AND METHODS:** The clinical charts of 52 patients (19males and 33females, 64.2±15.5years) who performed F18-FDG PET/CT due to a clinical suspicion of LVV were retrospectively reviewed. In each patient, presence or absence of LVV was confirmed or excluded by case base work-up, including clinical work-up, inflammatory markers, other imaging modalities, response to corticosteroid treatment(CST) and biopsies. The clinician's decision was used to classify a patient as a LLV or not. Patients were thus divided into 3 groups: (1)18 patients with active LLV without CST, (2)23 patients with LVV under CST, (3)11 patients in whom LLV was excluded. F18-FDG uptake was evaluated in the aorta and its major branches using a visual scoring system (0-no uptake, 1-less than liver uptake, 2-similar to liver uptake, 3-superior than liver uptake, positive if >1) and a semi-quantitative method (average SUVmax in 4 ROI manually generated in each arterial compartment). Also, all available biochemical data, including inflammatory markers, was recorded. Statistical analysis was performed using IBM© SPSS© Statistics, version22. **RESULTS:** 18F-FDG PET/CT was positive in at least one arterial compartment in 94.4% of group 1 patients, in 30.4% of group 2 patients and in 0% of group 3 patients ($p<0.05$). A statistical significant difference was found between SUVmax values in the 3 groups ($p<0.05$). Also a statistical significant correlation was found between the visual scoring system and the semi-quantitative method (spearmen rho: 0.942, $p<0.05$). The only clinical variables correlated with SUVmax were haemoglobin and reactive protein C, and with the sedimentation rate in the visual scoring system,. **CONCLUSION:** In this study F18-FDG PET/CT was able to differentiate between patients with active LVV without CST, patients with active LVV with CST and patients without active LVV, using both visual scoring system and the semi-quantitative method. Both scoring methods were strongly correlated.

Also, some clinical variables were correlated with SUVmax and the visual scoring system.

OP141

Evaluation of predictor variables of diagnostic [18F] FDG-PET/CT in fever of unknown origin

K. Okuyucu[1], E. Alagoz[1], S. Demirbas[2], **S. Ince**[1], A. Karakas[3], B. Gunalp[1], A. O. Karacalioglu[1], N. Arslan[1]; [1]Gulhane Military Medical Academy, Department of Nuclear Medicine, Ankara, TURKEY, [2]Gulhane Military Medical Academy, Department of Internal Medicine, Ankara, TURKEY, [3]Gulhane Military Medical Academy, Department of Infectious Diseases, Ankara, TURKEY.

Aim Fever of unknown origin (FUO) is defined as an illness having fever which lasts at least 3 weeks of duration and is higher than 38.3 °C on several measurements. The causes are infections, malignancies, noninfectious inflammatory diseases and miscellaneous. If [18F]FDG-PET/CT helps the final diagnosis, it is called contributory. The aim of the study is to evaluate the predictor variables effecting a contributory PET/CT for the diagnosis. Methods This is a retrospective cohort study conducted between June 2004 and May 2015 including 76 patients. The evaluated predictor variables are age, sex, ESR, CRP, fibrinogen, ferritin, albumin, haemoglobin level, platelet count, total leukocyte count, neutrophil percentage, lymphocyte percentage, ALP, LDH, ALAT, ASAT, GGT, total bilirubin, CK, RF, ANA, urinanalysis, chest radiography, abdominal US, lymphadenopathy, duration of fever, comorbid diseases and previous therapies. Results ESR ($p=0.001$), CRP ($p=0.001$), fibrinogen ($p=0.009$), lymphopenia ($p<0.001$), neutrophilia ($p<0.001$), ferritin ($p<0.001$), leukocytosis ($p=0.003$), duration of fever before PET/CT (<3 months) were found to be statistically significant for positive contribution of PET/CT results to the diagnosis. Conclusions [18F]FDG-PET/CT is helpful and contributory for the diagnosis of FUO in patients having higher levels of CRP, ESR, ferritin, fibrinogen, leukocytosis, neutrophilia and shorter durations of fever (<3 months).

OP142

Anti-granulocyte SPECT-CT for detection of sub-clinically infected neurostimulator lead prior to implantation of internal pulse generator

S. Vermeulen, M. Huylebrouck, L. Goethals, P. Gykiere, J. Heemskerk, M. Moens, H. Everaert; Universitair Ziekenhuis Brussel, BRUSSELS, BELGIUM.

Background: Neurostimulation (NS) by means of an implantable device is a well-validated technique in the treatment of medically intractable neuropathic pain. Because not all patients will benefit sufficiently from NS the effectiveness is measured during week(s) with NS-leads (subcutaneously implanted insulated wires delivering pulses to spinal cord) temporally connected to an external pulse generator (EPG). In patients benefitting from NS the EPG will be replaced by a much more expensive internally placed pulse generator (IPG). During the period of EPG patient are at risk for (subclinical) infection that becomes apparent months after insertion of the IPG and will ultimately necessitate explantation of entire device. The aim of this work was to evaluate whether anti-granulocyte SPECT/CT can be used to demonstrate subclinical infection of the NS-lead prior to the insertion of the IPG. Methods:In 77 patients (32 M, 45 F) with EPG the NS-leads were evaluated for infection using ^{99m}Tc anti-granulocyte SPECT/CT (^{99m}Tc-Besilesomab, 25 mCi, acquisition 4 hrs pi) immediately prior to the insertion of the IPG. Scans were interpreted visually and the results were confronted with clinical follow up. Results: In 5 patients focal tracer accumulation adjacent to the NS-lead was observed suggesting infection. All these patients developed clinical signs of NS-lead infection 2 weeks - 5 months after insertion of the IPG requiring antibiotics and explantation of the device. None of the patients with negative ^{99m}Tc anti-granulocyte SPECT/CT developed clinical signs of infection during ≥ 5 m follow-up period. Conclusion: ^{99m}Tc anti-granulocyte SPECT/CT can be used to accurately demonstrate presence / absence of subclinical infection of NS-leads prior to the insertion of IPG. A prospective trial using ^{99m}Tc anti-granulocyte SPECT/CT as a gatekeeper to decide about explantation of the NS-lead in case of suspected clinical infection prior to insertion of IPG is warranted. The cost effectiveness of systematic screening for subclinical infection using ^{99m}Tc anti-granulocyte SPECT/CT in this indication should be investigated.

OP143

Comparative effectiveness of ^{18}F-FDG PET-CT and contrast-enhanced CT in the diagnosis of suspected large-vessel vasculitis

S. Vaidyanathan, A. Chattopadhyay, S. Mackie, A. F. Scarsbrook; Leeds Teaching Hospitals NHS Trust, Leeds, UNITED KINGDOM.

Aims: To compare the accuracy of 2-[18F]-fluoro-2-deoxy-D-glucose positron emission tomography - computed tomography (FDG PET-CT) and contrast-enhanced CT (CECT) in the evaluation of a cohort of patients with suspected large vessel vasculitis (LVV). The aim was to validate the use of CECT assessment of vessel mural thickening as a surrogate to metabolic activity in a European population. Materials and Methods: A retrospective institutional database search for patients with suspected LVV undergoing both CECT and PET-CT between December 2011 to March 2016 yielded demographics, time interval between scans and type of vasculitis. Qualitative and quantitative PET-CT data analyses were performed including aorta:liver FDG uptake, bespoke FDG uptake distribution scores and vascular maximum standardized uptake values (SUVmax). Quantitative CECT data assessment for wall thickness and mural/lumen ratio were also performed. ROC curves were constructed to evaluate comparative diagnostic accuracy and a correlational analysis was conducted between SUVmax and wall-thickness. Results: 36 adults (17 proven LVV, 19 controls without LVV) with a mean age (range) 63 (38 - 89) years, of which 17 (47%) were males were included. Time interval between CT and PET was mean (standard deviation (SD)) 1.9 (1.2) months. Estimated mean (SD) SUVmax was 3.0 (1.0) and wall thickness was 2.37 (1.05) mm. Both parameters demonstrated a significant difference between patients with and without LVV, with a mean difference (95% confidence interval (CI)) for SUVmax 1.6 (1.1, 2.0) and wall thickness 1.25 (0.68, 1.83) mm, respectively. The area under the curve (AUC) (95% CI) for SUVmax was 0.95 (0.88-1.01), for mural thickening was 0.83 (0.66-0.99), and with a highly significant correlation ($P < .0001$, $R = 0.62$) between the two parameters. Conclusion: FDG PET-CT demonstrated excellent accuracy whilst CECT mural thickening showed good accuracy in the diagnosis of LVV, and both parameters showed a highly significant correlation. In hospitals without access to FDG PET-CT or in patients unsuitable for PET-CT (e.g. uncontrolled diabetes) CECT offers a viable alternative for assessment of suspected LVV. **Table . Baseline and group characteristics.**

Effect of CRP value on ^{18}F-FDG PET vascular positivity in Takayasu arteritis: a systematic review and per-patient based meta-analysis

L. Gomez[1], P. Chaumet-Riffaud[1,2], N. Noël[3], E. Durand[1,2], F. L. Besson[1,2]; [1]Department of Nuclear Medicine, Bicêtre university hospital APHP, 78 rue du Général Leclerc, 94270 Le Kremlin-Bicêtre, FRANCE, [2]IR4M, UMR 8081, Université Paris Sud/CNRS, Université Paris Saclay, 91405 Orsay, FRANCE, [3]Department of Internal Medicine, Bicêtre university hospital APHP, 78 rue du Général Leclerc, 94270 Le Kremlin-Bicêtre, FRANCE.

Purpose. The aim of this study was to conduct a systematic review and perform a meta-analysis on the potential effect of CRP value on vascular

activity assessed with ^{18}F-FDG PET in Takayasu arteritis (TA). *Methods*. The PUBmed/MEDLINE, database was searched from January 2000 to December 2015. Original articles focusing on TA and ^{18}F-FDG PET were reviewed and qualitatively analysed. To assess the relation between CRP and FDG PET vascular activity, studies that fulfilled the following criteria were included in a quantitative analysis: 1) Takayasu vasculitis according to the ACR criteria 2) No case mixed vasculitis 3) More than 5 cases per article 4) CRP values available 5) Per patient data 6) Predefined PET positivity criteria. Pooled Standard Mean Difference (SMD) of CRP values between positive and negative PET were computed using a fixed effect model. *Results*. Nine complete articles (210 patients) were qualitatively reviewed. A relationship between CRP and ^{18}F-FDG PET was observed in four studies, whereas five did not find any association. The meta-analysis of six selected studies (121 patients) provided the following results: Standard mean difference 0.54 [0.15; 0.92]; Heterogeneity Chi2 = 3.35; I2= 0%; Test for overall effect: Z=2.70 (P=0,007). *Conclusion*. In TA vasculitis, CRP value has a medium effect on ^{18}F-FDG PET vascular positivity.

OP145

Integrate FDG PET/CT Imaging for the assesment of plaque vulnerability in carotid stenosis compared to inflammation biomarkers, plaque echogenity and microembolic signals (MES)

S. Nicolosi, E. Giovannini, E. Borsò, P. Lazzeri, A. Chiti, E. Giorli, A. Mannironi, G. Celoria, M. Del Sette, A. Ciarmiello; Ospedale S.Andrea La Spezia, La Spezia, ITALY.

Background and Goal of study: 18F-FDG-PET/CT is a noninvasive imaging modality able to quantify carotid plaque inflammation, which seems to be a crucial event in plaque vulnerability and increased risk of ischemic stroke. 18F-FDG-PET/CT has been used to evaluate atherosclerotic plaque metabolic activity, and through its uptake by macrophages is believed to have the potential to identify vulnerable plaques, to predict plaque progression and subsequent cerebrovascular events. The main aim of this study is to assess the correlation between 18F- FDG uptake on PET scan of carotid plaques in symptomatic and asymptomatic patients, with other vulnerability markers, such as echogenicity of plaque on ultrasound, microembolic signals (MES), histological assessments of plaque inflammation and peripheral blood markers of inflammation. **Materials and Methods:** A total of 44 consecutive patients with carotid stenosis, 17 symptomatic and 27 asymptomatic, underwent Colour Duplex ultrasound, transcranial Doppler for MES monitoring, 18F-FDG-PET and blood tests. 18F-FDG-PET scans were acquired after fasting for 8 h, 190 min after intravenous administration of 18F-FDG (350-370 MBq) performed by a PET/CT Discovery T710 scanner, (GE Healthcare), 20 min/each bed position in the region of head-neck. Patients were stratified into two groups on the basis of presence or absence of previous stroke. Plaques were defined symptomatic when associated with ipsilateral cerebral ischemic symptoms within 15 days prior to inclusion. In symptomatic patients PET evaluation was made considering ipsylateral and contralateral sides. Plaques were assessed histologically following endarterectomy. The level of agreement between 18F-FDG uptake (TLG: Total Lesion Glicolisys), and target-to-background ratio, symptoms, blood and histological evidence of inflammation has been assessed. **Results and Discussion:** Analysis of variance with the one-way anova was performed on preliminary data from 45 patients. Symptomatic patients have a higher ipsilateral plaque metabolic rate than asymptomatic patients (P<0,05). Furthermore, a strong correlation was found between symptomatic patients with higher ipsilateral plaque uptake and lipid core ratio,erosion,MMP9, Plasmacells,presence of Calcium, Lipids, ac. Uric and PCR (P<0,05). **Conclusion**: Our data shows that 18F-FDG uptake on PET is higher in patients with symptomatic as opposed to asymptomatic carotid artery plaques. This data is confirmed by the strong correlation with inflammation biomarker. These results support the use of 18-FDG-PET for carotid plaque risk stratification.

OP146

Standardized Uptake Values in FDG PET/CT for Prosthetic Heart Valve Endocarditis: Need for Standardization of Acquisition and Reconstruction

A. M. Scholtens[1], H. J. te Kolste[2], L. E. Swart[3], R. P. J. Budde[3], M. G. E. H. Lam[4], H. J. Verberne[5]; [1]Meander Medical Center, Amersfoort, NETHERLANDS, [2]VU Medical Center, Amsterdam, NETHERLANDS, [3]Erasmus Medical Center, Rotterdam, NETHERLANDS, [4]University Medical Center, Utrecht, NETHERLANDS, [5]Amsterdam Medical Center, Amsterdam, NETHERLANDS.

***Purpose*:** ^{18}F-fluorodeoxyglucose positron emission tomography combined with computed tomography (FDG PET/CT) is of increasing interest and clinical impact in prosthetic heart valve endocarditis (PVE). The significance of and threshold values for the standardized uptake value (SUV) to diagnose PVE are unclear at present. We therefore evaluated the range of SUVs in a small cohort of patients with a prosthetic heart valve but without signs of PVE to ascertain a normal range and compared these values to the available literature on SUVs in PVE. ***Methods*:** Twelve patients, referred for FDG PET/CT for suspicion of PVE, with no signs of PVE on FDG PET/CT and without evidence of PVE during follow up (minimum two months) were retrieved from our database. Time since prosthetic heart valve implantation ranged from 1 day to 117 days. FDG PET/CT scans were performed according to the European Association of Nuclear Medicine Research Ltd. (EARL) scanning and reconstruction specifications. The SUV in the area of the prosthetic valve was measured. A review of the literature was subsequently performed to assess the currently available data on SUV in PVE which was compared to the values in our cohort. ***Results*:** Median SUVmax in our cohort was 2.70 (range 1.73-3.46). In the literature, SUVs for definite, possible and rejected PVE according to the modified Duke criteria varied across studies, most likely due to differences in acquisition, reconstruction and measurement protocols, with median SUVmax values for rejected PVE ranging from 0.5 to 4.9. ***Conclusion*:** SUV varies according to acquisition and reconstruction protocols, meaning potential cutoff values are not interchangeable between sites. Standardization of quantification on reconstructions based on EARL specifications is desirable, with normal SUVmax values likely in the range of 1.5-4.0.

Striatal Phosphodiesterase 10A and Thinning of the medial Prefrontal Cortex in Schizophrenia - a PET and MRI study

R. Boden, J. Persson, A. Wall, **M. Lubberink**, L. Ekselius, E. Larsson, G. Antoni; Uppsala University, Uppsala, SWEDEN.

Objectives: The enzyme phosphodiesterase 10A (PDE10A) is abundant in medium spiny neurons of the striatum and is crucial for cell energy metabolism and thus neural function. PDE10A has been implicated in the pathophysiology of schizophrenia in animal models and is investigated as a possible new pharmacological treatment target. A reduction of medial prefrontal cortical thickness has repeatedly been observed in patients with schizophrenia, but how this relates to PDE10A expression is unknown. The primary objective of this study was to compare the striatal non-displaceable binding potential (BPND) of the PDE10A ligand [11C]LuAE92686 between patients with chronic schizophrenia and healthy controls. A second objective was to assess the correlation of PDE10A BPND to cortical thickness.MethodsTen male patients with

chronic schizophrenia treated with clozapine, olanzapine or quetiapine and 16 healthy controls underwent 90 min dynamic scans after injection of circa 370 MBq [11C]LuAE92686 on an ECAT Exact HR+ PET scanner. MRI was performed for structural information. Clinical assessments of symptoms and cognitive function were performed and the antipsychotic dosage recorded. Volumes of interest were placed in the PET images over the striatal subregions putamen, caudate and nucleus accumbens, as well as thalamus, substantia nigra, globus pallidus and cerebellum, and PET data were analysed using the simplified reference tissue model using grey-matter cerebellum as reference tissue, giving BPND. Cortical thickness maps were calculated using Freesurfer.ResultsPatients with schizophrenia had a significantly lower BPND of [11C]LuAE92686 in whole striatum than healthy controls (Mean ± SD BPND 3.3 ± 0.7 versus 4.3 ± 1.0, p= 0.003). Differences were significant in all striatal subregions and thalamus, but not in substantia nigra and globus pallidus. Striatal BPND significantly correlated to cortical thickness in the medial prefrontal cortex and superior frontal gyrus in both patients with schizophrenia and healthy controls. No significant correlation was observed between striatal BPND of [11C]LuAE92686 and age in patient and control groups, and between BPND and schizophrenia symptoms, antipsychotic dosage, coffee consumption, smoking, duration of illness, or cognitive function in the patient group.ConclusionsStriatal PDE10A expression is lower in patients with schizophrenia than in healthy controls. The degree of PDE10A expression is also correlated to cortical thickness of distant frontal cortical areas. PDE10A may thus be important for functioning in the striato-cortical interaction and in the pathophysiology of schizophrenia.

OP148

Integrity of neurocognitive networks in dementing disorders as measured with simultaneous PET/fMRI

T. Stadhouders, C. Sorg, J. Diehl-Schmid, T. Grimmer, **I. Yakushev**, Klinikum Rechts der Isar, Technische Universität München, Munich, GERMANY.

Background: Disrupted integrity of resting state networks (RSNs) in patients with Alzheimer's disease (AD) and frontotemporal dementia (FTD) have been reported by a number of functional magnetic resonance imaging (fMRI) studies. Of particular interest have been so-called neurocognitive networks, such as default mode (DMN), salience (SN), and central executive networks (CEN). As neuronal activity is closely linked to glucose consumption, positron emission tomography with [18F]fluorodeoxyglucose (FDG-PET) represents an attractive tool for mapping RSNs. The aim of this combined FDG-PET/fMRI study was to characterize alterations in network integrity in patients with AD and FTD. **Methods:** Twenty seven patients with mild AD, 16 matched patients with FTD, and 26 healthy subjects underwent a simultaneous resting state fMRI and FDG-PET on a hybrid PET/MR system. After a standard pre-processing, images were subjected to spatial independent component analysis. Thus, a number of networks were extracted in a user-independent manner separately from fMRI and PET data. For PET, we quantified so-called loading coefficients, a degree of network expression in each subject. For fMRI, a goodness-of-fit of each network to a standard network template was calculated. Thus, fMRI- and PET-based indices of network integrity were derived for each network and subject. **Results:** Relative to healthy subjects, integrity of SN was reduced in FTD, while DMN and CENs were affected in both AD and FTD in fMRI data. In PET data, SN integrity was reduced in FTD, DMN in AD, while CEN was affected in both disease groups. In fMRI data, no significant differences between the AD and FTD groups were found. In PET data, SN integrity was reduced in FTD relative to AD ($p<0.001$), while DMN integrity was reduced in AD relative to FTD ($p<0.05$). In a step-wise binary logistic regression, PET indices of SN integrity alone differentiated between the AD and FTD groups with an accuracy of 81.4 % ($p<0.005$). Correlations between the PET- and fMRI-based indices of network integrity were low. **Conclusions:** These preliminary results in mildly affected patients with AD and FTD indicate limited disease specificity of neurocognitive networks in general and DMN in particular. Only SN as measured with FDG-PET appeared to discriminate between two patients groups. FDG-PET and fMRI seem to track partly different aspects of network integrity.

OP149

Theranostic perspectives of [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 in prostate cancer - First evidence for clinical translation with [^{68}Ga]NeoBOMB1 and PET/CT

B. A. Nock[1], **T. Maina-Nock**[1], A. Kaloudi[1], A. Giarika[1], E. Lymperis[1], A. Singh[2], H. R. Kulkarni[2], I. Klette[2], E. P. Krenning[3], M. de Jong[3], R. P. Baum[2]; [1]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, Athens, GREECE, [2]Theranostics Center for Molecular Radiotherapy & Molecular Imaging, Zentralklinik, Bad Berka, GERMANY, [3]Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS.

Aim: The gastrin releasing peptide receptor (GRPR) is highly expressed in prostate cancer and hence represents an attractive target for diagnosis and therapy with BBN-like radiopeptides. Especially, those based on GRPR-antagonists have recently shown excellent pharmacokinetics and higher biosafety for human use compared to agonists. We hereby introduce NeoBOMB1, (DOTA-*p*-aminomethylaniline-diglycolic acid-DPhe-Gln-Trp-Ala-Val-Gly-His-NH-CH[CH_2-$CH(CH_3)_2$]$_2$), based on a potent GRPR-antagonist and derivatized with DOTA to allow for labeling with diagnostic and therapeutic radiometals. The respective [$^{67/68}$Ga/^{111}In/^{177}Lu]NeoBOMB1 radioligands have been evaluated in GRPR-expressing prostate cancer PC-3 cells and mice models for potential application in prostate cancer diagnosis and therapy. In addition, first evidence for clinical translation with [^{68}Ga]NeoBOMB1 and PET/CT has been acquired in prostate cancer patients. **Materials and Methods**: The affinity of NeoBOMB1 and [^{nat}Ga/^{nat}In/^{nat}Lu]NeoBOMB1 for the GRPR was determined by competition binding assays against [^{125}I-Tyr^4]BBN in PC-3 cell membranes. The internalization of [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 at 37°C in PC-3 cells was compared at 1 h. Mouse blood collected 5 min post-injection (pi) of [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 was analyzed by HPLC to evaluate in vivo stability. Biodistribution of [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 was studied in SCID mice bearing subcutaneous PC-3 xenografts; for in vivo GRPR-blockade 40 nmol [Tyr^4]BBN were co-injected in mice. [^{68}Ga]NeoBOMB1 was administered in prostate cancer patients and PET/CT scans were acquired. **Results:** NeoBOMB1 and [^{nat}Ga/^{nat}In/^{nat}Lu]NeoBOMB1 showed comparable high affinity for the GRPR (IC_{50}s of 1-2 nM). At 37°C [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 strongly and specifically bound to the cell-membrane of PC-3 cells (35-40% at 1 h), as expected for radioantagonists. [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 were detected >95% intact in peripheral mouse blood at 5 min pi. In mice, [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 showed comparably high and GRPR-specific uptake in the PC-3 xenografts (e.g. 30.6±3.9%ID/g, 28.6 ±6.0%ID/g and >35%ID/g at 4 h pi, respectively). In prostate cancer patients [^{68}Ga]NeoBOMB1 rapidly localized in pathological lesions achieving high contrast imaging. **Conclusions**: Regardless of the radiometal used, [^{67}Ga/^{111}In/^{177}Lu]NeoBOMB1 displayed comparable behavior in prostate cancer models, highlighting the theranostic strength of NeoBOMB1. Translational evidence in patients was acquired after visualization of prostate cancer lesions by [^{68}Ga]NeoBOMB1 PET/CT with excellent target-to-background ratios and high diagnostic accuracy.

OP150

Therapeutic Efficacy of CXCR4-targeted Endoradiotherapy with Lu-177-pentixather in Patient-Derived Xenograft (PDx) Models of Leukemia

M. Schottelius[1], S. Habringer2, P. Herhaus[2], A. Poschenrieder1, K. Steiger[3], M. Schwaiger[4], U. Keller[2], H. Wester[1]; 1Pharmaceutical Radiochemistry, TU Munich, Garching, GERMANY, [2]III. Medical Department, Klinikum rechts der Isar, TU Munich, Munich, GERMANY,[3]Institute of Pathology, Klinikum recht der Isar, TU Munich, Munich, GERMANY, [4]Nuclear Medicine, Klinikum rechts der Isar, TU Munich, Munich, GERMANY.

First results in patients with multiple myeloma have demonstrated the therapeutic efficacy of [^{177}Lu] pentixather as a CXCR4-directed endoradiotherapeutic agent. To assess its potential for the therapy of human leukemic diseases, [^{177}Lu]pentixather was now evaluated in two PDx models of human-derived T-cell acute lymphoblastic leukemia (T-ALL).Murine PDx models were established by intravenous injection of patient-derived T-ALL cells with comparable CXCR4 expression, but different aggressiveness (ALL230:high, ALL0:low) into NOD/SCID/γ mice. Upon disease manifestation (monitored via ex vivo analyses and [^{68}Ga]pentixafor-PET), mice were treated with 25-35MBq [^{177}Lu]pentixather. Animals were sacrificed 3d and 7d after therapy, and biodistribution studies were performed. Spleen and bone marrow (BM) of treated and control (injection of unlabeled peptide only) mice were isolated, and the effect of [^{177}Lu]pentixather therapy on human ALL infiltration and on the murine BM niche were evaluated using FACS analysis and colony forming unit (CFU) assays.Biodistribution studies revealed high [^{177}Lu]pentixather uptake in ALL-infiltrated spleens and BM (ALL230: 22.9±16.6 and 1.1±0.5%iD/g, ALL0: 2.4±1.4 and 0.6±0.03%iD/g in spleen and femur (3d p.i.), respectively), which correlates with the different extent of ALL infiltration in the two PDx models (Additional Information). Accordingly, upon [^{177}Lu] pentixather treatment, the spleen size, which reflects ALL infiltration, was reduced by a factor of 12.1 (47.6) and 2.0 (2.8) compared to control in the high-tumor-burden (ALL230) and low-tumor-burden (ALL0) model at 3d (7d) p.i., respectively. FACS analysis of spleen, BM and blood confirmed a reduction of ALL infiltration by 83%, 61% and 47% in the ALL230 model versus 15% reduction of BM infiltration in the ALL0 model (7d p.i.). Despite low affinity of [^{177}Lu]pentixather to murine CXCR4, mouse hematopoietic progenitor cells in the BM are indirectly targeted by crossfire effect and are almost completely eradicated by [^{177}Lu] pentixather therapy in both PDx models (CFU count Control vs. [^{177}Lu] pentixather: 29.5±20.9 vs 0±0 (ALL230), 130.5±20.0 vs. 33.2±9.6 (ALL0) (3d p.i.)). In contrast, mesenchymal stromal cells isolated from the murine BM niche of [^{177}Lu] pentixather-treated animals were reduced, but able to regenerate, as shown by their potential to support the self-renewal and differentiation of mouse hematopoietic stem cells in co-culture experiments.CXCR4-targeted endoradiotherapy using [^{177}Lu] pentixather is highly efficient in reducing leukemia in murine ALL PDx models. Under consideration of the necessity of stem cell support, [^{177}Lu] pentixather thus represents a highly promising therapeutic option for patients with leukemia, complementing diagnostic [^{68}Ga] pentixafor-PET to a first powerful CXCR4-targeted theranostic concept, which is currently being translated into the clinic.

OP151

Comparison between the antagonist ^{68}Ga-OPS202 and the agonist ^{68}Ga-DOTATOC for somatostatin receptor PET/CT in gastroenteropancreatic NET patients: results of a phase 1/2 study

G. Nicolas[1], N. Schreiter[2], F. Kaul[1], J. Uiters[2], R. Mena[2], A. Bauman[1], J. Kaufmann[2], H. Bouterfa[2], J. Reubi[3], J. Rivier[4], H. Maecke[5], R. Cathomas[6], E. Christ[7], M. Fani[1], D. Wild1; [1]Dept of Radiology and Nuclear Medicine, University of Basel Hospital, Basel, SWITZERLAND, [2]OctreoPharm Sciences, Ipsen Group, Berlin, GERMANY, [3]Division of Cell Biology and Experimental Cancer Research, Institute of Pathology, University of Berne, Berne, SWITZERLAND, [4]Clayton Foundation Laboratories for Peptide Biology, Salk Institute, La Jolla, CA, UNITED STATES, [5]Department of Nuclear Medicine, University Hospital Freiburg, Freiburg, GERMANY, [6]Dept of Oncology, Kantonsspital Graubünden, Chur, SWITZERLAND, [7]Department of Endocrinology, University Hospital of Berne, Berne, SWITZERLAND.

Introduction/Background: ^{68}Ga-DOTATOC PET/CT is a reference method for imaging somatostatin receptor expressing neuroendocrine tumours (NET). Presence and extent of metastases, especially liver metastases, impact highly on patient management and prognosis. **Aims:** To investigate safety, biodistribution, dosimetry and preliminary efficacy of ^{68}Ga-OPS202, a radiolabelled somatostatin receptor antagonist for PET/CT imaging of gastroenteropancreatic (GEP) NET (ClinicalTrials.gov NCT02162446). **Materials and Methods:** Twelve metastatic G1/G2 GEP-NET patients were enrolled in a prospective phase 1/2 study. Safety, biodistribution, dosimetry and preliminary efficacy were assessed after administration of 2 single doses of ^{68}Ga-OPS202 (A: 15μg then B: 50μg within 3 to 4 weeks). Both ^{68}Ga-OPS202 PET/CT were compared to ^{68}Ga-DOTATOC PET/CT (~15 μg) in the same patient and using the same scanner. Uptake in normal organs (SUVmax) and tumour-to-background uptake ratios were compared for matched pairs using the Wilcoxon signed rank test. Two independent readers blinded from clinical information and type of scans reviewed the PET/CT. Follow-up imaging up to 9 months were used as standard of reference. **Results:** ^{68}Ga-OPS202 was well tolerated and no adverse reaction requested treatment. The median time between ^{68}Ga-OPS202 (dose A) and ^{68}Ga-DOTATOC PET/CT was 34 days. On the 1 hour post-injection scans, each ^{68}Ga-OPS202 dose showed lower SUVmax in the normal liver, the pancreas and the gastro-intestinal (GI) tract ($p<0.05$), but similar uptake in malignant lesions in comparison with ^{68}Ga-DOTATOC; thus image contrast and tumour detection rate were significantly improved over the agonist. The liver-lesions-to-normal-liver uptake ratio (mean±σ) increased from 3.0±4.1 for ^{68}Ga-DOTATOC to 5.7±6.9 (A)/6.0±7.4 (B) for ^{68}Ga-OPS202 ($p<0.05$). On a per-lesion basis sensitivity and diagnostic accuracy (pooled for both readers) improved from 52 and 52% for ^{68}Ga-DOTATOC to 81 and 83% (for ^{68}Ga-OPS202 dose A) and 89 and 90% for dose B respectively. **Conclusion:** ^{68}Ga-OPS202 is well tolerated, significantly improves imaging contrast, sensitivity and diagnostic accuracy compared to ^{68}Ga-DOTATOC PET/CT, especially in the liver. The lower GI and pancreatic uptake of the antagonist may increase the sensitivity of PET for detecting sites of primary tumours of GEP origin.

OP152

Radiolabeled Gastrin-Releasing-Peptide receptor antagonist (68Ga-RM2) PET/CT in newly-diagnosed prostate cancer (PCa), compared and combined with multiparametric prostate MRI

L. Michaud, I. Sandler, B. Beatty, A. Gopalan, S. Lyaschenko, N. Taunk, J. Lewis, H. Hricak, A. Vargas, K. Touijer, W. Weber; MSKCC, New York, NY, UNITED STATES.

Purpose: We evaluated the ability of ^{68}Ga-RM2 PET/CT to localize newly-diagnosed PCa, comparing it to MRI and assessing the additional value of combined ^{68}Ga-RM2 PET/CT-MRI. Methods: As part of an ongoing prospective study, we have so far included sixteen men (age 46-68 y) with biopsy proven PCa (2 low, 8 intermediate and 6 high risk). PSA range was 1.4-64.4 ng/mL with Gleason scores ranging between 6 and 9. All patients underwent multiparametric prostate MRI, no more than 4 weeks prior ^{68}Ga-RM2 PET/CT. PET/CT scans, from mid thighs to top of skull, were performed 60 minutes after injection of 150-200MBq ^{68}Ga-RM2. All patients underwent radical prostatectomy and lymph node dissection no more than 2 weeks after the PET/CT scan. For data analysis the prostate was divided in 4 areas (right anterior, right posterior, left

anterior and left posterior; total 64 prostatic areas). The presence of PCa was evaluated using a 5-point scale by a genitourinary radiologist for MRI and 2 nuclear medicine physicians for PET/CT. Lesions with a score of 4 or 5 were considered as positive. In addition, uptake of ^{68}Ga-RM2 uptake within each area was quantified by standardized uptake values (SUVmax). After the independent analysis of PET/CT and MRI a combined analysis of PET/CT fused to MRI was performed. Whole mount, step-section pathology of the prostate served as the reference standard. Presence of extracapsular extension (ECE), seminal vesicle involvement (SVI), and lymph node metastasis was also recorded. **Results**: On histology, PCa was present in 55 of the analyzed regions. Sensitivity of MRI, PET/CT and combined analysis was 67%, 81%, 84%; specificity 89%, 78%, 89%; accuracy 70%, 81%, 84%, respectively. Receiver-operating characteristic (ROC) analyses for SUVmax yielded an area under the curve of 0.79 (95% confidence interval 0.618-0.956, p = 0.006). Twelve patients had ECE; 11/12 were identified by MRI, only 4 detected by PET/CT. 4/16 tumors showed SVI; 2/4 reported on MRI, non on PET. 3/16 patients had lymph node (LN) metastasis; 2 detected only by MRI and 1 only by PET. One patient was false positive for LN metastasis on MRI. **Conclusion**: According to this preliminary analysis, ^{68}Ga-RM2 PET/CT is promising for detection and localization of primary PCa. Combined ^{68}Ga-RM2 PET-MRI provided complementary value for the evaluation of newly-diagnosed PCa.

OP153

Comparison between CT-based and PERCIST criteria for evaluation of response to immune checkpoint inhibitors in Non-Small Cell Lung Cancer (NSCLC): is there a role for 18F-FDG PET/CT?

M. Bauckneht[1], G. Rossi[2], R. Piva[1], C. Genova[2], E. Rijavec[2], G. Barletta[2], F. Biello[2], S. Menella[3], M. Dal Bello2, R. Di Stefano[2], G. Cittadini[3], D. Merlo[4], G. Sambuceti[1], F. Grossi[2], **S. Morbelli[1]**, [1]Nuclear Medicine Unit, IRCCS San Martino - IST, University of Genoa, Genoa, ITALY, [2]Lung Cancer Unit, IRCCS San Martino - IST, Genoa, ITALY, [3]Radiology Department, IRCCS San Martino - IST, Genoa, ITALY, [4]Epidemiology, Biostatistics and Clinical Trials Division, IRCCS San Martino - IST, Genoa, ITALY

Background: Immune checkpoint inhibitors exert their activity by blocking inhibitory signaling therefore enhancing T-cell activity against tumor cells. This peculiar mechanism of action may hamper dimensional CT-based response evaluation due to infiltration of inflammatory cells. The aim of this study was to compare CT-based and PERCIST criteria for evaluation of response to immune checkpoint inhibitors in NSCLC. Methods: From May 2015 to April 2016, 74 patients with advanced pretreated NSCLC were treated with the checkpoint inhibitor nivolumab in the frame of a single-institutional translational research trial. The patients underwent both contrast enhanced (ce)CT and 18F-FDG-PET at baseline and every four cycles. We evaluated the response to treatment by ceCT scan with either RECIST and Immuno-related Response Criteria (irRC) and metabolic response by means of PERCIST criteria. Concordance between CT-based and PERCIST criteria was computed with kappa value. Results: A low concordance between both CT-based criteria and PERCIST was highlighted with a relatively higher concordance between PERCIST and RECIST criteria (k=0.500). In particular PERCIST seems to underestimate the presence progressive disease (PD). In fact, 46% and 55% of patients defined in progression with RECIST and irRC criteria were considered in stable metabolic disease (SMD) according to PERCIST. Among these, only 50% were alive at 6 months and only one of them reached a partial metabolic response (PMR) by continuing treatment with nivolumab. Conversely, 9% and 18% of the patients considered in progression with irRC and RECIST criteria were classified as PMR with PERCIST. Of note, all these patients are still alive with a survival rate similar to those defined in partial response with RECIST and irRC criteria (>9 months). Capability of both CT-based and PERCIST criteria to predict overall survival could not be evaluated as patients' sample have not yet reached the median overall survival. Conclusion: Given the peculiar mechanism of action of immune checkpoint inhibitors, 18F-FDG-PET as evaluated with PERCIST criteria is not informative when patients are classified as SMD. SMD group includes both not- and late-respondents patients. In fact, when SMD patients were classified as PD according to RECIST they mantained (despite their metabolic stability) a poor prognosis compared to patients classified as RECIST-stable. Conversely, PERCIST evaluation could provide relevant information when it defines a PMR in presence of RECIST progressive disease. These patients seem to have a longer survival and thus 18F-FDG PET might impact on clinician's decision making in patients with suspected CT-based PD in the future.

OP154

Dose escalation experience with Ac-225-PSMA-617 in PSMA targeting alpha-radiation therapy of patients with mCRPC

C. Kratochwil[1], F. Bruchertseifer[2], F. L. Giesel[1], C. Apostolidis[2], U. Haberkorn[1], A. Morgenstern[2]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]European Commission - Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY

Aim: To develop a standard treatment protocol for Ac-225-PSMA-617 PSMA targeting alpha-radiation therapy. **Methods**: Treatment dose in kBq per kg body-weight (kBq/kgBW) was stepwise increased from 50 kBq/kg (n=2), 100kBq/kgBW (n=2), 150kBq/kgBW (n=2) and 200 kBq/kgBW (n=4). Additionally, a 2-monthly fractionation regime was compared with a 4-monthly administration interval (n=4). Hematological toxicity, clinical exam and patient self-reported side-effects were assessed every 4 weeks, in case of irregular findings every 2 weeks. In addition PSA was also checked every 4 weeks. **Results**: Severe xerostomia was dose-limiting before hematological toxicity became relevant. 3 patients with 200kBq/kg and 1 patient with 150kBq/kg requested dose reduction. Thus 100kBq/kgBW was defined as standard treatment dose per cycle. 2/4 patients with a 4-monthly treatment interval had PSA-progression before the succeeding cycle, which then also demonstrated also to be less effective than the 2nd cycle during the 2-monthly treatment regime. With doses above or equal to 100 kBq/kgBW per cycle tumor response in regard to a PSA-decline of >50% was demonstrated in about 70% of the treated patients. **Conclusions**: A standard treatment dose of 100kBq/kgBW administered every two month seems both associated with remarkable anti-tumor activity and tolerability. In our hospital it became the standard treatment activity for the first phase of routinely clinical application as a salvage therapy for mCRPC.

Cellular Distribution and Small-scale Dosimetry of [^{188}Re]-perrhenate: A Potential Therapeutic Radiotracer for Thyroid Disease

K. Chuamsaamarkkee[1,2], A. Divoli[3], P. J. Blower[2], L. Livieratos[2,4]; [1]Nuclear Medicine, Ramathibodi Hospital Mahiodol University, Bangkok, THAILAND, [2]Division of Imaging Sciences and Biomedical Engineering, King's College London, London, UNITED KINGDOM, [3]Institute of Cancer Research and the Royal Marsden NHS foundation Trust, London, UNITED KINGDOM, [4]Nuclear Medicine, Guy's & St Thomas' Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Background: Our recent studies with preclinical MIRD dosimetry ("macrodosimery") showed promising results for [^{188}Re]-perrhenate as candidate for therapy of thyroid benign disease. However, macrodosimetry assumes uniform distribution of radiotracer throughout the organ and this assumption is not always correct. Iodine (e.g. [^{131}I]-NaI) is taken up by follicular cells then incorporated into thyroid hormone and stored in colloid until exported. We hypothesise that, in contrast, non-metabolised tracers (e.g. [^{99m}Tc]-pertechnetate, [^{188}Re]-perrhenate) not involved in hormone synthesis are solely localised within thyrocytes, being imported by NIS but not further metabolised. No experimental data are available to confirm this. Therefore, this study aims to examine the cellular distribution of [^{99m}Tc]-pertechentate and [^{188}Re]-perrhenate in a thyroid model and use the resulting data for small-scale dosimetry ("microdosimetry") to assess the potential of [^{188}Re]-perrhenate for radionuclide therapy of thyroid diesease. **Methods:** [^{188}Re]-perrhenate was intravenously injected into Wistar rats. After 1 h, thyroids were harvested and cryosectioned to determine radionuclide distribution by microautoradiography (MAR). After developing and fixing, the combined MAR emulsion and tissue section was fluorescently stained with DAPI and viewed under a fluorescence microscope. Post-processing technique was used to enhance the silver grains. For microdosimetry, a geometrical model was derived from MAR images propagated in 3D. The matrix size was 128 x 128 x 5 voxels with voxel size 16 μm^3. Input files for the MCNPX version 2.5.0 Monte Carlo code were created using an IDL interface OEDIPE with tissue compositions taken from ICRU 44. Absorbed doses were recorded at each voxel and dose volume histograms were created using IDL. **Results & Discussion:** MAR showed that perrhenate localised only in thyrocytes and not present in colloid (the reverse of the known distribution of radioiodine). Microdosimetry demonstrated that [^{188}Re]-perrhenate has potential dosimetric advantages over [^{131}I]-iodide. By assuming follicular cells as targets for cell killing, ^{188}Re distributed in follicular cells resulted in absorbed doses higher and more uniform (FWHM: 10.62 - 19.86 mGy/MBq.s) than ^{131}I localised in colloid (FWHM: 6.03 - 17.78 mGy/MBq.s). **Conclusion:** Radiation dose delivered to the thyrocyte is strongly dependent on sub-cellular distribution of radiotracers. These pilot data provide microdosimetric support for the macrodosimetric prediction that [^{188}Re]-perrhenate for treatment of thyroid disease may have advantage or complementarity, encouraging radiobiological evaluation of [^{188}Re]-perrhenate treatment to assess the feasibility of clinical translation.

OP164

Automatic acquisition and analysis of whole-body time activity curves demonstrates distinct compartments during NaI treatment.

D. P. Rushforth, J. I. Gear, S. J. Chittenden, B. E. Pratt, I. A. Murray, G. D. Flux; The Joint Department of Physics, Sutton, UNITED KINGDOM.

Introduction: Following molecular radiotherapy (MRT), multiple measurements of whole-body activity (WBA) retention are required to determine the whole-body absorbed doses (WBD), excretion rates and external dose rates. This is necessary for treatment validation, as required by European council directive 2013/95/Euratom, and accurate radiation protection advice, as described by ICRP94. Aims: To provide a complete package for the acquisition of cumulated WBA measurements and the automatic production of WBDs and radiation protection advice. To investigate the potential of the system for improving personalised MRT treatment. Method: A program was created that interfaces with three Geiger counters, each positioned above beds within different therapy rooms. An intuitive interface was designed to make it easy for staff to collect multiple precise and accurate measurements throughout the day. The display constantly displays a live count rate from each detector and maximum visiting times, based on local dose constraints. A quality control mode facilitates testing of the detectors and an export function automatically saves data to the secure hospital network. Whole-body time activity curves, consisting of multiple simultaneous exponential phases, are derived using an algorithm that automatically determines the curve stripping solution with the least square residual; allowing standardised WBDs and restriction times to be calculated instantly. Results: To date the system has been used for 31 I-131 NaI treatments for thyroid carcinoma (ablation and therapy) and 11 Y-90 DOTATATE treatments, with an average of 6 readings per patient per day. In the case of the NaI treatments, all patients demonstrate a phase with a 13.0 ± 2.6 hour half-life. 70 % of patients also demonstrate a phase with a shorter 4.09 ± 1.83 hour half-life containing 17 ± 14 % of the total cumulated activity (max of 47 %). Slower phases with half-lives of 46 and 86 hours (81 and 87 % of total cumulated activity) were also detected in two patients with heavy disease burden, for whom later measurements were

made. Conclusion: A system was created which has enabled the acquisition of high quality WBA data and reduced the time necessary for dosimetry calculations. Analysis of the stripped phases has led to the observation of two well defined compartments that demonstrate consistency across patients. Results indicate that a third compartment may be identified from measurements made at later time points. Further work aims to determine if this compartmental approach can be used to localise the deposition of dose in individual patients.

OP165

A set of realistic thyroid phantoms for personalized radioiodine uptake measurement

T. BEAUMONT[1], P. CALDEIRA IDEIAS[2], O. CASELLES[3], D. BROGGIO[1], D. FRANCK[1]; [1]Institut de Radioprotection et de Sûreté Nucléaire (IRSN), Fontenay-aux-Roses, FRANCE, [2]Institut de Radioprotection et de Sûreté Nucléaire (IRSN), Le Vésinet, FRANCE, [3]Institut Universitaire du Cancer Toulouse - Oncopole, Toulouse, FRANCE.

Purpose According to the EANM recommendations for benign thyroid diseases therapy, the absorbed dose should be personalized. Consequently, the iodine thyroid uptake should be accurately measured. Calibration phantoms are quite crude representations of neck anatomy. In order to better simulate thyroid volumes and patient variability, a set of realistic thyroid phantoms with varying volumes have been developed and 3D printed. **Materials and methods** The designed thyroid shape follows the MIRD committee recommendations and includes the isthmus and two ellipsoidal lobes. Five volumes have been selected from 3.24 to 30 cm^3, following ICRP recommendations, to cover different clinical cases: children, adolescents, standard and pathologic adults. The linear attenuation coefficient of the selected material was determined by spectroscopic measurements at the photopeak energy of ^{131}I and the isthmus-neck distance was chosen accordingly. Neck, vertebra, spinal cord and trachea were also designed and put together to create the final phantoms. Care was taken to ensure the waterproofness and robustness over time of thyroid inserts: special epoxy glue and nylon screw have been used. The design was performed with a Computer Aided Design software and then the phantoms were 3D printed. For measurements, the thyroid inserts have been filled with a liquid ^{133}Ba solution (^{131}I substitute). **Results** An exponential fit of the experimental data gave an attenuation coefficient of 0.116 cm^{-1} at 356 keV, bearing out that the material can be considered as tissue equivalent. As a first experiment, the sensibility of a germanium (HPGe) probe was measured for each phantom. At contact with the probe, a 25 % difference in sensitivity between the smallest volume and the 19.05 cm^3 volume was observed, decreasing to 10% at 15 cm. Currently, measurements are underway for a NaI probe and gamma-camera in a nuclear medicine department. The goal is to compare the standard calibration procedure with ANSI phantom and a ^{131}I seed with a new procedure using the developed phantoms filled with an iodine solution. **Conclusion** With ^{131}I filled realistic thyroid phantoms of different volumes, the assessment of the time-dependent fractional uptake will be improved. Practically, volume dependent calibration factor can be measured and then used after ultrasonic evaluation of the thyroid volume. This procedure might be particularly interesting for children and to reduce the toxicity. Furthermore, the set of phantoms can be used for *in situ* thyroid monitoring of nuclear medicine workers which are presumably subject to chronic exposure.

OP166

Calculating dose to risk organs for complex differentiated thyroid cancers treated with combined I-131 and EBRT using Monte Carlo simulations

J. Nilsson[1], O. Ardenfors[1,2]; [1]Department of Medical Physics, Karolinska University Hospital, Stockholm, SWEDEN, [2]Medical Radiation Physics, Department of Physics, Stockholm University, Stockholm, SWEDEN.

Background: Patients with differentiated thyroid cancer are commonly treated with adjuvant radionuclide therapy (RNT) using I-131 after surgery. In more advanced disease with locoregional invasion and metastasis, adjuvant external beam radiotherapy (EBRT) in the head and neck region is sometimes also employed. For thyroid cancers with tracheal or esophageal invasion, RNT could cause high doses to the organs at risk (OAR). Tumour dose in EBRT is constrained by the doses to different OAR and not accommodating the RNT dose contributions can result in excessive combined OAR doses. Conventional RNT dosimetry using MIRD formalism is not feasible for complex and invasive cancers. The aim of this work was to estimate the dose contributions from RNT using Monte Carlo (MC) methods and to establish their impact on dose limits in EBRT. Methods: A patient with a non-radically excised intratracheal thyroid cancer underwent combined RNT and EBRT at our hospital in 2015. Three tumour/remnant sites and two OAR (trachea and esophagus) were delineated on a post-therapeutic SPECT/CT scan. The cumulated activity of iodine in the uptake sites were calculated from two SPECT/CT-acquisitions and three gamma probe measurements. The maximum and mean absorbed doses to OAR were calculated using MC simulations of gamma and beta doses with the code MCNP6. The MC simulations were performed on CT-based geometry and the absorbed doses were calculated from cumulated activity in the three uptake sites. The results were evaluated with regard to dose constraints commonly employed for the OAR in EBRT. Results: Mean absorbed doses to the OAR from MC simulations were 0.8 Gy to the trachea and 0.6 Gy to the esophagus (only gamma contributed to the dose). The corresponding maximum absorbed doses to the OAR were 117 Gy to the trachea and 5 Gy to the esophagus (only gamma contributed to the dose). The maximum tracheal dose was at the site of tumour invasion. Mean absorbed doses to the three tumour/remnant sites as calculated by MC simulation were 810 Gy, 560 Gy and 190 Gy. Conclusions: The results showed that RNT in non-radical complex tumours can cause doses that risk exceeding OAR limits in EBRT. The calculated doses were in agreement with previously published data for tumour/remnant doses. Monte Carlo dosimetry for RNT is a viable method for planning combined RNT and EBRT in differentiated thyroid cancer.

OP167

Previsional and post therapy Red Marrow Dosimetry in differentiated thyroid cancer : a method to optimize treatment and efficacy

G. ROSSI[1], M. Camarda[1], P. D'Avenia[1], E. Di Nicola[1], L. Montani[1], C. Bartolozzi[1], F. De Angelis[1], A. Dente[1], N. Gasparrini[1], E. Brianzoni[2], S. Fattori[1]; [1]Medical Phisic Unit, Macerata Hospital, MACERATA, ITALY, [2]Nuclear Medicine Unit, Macerata Hospital, MACERATA, ITALY.

Introduction In multi treated DTC patients(pts)it is fundamental knowing the maximum tolerated dose(MTD) to the red marrow(RM) in order to administer the best therapy, and subsequently verify the effective absorbed dose to evaluate the clinical utility and define the correct staging.Materials and methods We enrolled 66 pts(35 M 31 F)with DTC. 10 pts with 2 evaluation and 3 with 3, for a total of 85 calculations.All pts were in thyroid hormone withdrawal.On the first day,TSH,hTG,AbhTG,Ioduria and aematochemical routine were evaluated then ^{131}I was administered(median 18 MBq, range 8-21),fasting and no urine excretion for 2 hours. According to the AIFM protocol we collected blood sample(BS)and whole body(WB)counts at 2-24-48-96-120 h.We calculated tau(SAAMII)and the MTD(OLINDA/EXM)after blood/RM approximation considering the 2 GY/RM limit and 2960 MBq of WB retention at 48°h(if pulmonary metastases).Then considering dosimetry we administered the ^{131}I-therapy MTD(range 1019-9334 MBq) sometimes modulated.In therapy we repeated the data collection and calculations.Pts have made every 20 days for three months aematochemical routine.Results No pts overcame 2 Gy/RM.The pre-post comparison shows differences greater than 50% for WB in 18/66 pts(27%, 12 lower 6 higher),for the RM in 14/66(20%, 1 higher and 13

lower).The absorbed RM dose range is 0.17-1.9 Gy. In the 10 multidosimetry pts we found big deviation between different dosimetric evaluation: for 2/10 more than 400%(19-21 months between treatments),for 7 dosimetries from 3% to 76% for WB and 2% to 53% for RM(6-12 months). No side effect of elevated grade for the aemathological syneresis.Conclusions The previsional dosimetry allows to avoid to overcome 2 Gy/RM.High variation pre-post often is due to a significative modification of the staging at the WB scan post treatment.It is then desirable to repeat dosimetry for further treatment and to study metastases to modulate the following one.

OP168

Accuracy, Precision and Operator-Variability of Co-registered Early CT with Delayed SPECT in Quantitative Parathyroid Scans

S. Razavi, B. Ziebarth, L. Zuckier, R. Klein, **W. Zeng**; The Ottawa Hospital, Ottawa, ON, CANADA.

Introduction Dual phase parathyroid scintigraphy utilizing early (15-20 min) and delayed (2 hour) planar or SPECT images of the neck and the upper chest following ^{99m} Tc SestaMIBI is a well-established procedure for the diagnosis of parathyroid adenoma or hyperplasia. SPECT-CT allows for anatomical localization and attenuation correction, and is added to imaging at either early or delayed SPECT-CT in many centres; both early and delayed SPECT-CT is not usually performed due to concern over duplicated CT exposure. The goal of this study was to assess feasibility and reproducibility of reconstructing delayed SPECT-CT images by fusing early CT and delayed SPECT images. **Methods** 15 patients with suspected parathyroid adenoma or hyperplasia who had both early and delayed SPECT-CT of the neck were included for retrospective analysis. Delayed SPECT images were reconstructed using attenuation, scatter, and resolution recovery correction derived from the contemporaneous delayed CT and quantified in SUV units (HERMES HybridRecon); these were considered the gold standard values. Delayed SPECT (with all corrections) was manually co-registered with early CT on 3 occasions by an experienced technologist and once by a novice physicist. Maximum SUV of the thyroid lobes, parathyroid adenomas and ectopic parathyroid adenoma were measured by a board certified nuclear medicine physician on all 5×15 image sets. Bland-Altman and correlations analyses was used to evaluate accuracy, intra-operator variability of the experienced technologist, and inter-operator variability, and the results of which were summarized using bias, absolute SUV and relative to mean reproducibility coefficient (RPC = 95th percentile of errors) and Pearson r^2. **Results** Maximum SUV measurements were obtained for 14 right thyroids, 10 left thyroids, 6 parathyroid adenomas, and 4 ectopic adenomas. Due to the small sample size and challenging co-registration, ectopic adenomas were excluded from the analysis. For the 30 remaining regions, the accuracy on the 3 sets of reconstructed image from experienced-operator was excellent (no bias, p=0.2), with good reproducibility of true SUV at RPC=0.63 (33%), r^2=0.82. Suboptimal reproducibility of true SUV was recorded in images reconstructed by the novice operator, with RPC=0.88 (44%), r^2=0.70. Intra-operator reproducibility for experienced operator was excellent at RPC=0.22, (12%), r^2=0.85, but the agreement with the novice operator was less optimal at RPC= 0.49 (48%), r^2=0.64. **Conclusions** Delayed quantitative SPECT imaging of the parathyroid using manually registered early CT imaging is feasible, precise and accurate by experienced technologists. Training of technologists for accurate and reproducible co-registration is essential to achieve optimal quantitative measurements.

Truncated CD31 as a new molecular target for imaging of inflammation

J. Vigne[1,2], J. Senemaud[2], N. Anizan[3], S. Delbosc[2], D. Diallo[3], A. Truffier[2], L. Louedec[2], A. Nicoletti[2], F. Rouzet[1,2,3], G. Caligiuri[1,2], D. Le Guludec[1,2,3]; [1]Bichat University Hospital, Paris, FRANCE, [2]INSERM UMRS 1148 - LVTS, Paris, FRANCE, [3]University Paris Diderot, Paris, FRANCE.

FDG PET offers sensitive detection of inflammation but suffers from poor specificity and physiologic uptake in heart and brain. There is room for novel imaging agents of inflammation. CD31 is a transmembrane glycoprotein receptor constitutively expressed by leukocytes, platelets, and endothelial cells. Due to its homophilic and inhibitory functions it exerts a crucial role in the homeostasis of the circulation. In pro-inflammatory conditions, the homophilic portion of receptor is lost due to a cleavage and activated cells express a truncated CD31. We have identified a small peptide, named P8RI, able to specifically bind the truncated CD31 on activated endothelial cells, platelets and leukocytes, all present in close vicinity at sites of ongoing inflammation. The main objective of this work was to develop a 99mTc labelled-P8RI and test its potential as a radiotracer for molecular imaging of inflammation. Hydrazinonicotinamide (HYNIC) was coupled to the N-terminal amino-acid of P8RI. 99mTc labelling of HYNIC-P8RI was performed using tricine and EDDA as coligands. Radiochemical purity (RCP) was determined using HPLC. The radiolabelled peptide stability (% RCP) and protein binding (size exclusion chromatography) have been assessed in human plasma at 37°c over 4h. ^{99m}Tc P8RI biodistribution and specific uptake by activated platelets and leukocytes have been evaluated in a rat model of chronic vascular inflammation : the experimental abdominal aorta aneurysm (AAA) induced by local infusion of elastase. Immediately after intravenous injection of 74 MBq of radiolabelled HYNIC-P8RI, sequential whole-body acquisitions (every 10 minutes for the first hour) were performed with a hybrid SPECT/CT camera (NanoSPECT/CT, Bioscan Inc.). The RCP of [99mTc]EDDA/HYNIC-P8RI was >93% without any purification, and the specific activity was >71 GBq/μmol. There was no significant release of degraded radiolabelled peptide (RCP > 89%) and the radiotracer binding to plasma proteins was low (< 5% after 4 h incubation). In vivo blood clearance of the tracer was almost exclusively renal with a peak activity in kidneys and bladder 1 h after injection, corresponding to the unaltered form of the peptide on HPLC. In addition, ^{99m}Tc-HYNIC-P8RI uptake by AAA was detectable from 30 min after injection in animals and associated with activated platelets and leukocytes on immunohistochemistry. By specifically targeting activated cells involved in inflammation expressing truncated CD31, and with a rapid blood clearance, radiolabelled P8RI offers a promising novel approach in inflammation imaging. Further experiments will allow to determine its diagnostic value comparatively to FDG, particularly in models of heart or brain inflammation.

OP171

Prospects of targeting the gastrin releasing peptide receptor, the chemokine c-x-c motif receptor type 4 and the somatostatin receptor subtype 2 in primary breast cancer and metastases

S. U. Dalm[1], W. A. M. E. Schrijver[2], A. M. Sieuwerts[1], M. P. Look[1], A. C. J. Ziel - van der Made[1], V. de Weerd[1], J. W. Martens[1], P. J. van Diest[2], M. de Jong[1], C. H. M. van Deurzen[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]University Medical Center Utrecht, Utrecht, NETHERLANDS.

Background: Imaging and therapy using somatostatin receptor (SSTR) radioligands targeting SSTRs overexpressed on tumor cells are methods successfully used in patients with neuroendocrine tumors. Based on this success, gastrin releasing peptide receptor (GRPR) and chemokine c-x-c motif receptor type 4 (CXCR4) radioligands are currently being investigated for the same purposes. Previous research has demonstrated GRPR, CXCR4 and SSTR2 expression on breast cancer (BC) cells. These studies were solely performed in primary BC, probably due to scarcity of tumor material from metastatic lesions. However, targeting these receptors with radioligands could especially be advantageous for treatment of metastatic BC, since distant metastases are often not accessible for resection and most systemic agents are accompanied by severe side effects. Furthermore, imaging of primary and metastatic BC can offer possibilities such as image guided surgery/biopsy, disease monitoring and sentinel node visualization. Therefore, the aim of this study was to determine GRPR, CXCR4 and SSTR2 expression in primary BC and corresponding regional and distant metastases, in order to study the prospects of targeting these receptors in BC patients. **Materials and methods:** Fifty-two primary BCs and corresponding regional lymph node or distant metastases (lung, liver, brain and ovarian) were selected for this study. GRPR, CXCR4 and SSTR2 mRNA levels were determined on macro-dissected tumor cells using RT-qPCR. Receptor expression levels of primary BC and corresponding metastases were compared and correlated with clinico-pathological factors. Furthermore, GRPR and SSTR2 expression of 12 paired primary BC and regional lymph node metastases were analyzed by in vitro autoradiography using GRPR-targeting ^{111}In-JMV4168 and SSTR-targeting ^{111}In-DOTA-Tyr^3-octreotate, and correlated with corresponding mRNA levels. **Results:** There was no significant difference in GRPR and CXCR4 mRNA levels between primary BCs and corresponding metastases from different sites. SSTR2 mRNA expression of liver and ovarian metastases was significantly lower than that of corresponding primary tumors ($p=0.02$ and $p=0.03$, respectively). GRPR and SSTR2 mRNA levels showed a significant positive correlation with estrogen receptor (ER) expression in primary BC ($p<0.001$ for both receptors) and metastases ($p<0.001$, $p=0.02$, respectively). CXCR4 mRNA expression showed no significant association with the studied clinico-pathological factors. Binding of GRPR and SSTR2 radioligands to tumor tissue was target-specific and correlated significantly with receptor mRNA expression. **Conclusion:** Targeting the GRPR, CXCR4 and SSTR2 for nuclear imaging and/or treatment might improve BC care in primary and metastatic disease. GRPR and SSTR2 (but especially GRPR) could be good candidates for imaging and treatment of ER-positive primary and metastatic BC.

OP172

Influence of the N-terminal amino acid sequence on imaging properties of ^{111}In-labeled anti-HER2 scaffold protein ADAPT6

J. Garousi[1], S. Lindbo[2], H. Honarvar[1], J. Velletta[1], B. Mitran[3], M. Altai[1], A. Orlova[3], V. Tolmachev[1], S. Hober[2]; [1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]Department of Protein Technology, KTH - Royal Institute of Technology, Stockholm, SWEDEN, [3]Preclinical PET Platform, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim. ADAPTs (ABD-based Derived Affinity ProTein) constitute a novel type of imaging probes derived from an albumin-binding domain (ABD) sacffold of the protein G. Previous study concerning influence of purification tag composition on biodistribution of radiolabeled anti-HER2 ADAPT6 indicated that N-terminal amino acid sequence (DEAVDANS) may have an impact on targeting using ADAPTs. This sequence is a part of the scaffold, but does not participate in recognition of a molecular target. The aim of this study was to evaluate if modification of composition of the N-terminal sequence can improve imaging properties of ADAPTs. Materials and methods. A series of ADAPT6 variants with different N-terminal sequences GCH_6DANS, $GC(HE)_3DANS$, GCDEAVDANS and GCVDANS were constructed. A parental variant with $GCSS(HE)_3DEAVDANS$ sequence was used for comparison. DOTA chelator was site-specifically conjugated to a unique N-terminal cysteine of new constructs, and ADAPTs were labeled with ^{111}In. HER2-expressing cell lines, ovarian carcinoma SKOV-3 and breast carcinoma BT474, were using for evaluation of binding and cellular processing in vitro. Pre-saturation of receptors with anti-HER2 antibody trastuzumab was used to test the binding specificity. A series of comparative biodistribution studies in normal NMRI and BALB/C nu/nu mice bearing SKOV-3 xenografts was performed. Results. Affinity to HER2 was in the range of 1.0-2.7 nM (SPR measurements) for all ADAPT variants. All radiolabelled variants demonstrated specific binding to HER2-expressing cells. The internalization of all conjugates by HER2-expressing cells was rather slow (less than 50% after 24 h). The internalization of all variants was slow. The major finding of this study was the strong influence of the N-terminal sequence on uptake of ADAPTs in normal tissues and tumor xenografts in mice. In vivo comparison of ^{111}In-labelled DOTA-$GCSS(HE)_3$DEAVDANS-ADAPT6, DOTA- $GCCH_6$DANS-ADAPT6 and DOTA-$GC(HE)_3$DANS-ADAPT6 demonstrated that a presence of a hexahistidine tag is associated with elevated hepatic uptake. Uptake in blood, lung, spleen and muscle for all new variants was lower than for the parental variant. ^{111}In-DOTA-$GC(HE)_3$DANS-ADAPT6 and ^{111}In-DOTA-GCVDANS-ADAPT6 were the best variants, and provided tumor uptakes of 14.6±2.4 and 12.5±1.3 %ID/g at 4 h p.i., respectively. The tumor uptakes of these variants were significantly ($p<0.05$) higher than the uptake of the parental ^{111}In-DOTA-$GCSS(HE)_3$DEAVDANS-ADAPT6 (9.1±2.0%ID/g). Tumor-to-blood ratios for ^{111}In-DOTA- $GC(HE)_3$DANS-ADAPT6 and ^{111}In-DOTA-GCVDANS-ADAPT6, was 395±75 and 419±91 at 4 h p.i., respectively. Conclusion. The composition of N-terminus sequence of ADAPT molecules influences their biodistribution and targeting properties. The imaging contrast might be appreciably improved by selection of an optimal variant.

OP173

Comparison of In-111- and Tc-99m-labeled exendin-3 for determination of the beta cell mass with SPECT

L. Joosten, M. Brom, O. C. Boerman, M. Gotthardt; Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim The beta cell mass (BCM) plays a key role in the development and progression of diabetes. A non-invasive method to determine the BCM *in vivo* would allow measurement of the BCM during the development and progression of type 1 and 2 diabetes. Exendin-3 is a stable glucagon-like peptide-1 (GLP-1) analogue with high affinity for the GLP-1 receptor (GLP-1R). Recently, targeting of the GLP-1R on beta cells was proven to be a successful method to determine the beta cell mass *in vivo* in a rat model of chemically induced beta cell loss. In this study we compared the *in vivo* BCM quantification with SPECT with In-111- and Tc-99m-labeled exendin-3. **Materials and methods** Exendin-3 was conjugated with DTPA or HYNIC to the C-terminal Lysine residue to enable radiolabeling with In-111 or Tc-99m, respectively. The IC_{50} for the GLP-1R of both tracers was determined in a competitive binding assay using CHL cells, stably transfected with the GLP-1R. To assess SPECT quantification to determine the BCM, diabetes was induced by alloxan injection in twenty C57BL/6 mice and ten mice only received vehicle. When elevated blood glucose levels were measured in the alloxan-treated mice, either 15 MBq In-111-DTPA-exendin-3 or 10 MBq Tc-99m-HYNIC-exendin-3 was injected intravenously. SPECT/CT was acquired 2 h p.i., animals were euthanized afterwards and pancreas and relevant

organs were dissected, weighed and the radioactivity in the organs was measured in a gamma counter. **Results and conclusion** IC_{50} values were 7.8 nM (DTPA-exendin-3) and 13.1 nM (HYNIC-exendin-3). Biodistribution studies revealed higher uptake in pancreas for In-111-DTPA-exendin-3 (10.3 ± 0.7 %ID/g) than for Tc-99m-HYNIC-exendin-3 (6.6 ± 0.6 %ID/g). However, accumulation of Tc-99m-HYNIC-exendin in the kidneys was lower (94 ± 16 vs. 258 ± 25), resulting in a favorable kidney-to-pancreas ratio for Tc-99m-HYNIC-exendin-3 (26.0 ± 3.5 vs. 16.2 ± 2.0). With SPECT the pancreas could be visualized after In-111-DTPA-exendin-3 as well as Tc-99m-HYNIC-exendin-3 injection. The correlation between SPECT-based pancreatic tracer uptake and pancreatic uptake as determined determined ex vivo was higher for In-111-DTPA-exendin-3 (Pearson r = 0.82 , p = 0.0002) than for Tc-99m-HYNIC-exendin-3 (Pearson r = 0.71 , p = 0.0066). In conclusion, the pancreas can be visualized with both radiotracers and tracer uptake can be determined based on quantitative analysis of the SPECT images. This study shows a preference for In-111 labeled tracer when measuring the BCM, since the correlation of SPECT quantification with ex vivo counting is better.

OP174

131I Labeled CendR Peptide for Imaging Neuropilin-1 Positive Tumor

P. Dong, H. Cai, L. Li; West China Hospital of Sichuan University, Chengdu, CHINA.

Introduction: Neuropilin-1 (NRP-1) is a multifunctional single-pass transmembrane protein, which is overexpressed in a variety of cancers (eg. non-small cell lung cancer). CendR sequence motif (R/KXXR/K) could efficiently and specially bind with NRP-1, and transport diagnostic molecules into tumor cells based on the transmembrane capability of NRP-1. This study aimed to evaluate the use of ^{131}I-Tyr-tLyp-1, a kind of ^{131}I-labeled CendR peptide, as a diagnostic agent for SPECT imaging of NSCLC. **Methods:** Truncated Lyp-1 was designed to expose its C-end motif (R/K)XX(R/K), and conjugated to Tyrosine for radiolabeling. *In vitro* targeted binding of the Tyr-tLyp-1 peptide was evaluated by fluorescent cellular analysis. Radiolabeling of the conjugate with ^{131}I produced ^{131}I-Tyr-tLyp-1 in high radiochemical yield (≥95%). Mice bearing A549 (a kind of human NSCLC cell line) tumors (n=4 for each group) were subjected to static whole-body SPECT scans at different points after intravenous injection of ^{131}I-Tyr-tLyp-1. Dynamic scans were also obtained for A549 tumor-bearing mice. All mice were sacrificed at 72h after injection of ^{131}I-Tyr-tLyp-1 and biodistribution studies were performed. **Results:** Tyr-tLyp-1 displayed high and specific bingding to A549 cells under micromole concentration, whereas this binding was depend on surface NRP-1 in cells and could be inhibited by NRP-1 antibodies. *In vivo* ^{131}I-Tyr-tLyp-1 SPECT imaging demonstrated that the subcutaneous NSCLC A549 tumor could be visualized and the tumor uptake of ^{131}I-Tyr-tLyp-1 was 4.8 times ($p<0.05$) higher than in muscles at 6h after injection. **Conclusion:** Truncated Lyp-1 peptide specifically localized in NRP-1 positive tumors, highlighting the high potential of using ^{131}I-Tyr-tLyp-1 as a targeted imaging probe for NRP-1 positive tumors.

Characterization of [^{111}In]-labeled Glucose-Dependent Insulinotropic Polypeptide as a Radiotracer for Neuroendocrine Tumors

S. M. A. Willekens, L. Joosten, O. C. Boerman, M. Brom, M. Gotthardt; Dept of Radiology and Nuclear Medicine, Radboudumc, Nijmegen, NETHERLANDS.

Aims Nowadays, somatostatin receptor scintigraphy (SRS) is considered the gold standard for non-invasive imaging of neuroendocrine tumors (NET). However, not all NETs overexpress somatostatin receptors, or the subtypes relevant for imaging, hampering their detection using SRS. Therefore, the search for novel targets to visualize NETs, expressing low somatostatin receptor levels, is ongoing. Since many of these NET's have been shown to express the glucose-dependent insulinotropic polypeptide (GIP) receptor, this receptor might be a novel target for NET imaging. Therefore, we investigated whether imaging of NET with DTPA-conjugated GIP radiolabeled with ^{111}In is feasible. **Methods** The N-terminally acetylated GIP analogue [Lys^{37}(DTPA)]GIP$_{1-42}$ was synthesized, labeled with ^{111}In and the stability of the tracer was assessed in human serum. Receptor targeting was investigated *in vitro* using BHK-GIP receptor positive tumor cells, NES2Y cells (human beta cell line) and isolated islets of Langerhans of C3H mice. *In vivo,* GIP receptor targeting was examined in BALB/c nude mice with a subcutaneous BHK-GIP receptor positive tumors or subcutaneous NES2Y tumors, and optimal peptide dose and time point for *in vivo* imaging was assessed. **Results** [Lys^{37}(DTPA)]GIP$_{1-42}$ was radiolabeled with a specific activity of up to 1.2 TBq/μmol and [Lys^{37}(^{111}In-DTPA)]GIP$_{1-42}$ was stable in human serum up to 24h *in vitro. In vitro,* [Lys^{37}(^{111}In-DTPA)]GIP$_{1-42}$ showed preferential binding to BHK-GIP receptor positive cells, NES2Y cells and isolated islets that could be blocked with an excess of unlabeled ligand. Biodistribution studies revealed optimal tumor targeting 4 hours post-injection, at a peptide dose of 0.1 μg. Four hours post-injection, co-administration of an excess unlabeled peptide lowered GIP receptor positive tumor uptake from 4.2 ± 0.2 %ID/g to 0.8 ± 0.1 %ID/g (p=0.04), indicating GIP receptor mediated accumulation *in vivo*. Also in mice with NES2Y tumors, a more relevant model for diseased human beta cells, preferential tumor uptake was observed (0.5 ± 0.1 %ID/g). **Conclusion** [Lys^{37}(DTPA)]GIP$_{1-42}$ shows receptor mediated binding *in vitro*. Furthermore, the tracer specifically accumulated in BHK-GIP receptor positive tumors and preferential tumor uptake was observed in NES2Y tumors. Therefore, [Lys^{37}(^{111}In-DTPA)]GIP$_{1-42}$ is a promising tracer for SPECT imaging of somatostatin receptor negative NET.

Relationships between preoperative FMISO and FDG PET parameters and the prognosis in patients with oral squamous cell carcinoma

J. Sato[1], Y. Kitagawa[1], S. Watanabe,[2], K. Hirata[2], S. Okamoto[2], N. Ohga[1], T. Asaka[1], M. Miyakoshi[1], T. Shiga[2], M. Shindoh[3], T. Nagara[2]; [1]Oral Diagnosis and Medicine, Hokkaido University Graduate School of Dental Medicine, Sapporo, JAPAN, [2]Nuclear Medicine, Hokkaido University, Sapporo, JAPAN, [3]Oral pathology and Biology, Hokkaido University, Sapporo, JAPAN.

OBJECTIVES: Hypoxia is considered to be resistant to chemotherapy and radiotherapy in head and neck cancer. HIF-1α is a key player of the transcriptional response to hypoxia in cancers. We have already reported that ^{18}F-Fluoromisonidazole (FMISO)-PET uptake in oral squamous cell carcinoma (OSCC) can reflect a hypoxic environment with HIF-1α expression (*JNM*; 2013). Although Some PET parameters are reported as prognostic factors in patients with OSCC,

no studies demonstrated the relationship between hypoxic volume (HV) of the tumor and the prognosis in patients with OSCC. The aim of this study is to elucidate the relationships between FMISO- and FDG-PET parameters including HV of the tumor and the prognosis after surgery in patients with OSCC. **METHODS:** A total of 23 patients (Age: 42-84; M/F: 15/8) with OSCC who underwent radical surgery were enrolled in this study. Each patient underwent FMISO- and FDG-PET CT before surgery. The HV was measured by FMISO-PET CT, defining as hypoxic area if FMISO tumor to muscle ratio (TMR) was more than 1.25. Metabolic tumor volume (MTV) was measured using the cut off values with 2.5 of SUV max of FDG-PET. In statistical analyses, the cutoff values of PET parameters were determined using ROC curves. The follow-up periods of the 23 patients were more than four years. Disease free survival (DFS) rates are calculated by Kaplan-Meier methods. **RESULTS:** The medians of HV and MTV were 0.45ml, ranged from 0 to 7.7ml and 5.8ml, ranged 0.3-36.1ml, respectively. The HV was significantly higher in patients with T3+T4 than T1+T2 tumors (medians; 2.8ml vs. 0 ml, P=0.02). However, the MTV was not significant different between T1+T2 and T3+T4 tumors (medians; 3.5ml vs. 15.5ml, P=0.07). During follow-up after radical surgery, there were 6 cases with locoregional recurrences, 3 cervical lymph node metastases and one distant metastasis. There was a significant difference of DFS rate between the patients with high and low HV volumes of the tumor (P=0.01, cutoff value: 3.6ml). However, the MTV was not a significant factor to be relating to DFS. The HV and MTV were not significant factors to be related to overall survival (OS) rates (P=0.08 and 0.17). **CONCLUSIONS:** This study first suggests that the HV of the tumor evaluated by pre-operative FMISO-PET CT may reflect the prognosis of the patients with OSCC treated by radical surgery.

OP178

Multiparametric imaging in predicting prognosis of patients with primary hypopharyngeal squamous cell carcinoma using 18F-FDG PET/CT heterogeneity and dynamic contrast-enhanced or diffusion-weighted MRI parameters

S. Chan[1], S. Ng[2], C. Hsu[2]; [1]Keelung Chang Gung Memorial Hospital, Keelung, TAIWAN, [2]Linkou Chang Gung Memorial Hospital, Taoyuan, TAIWAN.

Background: The prognostic significance of combination of 18F-FDG PET heterogeneity with dynamic contrast-enhanced MR imaging (DCE-MRI) or diffusion-weighted MR imaging (DWI) parameters for the prediction of survival in patients with primary hypopharyngeal cancer is not clear. In this study, we investigate the utility of multiparametric imaging in the prognosis prediction of these patients. **Methods:** We examined 61 patients with primary hypopharyngeal cancer who underwent pretreatment ^{18}F-FDG PET/CT, DCE-MRI and DWI. Conventional and heterogeneity parameters from ^{18}F-FDG PET as well as DCE-MRI and DWI parameters were analysis in relation to recurrence-free survival (RFS) and overall survival (OS). Independent prognosticators were identified by Cox regression analysis. **Results:** The median follow-up time was 3 years for the survival patients. Twenty-two patients were expired and 32 had tumor recurrence. After multivariate analysis, higher DCE-MRI parameter K^{trans} (p = 0.031, Hazard ratio (HR) = 0.448), total lesion glycolysis (p = 0.031, HR = 3.398), and PET heterogeneity parameter entropy (p = 0.033, HR = 4.042) values independently predicted RFS. DCE-MRI parameters Vp (p = 0.026, HR = 2.831), Ve (p = 0.005, HR = 0.203), and PET heterogeneity parameter uniformity (p = 0.005, HR = 0.243) retained their independent prognostic significance for OS. Integrating the PET heterogeneity parameter with DCE-MRI parameters allowed distinct prognostic stratification by dividing the patients into three groups with OS (p=0.234, 3-year rates=83.2%/47.9%/14.3%) and four groups with RFS (p < 0.042, 3-year rates=51.2%/31.3%/0%). **Conclusions:** The heterogeneity parameters of ^{18}F-FDG PET appeared to be the independent prognostic factors of overall and recurrence-free survivals for hypopharyngeal cancer patients. Multiparametric imaging combing PET heterogeneity with DCE-MRI parameters could be used to improve prognostic stratification of these patients.

OP179

Performance evaluation of 18F-FDG PET/CT tumour delineation methods for volume assessment in head and neck cancer (SCCHN)

R. Lorenz[1], A. Boehm[2], M. Fischer[2], L. Kurch[1], T. W. Georgi[1], D. Hasenclever[3], G. Wichmann[2], A. Dietz[2], O. Sabri[1], R. Kluge[1]; [1]University Hospital Leipzig, Department of Nuclear Medicine, Leipzig, GERMANY, [2]University Hospital Leipzig, Department of Otorhinolaryngology, Leipzig, GERMANY, [3]University Leipzig, Institute for Medical Informatics, Statistics and Epidemiology (IMISE), Leipzig, GERMANY.

Aim: The aim of this study was to evaluate the performance of automated tumour delineation methods for 18F-FDG PET, to investigate factors potentially affecting the segmentation result and to deduce recommendations for the use of certain delineation methods. *Method*: Eight different 18F-FDG PET delineation methods were applied to assess the primary metabolic tumour volume (MTV) of 39 patients with untreated head and neck cancer. All volume segmentations based on region growing algorithms with varying SUV-thresholds (T) calculated as follows: T=1.5×$\bar{x}$BG; T=$\bar{x}$BG+3SD; T=1.5×$\bar{x}$BG+2SD; T=2×$\bar{x}$BG+2SD; T=0.4×SUV_{max}; T=0.5×SUV_{max}; T=0.4×(SUV_{max}-$\bar{x}$BG)+$\bar{x}$BG; T=0.5×(SUV_{max}-$\bar{x}$BG)+$\bar{x}$BG.All regional voxels greater than these calculated intensity values were assigned to the FDG-avid vital tumour volume. For methods requiring a mean background uptake ($\bar{x}$BG) a cuboid volume of interest (VOI) of 30 millilitres was positioned in the right lobe of the liver. The volume error (VE) was determined using manual CT-morphologic delineations (GTV) as reference standard. Additionally, volumetric information, different SUV-parameters (SUV_{mean}, SD_{SUV}, SUV_{max}, SUV_{min}), the tumour-to-background ratio (TBR), plasma glucose level, administered activity, time interval to image acquisition, and body mass index were correlated with VE using Spearman's rho. *Results*: The median VE was lowest with T=2×$\bar{x}$BG+2SD (0.88ml; 6.34%); T=0.4×SUV_{max} (0.92ml; 10.20%); T=0.5×SUV_{max} (-3.01ml; 27.54%) and T=0.4×(SUV_{max}-$\bar{x}$BG)+$\bar{x}$BG (-2.48ml; 28.25%). VE interquartile range (IQR) varied between 6.15ml for T=0.4×(SUV_{max}-$\bar{x}$BG)+$\bar{x}$BG to 16.50ml for T=$\bar{x}$BG+3SD. Rank analysis of VE showed that T=0.4×SUV_{max} and T=0.4×(SUV_{max}-$\bar{x}$BG)+$\bar{x}$BG were the two best performing algorithms. Correlation analysis revealed that the tumour volume itself (GTV or MTV) noticeably affects the segmentation result. The impact of other parameters on VE was more variable and less systematic. *Conclusion*: Although performance of central tendency was satisfactory for some algorithms, statistical dispersion is a major limitation of automated delineation methods. Considering the tumour volume for method selection may improve the accuracy of tumour segmentation.

OP180

18F-FDG PET/CT In The Diagnosis Of Suspected Recurrence In Patients With Head And Neck Cancer (HNC)

S. Rizkallal Monzon, S. Rodado Marina, M. Coronado Poggio, Y. Ramírez Escalante, G. Villoria Almeida, C. Escabias del Pozo, M. Orduña Díez, I. Santos Gómez, J. Guzmán Cruz, L. Domínguez Gadea; Hospital Universitario La Paz, Madrid, SPAIN.

OBJECTIVE: The aim of this retrospective study was to determine the benefits of hybrid 18F-FDG PET/CT in diagnosis of suspected recurrence of HNC and distant metastases after treatment, and study its accuracy regard other imaging techniques (CT, RM)/ physical examination.

METHODS: 77 FDG PET/CT examinations were performed to 72 patients (50 men, 22 woman, mean age: 63, 5 years) between January 2014 and November 2015; all of them curatively treated for HNC. 59 studies were performed in patients with high recurrence suspicion (findings in CT, RM or physical examination) and 18 in follow-up. All patients underwent a whole-body 18F-FDG examination that was classified by visual analysis as: positive, negative or indeterminate. The final diagnosis was determinate by histopathology findings or clinical/imaging follow up (gold standard) RESULTS: The primary tumor location was larynx (27), oral cavity (20), oropharynx (8), nasopharynx (5), hypopharynx (4), maxilar (4), salivar gland (3) and nasal cavity (1). The final diagnosis was determined by histopathological 34studies and 25 by imaging/clinical follow-up. In the 59 studies with recurrence suspicion, 50 were detected by imaging (CT/RM) and 9 by physical examination. The whole-body 18F-FDG PET/CT examinations had positive results in 28 studies, negative in 26 and indeterminate in 5. Only one of who exhibited abnormal 18F-FDG uptake in the head and neck area did not have confirmed recurrence (false positive). The other 27 had proven recurrence. All negative PET/CT, were negative for recurrence in the final diagnosis. The sensitivity and specificity of 18F-FDG PET/CT was 100% (27/27) and 96% (26/27) respectively. The positive predictive value was 96% (27/28) and the negative predictive value was 100% (26/26). The overall accuracy was 98%. In the 27 positive PET/CT studies with positive final diagnosis, the CT/RM results were positive in 74% (20/27) and indeterminate in 26% (7/27). In the group with PET/CT performed as a follow up (18), the PET/CT was: positive in 2 (both positive in the final diagnosis), negative in 14 (all negative in final diagnosis) and indeterminate in 2 (both negative in final diagnosis). CONCLUSIONS: The high diagnostic performance of FDG PET/CT in detecting recurrence in curatively treated patients with HNC supports its use in clinical practice for patient follow-up, obviating further radiologic imaging. Further studios are needed to evaluate the prognostic utility of PET/CT in the follow-up of HNC in patients without suspected recurrence.

OP181

High FDG Uptake on Pre-radiotherapy PET/CT and Preferential Sites of Local Relapse after Chemoradiotherapy for Locally Advanced Head and Neck Cancer

A. CHAPUT[1], J. CALAIS[2,3], P. ROBIN[1], S. THUREAU[3], D. BOURHIS[1], R. MODZELEWSKI[3], U. SCHICK[1], P. VERA[3], P. SALAÜN[1], R. ABGRAL[1]; [1]Brest University Hospital, Brest, FRANCE, [2]Bichat University Hospital, Paris, FRANCE, [3]Henri Becquerel Center, Rouen, FRANCE.

Purpose: The potential benefits of 18F-fluorodesoxyglucose positron emission tomography (FDG-PET/CT) imaging for radiotherapy (RT) planning treatment of head and neck cancer (HNC) are increasingly being recognized. It has been suggested that intra-tumor sub-volumes with high FDG avidity are potential target for selected dose escalation. Our aims were to demonstrate that pre-RT FDG PET/CT can identify intra-tumor sites at increased risk of local relapse (LR) after RT and to determine an optimal maximum standardized uptake value (SUVmax) threshold to delineate smaller RT target volumes that would facilitate RT dose escalation without impaired tolerance. **Methods:** The study included 72 consecutive patients with locally advanced HNC treated by radiotherapy ± concurrent chemotherapy. All patients underwent FDG PET/CT at initial staging (PET_A) and during systematic follow-up (PET_R) in a single institution. FDG PET/CT acquisitions were co-registered on the initial CT scan with a rigid method. Various subvolumes (A_X; X=30, 40, 50, 60, 70, 80 and 90% SUVmax thresholds) within the initial tumor and in the subsequent LR (R_X; X=40 and 70% SUVmax thresholds) were pasted on the initial PET/CT and compared together [Dice, Jaccard, overlap fraction (OF), common volume/baseline volume, common volume/recurrent volume] **Results:** Nineteen patients (26%) had LR. Using a 40% of SUVmax threshold, initial metabolic tumor volume (MTV) was significantly higher in all relapse patients (local and distant relapse) than in controlled patients (mean: 11.3 ± 9.8 vs. 5.1 ± 4.9 cc, p = 0.001) as well as total lesion glycolysis (TLG) (mean: 134.6 ± 116 vs. 60.6 ± 80.4, p=0.002). For both using methods, the overlap index between A_{30}, A_{40}, and A_{50} sub-volumes on PET_A and the whole metabolic volume of recurrence R_{40} and R_{70}, on PET_R showed a moderate agreement (between 0.40 and 0.60). **Conclusion**: We confirm that TLG and MTV are independently correlated with recurrence-free survival in patients with HNC. Due to sub-optimal co-registration, we could not reach high overlap index values between initial tumor and recurrence sub-volumes. Further larger prospective studies with FDG-PET/CT performed in the same RT position and with a validated elastic registration method are needed.

OP182

Diagnostic Performance Of ^{18} F - FDG PETCT In Suspected Recurrence In Treated Cases Of Oral, Pharyngeal and Laryngeal Malignancy

S. Padma, P. Shanmuga Sundaram, B. R Arun; Amrita School of Medicine, Amrita Institute of Medical Sciences, COCHIN, INDIA.

Introduction: Excluding local recurrence in treated cases of oropharyngeal, laryngeal malignancies is a challenge as there is local tissue distortion and edema after chemoRT and surgery. Anatomical imaging modalities fair poorly in the identification of local recurrence. It is also imperative to accurately assess the disease extension in order to plan the most appropriate treatment, which has important implications for patient outcomes. Data is controversial on the role of PET in post chemoRT setting in patients with suspected recurrence. **Aims & Objectives:** To determine the diagnostic performance of ^{18}F FDG PETCT in suspected cases of local recurrence and its ability to assess disease extension in treated cases of oral, pharyngeal, laryngeal cancers. **Materials & Methods:** Data of 52 treated cases of oropharyngeal, laryngeal malignancy (M: F= 40:12, mean age 58 yrs), who presented to our dept for PETCT between Jan 2013 to Nov 2014 with suspected local recurrence were retrospectively analysed. Imaging was performed after a minimum interval of three months post treatment. PETCT findings were correlated with histopathology from the PET detected site of local recurrence. Stastistical analysis was also performed. **Results:** 32/52 pts revealed FDG avid lesions locally (tongue; alveolus; floor of mouth: pyriform sinus; vocal cord; pharynx = 10: 3: 3: 14: 2) with no corresponding CT lesion. Dual timepoint imaging was conducted in 23/32 pts to rule out inflammation. PETCT was negative in 20/52 pts. Biopsy correlation was performed in all. Sensitivity, Specificity, Positive Predictive Value and Negative Predictive values for detection of local recurrence were found to be 87.5%,80%,87.5% and 80% respectively. 9/32 (28%) pts (tongue : alveolus : floor of mouth : pyriform sinus = 4 : 1 : 3 : 1) had unsuspected lymphnodal involvement & same was also correlated with histopathological findings. Sensitivity, Specificity, Positive Predictive Value and Negative Predictive values for detection of local recurrence were found to be 100%, 89 %, 100 %, 89% and 80% respectively. **Conclusion:** ^{18} F FDG PETCT is reliable in the assessment of local recurrence in oropharyngeal and laryngeal malignancy. High negative predictive value of FDG PETCT performed at least 8 weeks post chemoRT allows prevention of unnecessary diagnostic invasive procedures and neck dissection, with a significant impact on clinical outcome. Dual timepoint imaging serves as a useful tool in decision making. FDG PETCT is superior as it identifies viable tumour within the treated region, thus overcoming the known limitations of morphological imaging modalities.

OP183

Initial feedback of 18F-FDG PET/MR in head and neck oncology in clinical practice

R. de Laroche[1,2], M. Sahli-Amor[3], G. Bera[2], C. Bertolus[4], G. Herve[5], N. Pyatigorskaya[3], M. Soret[2], M. Bertaux[2], M. Habert[2], A. Kas[2]; [1]University Hospital of Brest, Department of Nuclear Medicine, Brest, FRANCE, [2]Hôpital de la Pitié-Salpetrière, Department of Nuclear Medicine, Paris, FRANCE, [3]Hôpital de la Pitié-Salpetrière, Department of Neuroradiology, Paris, FRANCE, [4]Hôpital de la Pitié-Salpetrière, Department of Oral and Maxillofacial Surgery, Paris, FRANCE, [5]Hôpital de la Pitié-Salpetrière, Department of Cytopathology, Paris, FRANCE.

Aim Hybrid PET/MR imaging is a promising tool for initial assessment of head and neck cancers. Combination of the metabolic information from 18F-FDG PET with the high soft tissue contrast and multiparametric characterization of MRI should yield to a better understanding and management of these poor prognosis malignancies. Our objective is to evaluate the feasibility and the potential interest of 18F-FDG PET/MR in head and neck oncology in clinical practice. **Materials and Methods** Between October 2015 and April 2016, 62 patients (31 men, 31 women, mean age 61±18) underwent PET/MR for head and neck malignant tumor. Images were acquired 1 hour after injection of 3.7 MBq/kg on a hybrid TOF 3T Signa PET/MR (GE Healthcare). Imaging workflow comprised dedicated head and neck 18F-FDG PET acquisition simultaneously with axial T1w, axial T2 IDEAL, and axial diffusion weighted imaging sequences, and after gadolinium injection coronal T2 IDEAL, T1w 3-dimensional and axial T1 IDEAL sequences, followed by a whole body (4 beds) PET and MRI (Lava-Flex, GE Healthcare) acquisition. For head and neck attenuation correction, two methods were tested : the MR based method (Dixon sequence) and the pseudo CT-based atlas method. Useful MR sequences have been selected in order to reduce the time of acquisition. **Results** Thirty-two patients were scanned for initial staging, 22 for restaging, 2 for carcinoma of unknown primary, 3 for therapeutic assessment and 3 for characterization of a suspicious lesion. A total of 37 squamous cell carcinomas, 8 adenoid cystic carcinomas, 3 adenocarcinomas, and 11 other carcinomas was explored. Distant metastases were identified for 6 patients (10 %) and suspicious cervical lymph nodes for 25 patients (40 %). Total acquisition time was about 50 minutes. The atlas method for attenuation correction was not suitable. For all patients, PET/MR images accurately defined local extension of primary tumor site. Both MRI and PET, particularly when there were void artifacts on MRI images, contributed to tumor delineation. Both PET and morphologic MRI sequences were helpful to characterize cervical lymph nodes. Fusion quality, image quality and anatomic location of focal uptake were good on both head and neck and whole body images. **Conclusion** This initial feedback confirmed the feasibility of 18F-FDG PET/MR for head and neck oncology in clinical practice. The added value lies particularly on the improved specificity from the registration of PET and MR images. Attenuation correction in this region is still insufficient, further studies are needed to improve it.

OP184

Advancing Precision Nuclear Medicine for Head and Neck Cancers with Higher Definition Digital PET/CT

C. L. Wright, A. D. Bhatt, K. Binzel, P. Bhatia, P. Subramanian, J. Zhang, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

The introduction of next-generation, solid-state, digital photon counting PET detector (dPET) technology represents an innovative leap over conventional photomultiplier tube-based PET (cPET) technologies to enable precision nuclear medicine practices for oncology patients. This dPET technology enables higher definition PET imaging with smaller voxel volumes which reduces partial volume effects. The objective of this study is to evaluate the clinical capabilities of dPET technology as it relates to patients with head and neck cancer. In an intra-individual matched pair comparison study, 12 head and neck cancer patients underwent both ^{18}F-FDG dPET/CT (pre-commercial release Vereos, Philips) and cPET/CT (Gemini TF 64, Philips). Standard cPET/CT was performed using a target dose of 481 MBq FDG at ~75 min p.i. and investigational dPET/CT was performed at ~55 min p.i. or ~95 min p.i. All images were reconstructed with ToF using a standard definition (SD) voxel volume of 4x4x4 mm^3. In addition, the dPET images were reconstructed at high definition (HD, 2x2x2 mm^3) and ultra-high definition (UHD, 1x1x1 mm^3). Independent visual assessment for overall image quality, background quality, lesion detectability, and diagnostic confidence for cPET and dPET image sets were performed by a blinded reader panel. All 12 cPET and dPET data sets were evaluable. The UHD dPET reconstructions were consistently rated the best in terms of overall image quality for evaluating primary and metastatic lesions with no appreciable effect on the background FDG intensity. Higher definition dPET data sets consistently demonstrated improved lesion detectability for small lesions (< 15 mm) when compared with cPET. The clinical impact of UHD dPET was consistently rated preferable compared to cPET, indicating that it can potentially impact clinical outcome. This improved lesion detectability likely relates to the faster timing resolution of dPET (~325 ps) compared with cPET (~550 ps) and the higher definition reconstructions, both of which decrease partial volume effects. In head and neck cancer, FDG PET imaging is clinically invaluable for the routine detection of occult malignancy, staging and assessment of treatment response. This study demonstrates that HD and UHD dPET imaging of head and neck cancer improves lesion detectability (especially for smaller lesions), lesion characterization (especially in heterogeneous masses) and overall diagnostic confidence for the reader. These essential advances strengthen the utilization of PET as an imaging biomarker in head and neck cancer, where large, heterogeneous primary tumors and small metastatic lesions are common, further lending support to the vision of precision nuclear medicine.

Comparison of Contrast-enhanced MRI versus ^{68}Ga-DOTATOC-PET/CT in Patients with Suspected Cardiac Involvement of Sarcoidosis

F. C. Gaertner[1], U. Schlesinger-Irsch[2], C. Pizarro[3], T. Reiter[4], D. Skowasch[3], W. R. Bauer[4], D. Thomas[2], R. A. Bundschuh[1], C. Lapa[5]; [1]Department of Nuclear Medicine, Universitaetsklinikum Bonn, Bonn, GERMANY, [2]Department of Radiology, Universitaetsklinikum Bonn, Bonn, GERMANY, [3]Department of Internal Medicine II, Universitaetsklinikum Bonn, Bonn, GERMANY, [4]Department of Internal Medicine I, Universitaetsklinikum Wuerzburg, Wuerzburg, GERMANY, [5]Department of Nuclear Medicine, Universitaetsklinikum Wuerzburg, Wuerzburg, GERMANY.

Purpose: Cardiac involvement is rare but important for the prognosis and therapy decisions in patients with sarcoidosis. Diagnosis is demanding and often based on cardiac function. Recently late contrast enhancement in magnetic resonance imaging (MRI) as well as somatostatin-receptor positron emission tomography has been described for diagnosis of cardiac sarcoidosis. In this analysis we directly compared both imaging modalities to each other.*Material and Methods:* 16 patients from two centers with proven sarcoidosis who underwent contrast enhanced MRI and ^{68}Ga-DOATATOC PET/CT due to clinical suspicion of cardiac involvement were retrospectively analyzed. In MRI data presence of late enhancement was analyzed using the 17-segment American Heart Association model. ^{68}Ga-DOTATOC uptake was analyzed using the same model.*Results:* In 6 patients pathological uptake was found in PET as well as late enhancement in MRI, here in average 72.4 % of the segments did overlap. In 4 patients with negative PET findings, late enhancement was found in MRI. The remaining 6 patients were negative in PET and MRI. In patients with PET positive findings, the ratios lesion-to-blood-pool and myocardium-to-blood-pool showed better ability to differentiate between lesions and normal myocardium compared to SUV. *Conclusion:* In 75 % of the patients PET and MRI showed agreement in diagnosis of cardiac involvement of sarcoidosis. Lesion localization showed an overlap of 72 %. For quantitative discrimination in PET, ratios of the uptake compared to blood pool showed better discrimination than absolute uptake values (SUV). However late enhancement in MRI showed pathological findings in 4 PET-negative patients. This may either be due to differences in sensitivity of the modalities (e.g. caused by differences in spatial resolution) or due to scar tissue without active inflammation showing late enhancement in MRI. Further clinical follow-up might help to clarify this point.

OP190

Quantification of 11C-PIB uptake in cardiac amyloidosis

T. Kero[1], J. Sörensen[1], G. Antoni[2], H. Wilking[2], K. Carlson[3], O. Vedin[3], G. Wikström[3], M. Lubberink[1]; [1]Surgical sciences, Uppsala, SWEDEN, [2]Medical Chemistry, Uppsala, SWEDEN, [3]Medical Sciences, Uppsala, SWEDEN.

Aim: Recent studies have shown promise for ^{11}C-PIB PET as a non-invasive diagnostic and quantitative tool in cardiac amyloidosis. The aims of this study were to determine the optimal tracer kinetic model of ^{11}C-PIB and to evaluate the performance of two simplified methods, retention index (RI) and standardized uptake value (SUV), in the quantification of cardiac ^{11}C-PIB uptake in amyloidosis. **Materials and methods:** Six patients with systemic amyloidosis and cardiac involvement underwent dynamic 35-min ^{11}C-PIB PET scans with arterial blood sampling for measurement of blood radioactivity and metabolite analysis. Volumes of interest were drawn over the left myocardial wall according to the 17 segment model of the American Heart Association. Single-tissue and reversible and irreversible two-tissue models were fitted to the data using a metabolite-corrected arterial input function, both based on individual metabolite data and on a population-average metabolite correction. The optimal kinetic model was determined using the Akaike information criterion (AIC) and Akaike weights. RI and SUV (15-25 min p.i.) were compared with the rate of irreversible binding (K_i). In a retrospective analysis, data from 10 amyloidosis patients and 5 healthy controls for which no blood data was available were analysed in a similar way using a population-average metabolite correction. **Results:** The irreversible two-tissue (2Tirr) model was preferred based on AIC and Akaike weights and robustness of fits. RI and SUV correlated moderately well with the rate of irreversible binding (K_i) from the 2Tirr model (r^2=0.73 and r^2=0.66 respectively). Correlation (r^2=0.86) and agreement (ICC=0.91) were high between K_i using individual metabolite corrections versus K_i using population-averaged metabolite correction. In the retrospective analysis using population-averaged metabolite correction, K_i was higher in amyloidosis patients than in healthy controls (p=0.008). However, there was an overlap between the lowest K_i in amyloidosis patients and the highest K_i in controls, whereas both RI and SUV both showed higher values in patients than controls (p=0.001 for both), without an overlap in values. **Conclusion:** An irreversible two-tissue model best describes the ^{11}C-PIB uptake in cardiac amyloidosis. RI and SUV showed modest correlation with quantitative results from this kinetic model. However, RI and SUV are more feasible for use in clinical routine and also showed better discrimination between amyloidosis patients and controls than K_i. Therefore, RI and SUV are preferred in clinical diagnosis of cardiac amyloidosis.

OP191

Quantitative assessment of cardiac amyloid burden in patients with suspected transthyretin cardiac amyloidosis (ATTR): a feasibility study

S. Ben-Haim[1,2], M. Smechov[1], E. Goshen[1], M. Arad[1], I. Medini[3], A. Bar-Shalev[3], J. Bomanji[2], L. Menezes[2]; [1]Chaim Sheba Medical Center, Ramat-Gan, ISRAEL, [2]University College London and UCL Hospitals, London, UNITED KINGDOM, [3]GE Healthcare, Nuclear Medicine, Haifa, ISRAEL.

Objectives: 99mTc-diphosphono-propano-dicarboxylic acid (Tc-DPD) can be used for the diagnosis of ATTR by visual interpretation. Recent developments in therapy may require a more precise quantitative assessment. We have assessed the feasibility of absolute quantitation of myocardial Tc-DPD in patients with suspected ATTR using a quantitative software package (Q.Metrix, GE Healthcare). **Methods:** Tc-DPD whole body planar and SPECT/CT studies of the chest of 80 patients with suspected ATTR were evaluated. Data were corrected for patient motion, attenuation and collimator blurring, and absolute quantitation was performed given the injection information and system sensitivity. Mean cardiac uptake (MBq/ml), % injected dose within the heart (%ID) and the ratio of heart/spine concentrations were obtained and were compared to semi-quantitative visual assessment (Perugini score [PS] 0 - no cardiac uptake to PS 3 - cardiac uptake greater than bone). **Results:** At 3 hours after injection there were 68 patients with PS 0. Cardiac activity was seen in 12 patients on planar and on SPECT/CT studies (m=10, age:76.6±6.8 years). There was one patient with PS1, eight had PS2 and 3 had PS3. %ID in PS1 was 0.41, compared to 2.54±0.53 and 2.72±0.5 in PS2 and PS3, respectively. The average concentration in the heart was 0.015 MBq/ml in PS1, 0.048±0.01 in PS2 and 0.042±0.0 in PS3. The ratio of heart/spine concentrations was 0.34 in PS1, 2.11±0.6 in PS2 and 2.44±0.8 in PS3. **Conclusion:** Absolute quantitation of cardiac Tc-DPD uptake is feasible using Q.Metrix. These initial findings suggest significantly lower

cardiac uptake in PS1, whereas no significant differences were demonstrated between PS2 and PS3, suggesting perhaps patients with PS2 and patients with PS3 can be grouped together. Further assessment in larger patient cohorts is needed to determine the clinical relevance of these findings.

OP192

Comparison of MIBG and Diphosphonate scintigraphy in patients with aTTR-FAP

R. CHEQUER[1], H. REGAIEG[1], R. BEN AZZOUNA[1], V. ALGALARRONDO[2], B. MAHIDA[1], E. PIEKARSKI[1], M. SLAMA[2], D. LE GULUDEC[1], F. ROUZET[1]; [1]BICHAT HOSPITAL, PARIS, FRANCE, [2]CARDIOLOGY DPT HOPITAL BECLERE, PARIS, FRANCE.

Background. In familial aTTR amyloid polyneuropathy (FAP), cardiac involvement is of major prognostic value. Two approaches using radionuclide imaging proved relevant in the assessment of aTTR-related cardiac amyloidosis: detection of amyloid deposits with disphosphonates (DPD) and of sympathetic denervation with MIBG. The study aimed to compare the respective value of both approaches in patients with aTTR-FAP with suspected cardiac involvement. Methods. 76 consecutive patients with genetically proven aTTR-FAP were prospectively included (males 62%, Val30Met: 42%, domino-liver transplantation 13%, symptomatic 57%, interventricular septum (IVS)≥12 mm: 52%; left ventricular ejection fraction: 63±10%). They underwent both MIBG and DPD scintigraphy in a delay <3 months. For DPD SPECT, acquisitions were performed 3 hours after tracer injection. Cardiac uptake was visually scored as present or absent and quantified by the ratio of 3D isocount volume of interest generated over the myocardium to a standard volume in lung (H/L). For MIBG, heart-to-mediastinum ratio (HMR) was calculated on planar acquisitions performed 4 hours after tracer injection. Cardiac MIBG was classified as normal, mildly, moderately, or severely abnormal. Results: The delay between MIBG and DPD 6±12 days. MIBG was abnormal in 50 patients (66%) and DPD in 30 patients (39%; p=0.002). When MIBG was normal (n=26), DPD scintigraphy was normal except for 1 patient. When MIBG was abnormal (n=50), DPD scintigraphy was normal in 21 patients (42%). The uptake of DPD increased with the denervation score (normal: 0.6±0.2; mild: 0.6±0.4, moderate: 3.4±3.3; severe: 4.5±3.7; p<0.001 between normal and moderate/severe). In patients with a previous domino liver transplantation (n=10), the overall pattern was similar. In asymptomatic patients (n=31), all those with a normal MIBG (n=17) had a normal DPD; MIBG was abnormal in 45% (n=14), 50% had a normal DPD. In addition, HMR was greater (1.8±0.3 vs. 1.6±0.4; p=0.008) and H/L was lower (1.7±2.3 vs. 3.2±3.5; p=0.04) compared to symptomatic patients. Conclusion: in patients with suspected cardiac involvement of aTTR-FAP, MIBG was abnormal more frequently than DPD. In particular, DPD abnormalities are delayed compared to MIBG since it was abnormal only when denervation was moderate or severe. In the group of asymptomatic patients, only half of those with cardiac denervation had a positive DPD scintigraphy. This suggests that innervation abnormalities detected by MIBG are more frequent and appears earlier than amyloid deposits detected by Diphosphonates.

OP193

Usefulness of combined FDG-PET/MR to diagnose active cardiac sarcoidosis

R. Abgral[1,2], M. R. Dweck[1,3], M. G. Trivieri[1], P. M. Robson[1], N. Karakatsanis[1], V. Mani[1], M. Padilla[4], J. Sanz[5], J. Narula[5], V. Fuster[5], J. Contreras[5], J. C. Kovacic[5], Z. A. Fayad[1]; [1]Translational and Molecular Imaging Institute, Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES, [2]Department of Nuclear Medicine, European University of Brittany, EA3878 GETBO, IFR 148, CHRU Brest, Brest, FRANCE, [3]British Heart Foundation/University Centre for Cardiovascular Science, University of Edinburgh, Edinburgh EH16 4SB, Edinburgh, UNITED KINGDOM, [4]Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES, [5]Cardiovascular Institute, Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES.

Aim: Sarcoidosis is a granulomatous disease of unknown etiology affecting commonly lung and mediastinal lymph nodes. Heart involvement poses an increased risk of sudden death but is probably underdiagnosed due to frequent absence of clinical symptoms and the inability to easily diagnose cardiac sarcoidosis (CS) with a non-invasive method. Several imaging techniques are already used to assess CS including 18F-fluorodesoxyglucose/positron-emission tomography (FDG-PET) to underline inflammatory disease and magnetic resonance (MR) with late Gadolinium enhancement (LGE) to determine the pattern of myocardial injury. Recent advances now allow combining these 2 techniques to benefit from the best of these modalities. Our aim was to assess the usefulness of FDG-PET/MR in the diagnosis of CS. *Methods:* Patients with previous histologically proven extra-cardiac sarcoidosis and/or clinical symptoms consistent with CS were referred to our department for PET/MR imaging. PET data were reconstructed using a Dixon-MR attenuation correction map. Different quantitative parameters were measured on images: mean and maximal myocardial standardized uptake values (SUVmax, SUVmean) around area positive for LGE, if present; mean T2 mapping value (T2mean) in the same volume; target-to-blood pool ratios (TBRmax, TBRmean); and target-to-negative LGE myocardium ratios (TNRmax, TNRmean). A final diagnosis of active cardiac sarcoidosis (CS+) or no (CS-) was defined by a consensus of clinical experts. Mean values of imaging parameters in CS+ and CS- patients were compared using a Student t-test and a ROC analyses was performed to assess their diagnostic accuracy. *Results:* Twenty-five patients (11M/14F; 55.2±9.7 yo) were prospectively enrolled in 9 months. They underwent a PET/MR 68.6±9.4 min after injection of 4.8±0.2 MBq/Kg of FDG. Eight patients were considered as CS+ and 17 as CS-. There was no statistically significant difference in terms of SUVmax (p=0.266), T2mean (p=0.320), TBRmax (p=0.239) and TBRmean (p=0.248) between CS+ and CS- patients. Mean TNRmax were respectively 1.68±0.41 and 1.09±0.08 in CS+ and in CS- patients (p<0.0001). Mean TNRmean were respectively 1.52±0.27 and 1.03±0.14 in CS+ and in CS- patients (p<0.0001). ROC analysis revealed a threshold of TNRmax=1.21 (AUC=0.978) and TNRmean=1.24 (AUC=0.993) to differentiate all patients as being CS+ or CS- (accuracy=96%). Two previously unknown cases of sarcoid involvement (bone, liver) were identified. FDG-PET/MR identified an alternative cause for cardiac symptoms in 6 (35%) of CS- patients. *Conclusion:* Our results show the usefulness of combined FDG-PET/MR in the diagnosis of CS using TNR measurements and confirm its clinical ability to evaluate extra-cardiac involvement of sarcoidosis and in assessing alternative myocardial pathologies.

OP194

Does quantification of FDG uptake with TBR improve the assessment of disease activity in Takayasu arteritis ?

B. Emsen[1], K. Benali[1], D. Larivière[2], B. Mahida[1], T. Papo[2], K. Sacré[2], F. Hyafil[1]; [1]Department of Nuclear Medicine, Bichat Hospital, AP-HP, PARIS, FRANCE, [2]Department of Internal Medicine, Bichat Hospital, AP-HP, PARIS, FRANCE.

Background. Takayasu arteritis (TA) is a rare autoimmune vasculitis, which predominantly affects the aorta and its branches. The role of FDG-PET imaging for the assessment of the disease activity remains controversial. **Objective.** The aim of this study was to assess whether the precise quantification of FDG uptake in the vessel wall using tissue

to background ratio (TBR) might be useful for the assessment of disease activity at the time of diagnosis and for monitoring the efficacy of immunosuppressive therapy (IS). **Methods.** A total of 62 FDG-PET scans with TA were analyzed retrospectively. All patients received corticosteroids or immunosuppressive treatments. The diagnosis of TA was based on the American College of Rheumatology criteria. TBR were calculated as the ratio between max. SUV in the aortic wall and mean SUV of blood. For each patient, the disease was established as clinically active or inactive at the time the FDG PET imaging based on the clinical criteria included in the NIH assessment of disease activity for TA patients. **Results.** A total of 15 patients were included in this study and imaged on average 5 times with FDG-PET scans. Eight patients were imaged before the initiation of IS therapy. An average of 5 ± 2 vascular lesions were present on the first FDG-PET scan with a maximal TBR of 2.7 ± 0.9. On the second FDG-PET scan after introduction of IS therapy, the max. TBR was reduced by ca. 40 % with a mean TBR value of 1.45 ± 0.5 on the second PET scan. In the 24 FDG-PET scans of patients classified as inactive after initiation of therapy, TBR was always < 2.3 ± 0.3. The disease was classified as clinically active in 40 % of patients with max. TBR value > 2.3 and in only 27 % of the patients with max. TBR between 1.6 and 2.3. Max. TBR measured in vascular lesions changed by + 51 ± 64% % when the disease became active, - 18 ± 25 %, when the disease became inactive and - 5 ± 26 % when the disease was considered as stable. **Conclusions.** In TA patients, high TBR value are measured at the time of diagnosis but decrease by ca. 40 % after initiation of IS therapy. During follow-up, we confirmed important discrepancies between clinical activity and vascular FDG uptake for intermediate values of TBR on FDG-PET imaging.

OP195

Semiquantitative analysis of 18F-FDG PET/CT in the follow-up of large vessel vasculitis

M. Jimenez-Alonso[1], I. Martinez-Rodriguez[1], C. Lavado-Perez[1], J. Lopez-Defillo[1], R. Quirce[1], J. Jimenez-Bonilla[1], M. De Arcocha-Torres[1], D. Meza-Escobar[1], J. Loricera[2], M. Gonzalez-Gay[2], I. Banzo[1]; [1]Nuclear Medicine Service. Molecular Imaging Group (IDIVAL). Marqués de Valdecilla University Hospital. University of Cantabria, Santander, SPAIN, [2]Rheumatology Service. Marqués de Valdecilla University Hospital. University of Cantabria, Santander, SPAIN.

Aim: Large vessel vasculitis (LVV) is the most common type of systemic vasculitis, especially in older female population. Treatment of LVV includes steroids and immunosuppressive drugs. 18F-FDG PET/CT has proven its value for diagnosis and evaluation of the extent of disease. However, its role in the follow-up is not well established. Our aim was to evaluate the usefulness of the semiquantitative analysis of 18F-FDG PET/CT in the follow-up of these patients. **Materials and methods:** This study included 38 patients (28 women and 10 men, mean age: 66.5±9.8 y.) with LVV who had an initial (at diagnosis) and follow-up 18F-FDG PET/CT scan. Follow-up PET/CT was carried out 3-12 months after the initial scan (mean time: 7.5±2.9 months). 18F-FDG PET/CT scan was obtained 180' after intravenous injection of 7 MBq/Kg 18F-FDG. A semiquantitative analysis of images based on the target (aortic wall) to background (aortic blood pool) ratio (TBR) was performed. The initial and the follow-up scans results and clinical and biochemical outcome were compared. **Results:** Overall, mean TBR decreased significantly from 1.71±0.5 in the initial scan to 1.41±0.28 in the follow-up (p=0.0002). In a patient-based analysis, TBR decreased in 30 out of 38 patients (19 of them had clinical improvement), and increased in 8 patients (6 of them presented clinical worsening). In the 21 patients with clinical improvement the mean TBR decreased significantly from 1.83 ±0.59 to 1.47±0.29 (p=0.0002). In the 17 patients with no changes or clinical worsening the mean TBR decreased from 1.56±0.24 to 1.48 ±0.28, although the difference was not significant (p=0.1848). Twenty-four out of 38 patients showed biochemical data improvement. The mean TBR decreased from 1.74±0.57 to 1.52±0.34 (p=0.0097). In the other 14 patients who presented worsening of biochemical data, TBR decreased from 1.65±0.29 to 1.4±0.14 (p=0.0041). Mean TBR was higher at the initial scan in patients who presented clinical and/or biochemical improvement, although the difference were not significant (p=0.0859 and 0.7737, respectively).**Conclusions:** The semiquantitative analysis of 18F-FDG PET/CT is useful in the follow-up of patients with LVV. In addition, it could identify patients with a favorable clinical outcome. Although mean TBR decreased in the follow-up, some degree of vascular uptake remained. No relationship was found between mean TBR and biochemical data.

Decreased Cerebral Glucose Metabolism Associates with Risk Factors for Poor Neurodevelopmental Outcome in Very Low Birth Weight Infants

H. Kim, K. Won, B. Song, H. Lee, S. Lee, C. Kim, J. Park; Keimyung University, School of Medicine, Daegu, KOREA, REPUBLIC OF.

Purpose: Although brain MRI shows no structural abnormality in very low birth weight infants (VLBWI), these VLBWI have an increased risk of poor neurodevelopment. The aim of this study was to evaluate clinical significance of decreased cerebral glucose metabolism in VLBWI without structural abnormality on brain MRI. **Methods:** Forty VLBWI (gestational age (GA): 24 - 29 weeks) who had no structural abnormality (severe intraventricular hemorrhage, cystic periventricular leukomalacia, punctate lesion, loss of volume, and ventricular dilatation) on brain MRI were enrolled in this study. All infants performed brain MRI and fluorine-18 fluorodeoxyglucose (F-18 FDG) brain PET at term-equivalent age. F-18 FDG brain PET images were quantitatively analyzed using the infant automated anatomic labeling template after spatial normalization. The regional glucose metabolic ratio (MR) and asymmetric index (AI) for each VOI of the cerebral cortices, striatum and thalamus were calculated. Asymmetric glucose metabolism was considered as significant when AI is higher than 110% or lower than 90%. The relationships between regional MR and risk factors, including multiple gestations, gestational diabetes mellitus (GDM), pregnancy induced hypertension, premature rupture of membrane (PROM), GA, birth weight, bronchopulmonary dysplasia (BPD) and Apgar score at one and five minutes, were evaluated. **Results:** Seventeen infants (42.5%) had right > left asymmetry and three infants (7.5%) had right < left asymmetry of the cerebral glucose metabolism. The MRs of the left cerebral cortices, striatum and thalamus were significantly lower than those of right cerebral cortices, striatum and thalamus. The MRs were significantly correlated with GA, birth weight and Apgar score at one minute. The MRs in infants with multiple gestations, GDM, PROM or BPD were significantly lower than those in infants without multiple gestations, GDM, PROM or BPD. **Conclusion:** VLBWI had relatively low glucose metabolism of the left cerebral hemisphere compared with the right cerebral hemisphere. Decreased cerebral glucose metabolism associates with risk factors for poor neurodevelopmental outcome in VLBWI. Future studies will be required to assess predictive accuracy of F-18 FDG brain PET for predicting long-term neurodevelopmental outcomes.

OP197

Hybrid PET/MRI Imaging in Healthy Unsedated Newborn Infants with Quantitative rCBF Measurements using ^{15}O-water PET

J. B. Andersen, U. Lindberg, O. V. Olesen, D. Benoit, C. N. Ladefoged, H. B. W. Larsson, L. Højgaard, G. Greisen, I. Law; Copenhagen University Hospital, Rigshospitalet, København Ø, DENMARK.

Aim: The purposes of this study was to investigate the feasibility of quantitative regional cerebral blood flow (rCBF) in healthy newborn subjects using PET with low-activity ^{15}O-water and an image derived input function (IDIF) previously developed in a piglet model on a hybrid PET/MRI scanner (Andersen JB, J Cereb Blood Flow Metab, 2015). Especially we wished to establish a proof-of-concept of the applied PET method for medical research use in newborn infants. Materials and methods: Four healthy full-term newborn subjects with a mean age of 2.5 days (range 2-3 days) and mean weight of 3.4 kg (range 3.3-3.7 kg) were scanned in a PET/MRI (Siemens mMR) during natural sleep injecting a median dose of 14 MBq ^{15}O-water. This corresponds to an upper effective dose limit of 0.33 mSv, which is the approximate background radiation dose per month for the general public in Denmark (4.0 mSv/year). The study was approved by the Regional Scientific Ethical Committee of the Capital Region of Denmark, and oral and written informed consent was obtained from the children's' parents according to the Helsinki II declaration. Regional CBF was quantified using a 1-tissue compartment model (PMOD version 3.3) employing an image derived input function (IDIF) from a dynamic sequence of images of the left ventricle. Volumes of interest (VOIs) were drawn individually including whole brain, periventricular unmyelinated white matter, thalamus, striatum, mesencephalon and cortex. Results: PET rCBF distribution showed relatively high rCBF in the striatum, thalami, mesencephalon, pons, cerebellar vermis, and medulla, and to a lesser degree in the perirolandic cortex, mesial occipital cortex and hippocampal area. The global CBF was mean 17.8 ml/100g/min. The mean rCBF in periventricular unmyelinated white matter and thalami were 10.3 ml/100g/min and 31.3 ml/100g/min, respectively. The average white matter/thalamic ratio CBF was 0.36. Conclusions: Minimally invasive PET using ^{15}O-water with a very small radiation dose yielded expected values of global and regional CBF using an image derived non-invasive obtained arterial input function. The method may be used for quantitative rCBF measurements in unsedated newborn infants for clinical research purposes.

OP198

Investigating the Utility of FDG-PET/CT for Pediatric Encephalitis

P. Martineau[1], R. Lambert[2], J. Decarie[2], S. Turpin[2]; [1]The University of Ottawa, Ottawa, ON, CANADA, [2]CHU Sainte-Justine, Montréal, Montreal, QC, CANADA.

Introduction:Encephalitis in children is a potentially debilitating neurological condition associated with a host of different etiologies. Treatment of this condition depends on the cause; however, clinical diagnosis can be difficult, and conventional radiological findings can be non-specific. To date, there have been few studies examining the role of FDG-PET/CT in the diagnosis of encephalitis, particularly in the pediatric setting. To better understand the PET manifestations of this condition, we conducted a retrospective study comparing the findings on Fluorine-18 fluorodeoxyglucose positron emission tomography (FDG-PET/CT) to those of magnetic resonance imaging (MRI) in a cohort of children with acute encephalitis.Methods and Materials: A retrospective study of 55 pediatric patients with suspected encephalitis who underwent FDG-PET/CT was performed. Areas of abnormal brain metabolism were identified by both qualitative and quantitative analysis. Quantitative analysis was performed using commercially available software (NeuroQTM). These findings were then compared with the MRI results and the final clinical diagnosis. Results: MRI was performed in 48 patients and was abnormal in 23 (48%), while FDG-PET/CT was visually abnormal in 37 of 55 (67%) patients. Using quantitative analysis to compare to a normal pediatric database, 54 (98%) studies were found to contain abnormalities. The pathologies represented in our cohort included collagen-vascular diseases, psychiatric conditions, anti-NMDAR encephalitis, Hashimoto's encephalitis, infectious encephalitis, PANS/PANDAS, ADEM, chorea, and patients in which a definitive etiology for encephalitis could not be determined. Anti-NMDA encephalitis was associated with a large number of abnormal MRI (4/5) and FDG-PET/CT (5/5). Both patients with ADEM had abnormal MRI but normal qualitative FDG-PET/CT. Only one of seven patients with collagen-vascular disease had MRI anomalies. In this group qualitative FDG-PET/CT was abnormal in 4 and quantitative in 6. Similarly, no patients with PANS/PANDAS had abnormal MRIs, while qualitative FDG-PET/CT was abnormal in 2 of five. 11 of 16 patients had encephalitis of aseptic, infectious or unknown etiology with abnormal MRIs while FDG-PET/CT was positive in all cases. Of 7 patients presenting with chorea, 4 of 6 had abnormal MRI results while all had abnormal PET findings. Finally, qualitative FDG-PET/CT and MRI were normal in the majority of patients with neuropsychiatric symptoms (7/10 for PET and 7/8 for MRI). Conclusion: Our results suggest that FDG-PET/CT was more sensitive than MRI for the detection of encephalitis and sensitivity was improved by the use of quantification. Different metabolic abnormalities seemed to be characteristic of particular types of encephalitis.

OP199

Distinct Cerebral 18F-FDG PET Metabolic Patterns in Anti-N-methyl-D-aspartate Receptor Encephalitis Patients with Different Trigger Factors

J. Ge, B. Deng, C. Zuo, X. Chen; Huashan Hospital, Shanghai, CHINA.

Aim: Anti-*N*-methyl-*D*-aspartate receptor (anti-NMDAR) encephalitis is a subgroup of treatable autoimmune encephalitis, characterized by rapid development of psychosis, cognitive impairments and seizures. Etiologically, anti-NMDAR encephalitis could be divided into three subgroups, which are paraneoplastic (especially associated with ovarian teratoma), viral encephalitis-related and cryptogenic. Each type is different in clinical course, treatment strategies and prognosis. Cerebral glucose metabolic abnormalities have been reported in patients with anti-NMDAR encephalitis using 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) imaging. While previous studies commonly demonstrated a general pattern of FDG PET abnormalities associated with the disease, this study aim to investigate distinct cerebral metabolic patterns of encephalitis patients confirmed with antibodies against NMDAR according to different trigger factors. **Materials and Methods:** Twenty patients with anti-NMDAR encephalitis from Huashan Hospital, Shanghai were consecutively recruited in this study. All patients were diagnosed based on clinical manifestations and positive anti-NMDAR antibodies both in serum and in CSF samples. Each patient was classified into an etiological subgroup (paraneoplastic, viral encephalitis-related and cryptogenic) by two senior neurologist based on clinical and laboratory information. 18F-FDG PET brain imaging was performed after confirmed diagnosis. To evaluate the cerebral metabolic activity of recruited patients, the PET images of individual patients were compared with those of the same ten normal controls using a voxel-wise statistical parametric mapping analysis, respectively. **Results:** Twelve patients with anti-NMDAR encephalitis were divided into cryptogenic group, four patients were paraneoplastic and the remaining four were considered secondary to virus infection of central nervous system. Both groups of patients with cryptogenic and paraneoplastic anti-NMDAR encephalitis showed bilateral hypermetabolism in the frontal-temporal lobes and basal ganglia, covarying with bilateral hypometabolism in the occipital regions. Notably, the changes of hypermetabolism in the cortical and subcortical regions were usually asymmetric in the patients with cryptogenic encephalitis, but relative symmetric in those associated with tumor. Moreover, the anti-NMDAR encephalitis patients secondary to viral encephalitis presented with significant hypometabolism in the bilateral occipital regions, as well as in the unilateral temporal lobes and basal ganglia (also is virus infection side), but hypermetabolism in the contralateral temporal areas and basal ganglia. **Conclusion:** This study revealed that anti-NMDAR encephalitis patients triggered by different factors presented distinct cerebral metabolic patterns. We propose that

awareness of these patterns may help to better understand the various occurrence and development of anti-NMDAR encephalitis in each subgroup, and could offer valuable information to the diagnosis, treatment and prognosis of this elusive, but treatable disorder.

OP200

PISCOM: PET-FDG Interictal Substracted ictal SPECT COregistered with MRI for seizure focus localization

A. Perissinotti[1], A. Niñerola-Baizán[1], S. Rubí[2], F. Maite[1], C. Mar[1], A. Donaire[1], N. Bargalló[1], J. Rumià[1], A. Tapia[1], J. Pavía[1], F. Lomeña[1], X. Setoain[1]; [1]Hospital Clínic de Barcelona, Barcelona, SPAIN, [2]Hospital Universitari Son Espases, Palma de Mallorca, SPAIN.

Aim: To develop and validate a new processing nuclear imaging procedure consisting of ictal perfusion SPECT studies subtracted with interictal FDG-PET images corregistered to MRI (PISCOM) for seizure focus (SF) localization in patients with intractable complex partial seizures. **Methods**: A retrospective selection from our clinical practice between 2008 and 2012 included 18 patients (8 male and 10 female, from 18 to 61 years - mean age: 37 years) who had been diagnosed of medically refractory epilepsy, studied with MRI, ictal SPECT, interictal SPECT, interictal FDG-PET and also that remained seizure free for at least two years after surgical resection of the SF. To perform PISCOM analysis, interictal FDG-PET images were resampled and filtered to obtain a same matrix, voxel size and a similar degradation to that of 99mTc-interictal perfusion SPECT. Finally, a brain mask was used to avoid extracerebral differences between both radiotracers. PISCOM and SISCOM images were obtained using Focus-DET software and SF localization in PISCOM and SISCOM studies was determined blinded for clinical data by two nuclear medicine experts. Results of both studies were compared with each other and with the known surgical site of resection (15 temporal and 3 extratemporal). **Results**: PISCOM and SISCOM showed localizing findings in the same cerebral lobule in 15/18 (83.33%) cases. The SF was correctly identified as compared to surgical resection brain area and post-surgical outcome in 15/18 patients by both PISCOM and SISCOM, with a good concordance among them (global agreement of 88.89% and a Kappa coefficient equal to 0.60). In two cases only one of the studies (PISCOM or SISCOM) correctly identified the SF. In two subjects both modalities failed to correctly identify SF, one of them with both PISCOM and SISCOM concordant incorrect localizing findings. In 4/18 (22%) cases MRI (not blinded from clinical data and other tests) failed to identify SF: three of them were successfully identified by both PISCOM and SISCOM, and in the remaining case SF was exclusively identified by PISCOM. **Conclusions**: Even though further research is needed, the preliminary findings of this new processing nuclear imaging technique are promising as a high rate of PISCOM/SISCOM concordance for correct seizure focus localization has been found. Possibly, with further development of the PISCOM technique, the need to obtain interictal SPECT images could be minimized or even be avoided and replaced by interictal FDG-PET images.

OP201

Grey matter metabolism in relation with white matter lesions in older hypertensive patients with subjective memory complaints: a pilot voxel-based analysis study

A. Verger[1], G. Hossu[2], A. Kearney-Schwartz[3], S. Bracard[4], V. Roch[1], A. Van der Gucht[1], R. Fay[5], A. Benetos[3], P. Marie[1], L. Joly[3]; [1]Nuclear Medicine Department CHRU Nancy, Nancy, FRANCE, [2]CIC-IT, CHRU Nancy, Nancy, FRANCE, [3]Geriatric Medicine Department CHRU Nancy, Nancy, FRANCE, [4]Neuroradiology CHRU Nancy, Nancy, FRANCE, [5]CIC-P, CHRU Nancy, Nancy, FRANCE.

Aim. This study aimed at assessing the changes in brain metabolism, related to white matter magnetic resonance (MR) hyperintensities of presumed vascular origin, with a voxel-based quantitative analysis of [^{18}F]-fluorodesoxyglucose Positron Emission Tomography (FDG-PET) imaging. **Methods.** Sixty older hypertensive patients with subjective memory complaints (75±5 years, 34 women) were prospectively referred to FDG-PET and MRI brain imaging. The Statistical Parametric Mapping software was used to assess the correlation between brain distribution of FDG and white matter hyperintensities assessed by the Fazekas score on MRI images. **Results.** The Fazekas score was inversely related to FDG uptake, independently of age and gender, within 14 Brodmann areas located mainly in the frontal lobe but also in certain limbic, insular and temporal areas. This relationship was also found to be largely independent of the volume of grey-matter expressed in % of cranial volume, an index of atrophy. **Conclusions.** White matter MR hyperintensities of presumed vascular origin are cross-sectionally associated with a lower grey-matter metabolism, mainly but not only within frontal areas and independently of age, gender and grey-matter atrophy. **Keywords:** White matter lesions, Brain FDG-PET, Brain MRI, hypertension.

OP202

Moderate regional differences in sequential FDG brain PET images caused by bio-kinetic heterogeneity can be detected regardless of the acquisition technique (static vs. flow-motion)

G. Berding[1,2], F. Wilke[3], M. Kessler[1,2], N. Owsianski-Hille[1], M. Mamach[1,2,3], L. Geworski[3], F. Bengel[1]; [1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Cluster of Excellence Hearing4all, Hannover Medical School, Hannover, GERMANY, [3]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY.

Aims Sequential F-18-Fluorodeoxyglucose (FDG) brain-PET within 70min post injection revealed a characteristic difference pattern in regional glucose metabolism (relative frontal increase and cerebellar decrease). We evaluated, if this pattern can be related to bio-kinetic differences between brain regions and is present at later time points as well. Moreover, we investigated, whether a new acquisition technique, flow motion - aiming for increased uniformity of the sensitivity profile in axial (z) direction - is capable to detect such differences equally to static imaging. **Methods** 108 FDG brain-PET/CT (Biograph mCT, Siemens) scans were enrolled. In three groups of oncologic patients (mean-age 56, 24 female) without malignancy in the brain or neuropsychiatric disease always two sequential scans were acquired at the following times post injection: (i) n=21, flow-motion 84min, static 108min, (ii) n=23, static 78min, flow-motion 105min, (iii) n=10 static 82 and 112min. After proportional scaling of PET data, VOI and SPM analyses were applied (paired t-test). Additionally, 9 dynamic 50min FDG brain scans without appreciable findings were enrolled (mean patient-age 58, 3 female). These scans were quantified including simultaneously obtained arterialized venous blood samples using a 2-tissue compartment model with and without fitting for k4 (PMOD 2.9). **Results** Based on VOI data the most pronounced differences ($p<0.0025$) in all three comparisons were: uptake increase early to late in frontal cortex (Flow-motion/static: +2.8%, static/flow-motion: +1.1%, static/static: +2.2%) and relative decrease early to late in cerebellum and occipital cortex (Flow-motion/static: -2.5%, -0.8%, static/flow-motion: -2.1%, -1.6% static/static: -2.7%, -1.8%). Clearly the same pattern was detected in SPM analyses. Bio-kinetic modeling revealed significantly higher net influx of FDG in the frontal cortex compared to the cerebellum (Ki: 0.034 vs. 0.018, p=0.001). Conversely, k4 was significantly higher in the cerebellum compared to the frontal cortex (0.021 vs. 0.016, p=0.002). **Conclusions** The difference pattern between sequential FDG scans up to 70min post injection is also observable later. Therefore constant uptake duration has to be ensured in longitudinal studies even for late imaging time points. The difference

pattern seems to be caused by a bio-kinetic heterogeneity, notably higher influx and lower reflux of FDG in the frontal cortex compared to the cerebellum. Relatively higher occipital uptake in early images might be related to the eyes open condition after tracer injection in oncologic patients. Since the present differences could be detected regardless of the acquisition technique (flow-motion vs. static) both seem to be interchangeable in follow-up scans of brain glucose metabolism.

OP203
18F-FDOPA PET for the differential diagnosis between brain tumor recurrence and radiation necrosis: correlation with pathological results obtained from surgery

J. Darcourt[1,2], M. Dufour[1], A. Schiazza[1,2], F. Almairac[3], C. Zwarthoed[1], V. Bourg[3], M. Ouvrier[1], P. Bondiau[1], D. Benisvy[1], L. Mondot[3], F. Vandenbos[3,2]; [1]Centre Antoine Lacassagne, Nice, FRANCE, [2]Université de Nice, Nice, FRANCE, [3]CHU, Nice, FRANCE.

During the follow-up of patients treated for a malignant brain tumour, the differential diagnosis between recurrence (REC) and radiation necrosis (RN) is often difficult on MRI (pseudoprogression···). 18F-FDOPA PET can be used in this situation. We report on a retrospective study in which PET 18F-FDOPA findings are compared to pathological results obtained from surgery. **Materials and methods** 25 patients mean age 59 years old (11M; 14F) were included: 10 GBM, 3 grade III oligoastrocytomas, 12 metastases. They were studied after initial treatment by 18F-FDOPA PET for differential diagnosis between recurrence and radiation necrosis. A 10 min static PET-CT was performed 20 min post injection of 2 MBq/kg of 18F-FDOPA (mCT-Siemens; OSEM 5 it and 24 subsets). MRI T1 weighted images were coregistered to PET data. Images were graded visually using Lizarraga et al. criteria (JNM 2014), comparing tumour uptake with striatal activity: 0 lesion not visible, 1 uptake inferior to striatum, 2 lesion uptake equal to striatum and 3 uptake higher than striatum. PET was considered positive for a score > 1. SUV values were measured for quantitative analysis. All patients underwent neurosurgery for suspicion of REC based on MRI and PET data (mean delay 37 days; 8-70). The final diagnosis of REC and RN was based on pathologist diagnosis. Aminoacid transporter LAT1 expression was measured by immunohistochemistry using a semiquantitative score (from 0 to 400). **Results** 20 patients showed REC and 5 RN. 18F-FDOPA PET was positive in all REC and was negative in 3 and positive in 2 of the 5 RN (sens 100%; spec 60%). Tumour to striatum SUV values were significantly higher in REC ($p<0,005$) than in RN. The 2 false positive 18F-FDOPA patients had high astrocytic LAT1 expression (270 and 300) despite pure RN without REC explaining 18F-FDOPA uptake. **Conclusion** In the difficult situation of post initial treatment differential diagnosis between REC and RN in brain tumours, 18F-FDOPA PET has a high sensitivity. However, over expression of LAT1 in radiation necrosis tissues may decrease its specificity.

Pediactric low-dose CT: How low can we go?

G. Caan, **A. Almeida**, M. Segbers; ErasmusMC, Rotterdam, NETHERLANDS.

Aim: It is well known that pediatric patients are more sensitive to radiation than adults. We therefore reduced the dose for low-dose CT's in this patient group. We studied the effect on image quality and investigated the behavior of Automatic Exposure Control (Caredose4D) for pediatric patients. Materials and Methods:We performed a retrospective study of 40 patients scanned on Siemens Biograph mCT40 and 128 slice scanners. To reduce dose, scanner parameters were set to 80kV and 40 reference mAs (ref.mAs). In comparison adults are scanned at 120kV and 40 ref.mAs. Patients ranged from 1 to 16 years of age, with body mass varying from 6.5kg to 58kg and length from 0.68m to 1.65m. To quantify image quality in all subjects, a circular ROI with a fixed diameter of 3cm was drawn in one slice in a homogeneous part of the liver. The noise level was derived by computing the standard deviation (SD) within the ROIs. The noise level was used as a parameter for image quality. The noise was then correlated to patient parameters as body mass, bodymass per length and BMI. Results: Eff.mAs values were in between 20 and 40 mAs. CT dose index (CTDI) was from 0.39 to 1.82. The range of SD was 27 to 89 with a mean value of 54.SD showed the best significant correlation with body mass per length($p < 0.001$, $R^2=0.3$) and BMI ($p < 0.001$, $R^2=0.3$). Bodymass gives $p < 0.001$, $R^2=0.25$. In general, image quality was best for the smallest patients. For larger patients the image quality was reduced. All parameters showed a significant correlation with CTDI. The best significant correlation was found for body mass length($p < 0.001$, $R^2 = 0,6$). CTDI remained virtually constant (0,40-0,50) for patients up to 45 kg. Over 45 kg

there was a clear increase of dose. Conclusion: The scan protocol resulted in unwanted variations in image quality (noise). CareDose4D does not adapt the dose such that the image noise level is constant across all patient sizes. Image noise for large patients was too high. The dose should be increased in our pediatric low-dose CT protocol.

OP212

Feasibility study of a human tissue equivalent phantom for PET/CT

M. Szoliková[1], G. Nagy[1], A. Forgács[1], M. Zentai[2], I. Garai[1]; [1]ScanoMed Ltd., Debrecen, HUNGARY, [2]Mediso Medical Imaging Systems, Budapest, HUNGARY.

Aim: A proper CT based attenuation correction of a positron emission tomography (PET) image is essential for reliable quantification. To check the comparability of the goodness of the attenuation corrections applied by different manufacturers makes the necessity of a phantom, which can represent the whole range of the attenuation coefficient specific for human body. In the study we aimed to create an in-house human tissue equivalent phantom, which includes lung, fat, muscle and bone equivalent material containing F-18 isotope. **Methods:** The lung equivalent compartment was Styrofoam® beads surrounded by F-18 and water solution ((-650 Hounsfield Unit (HU))- (-800 HU)), as it is frequently applied for anthropomorphic phantoms. To mimic the fat tissue, firstly the F-18 FDG synthetized in water was evaporized, then it was diluted in isopropyl alcohol, finally it was mixed with the oil. With this method a homogeneously distributed F-18 FDG isotope was created in oil in the range of (-50) - (-100) Hounsfield Unit (HU), accordingly to the fat HU range. The muscle was simulated by ballistic gel mixed with F-18 FDG, resulting (+50) - (+100) HU material. The bone was a hollow shin bone of a cattle. Finally the phantom was measured on two PET/CT scanners. **Results:** F-18 FDG diluted in ballistic gel and oil were feasible to extend the HU scale. The phantom covered the whole Hounsfield Unit spectrum of human body, measured from the lung till the bone. With the help of this phantom the two compared PET/CT systems provided the same standard uptake values within 3% error. **Conclusion:** The introduction of the ballistic gel and the oil as a possible candidate of new phantom material, facilitates the construction of a human tissue equivalent phantom to assist a new way of comparing PET/CT scanners.

OP213

Radiation dose reduction using a bismuth-coated latex shield over the eye lens in Brain SPECT/CT

N. Matsutomo[1], M. Fukunaga[2], T. Yamamoto[1], H. Onishi[3]; [1]Kyorin University, Mitaka, JAPAN, [2]Kurashiki Central Hospital, Kurashiki, JAPAN, [3]Prefectural University of Hiroshima, Mihara, JAPAN.

Purpose For brain SPECT/CT, although CT images provide precise anatomical information and accurate attenuation correction, their use increases the radiation dose to the patient, especially to the eye lens. The eye lens is particularly radiosensitive: ICRP has reviewed that the threshold in absorbed dose for the eye lens is considered to be 500 mGy. Therefore, because of the radiation effect, the eye lens is at high risk when brain SPECT/CT is performed. The purpose of this study was to assess the usefulness of a bismuth-coated latex shield (B-shield) as an eye protectant during brain SPECT/CT. **Methods** Three types of B-shields containing heavy metal bismuth (0.15, 0.25 and 0.35 mm lead equivalent) were employed. Each B-shield was pleased over the cylindrical phantom and the eyes of a 3-dimensional brain phantom filled with Tc-99m solution. Subsequently, SPECT/CT was performed on the phantoms both with and without the B-shields. The CT scan parameters were set to 30-200 mA and 130 kV. Dose reduction due to the supposed radioprotection was measured using a pencil-shaped ionization chamber. In addition, the image artifacts (changes in CT number), linear attenuation coefficients, coefficients of variation (CV) on SPECT images and the relative radioactivity concentrations were evaluated for the protective effect of the B-shield. **Results** The B-shields decreased the average radiation dose by 60.1%, 68.6% and 73.5%. The radiation doses with/without the B-shield were 0.62-0.93 mGy and 2.31 mGy. Although increasing the mean CT number caused by B-shield, it was just beneath the surface level on the phantom. Beam hardening was detected as streaks of higher density in close proximity to the underside of the B-shield. The linear attenuation coefficients and CVs were not significantly different between phantoms with/without the B-shield. The relative radioactivity concentrations when using Tc-99m were not affected by B-shield thickness. **Conclusions** The B-shields decreased the radiation dose without affecting attenuation correction or radioactivity concentration. Although B-shields increased artifacts in the surface level, the SPECT image quality was acceptable. The use of B-shields could prove beneficial in pediatric patients and those with preexisting eye disease.

OP214

Design and physical performance of a plastic scintillator detector to control radioactive waste in a nuclear medicine unit

F. Zito[1], A. D'Alessio[2], G. Galetta[3], L. Rossi[2], R. Benti[1]; [1]FONDAZIONE IRCCS CA' GRANDA Ospedale Maggiore Policlinico, Milan, ITALY, [2]Specialization School of Medical Physics Università di Milano, Milan, ITALY, [3]Specialization School of Medical Physics Università di Milano, FONDAZIONE IRCCS CA' GRANDA Ospedale Maggiore Policlinico, Milan, ITALY.

Purpose: Management of solid radioactive waste produced in a nuclear medicine unit (NM-unit) has to be arranged according with country regulatory requirements. For disposal of waste, containing radionuclides with half life less than 75 days, the exempt activity concentration < 1 Bq/g is fixed by the Italian regulation. Aim of the present work is to describe physical performance of a plastic scintillator detector dedicated to control boxes containing contaminated solid materials produced during nuclear medicine activities (residuals of radiopharmaceutical preparations and administrations, absorbing papers and tissues contaminated by biological fluid of administered patients and any object suspected of contamination). Methods : Three polyvinyl-toluene (PVT) modules, each of 35 cm x 15 cm size and 2 cm thickness coupled to a photomultiplier (PMT), were assembled to realize a 35 cm width x 45 cm height detector surface (ELSENUCLEAR Milan-Italy). This surface sufficiently covered the largest face of the waste box. After assessing background level, sensitivity was determined for the principal radionuclides used in a typical NM-unit: ^{99m}Tc, ^{123}I.^{131}I, ^{111}In and ^{18}F. For each radionuclide a calibrated radioactive solution was prepared and a source realized with 0.5 ml volume in a tube of 1 cm diameter was positioned at the container center at a distance of 15 cm from the detector surface. Minimum detectable activity (MDA) at 4.65 standard deviation of the background (SD-bkg) and at 2 SD-bkg were determined. Sensitivity for a ^{137}Cs point source with certified activity was also assessed and used for periodical check of equipment stability response. A mean weight of 4 Kg was supposed for waste containers. The dectector system was equipped with auditory and red light allarms activated when net counts of the container under control are higher or equal to the set threshold level. Results: Background level was 350 cps. For 1 minute acquisition, for all considered radionuclides, moving from the lowest to the highest energy radionuclides (^{99m}Tc, ^{123}I. ^{111}In, ^{131}I, ^{18}F) MDA values were: 4.4, 3.4, 2.5, 1.6, 0.7 KBq at 4.65 SD-bkg and 1.8, 1.4, 1.1, 0.7 and 0.3 KBq at 2 SD-bkg By assuming the 4Kg mean weight of the containers MDA resulted sufficiently lower than exempt activity concentrations (< 1 kBq/ kg). For ^{137}Cs the sensitivity was 750 net cpm/KBq. Conclusion: The designed PVT detector showed good sensitivity and a threshold set to 2SD-BKg is suitable and conservative to control radioactivity concentrations of waste containers produced by a conventional NM-unit.

OP215

Evaluation of the use of the scatter limit option to reduce wash-out artefacts on the GE Discovery 710

C. Abreu, L. C. Pike; PET Imaging Centre, Division of Imaging Sciences and Biomedical Engineering, King's College London, King's Health Partners, St. Thomas' Hospital, London, London, UNITED KINGDOM.

Patient motion during PET/CT acquisitions causing misalignment between CT and PET images can result in wash-out artefacts due to incorrect scatter correction scaling. The GE Discovery 710 includes a scatter limit (SL) option in the reconstruction to limit scaling and reduce artefacts.The aim of the study was to investigate image quality and quantitative accuracy using the SL option for ^{18}F-FDG-PET/CT for eliminating wash-out artefacts.This study analysed wash-out artefacts in ^{18}F-FDG PET/CT images acquired from 81 patients and from a NEMA image quality phantom. Images were acquired of the NEMA image quality phantom using six hot spheres (10, 13, 17, 22, 28 and 37mm diameter) to background ratio of 4. To simulate arm motion, a cylinder of 8.5 cm radius was filled with the same ^{18}F solution as the phantom background. PET/CT data were acquired with the arm correctly aligned and then the cylinder misaligned on CT. A hot syringe was placed by the side of the cylinder and on top of the phantom, to simulate a tissued injection. PET data were reconstructed using ordered subset expectation maximisation (OSEM) with and without time-of-flight (TOF) information. Images were also reconstructed using a propriety GE reconstruction 'QClear'. Comparisons were made of the PET images reconstructed with the correctly aligned CT versus the misaligned CT both with and without the SL option on. Clinical PET images were retrospectively reconstructed without the scatter correction and with SL on, and analysed for the presence of artefacts. With SL off, the maximum error between matched and mismatched images was 83.8, 72.1 and 54.7% for non-TOF, TOF and QClear, for the 10mm sphere. The highest percentage errors for the 10 and 37mm spheres were 83.6% and 50.5% with SL off and 40.1% and 57.8% with SL on, respectively. There was improvement in quantitative accuracy for all spheres and background with SL on. From the 81 patients analysed, 3 of those required rescanning. Whilst image quality was improved using SL, quantitative accuracy was still significant with underestimation of uptake in the region near the artefact. SL worked better eliminating artefacts caused by arm motion. The results of our study show using SL is useful and could be used clinically to reduce wash-out artefacts and improve quantitative accuracy. The SL option must be used with caution particularly if there is a lesion in the vicinity of the artefact, rescanning may still be required so a clinical opinion should be sought.

OP216

Radiation Exposure of the Nuclear Medicine Personnel during new therapy procedures, the Lutetium-177 DOTATATE Production, Administration and Imaging

B. G. Hoving, B. J. de Wit-van der Veen; Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.

Introduction The Antoni van Leeuwenhoek hospital started with Lu-177-DOTATATE therapy. The administered dose is 7,4 GBq per cycle which is repeated every 10 weeks for 4 cycles. To assess the dose distribution, 4 post-injection scans are performed each cycle. Thus for 25 patients, 100 productions and 400 extra scans per year are needed, resulting in a potentially increase of radiation dose to our personnel. **Aim** This study will determine the impact of Lu-177-DOTATATE therapy on the radiation dose of the personnel involved in the labelling, quality control (QC), dose administration and imaging procedure. **Materials and Methods** The Lu-177-DOTATATE therapy workflow is divided into three sub-procedures; I. production (including labelling using the automated system, QC and syringe preparation), II. patient administration, and III. imaging. Lu-177 DOTATATE is prepared on a fully automated system (Scintomics GmbH, Germany), QCs are performed with HPLC and administration was done using a shielded dispensing cart. The durations of all actions were denoted, and a dose rate monitor (Thermo Eberline ESM FH 40 G-L) was used to estimate the dose rate for each action. We measured during 5 productions, 4 administrations and 16 imaging procedures. **Results** The administered dose to the patient was 7233 ± 55 MBq. On average, the dose rate during production was 7.2 μSv/h, with removing the Lu177-DOTATATE vial after labelling (35 μSv/h) and preparing the synthesis system (13.9 μSv/h) being the most crucial steps. The dose rate during administration was 5.6 μSv/h, with the crucial actions being dismantling of the cart (7.9 μSv/h) and patient transport to the scanner (14.8 μSv/h). Imaging had an average dose rate of 21.4 μSv/h, with helping the patient throughout the first scan as critical action (52.6 μSv/h). Still, the time-corrected total average dose during production, administration and imaging was 3.1, 5.2 and 8.3 μSv, respectively. The radiation dose to one person from a Lu-177 DOTATATE cycle is 16.6 μSv, with a total handling time of 2 hours and 25 minutes. **Conclusion** The impact of the 4 patients with 1 cycle Lu-177 therapy on the personnel radiation dose is rather small, 66.3 μSv. The Lu-177 therapy of 25 patients leads to an extra radiation dose of 1.66 mSv per year. This extrapolated dose will be divided over >10 persons of different disciplines. The current effective dose to technicians is below the legal annual limit (< 6 mSv/yr) with an average dose of 1.5 mSv/yr in our hospital.

OP217a

A European phantom study to cross-calibrate myocardial ^{123}I-mIBG scintigraphy

E. Poel[1], D. O. Verschure[1], K. Nakajima[2], K. Okuda[3], B. L. F. van Eck-Smit[1], G. A. Somsen[4], H. J. Verberne[1]; [1]Academic Medical Center, Amsterdam, NETHERLANDS, [2]Kanazawa University Hospital, Kanazawa, JAPAN, [3]Kanazawa Medical University, Uchinada, JAPAN, [4]Cardiology Centers of the Netherlands, Amsterdam, NETHERLANDS.

Aim: Planar ^{123}I-*meta*-iodobenzylguanidine (^{123}I-*m*IBG) scintigraphy is a highly reproducible technique to assess cardiac sympathetic activity and helps differentiating high and low risk heart failure patients. ^{123}I-*m*IBG has a small inter- and intra-observer variation. However differences in the collimators used is one of the most important factors that cause variation in the commonly used heart-to-mediastinum ratio (H/M) among institutions and studies. Therefore standardization among various gamma camera-collimator combinations is needed. reviously a phantom for ^{123}I-*m*IBG planar imaging has been developed to cross-calibrate different acquisition conditions in Japan. However, data from European institutions is still lacking. Therefore, to further cross-calibration of ^{123}I-*m*IBG in Europe, the aim of this study was to accumulate ^{123}I-*m*IBG data for the H/M from common vendors in Europe. **Methods:** A total of 163 phantom experiments were performed in 21 institutions in Austria, Belgium and the Netherlands to calculate cross-calibration coefficients of H/M. Based on the phantom study, a conversion coefficient for each gamma camera-collimator system was created, including low-energy (LE) (n = 93) and medium-energy (ME) (n = 70) collimators. An average conversion coefficient from the most common ME group was used to calculate a standardized H/M.**Results:** On average the LE collimator derived H/Ms were significant lower compared to the ME-collimator derived H/Ms. The mean conversion coefficients from the individual gamma camera-collimator combination to the mathematically calculated reference H/M ranged from 0.53 to 0.67 for the LE collimator group and from 0.91 to 1.00 for the ME collimator group. A conversion coefficient of 0.88 was established that unifies H/Ms from all acquisition conditions. **Conclusion:** H/Ms can be converted into standardized H/Ms by using the reference H/M and

conversion coefficients for each acquisition condition. This standardization is also important for identifying appropriate thresholds for differentiating high and low risk heart failure patients. In addition this cross-calibration would enable a better comparison between European and Japanese data.

OP217b

Audit on staff exposure when administering Radium 223 Dichloride Therapy

A. S. F. Ribeiro, S. Summers, L. Causer, T. Shepherd, I. Murray, J. Gear, G. Flux, M. Meintjes, Y. Du; Royal Marsden Hospital, Sutton, UNITED KINGDOM.

Background: Prostate cancer is the fourth most common cancer in both sexes combined and the second most common cancer in men. In 2012 an estimated 1.1 million men worldwide were diagnosed with prostate cancer according to the World Health Organization. Radium dichloride therapy (^{223}Ra) has a half-life of 11.4 days which emits short-range alpha-particles with high-energy that selectively targets areas of increased bone turnover such as bone metastases. A range of methods to administer ^{223}Ra have been reported from using protective suits with face masks to more commonly personal protective equipment such as gloves and aprons. This audits intends to evaluate our current practice with regards to staff exposure and method of administration of ^{223}Ra. Materials and Methods: Since 2004 we have been involved with administering ^{223}Ra. We currently perform an average of four patients a week (clinical and research). Data from 18 administrations was collected over a period of 3 months. Specialized techniques, such as two staff members for therapy administration, use of personal protective equipment (double gloves, apron and Inco pad sheets) are current practice when administering the therapy within our general Nuclear Medicine Service. Administration is currently performed under the Ionising Radiations Regulations 1999 (IRR99) by a team of four experienced members of staff (two clinical nurse specialists; two nuclear medicine research technologists). The average patient activity was 4.35 MBq of ^{223}Ra , ranging from 3 MBq - 6.7 MBq. A dose meter was used at a 50 cm distance from the syringe (approximate distance from administrator to syringe) as well as Electronic Personal Dosimeter (EPD). Results: Our data showed the average dose rate from administering the therapy was 3.67 μSv/hr (±1.4) No EPD readings were observed for all 18 administrations. The room monitoring (injection chair; trolley and surrounding areas) and self-monitoring were both not significant. Conclusion: This audit confirmed that according with the methods and practices used in our service, most Nuclear Medicine Departments can potentially deliver this treatment, providing adequate staff training is in place as well as good communication with all teams involved. ^{223}Ra can be administered with safety for both patients and staff involved.

OP218

Design and Development of a Dedicated Robotic SPECT System for Cardiac Imaging

M. R. Ay[1], B. Teimourian[2], S. Sajedi[1], A. Akbarzadeh[1], S. Kaviani[1], M. Farahani[1], S. Farzanefar[3], Z. Shapouri[1]; [1]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Faculty of Physics and Nuclear Engineering, Amir Kabir University of, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Depatment of Nuclear Medicine, Valiasr Hospital, Tehran University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: Cardiac imaging has become an integrated part in the diagnostic and prognostic work-up of patients with cardiovasular disease. In order to improve the quality of cardiac imaging dedicated cardiac scanners with small file of view introduced in last couple of years. We designed and developed a dedicated cardiac SPECT system in our lab for cardiac imaging called RoboSPECT. This name was chosen because of robotics motions of detectors and arms in this scanner. The reclining seat design of the scanner provides maximum patient comport. It should be noted two perpendicular detector heads designed and optimized for cardiac imaging. The aim of this study is to introduce the concept design of the scanner and also evaluates and characterizes the performance of RoboSPECT based on NEMA-NU2 2007 standards for gamma cameras. **Method:** The detector of the scanner is based on NaI(Tl) crystal and 24 rectangular PMTs (76x76 mm) in 4x6 form cover the detection area. Rectangular shape of PMT allows the full coverage of active crystal area without any dead zone. The scannr equipped with LEHR lead Parallel-hole collimators with 1.5 mm hexagonal holes, 35 mm hole length, and 0.2 mm septal thickness. The gantry of the scanner is based on robotic motion of both arm and detectors that fixed in 90 degree position. All readout electronic in the detector designed based on our US patient called non linear recursive filter. **Results:** The experiments showed that the intrinsic spatial resolution was 3.6 mm on the surface of crystal. The system spatial resolution and the sensitivity of the system on the collimator surface were 7.8 mm and 179 cps/MBq, respectively. The extrinsic energy resolution resolution was determined as about 9.3 %. In addition, the integral uniformity and the differential uniformity, after uniformity correction, in UFOV were measured 2.2% and 1.2%, respectively. Also the absolute and differential linearity were evaluated 0.8 and 0.1 mm in UFOV. In order to validate the accuracy of images acquired by this scanner 50 patients were scanned both with RoboSPECT and ADAC camera. The results showed good agreement between the images of both scanners. **Conclusion:** This study showed that the designed scanner called RoboSPECT has acceptable performance for cardiac imaging.

Role of single-nucleotide polymorphisms (SNPs) of glucose transporter 1 (GLUT1) in differentiated thyroid cancer (DTC) patients

V. Stebner[1], N. Becher-Boveleth[1], S. Ting[2], A. Sabet[1], A. Bockisch[1], J. Nagarajah[3]; [1]Department of Nuclear Medicine, Medical Faculty, University Duisburg-Essen, Essen, GERMANY, [2]Department of Pathology, Medical Faculty, University Duisburg-Essen, Essen, GERMANY, [3]Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES.

Aim: The human genome has about 35 million SNP. Some SNP are more common than other. Our aim was to identify SNP, which are presented more frequently in patients with DTC or which change for the worse of this disease. GLUT1 is up regulated in solid tumors like DTC and patients with higher standardized uptake values (SUV) on F-18-FDG (FDG)-PET show a poorer prognosis. For this we evaluated the effect of the three mostly reported SNP XbaI, HpyCH4V and HaeIII for the GLUT1 on progression free survival and overall survival in DTC patients. Methods: A total of 69 patients (P) with DTC and a follow-up of minimum 60 months were included in this retrospective study. All these patients had archival tumor free tissues for SNP analyses. Restriction fragment length polymorphism (RFLP) technique was used to identify SNP. Progression was defined as either increasing Tg-values and/or progress on imaging. FDG-PET was performed for all P and SUVmax was used to quantify glucose uptake. Kaplan Meier curve was made for progression-free and overall survival. Results: The allele frequencies were: XbaI G>T: G=0,37 , T=0,63; HpyCH4V A>T: A=0,15 , T=0,85; HaeIII T>C:

T=0,17, C=0,83. XbaI GT has a shorter PFS than GG/TT (Median: GT 23 months (m) vs. GG/TT 55,5 m; p=0,045). The PFS of HpyCH4V and HaeIII show a strong correlation with each other (p=0,0001). There is an implied correlation between Xbal and M-stage. There is a linear trend between Xbal and UICC-stage. Xbal GT shows a higher SUVmax. in FDG-PET/CT than GG/TT. Conclusion: Xbal GT SNP of GLUT1 seems to be correlated with a lower PFS and a higher SUVmax. HpyCH4V and HaeIII seems to co-occur in these patients.

OP220

Circulating Tumor Cells, a New Prognostic Factor In Minimally Invasive Follicular Thyroid Carcinoma

C. Badulescu[1,2], A. Piciu[1,2], M. Larg[1], E. Barbus[1], C. Pestean[1], M. Saftencu[2], O. Barbos[1], G. Chereches[1], N. Bejinariu[1], **D. Piciu[1,2]**; [1]Institute of Oncology, CLUJ-NAPOCA, ROMANIA, [2]University Of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, ROMANIA.

Introduction: Follicular thyroid carcinoma (FTC) is a well-differentiated carcinoma, with a worldwide incidence of 5-15 %. FTC has been classified, according to histological criteria, as minimally invasive (MIFC) or widely invasive carcinoma (WIFC). Objectives: The aim of this study was to determine the presence of circulating tumor cells (CTC) in the blood of patients with MIFC, in order to define the treatment and the prognosis. **Methods:** Between January-June 2015, we conducted a study on 16 cases of MIFC who underwent total thyroidectomy. One month after the surgery, we recorded: gender, age, histological features, tumor size, serum thyroglobulin (Tg) and we analyzed the presence of CTC from venous blood on an immunomagnetic segregation method. **Results:** Females were 81.3%; the mean +/- SD age was 47.2 +/- 15.79 years. The tumoral size mean+/- SD was 2.2 +/- 1.74 cm; 5 patients had tumor size <1 cm; 5 patients presented capsular and vascular invasion, 4 only capsular invasion; 10 patients out of 16 had CTC present one month after surgery, with values ranging between 1 CTC/6ml to 13 CTC/6ml. This study shows the relation between the type of invasion and CTC value. Patients with a change in CTC status from positive to negative had a good prognosis, as well as patients without baseline CTC. **Conclusion:** This study opens the opportunity to improve the management of MIFC, making the CTC status a part of the therapy algorithm. Further studies are needed to determine the accuracy of the test and its role in the long-term follow-up.

OP221

Predictive and prognostic value of 18F-DOPA PET/CT in patients affected by recurrent medullary carcinoma of the thyroid

F. Caobelli[1], A. Chiaravalloti[2], L. Evangelista[3], M. Vadrucci[4], F. Scalorbi[5], D. Donner[5], P. Alongi[6], Y. Working Group[1]; [1]Universitätsspital Basel, basel, SWITZERLAND, [2]Università Cattolica del Sacro Cuore, roma, ITALY, [3]Istituto Oncologico Veneto, padova, ITALY, [4]Università Milano Statale, Milano, ITALY, [5]Hospital of Trento, Trento, ITALY, [6]San Raffaele G. Giglio Institute, Cefalu' (PA), ITALY.

Background. Medullary thyroid carcinoma (MTC)is a malignancy that originates from thyroid parafollicular C cells and accounts for about 5% of thyroid cancers.The measurement of calcitonin in washout fluids of thyroid nodule aspirate is widely used to monitor disease progression.However, prognostic factors to predict outcomes and allow the planning of the most appropriate therapy are highly warranted.18F-DOPA PET/CT has been investigated in patients with MTC, and showed promise in diagnosing, staging, detecting recurrent lesions, and monitoring treatment response.Specifically, this technique has been demonstrated to be superior to 18F-FDG PET/CT in detecting disease recurrence, also for low carcinoembryogenic antigen(CEA)and calcitonin levels. It remains unclear, whether 18F-DOPA PET/CT can have a prognostic role in the restaging process. **Methods.**60 patients affected by MTC(mean age: 63.6±13 years, range 44-82 years)were eligible from a multicenter database. All patients underwent a restaging 18F-DOPA PET/CT,performed at least 6 months from surgery or first-line therapy.CEA/calcitonin levels, local recurrences, nodal involvement and distant metastasis at PET/CT were recorded. SUVmax-SUVmean (normalized using mediastinal uptake as reference) and metabolic tumoral volume were automatically calculated for each lesion, by placing a volume of interest (VOI)around the lesion with a 30% threshold.The patients were clinically and radiologically followed up for a period of 19±10 months. ROC curve was used to determine the best cut-off value for CEA and calcitonin to predict a positive PET/CT.Progression free survival (PFS) and overall survival (OS) were calculated by using Kaplan-Meier curves. Increased odd ratio was also assessed using Cox regression analysis by testing all parameters associated to the lesions revealed. **Results.**Optimal thresholds to predict a recurrence of disease at 18F-DOPA PET/CT were 400 ng/L for calcitonin (AUC 0.81; p<0.001) and 5 ng/ml for CEA (AUC 0.78; p=0.007).PFS was significantly longer in patients with a negative PET/CT scan (median survival: 37 vs 29 months respectively for negative and positive PET; p=0.019). Similarly, a negative PET/CT study was associated with a significantly higher 2-year OS than a positive PET/CT examination (100% vs 61%; p<0.001). The hazard ratio for OS of a positive PET/CT study was 4.3 (95% confidence interval: 1.244-8,982). Neither SUVmax nor SUVmean thresholds were found to be predictive of a worse PFS and OS in patients with recurrent MDT. **Conclusions.** A high correlation between 18F-DOPA PET/CT results and biochemical assessment was demonstrated.Moreover, PET/CT seems to have an important prognostic value in predicting disease progression and mortality rate. Therefore, an effective therapy planning might effectively rely on 18F-DOPA PET/CT findings.

OP222

^{68}Ga-HBED-CC-PSMA PET/CT to visualize PSMA expression in metastatic differentiated thyroid cancer

S. Lütje[1], B. Gomez[1], J. Cohnen[1], L. Umutlu[1], M. Gotthardt[2], T. D. Poeppel[1], A. Bockisch[1], S. Rosenbaum-Krumme[1]; [1]University Hospital Essen, Essen, GERMANY, [2]Radboud university medical center, Nijmegen, NETHERLANDS.

Aim: The prostate-specific membrane antigen (PSMA), which was originally thought to be specific for prostate carcinoma, was recently shown to be overexpressed on endothelial cells of the neovasculature of several malignancies. Here, we evaluate the role of ^{68}Ga-HBED-CC-PSMA (^{68}Ga-PSMA) PET/CT for the detection of PSMA expression in patients with metastasized differentiated thyroid cancer (DTC). **Material and methods:** Five patients with ^{131}iodine-negative and [^{18}F]-fluorodeoxyglucose (FDG)-positive metastasized DTC (mean TG: 1906.2 ng/ml) received 80±9 MBq of the ^{68}Ga-labeled PSMA ligand and underwent PET/CT at 61±7 min p.i.. 2 patients additionally underwent ^{68}Ga-PSMA PET/MRI. Data were analyzed regarding the tumor accumulation capacity of the tracer and the detection rate of local recurrences and metastases compared to [^{18}F]-FDG. Tracer uptake was quantified in terms of the maximal standardized uptake value (SUV_{max}) within a spheroidal volume of interest (VOI). A characterization for malignancy was made in consensus taking into account existing prior examinations. **Results:** In all patients, sites of putative metastatic disease could be identified using ^{68}Ga-PSMA PET/CT. All lesions detected with ^{68}Ga-PSMA PET/CT (n=50) could be visualized with ^{68}Ga-PSMA PET/MRI. The tumor lesions detected included local recurrences (2/5 patients), lymph node lesions (5/5 patients,), bone lesions (4/5 patients) as well as soft-tissue metastases (5/5 patients). Using ^{68}Ga-PSMA PET/CT and PET/MRI, all tumor lesions identified with [^{18}F]-FDG-PET/CT imaging could be visualized in 3/5 patients. In 2 patients, only the most prominent lesions detected with [^{18}F]-FDG-PET/CT imaging were visualized with the PET component of

^{68}Ga-PSMA PET/CT and PET/MRI. ^{68}Ga-PSMA uptake ranged from low in 1 patient (mean SUV_{max} 3.3) to intermediate (1 patient, mean SUV_{max} 6.1) to intense (3 patients, mean SUV_{max} 12.8, 16.2 and 18.3). The highest SUV_{max} were observed for soft-tissue lesions, reaching 39.7. **Conclusion:** These preliminary results indicate that ^{68}Ga-PSMA PET/CT and PET/MRI are suitable for staging of patients with metastasized DTC. ^{68}Ga-PSMA PET/CT and PET/MRI could be useful for the identification of patients that might qualify for PSMA-based endoradiotherapy due to high PSMA uptake.

OP223

68Ga-PSMA HBED-CC PET/CT imaging may be useful in detection of differentiated thyroid cancer: a comparative study with 68Ga-DOTA-TATE PET/CT and 18F-FDG PET/CT imaging

B. Vatankulu[1], E. Akgün[1], M. Ocak[2], E. Demirci[1], L. Uslu[1], S. Sağer[1], M. Halaç[1], L. Kabasakal[1], K. Sönmezoğlu[1]; [1]İstanbul University Cerrahpaşa Medical Faculty Department of Nuclear Medicine, İstanbul, TURKEY, [2]İstanbul University Cerrahpaşa Medical Faculty Department of Pharmacy, İstanbul, TURKEY.

Aim: The prostate-specific membrane antigen (PSMA) is overexpressed in the neovasculature of several malignancies, therefore it might serve as a target in oncology. Although 68Ga PSMA HBED-CC PET/CT (PSMA PET/CT) is most commonly used in the diagnosis of prostate cancer, few cases described that PSMA PET/CT could show avid uptake in differantiated thyroid cancer (DTC). The aim of this study was to evaluate the diagnostic value of PSMA PET/CT in DTC and to compare with 68Ga DOTA-TATE PET/CT (TATE PET/CT) and FDG PET/CT imaging. **Materials and methods:** Twelve DTC patients with progressive rising thyroglobulin (Tg) levels and negative iodine-131 wholebody scan were prospectively enrolled to this study. All patients underwent PSMA PET/CT and TATE PET/CT and FDG PET/CT scan were performed to 10 of 12 patients within interval of two months. PET/CT analysis was done based on a lesion wise, location wise and per patient basis. PET/CT lesion were examined in according to four categories as local, nodal, pulmonary and skeletal. Detection rates of metastatic lesions were compared between all these functional imaging studies. **Results:** The study group consisted of 8(67%) females and 4(33%) males with a mean age of 58 years. The mean levels of Tg and anti-thyroglubulin were 616.5 mg/dl (min-max:38.2-1000 mg/dl) and 166.4 pg/dl (min-max:20-207 pg/dl) with thyroid hormone suppression therapy, respectively. In patient based analysis, we observed at least one focus of abnormal uptake in 11 of 12 patients in both of PSMA and TATE PET/CT, 10 of 12 patients in FDG PET/CT scans. One of 12 patients who had lower Tg levels (38.3 mg/dl) compared to other patients had no pathological uptake in both PSMA and TATE PET/CT scan. In the lesion based analysis, 92 lesions were detected with FDG PET/CT, 159 lesions with TATE PET/CT and 154 lesions with PSMA PET/CT. There are no difference in location wise analysis between all imaging modalities.**Conclusions:** PSMA PET/CT may be an efficient imaging modality in DTC patients with increased Tg levels for localizing metastatic disease.

OP224

[68Ga]DOTATATE-PET/MRI and [18F]FDG-PET/CT are complementary and superior to diffusion weighed MR imaging for radioactive-iodine-refractory differentiated thyroid cancer

A. Vrachimis, L. Stegger, C. Wenning, M. Schäfers, B. Riemann, M. Weckesser; University Hospital Münster, Münster, GERMANY.

Purpose: Whether [68Ga]DOTATATE-PET/MRI with diffusion weighted imaging (DWI) can replace or complement [18F]FDG-PET/CT in patients with radioactive-iodine-(RAI)-refractory differentiated thyroid cancer (DTC). Methods: 12 thyroidectomized and remnant ablated DTC patients underwent [18F]FDG-PET/CT and [68Ga]DOTATATE-PET/MRI within 8 weeks of each other. Localization of recurrent cancer was evaluated on a per-patient, per-organ and per-lesion basis. Histology, prior and follow-up examinations served as standard of reference. Results: Tumor masses were correctly identified in all of the 11 from 12 DTC patients with RAI-refractory tumor burden by [68Ga]DOTATATE-PET(/MRI), whereas one patient with local relapse was missed by [18F]FDG-PET/CT. In the lesion based analysis overall lesion detection rates were 79/85 (93%), 69/85 (81%) and 27/82 (33%) for [18F]FDG-PET/CT, [68Ga]DOTATATE-PET/MRI and DWI respectively. [18F]FDG-PET(/CT) was superior to [68Ga]DOTATATE-PET(/MRI) in the overall evaluation and with regards to detection of pulmonary. For the extrapulmonary metastases, [68Ga]DOTATATE-PET(/MRI) showed a superior sensitivity over [18F]FDG-PET(/CT), to the disadvantage of specificity. On the contrary, DWI achieved only poor sensitivity rates and was significantly different from [18F]FDG-PET in the lesion based overall evaluation, pulmonary metastases and overall evaluation excluding pulmonary metastases. Conclusion: [18F]FDG-PET/CT overall performs better than [68Ga]DOTATATE-PET/MRI in RAI-refractory DTC mostly due to the superiority in the detection of lung metastases. However, in the evaluation of extrapulmonary lesions [68Ga]DOTATATE-PET(/MRI) is the more sensitive and [18F]FDG-PET(/CT) the more specific imaging modality. Furthermore, DWI is not essential in clinical PET/MRI protocols and cannot replace [18F]FDG-PET for monitoring postoperative DTC patients with suspected RAI-refractory tumor burden.

OP225

The relationship of mRNA ABCC1 expression and uptake of MIBI-Tc99m in patients with hyperparathyroidism

M. Listewnik[1], H. Piwowarska-Bilska[1], M. Kurzawski[1], K. Safranow[1], M. Ostrowski[1], A. Borowiecki[1], M. Laszczyńska[1], M. Chosia[1], K. Jasiakiewicz[2], J. Iwanowski[1], T. Sulikowski[1], **B. Birkenfeld**[1]; [1]Pomeranian University of Medicine in Szczecin, SZCZECIN, POLAND, [2]Independent Public Clinical Hospital No 1 in Szczecin, SZCZECIN, POLAND.

Introduction: The genetic factors influencing parathyroid MIBI-Tc99m uptake in patients with hyperparathyroidism were postulated in many publications. The aim of our study was to elucidate this issue. Material and Methods:A total number of 332 (93 men and 239 females) prospectively investigated patients, aged 11-89 (mean 56,1)years, referred to nuclear medicine department for preoperative parathyroid scintigraphy with clinical, biochemical and/or sonographical suspicions of hyperparathyroidism were included for analysis. Primary, secondary and tertiary hyperparathyroidism was diagnosed in 241 (72,6%), 79 (23,8%), 12 (3,6%) patients, respectively. All of them were genotyped for MDR1 (ABCB1) and MRP1 (ABCC1) genes. They underwent double phase-one tracer ("washout") SPECT/CT scintigraphy with MIBI-Tc99m. All together 413 scintigraphic examinations with 618 lesions of increased tracer uptake (early and delayed planar scintigraphy) were analyzed. Among them 70 patients were operated. During surgery 116 tissue specimens suspected for parathyroid adenoma were removed and in 69 of them mRNA expression was analyzed. Results: Different parameters of MIBI-Tc99m uptake in parathyroid adenoma was calculated. Maximal uptake in tumor divided by uptake in 10 minutes (TBR10max) and 120 minutes (TBR120max) background after i.v. injection showed statistically significant relationship (p=0,00034 and p=0,000914 for TBR10max and TBR120max, respectively) with mRNA expression of MRP1 (ABCC1) gene. Conclusion: Genetic background for MIBI-Tc99m uptake was confirmed and relationship of mRNA ABCC1 expression and TBR max in early and delayed phase was found. Carbon-11-Methionine PET/CT derived functional parameters in patients with primary hyperparathyroidism reflect PTH-secretory activity of parathyroid glands: a retrospective single-centre evaluation

C. Caldarella[1], S. Annunziata[1], M. Isgro'[2], A. Giordano[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [2]Clinical Chemistry and Hematology Laboratory, Ospedale di Circolo e Fondazione Macchi, Varese, ITALY.

Aim: Positron Emission Tomography/Computed Tomography (PET/CT) using Carbon-11-Methionine (C-MET) is a reliable imaging method for detecting abnormal parathyroid glands in patients with primary hyperparathyroidism (pHPT). Uptake mechanisms of C-MET in abnormal glands are not yet fully understood, although it is presumed to be involved in the synthesis of PTH precursors. Aim of our study was to determine whether C-MET PET/CT-derived functional parameters reflect PTH-secretory activity. **Materials and Methods:** Medical records of patients with pHPT undergoing C-MET PET/CT from September 2014 to January 2016 were reviewed. Patients with renal failure and/or no evidence of C-MET uptake were excluded. Intact serum PTH (iPTH) levels were collected. Several PET/CT-derived functional parameters of C-MET-positive lesions, such as SUVmax, SUV-R (lesion SUVmax/SUVmean of lungs) and functional lesion volume (FLV) at SUVmax thresholds 40%, 70% and 90% of SUVmax (FLV_{40}, FLV_{70} and FLV_{90}, respectively) were obtained. Different regression models were explored and relative R^2 coefficients evaluated to assess a possible correlation between these functional parameters and abnormal glands' secretory activity expressed as iPTH levels. Mann-Whitney U-test was performed to detect a possible association between FLVs values and positive/negative findings on neck ultrasonography and/or ^{99m}Tc-MIBI scintigraphy. **Results:** According to the aforementioned criteria, 25 patients with pHPT were included. SUVmax, SUV-R, FLV_{40}, FLV_{70} and FLV_{90} median values were 3.73 [interquartile range (IQR) 2.87-5.22], 7 [IQR 5.52-11.39], 0.77 cm^3 [IQR 0.4-1.46], 0.32 cm^3 [IQR 0.16-0.71] and 0.12 cm^3 [IQR 0.06-0.16], respectively. Regression models performed (linear, power, sigmoid and exponential) showed a positive correlation between iPTH levels and C-MET PET/CT functional measures, even though at different degrees. Among all, FLV_{70} showed to better correlate with iPTH levels, according to an exponential model ($R^2 = 0.959$, $P<0.001$), thus demonstrating an excellent direct linear relation between FLV_{70} measure and $\log_n$[iPTH] or $\log_{10}$[iPTH]. Only FLV_{40} resulted significantly higher in 13/23 patients with positive findings on ^{99m}Tc-MIBI scintigraphy (median 1.38 cm^3, IQR 0.51-2.75 *vs* median 0.59 cm^3, IQR 0.23-0.84; $P = 0.03$). **Conclusions:** In a small cohort of patients with pHPT, for the first time, we propose C-MET PET/CT functional parameters as in-vivo reliable measures of PTH-secretory activity of abnormal glands, demonstrating a remarkably high positive relation between FLV_{70} and iPTH levels. The potential clinical usefulness of these findings still has to be determined; however, the possibility to non-invasively explore the biochemical behaviour of abnormal glands may allow to take the first steps towards a deeper insight in pHPT physiopathology.

Zr-89 Labelling of Immunotherapeutic Tumour Specific T-Cells to measure L-Selectin Dependent Homing in a Murine Cancer Model

S. J. Paisey, J. Ohme, C. Marshall, A. Ager; Cardiff University, Cardiff, UNITED KINGDOM.

Aim: L-selectin sufficient tumour specific T cells have been shown to control the growth of solid tumours more effectively than L-selectin deficient cells1. This is thought to be due to L-selectin mediated homing to sentinel lymph nodes where T cells are activated by tumour derived antigens. The aim of this study was to label murine tumour specific CD8+ T-cells with Zr-89-Oxine and use micro-PET/CT to follow L-selectin dependent homing to lymphoid organs and tumour tissue following adoptive transfer to tumour bearing mice. Materials and methods: Freshly harvested CD8+ T cells from L-selectin sufficient and L-selectin deficient CD90.2 mice were labelled with Zr-89 Oxinate4 using published methods 1,2 and cell viability was assessed by trypan blue staining. Labelled cells were then injected intravenously via the tail vein into CD90.1 mice which were PET/CT scanned for up to 14 days after injection. Cell distribution was assessed by roi assessment of images and confirmed by flow cytometric and immunohistochemical analysis of post mortem tissues for donor CD90.2 cells. Results: Labelling yields of up to 2MBq in 20x106 cells were obtained without significantly reducing cell viability. Labelled cells survived in vivo and cell tracking was possible for the imaging period. Significant differences between the biodistribution of L-selectin deficient and L-selectin sufficient cells CD8+ were observed. The radioactive biodistribution pattern matched the distribution of CD90.2 donor cells in lymphoid and non-lymphoid organs observed at post mortem. Conclusions: The Zr-89 Oxine cell labelling technology can be translated to track the migration pathways of immunotherapeutic cell grafts. This technology will be used in future studies to dissect the relationship between T lymphocyte accumulation inside tumour tissue and tumour progression. Feasibility of gene-transferred glucagon-like peptide 1 receptor gene as a novel imaging reporter gene

Y. Zhang[1], Y. Pan[1], J. Lv[1], M. Yang[2], D. Pan[2]; [1]Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [2]Ministry of Health, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Nuclear medicine molecular imaging techniques, especially the radionuclide reporter gene imaging systems, could provide much information on underlying processes at the molecular level or noninvasively monitor the fate of transplanted therapeutic cells, which have attracted considerable attention. Glucagon-like peptide 1 receptor (GLP-1R) is a G protein-coupled receptor, the natural or analogue ligands of which have been radiolabelled in different methods and mainly been used to image the GLP-1R highly-expressing normal (e.g. islets β cells) or abnormal (e.g. insulinoma) tissues in recent studies. In this study, we firstly put forward the idea of utilizing this GLP-1R gene and its radionuclide-labelled ligands as a novel receptor-based reporter gene imaging system. We constructed the human GLP-1R gene within a baculoviral vectors, which combined the adeno-associated virus-derived inverted terminal repeats for higher transgene expression (BV-AAV). Real-time PCR revealed that BV-AAV vectors-mediated GLP-1R mRNA expression level in human umbilical cord blood-derived mesenchymal stem cells (hUCB-MSCs) was about 6-fold higher than INS-1 insulinoma cells type and much higher than another insulinoma cells type RIN-m5f. Micro-PET imaging with synthetic radiotracer [^{18}F]AlF-NOTA-MAL-Cys^{39}-exendin-4

showed that the BV-AAV-infected hUCB-MSCs were clearly imaged at 30, 60 and 120 time points after radiotracer administration with an excellent target-to-background ratio, while the mock-infected cells were not detected. And the radiotracer accumulation could be blocked by high-dose exendin-4 administration. In addition, the rodent endogenous GLP-1R expressing tissues like pituitary gland, lung and pancreas were imaged as well. These results indicated that the gene-transferred GLP-1R gene has the tremendous potential of being ideal and broadly accepted radionuclide reporter gene, considering its distinctive advantages like excellent target-to-background ratio, less endogenous GLP-1R interference, and numerous types of deeply developed radionuclide-labelled ligands, some of which (like the radiotracer in this study) even has the blood-brain-barrier passing effects, also implying its great potential in brain reporter gene imaging.

Feasibility of Gallium-68 Chelates as Diffusible PET Tracers for Cardiac Imaging

S. España[1], T. Arias[1], C. Velasco[1,2], J. Pellico[1,2], F. Herranz[1,2], J. Ruiz-Cabello[1,2], J. Mateo[1,2]; [1]CNIC, Madrid, SPAIN, [2]Ciber de Enfermedades Respiratorias (CIBERES), Madrid, SPAIN.

Introduction PET radiotracers for assessment of myocardial perfusion include $^{13}NH_3$, ^{82}Rb and $H_2{}^{15}O$. However, their short half-life limits widespread clinical use due to the need of a nearby cyclotron (^{13}N and ^{15}O) or of expensive generators (^{82}Rb). Furthermore, current techniques for assessment of extracellular volume fraction (ECV) as late gadolinium-enhancement MRI are limited for detection of diffuse or interstitial myocardial fibrosis and have limited spatial coverage. In contrast, $^{68}Ge/^{68}Ga$ generators have a low cost and provide easy access to positron emitting radionuclides compared with those produced by a cyclotron. We propose the use of ^{68}Ga-DOTA PET imaging for quantification of myocardial perfusion and ECV. The results obtained in pig studies are presented here. **Methods** Pigs with induced cardiac infarcts by 40 min ischemia of the left anterior descending coronary artery followed by chronic reperfusion where used in the PET/CT studies 7- (n=5) and 45-days (n=5) after infarction. In addition, a series of PET scans at intervals of 30 min were obtained in healthy pigs (n=4) during intravenous infusion of adenosine (0, 100, 200, 400, 600, and 800 mg/kg/min). Each PET scan was performed as a 10-min dynamic scan started 50 s before tracer injection (~100 MBq). ^{68}Ga-DOTA was intravenously injected as a 10-s bolus with an automated pump. The amount of free tracer in plasma was determined from blood samples withdrawn at different time-points under rest and stress conditions. Segmentation of the myocardium, ventricles and aorta was performed. Time-activity curves were introduced in a single-tissue compartment model implemented obtaining the perfusion and ECV values at the ROI and voxel levels. **Results** Myocardial perfusion values obtained in the infarcted areas were significantly reduced in comparison to remote regions in both groups, 7- and 45-days post-infarction. ECV was considerably increased in the infarcted areas in pigs 7-days after infarction while the other group showed only minor increase. Polar plots showing full myocardial information were also obtained (see figure 1). Dose-response studies with adenosine showed an increase in perfusion that was in agreement with previous studies using different radiotracers[2]. **Conclusions** ^{68}Ga-DOTA PET allowed us to successfully quantify myocardial perfusion and ECV in pigs with induced myocardial infarction and in healthy pigs. This technique provides wide access to quantitative measurement of both perfusion and ECV with PET imaging.

Imaging atherosclerosis of aortic arch and pulmonary arteries with ^{18}F-FDG and ^{18}F-NaF in high-fat western diet ApoE knockout rats

X. Zhuang[1], F. Yue[2], Q. You[2], Y. Chen[2], J. Li[1]; [1]General Hospital of Ningxia Medical University, Yinchuan, CHINA, [2]Southwest Medical University, Luzhou, CHINA.

Aims: Inflammation and calcification are risk factors of atherosclerosis, but their relationship is still unknown. This study was designated to investigate the correlation of inflammation and calcification, and the difference of atherosclerotic plaque between aorta and pulmonary arteries using ^{18}F-FDG and ^{18}F-NaF PET/CT imaging in high-fat western diet apoE knockout rats. **Materials and Methods:** Male ApoE knockout rats (n=19) (Biocytogen, Beijing, China) were maintained on high-fat western diet (42% fat) from 12 wk. Combined PET and CT imaging was performed with a hybird scanner (Siemense Inveon PET/CT) at 12 wk (before high-fat western diet), 27 wk and 46 wk. Rats were imaged at 1 h after ^{18}F-FDG or ^{18}F-NaF injection after 12 h fasting. Maximal and mean standardized uptake values (SUV_{max} and SUV_{mean}) were measured over aortic arch and pulmonary arteries. Gross examination and dissection microscopy also were performed. **Results:** Plaque regions have not shown to take ^{18}F-FDG and ^{18}F-NaF always simultaneously. Uptake of ^{18}F-FDG is mainly on aortic arch, meanwhile ^{18}F-NaF on pulmonary arteries. From 12 wk to 46 wk, uptake of ^{18}F-FDG on aortic arch and ^{18}F-NaF on pulmonary arteries is increased, related to the size of lesions. In aorta, ^{18}F-FDG SUV_{mean} is increased from 1.17±0.38 to 1.44±0.48 to 1.87±0.62, respectively, SUV_{max} from 1.96±0.73 to 2.66±1.17 to 3.45 ±1.36, respectively, both $p<0.05$. In left pulmonary artery, ^{18}F-NaF SUV_{mean} is increased from 0.69±0.09 to 0.79±0.24 to 0.95±0.38, respectively, SUV_{max} from 1.01±0.16 to 1.33±0.26 to 1.50±0.48, respectively, both $p<0.05$. In right pulmonary, ^{18}F-NaF SUV_{mean} is increased from 0.82±0.12, to 0.85±0.21, to 0.91±0.31, respectively, SUV_{max} from 1.12 ±0.15 to 1.33±0.28 to 1.43±0.4, respectively, both $p<0.05$. Morphological observations show that atherosclerotic lesions in pulmonary arteries were severer than in aortic arch. **Conclusion:** Based on apoE knockout rat studies, we found that atherosclerotic uptake of FDG and NaF is different between pulmonary and aortic arch, implying that calcification is independent of inflammation in atherosclerosis, and inflammation is not the precondition of calcification. **Research Support:** This work was supported by the NNSF of China (No.81360226).

Dynamic PET/CT Receptor Imaging Using ^{68}Ga-Labelled asialoglycoprotein

q. xia; Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Background: Liver asialoglycoprotein receptor (ASGPR), a specific endocytic receptor on the surface of hepatocytes, is an accurate index reflecting liver reserve function, and the quantity of ASGPR expression directly reflects the level of functional reserve of the liver. This study was the development of labeling the ASGP using ^{68}Ga to construct a new type of positron molecular probe ^{68}Ga-NOTA-LSA to target ASGPR in the liver for the potential use with dynamic PET/CT imaging.**Methods:** LSA was synthesized by conjugating α-lactose to human serum albumin (HSA) by reductive amination. LSA was conjugated with 2- (p-isothiocyanatobenzyl) -1,4,7-triazacyclononane-1,4,7-triacetic acid (SCN-NOTA) and the resultant NOTA-LSA was labeled with ^{68}Ga at 37 °C . For quality control thin-layer chromatography (TLC) technique were evaluated. Stability of ^{68}Ga-NOTA-LSA was studied in phosphate-buffered saline (PBS). Biodistribution and dynamic PET/CT studies of ^{68}Ga-NOTA-LSA were performed in SD rat following tail vein injection of radiotracer. Time-activity curves (TAC) for liver and other organs were generated and corresponding parameters calculated.**Results:** ^{68}Ga-NOTA-LSA can be produced with high radiochemical purity. The best TLC methods for determining potential free ^{68}Ga include 0.1 M sodium citrate as eluent. Stability after 120 min incubation at 37 °C was high in PBS (>95 % intact tracer). Biodistribution and animal PET/CT studies showed specific retention of ^{68}Ga-NOTA-LSA in liver following intravenous administration. ^{68}Ga-NOTA-LSA rapidly accumulated and persisted mainly in the liver at 40mins after injection. Other organs including heart, bone,

marrow, kidney and bladder with the uptake were much lower than liver.**Conclusion:** This study provides a promising new ^{68}Ga-labelled compound for evaluation of hepatic function by PET/CT is important for optimizing treatment and improving the prognosis of functional diseases of the liver.

OP232

^{68}Ga/PET imaging and quantification of fibrosis using peptide-based tracers

I. Velikyan[1,2], U. Rosenström[3], O. Eriksson[2], G. Antoni[2]; [1]Uppsala PET Centre, Uppsala, SWEDEN, [2]Division of Molecular Imaging, Uppsala University, Uppsala, SWEDEN, [3]Division of Organic Pharmaceutical Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim: Positron emission tomography (PET) being a powerful non-invasive and quantitative molecular imaging technique may enable accurate diagnosis and progression monitoring of fibrosis involved in many chronic diseases. Imaging agents specifically targeting collagen present in fibrotic tissue are under development for the realization of such diagnostic technology. **Materials and Methods:** Eighteen amino acid residue cyclic peptide conjugated either to 2-(4,7-bis(2-(tert-butoxy)-2-oxoethyl)-1,4,7-triazonan-1-yl)acetic acid (NOTA(tBu)$_2$) or 4-(4,7-bis(2-(tert-butoxy)-2-oxoethyl)-1,4,7-triazacyclononan-1-yl)-5-(tert-butoxy)-5-oxopentanoic acid (NODAGA(tBu)$_3$ via ethylene glycol linker (EG$_2$) was synthesized and labelled with ^{68}Ga. Organ distribution in rat was investigated ex vivo at 5, 10, 20, 40, 60, and 120 min time points as well as in vivo by dynamic scanning for both imaging agents. The pharmacokinetics was analyzed. The extrapolation of the biodistribution data was conducted for the estimation of human organ and total body absorbed and total effective doses using Organ Level Internal Dose Assessment Code software (OLINDA/EXM 1.1) assuming similar organ distribution pattern between the species. **Results:** The peptide bioconjugates were synthesized with chemical yield ranging from 40 to 55%. The subsequent ^{68}Ga-labelling demonstrated high radioactivity incorporation of over 90%. Ex vivo and in vivo organ distribution results demonstrated fast blood clearance and renal excretion. The analogues differed in total charge of the [^{68}Ga]Ga-chelator moiety which resulted in the lower uptake in liver, spleen, and kidney for the positively charged one. The dosimetry estimations revealed the highest organ absorbed dose was for kidneys (0.1 mGy/MBq), still it would allow for the administration of over 1460 MBq per year. It was the total effective dose that was the limiting parameter for both analogues, allowing for at least six examinations with total administration of 621 to 643 MBq yearly before reaching the annual limit of 10 mSv. **Conclusions:** Peptide based agents for the imaging of fibrosis by PET were developed and preclinically investigated. The rat organ distribution of the analogues differed in liver, spleen, and kidney uptake dependent on the total charge of [^{68}Ga]Ga-chelator moiety. The fast radioactivity clearance from normal lung, heart, and liver was observed indicating strong potential for the visualization of fibrosis in these organs. Dosimetry estimations revealed possibility of at least six examinations per year that might be sufficient for the adequate disease monitoring in longitudinal studies and routine clinical setup.

Metabolic pattern of transgenic mice overexpressing lipocalin-2: a microPET study

A. Buschiazzo[1], F. Ticconi[1], E. Principi[2], L. Garaboldi[1], A. Bozzano[1], A. Orengo[1], I. Calamia[1], S. Morbelli[1], C. Ghersi[1], A. Democrito[1], C. Marini[3], S. Tavella[2], G. Sambuceti[1]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa and IRCCS AOU San Martino-IST, Genoa, ITALY, [2]Laboratorio di medicina rigenerativa e ingegneria dei tessuti, Department of Experimental Medicine, University of Genoa and IRCCS AOU San Martino-IST, Genoa, ITALY, [3]CNR Institute of Bioimages and Molecular Physiology, Section of Genoa, Genoa, ITALY.

Aims. Recent literature suggests that the overexpression of Lipocalin-2 (Lcn2) contributes to the development of metabolic syndrome through largely ignored mechanisms. To explore Lcn-2 target tissues, we tested glucose consumption in the whole body and in specific tissues (skeletal muscle-SM, brown adipose tissue-BAT and liver) of wild type (WT, n=6) and transgenic mice overexpressing Lcn2 (Lcn2-Tg, n=6). **Materials and Methods.** The Licensing and Ethical Committee approved animal experiments. All mice were submitted to FDG-PET imaging after 6 hours fasting with a dedicated microPET system (Albira, Bruker, US) injecting 3-4 MBq of FDG through a tail vein, soon after start of a list-mode acquisition lasting 50 minutes. Animals were studied, twice in random sequence, 15 minutes after intraperitoneal glucose load (1.5 g/Kg) or saline with a time gap of two weeks. A volume of interest (VOI) was manually drawn in the left ventricular chamber to define tracer input function that was used to estimate glucose metabolic rate (MRGlu) in BAT and SM of hindlimb using the Patlak routine of a dedicated software (PMOD, Zurich, CH). To avoid the interference of variable hormone concentrations, liver tracer handling was estimated only under fasting conditions by a previously validated approach that combines arterial input function with tracer-concentration curves in gut and liver VOIs. **Results.** Fasting serum glucose level was lower in Lcn2-Tg than in WT mice (76 ±38 vs 144±38 mg/100mL, respectively, $p<0.05$) but not after glucose load. However, this effect was not related to increased monosaccharide utilization. In fact, whole body glucose disposal, calculated with the conventional stochastic analysis, was lower in Lcn2-Tg than in WT mice under fasting conditions (0.19±0.15 vs 0.42±0.13 μmol/min/g body weight, $p<0.05$), but not after glucose load. Similarly, MRGlu was significantly lower in Lcn2-Tg than in WT mice both in SM (0.23±0.31 vs 1.57±1.42 μmol/min/100 g, $p<0,05$) and BAT (12.5±6,5 vs 5,8±4,9 μmol/min/100 g, $p<0,05$). Again, this difference disappeared after glucose load. Moreover, under fasting conditions, tracer entrapment in hepatocytes (k_{mf}) was significantly higher in Lcn2-Tg than in WT mice (0.11±0.05 vs 0.001±0.001 min^{-1} $p<0.01$) while FDG dephosphorylation rate (k_{fm}) was superimposable in both groups. **Conclusion.** In mice overexpressing Lcn-2, serum glucose level is reduced under fasting condition. This behaviour reflects an increased liver entrapment of FDG by phosphorylation and not an increased glucose utilization by peripheral tissues.

OP234

Pretargeting trastuzumab and cetuximab with 18F-tetrazine tracer

O. Keinänen[1,2], J. Pourat[2], J. S. Lewis[2,3], A. J. Airaksinen[1], M. Sarparanta[1,2]; [1]Laboratory of Radiochemistry, Department of Chemistry, University of Helsinki, Helsinki, FINLAND, [2]Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES, [3]Program in Molecular Pharmacology, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES.

Aim: We have used ^{18}F-labeled tetrazine (5-[^{18}F]fluoro-5-deoxy-ribose-tetrazine, [^{18}F]TAF)[1] for *in vitro* pretargeting of two clinically used antibodies, trastuzumab and cetuximab. Pretargeted PET-imaging experiments are currently underway. Trastuzumab is known to internalize making it possibly out of reach for a tracer that doesn't internalize. We wanted to explore the sensitivity of [^{18}F]TAF to locate trastuzumab inside living cancer cells and compare this to pretargeting cetuximab, that is mainly bound to the cell membrane. **Materials and methods:** Trastuzumab and cetuximab were functionalized with TCO groups (2 TCO-groups/antibody). Pretargeting of HER2 expressing cancer cells with trastuzumab was tested using BT-474 and SKOV3 cell lines. A549 cell line was used for pretargeting EGFR expressing cancer cells with cetuximab. The cells (1x10^6 per well on a 6-well plate) were preincubated with TCO-antibody in DMEM media for 60 min at 37 °C (n=6), followed by incubation with [^{18}F]TAF in cell media for 60 min at 37 °C. The free and cell-associated fractions of radioactivity were determined by automated gamma counting. Three control sample sets were used. First control had 50 eq. excess of antibody incubated (60 min at 37 °C) with the cells

before incubating with TCO-antibody. In second control 100 eq. excess of cold TAF was added to compete with the [^{18}F]TAF. In third control [^{18}F]TAF was incubated with cells without preincubation with TCO-antibody. **Results:** *In vitro* binding of [^{18}F]TAF to TCO-antibody pretreated cells exceeded nonspecific uptake by untreated cells over 10-fold, 20-fold, and 8-fold in BT474, SKOV3, and A549 cells, respectively. A significant reduction of radioactivity bound to cells was observed when presaturated with antibody or under competition with large excess of cold TAF. **Conclusions:** We have demonstrated that [^{18}F]TAF binding depends on the interaction of TCO-antibody with receptors and on the reaction between [^{18}F]TAF and TCO, thus confirming *in vitro* pretargeting. Surprisingly, *in vitro* pretargeting was more efficient with trastuzumab than with cetuximab. Optimization of the *in vitro* assay is being done to ensure that the system hasn't been saturated with the amount of [^{18}F]TAF. *In vivo* pretargeted PET-imaging studies in xenograft models are currently underway. **Acknowledgements:**Supported by the Academy of Finland, CHEMS Doctoral Program, Memorial Sloan Kettering Cancer Center core grant P30 CA008748, Mr. William H. Goodwin and Mrs. Alice Goodwin and the Commonwealth Foundation for Cancer Research and The Center for Experimental Therapeutics at Memorial Sloan Kettering Cancer Center **References:** 1. ^{68}Ga-Pentixafor PET for Imaging of Chemokine Receptor CXCR4 in Patients with Breast Carcinoma and Correlation with Histopathology

T. Vag[1], A. Rossmann[1], S. Paepke[2], K. Steiger[3], M. Niemeyer[2], H. Wester[4], M. Schwaiger[1]; [1]Clinic of Nuclear Medicine, Klinikum Rechts der Isar, Munich, GERMANY, [2]Clinic of Gynecology, Klinikum Rechts der Isar, Munich, GERMANY, [3]Institute of Pathology, Klinikum Rechts der Isar, Munich, GERMANY, [4]Faculty of Pharmaceutical Radiochemistry, Technical University Munich, Munich, GERMANY.

Purpose: CXCR4 is a chemokine receptor that is overexpressed in several types of human cancers including breast cancer and is reported to have a key role in signaling pathways of metastases. The aim of this study was to assess the feasibility of CXCR4 directed imaging in patients with breast cancer using the novel CXCR4 targeted Positron Emission Tomography (PET) probe ^{68}Ga-Pentixafor. **Material and Methods:** 10 patients suffering from breast cancer (9 patients with primary breast cancer, one patient with local recurrent breast cancer) underwent PET imaging (either PET/MR or PET/CT) using ^{68}Ga-Pentixafor. The lesions included 9 invasive ductal carcinomas (IDC) and one invasive lobar cancer (ILC). Four of the patients were known to have lymph node or distant metastases detected by previously performed imaging modalities. Maximum standardized uptake values (SUVmax) and tumor-to-background ratios (T/B ratio) were determined in the breast cancer lesions and metastases and correlated with immunohistochemistry, when available. **Results:** 8 of 10 breast cancers were visually detectable with a mean SUVmax of 3.1 (range 1.7 to 4.5) and a mean T/B ratio of 2.8. The visually undetectable lesions included the case of ILC and one IDC (T2 Grade 2). Immunohistochemistry revealed highest CXCR4 staining intensity in the patient with local recurrent breast cancer which also showed highest T/B ratio of all examined lesions. Lowest CXCR4 staining intensity was observed in the visually undetectable case of ILC. T/B ratio of metastases were similar to T/B ratios of corresponding breast carcinomas. **Conclusion:** CXCR4 directed PET imaging of breast cancer is feasible. Based on our first observations in this small patient cohort, CXCR4 expression profile on the tumor cell surface seems to correlate with signal intensity in PET imaging. Moreover, CXCR4 expression of breast cancer metastases seems to be similar to primary lesions.

OP240
Metabolic tumor burden assessed by dual time point 18F-FDG PET/CT in breast cancer: Relation with tumor biology

A. Garcia Vicente[1], J. Pérez-Beteta[2], M. Tello Galán[1], D. Molina-García[2], G. Jiménez Londoño[1], V. Pérez-García[2], A. Martínez-González[2], F. Pena Pardo[1], Á. Soriano Castrejón[1]; [1]Nuclear Medicine Department. Hospital General Universitario de Ciudad Real, CIUDAD REAL, SPAIN, [2]Instituto de Matemática Aplicada a la Ciencia y a la Ingeniería. UCLM., CIUDAD REAL, SPAIN.

Aim: To investigate the influence of dual time point 18F-FDG PET/CT in the SUV and volume-based metabolic variables of breast lesions and their relation with biological characteristics and molecular phenotypes. **Material and methods:** Prospective study including 67 patients with locally advanced breast cancer (LABC). All patients underwent a standard 18F-FDG PET/CT (PET-1) followed by a delayed acquisition (PET-2). After breast tumor segmentation following a tridimensional methodology, semiquantitative metabolic variables (SUVmax, SUVmean and SUVpeak) and volume-based variables as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were obtained. Biologic prognostic parameters, such as the receptor status, p53 and HER2 expression, proliferation rate (Ki-67) and grading were obtained and molecular phenotypes and risk-classification [low: luminal A, intermediate: luminal B HER2 (-) or luminal B HER2(+) and high: HER2pure or triple negative] were established. Spearman test was used to study the relation between clinical and biologic variables with all the metabolic parameters. **Results:** Metabolic variables obtained in the PET-1 showed high and significant relations between them and the same happened for the obtained in the PET-2, except for the MTV and SUV variables (SUV max, SUV mean and SUV peak). PET-1 metabolic variables showed significant and high association with the obtained in PET-2 except for the MTV and SUV variables, with low but significant association. SUV variables showed associations with receptor status ($p<0.001$) and risk-classification attending phenotype ($p<0.005$). With respect to volume-based variables, only

TLG showed association with receptor status, risk-classification and grade (p=0.001, p<0.01 and p<0.05 respectively). Receptor negative tumors, high grade tumors and high-risk phenotypes showed higher values compared to the others. No association was found with the Ki-67, HER2 and p53 expression. **Conclusion:** Most of PET-1 SUV and volume-based variables were predictors of the obtained in PET-2. PET-derived parameters, such as the SUV variables and TLG, could act as predictors of tumor biology based on their association with histopathological factors of breast cancer.

OP241

Breast cancer grading of ^{18}F-FDG-PET/CT and patient-derived statistical features based on supervised machine-learning approaches

L. Papp[1], T. S. Nakuz[1], H. F. Magometschnigg[2], K. Pinker[2], A. Haug[1], T. H. Helbich[2], T. Beyer[3], M. Hacker[1], G. Karanikas[1]; [1]Medical University of Vienna, Division of Nuclear Medicine, Vienna, AUSTRIA, [2]Medical University of Vienna, Division of Radiology, Vienna, AUSTRIA, [3]Medical University of Vienna, Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA.

Introduction To date, breast cancer grading is possible only through histopathological biopsy analysis. We propose a novel, non-invasive method of tumour grading in breast cancer. Specifically, we had the following objectives: (1) to identify [^{18}F]FDG-PET/CT features and patient characteristics that correlate with tumour grades as derived from histopathological analysis, and (2) to define a novel computer-aided decision support system to automatically predict grading of breast cancer built on pre-selected features. **Materials and Methods** To date, 51 data sets ([^{18}F]FDG-PET/CT and histology-based grades ranging from G1 to G3 of which 44 were IDC and 7 ILC) of breast cancer patients were included. Tumour and reference regions (mediastinum) were delineated manually on PET/CT using the Hybrid-3D software (Hermes Nuclear Diagnostics, Stockholm, Sweden). The voxel values of each [^{18}F]FDG-PET tumor regions were normalized to the mean of the respective reference region to calculate tumour-to-background ratio (TBR). The following features were calculated for each tumour region from both [^{18}F]FDG-PET TBR and CT: mean, variance, min, max, volume (general); entropy, homogeneity, contrast, correlation, uniformity, dissimilarity (Textural grey-level co-occurrence matrix (GLCM)); coarseness, contrast, busyness (Textural neighbourhood grey-tone difference matrix (NGTDM)); and patient age (Non-image). To identify relevant key features for classifying tumours, a novel machine-learning algorithm was implemented that builds on evolutionary algorithm (EA) principles. In each iteration of the EA, a second machine-learning algorithm was executed over the residual features to optimize the variables of our classifier model by a Levenberg-Marquardt (LM) approach. The classifier model utilized weighted fuzzy clustering of features to grade breast cancer regions. The EA and LM methods were programmed to minimize the summed Receiver Operator Characteristic distance of the grade-groups. Our optimized classifier was validated (sensitivity and specificity) with histopathological grading serving as standard-of-reference. **Results** The EA algorithm selected the following features as relevant for classification: [^{18}F]FDG-PET TBR (min, max, variance, volume, entropy-GLCM, dissimilarity-GLCM, uniformity-GLCM, correlation-GLCM, busyness-NGTDM), CT (min, max, homogeneity-GLCM, contrast-NGTDM, correlation-GLCM) and patient age. Based on these features the LM algorithm provided the following sensitivity and specificity values for the grade groups: 98% and 94% (G1), 89% and 96% (G2), as well as 91% and 96% (G3), respectively. **Conclusions** We have successfully tested a novel machine-learning approach that automatically selects relevant features and optimizes classifier variables to generate a computer-aided decision making model for grading breast cancer patients.

OP242

Prognostic evaluation of ^{18}F-FDG-PET/CT in endometrial cancer

A. A. Lund[1,2], M. H. Vilstrup[1], K. Jochumsen[1,2], P. Høilund-Carlsen[1,2], S. Hess[1,3,2]; [1]Odense University Hospital, Odense, DENMARK, [2]University of Southern Denmark, Odense, DENMARK, [3]Hospital of Southwest Jutland, Esbjerg, DENMARK.

Aim: To ascertain if semi-quantitative measurements derived from ^{18}F-FDG-PET/CT can be used as prognostic markers in patients with newly diagnosed endometrial cancer. This may help stratify patients, who may benefit from a more aggressive treatment plan or closer surveillance. **Materials and methods:** Included were patients with high-risk endometrial cancer (grade 3 endometrial adenocarcinoma or non-endometrioid histology) or clinically suspected spread of disease at the time of initial diagnosis. All underwent ^{18}F-FDG-PET/CT before curatively intended treatment. The scans were evaluated using standard uptake values (SUVmax and partial volume corrected SUVmean) and whole-body partial volume corrected total lesion glycolysis (TLG), which were analyzed as prognostic factors in relation to overall survival. ROC curves were performed on all three PET measurements to find the optimal cut-off for predicting high risk of mortality. Multivariate COX proportional regression models were used for exploring the relationship between survival and the following explanatory variables: SUVmax, SUVmean, TLG and other known prognostic factors. **Results:** 83 patients (mean age 69.7 years, range 26.8-91.1) with high-risk endometrial cancer or suspected high FIGO stage were included. Mean follow-up time was 3.48 years (range 0.31-6.87), 24 patients died during follow-up. Regional lymph node involvement, lymphovascular space invasion, SUVmax and TLG were associated with overall survival in univariate analyses, whereas FIGO stage, histological type and grade, peritoneal cytology, and age were not. In multivariate analyses with adjustment for other known prognostic factors, a SUVmax of ≥14.3 and SUVmean of ≥12.7 of the primary tumor yielded a HR for higher risk of mortality of 3.18 (1.19-8.49) and 1.93 (0.80-4.68), respectively. Whole-body TLG of ≥176.1 yielded an HR of 5.70 (1.94-16.78) for higher risk of mortality in a multivariate analysis. **Conclusion:** Preoperative SUVmax and TLG showed potential as independent prognostic markers of overall survival in patients with high-risk endometrial cancer. SUVmean was not a strong prognostic marker in this patient group. SUVmax and TLG might help identify patients who could benefit from a more aggressive treatment strategy or closer surveillance.

OP243

Advanced ^{18}F-FDG PET/CT Imaging Analysis In Selected Series Of Breast Cancer Patients

L. Antunovic[1], F. Gallivanone[2], A. Sagona[1], G. Manfrinato[1], M. Sollini[3], M. Kirienko[1], I. Castiglioni[2], A. Chiti[3]; [1]Humanitas Clinical and Research Center, MILAN, ITALY, [2]Institute of Molecular Bioimaging and Physiology, National Research Council, MILAN, ITALY, [3]Humanitas University, MILAN, ITALY.

Aims Texture analysis of medical images has been proposed as a non invasive tool for tumour heterogeneity assessment, containing information about tumour histology, disease stage, tumour metabolism and even patient outcome. The main purpose of our study was to evaluate imaging biomarkers obtained from ^{18}F-FDG PET/CT enabling to 'in vivo' characterize breast cancer. **Methods** 44 patients with breast cancer (age 51,9±13,9, range 35-88 years), who underwent staging ^{18}F-FDG PET/CT over a time period of 4 years (2012- 2015), were reviewed. Thirty-nine patients had ductal invasive breast cancer, while 3 had lobular cancer; the remaining 2 were unclassified. According to molecular tumor subtype, 13 patients were classified as luminal A, 16 as luminal B, 6 as luminal B Her-2 positive, 5 patients had HER2-enriched tumor subtype and 4 were classified as basal-like tumors. Metabolic Tumor Volume (MTV) of breast lesions was obtained using a fully automatic

image segmentation method, combining an automatic threshold-based algorithm for the definition of MTV and a k-means clustering algorithm for the estimation of the background. Average and maximum SUV of the primary lesion were calculated within the segmented MTV. Mean SUV was corrected for partial volume effect and Total Lesion Glycolysis (TLG) was calculated as the product between mean SUV and MTV. Texture-based features were evaluated using the segmented MTV. Fourteen features were extracted as first order statistics features enabling to describe the characteristics of the histogram of the PET voxel intensities within the segmented MTV. Four shape and size features were extracted, enabling to describe the shape and size of the segmented MTV. Univariate correlation between imaging quantitative features and histological parameters was performed and values of $p \leq 0.05$ were considered significant. **Results** On image analysis, considering standard quantitative measures, statistically significant correlation was found between partial volume corrected (PVC)-SUV and tumor grade ($p<0.05$), Ki67 level ($p=0,01$), overexpression of HER2 receptor ($p<0,05$) and presence of local vascular invasion ($p<0,05$); PVC-TLG also correlated with Ki67 level ($p<0,05$). Histogram Energy was found correlated with tumor grade ($p<0.002$), Ki67 level ($p<0,01$) and molecular subtype ($p<0,05$), while other intensity-based features (maximum, mean, median, root mean square) correlated with molecular tumor subtype ($p<0,05$). **Conclusions** This initial experience generate interesting data from PET images, beyond standard quantitative parameters. Further analysis are needed in order to define clinical impact of these features, especially regarding correlation with patient outcome.

OP244

Reproducibility of Response Assessment in Metastatic Breast Cancer Patients with Contrast-enhanced CT and FDG PET/CT

L. Lebron[1], C. Riedl[1], N. Long[1], K. Pinker-Domenig[1,2], W. Weber[1]; [1]Memorial Sloan-Kettering Cancer Center, New York, NY, UNITED STATES, [2]Medical University Vienna, Vienna, AUSTRIA.

Objectives: To evaluate the reproducibility of PERCIST 1.0 and RECIST 1.1 criteria in metastatic breast cancer patients receiving systemic therapy. **Materials and Methods:** Retrospective study of patients with metastatic breast cancer who received first or second line systemic therapy on protocol, from 2007 to 2012, and underwent contrast-enhanced (CE)-CT of the chest, abdomen, and pelvis and FDG PET/CT within 4 weeks prior and 3 months after treatment initiation. Two radiologists with specialty training in Oncologic Body Imaging and Molecular Imaging assessed response by PET/CT using PERCIST 1.0. Two different radiologists with specialty training in Oncologic Imaging assessed response by CE-CT based on RECIST 1.1. The degree of agreement between observers was quantified by kappa statistics, using the four categories defined by RECIST and PERCIST: complete response, partial response, stable disease and progression of disease. Results were also dichotomized into responders (complete response and partial response) and non-responders categories (stable disease and progression of disease), and kappa was again calculated. After the analysis, reasons for discrepancies were identified in consensus. **Results**: Sixty-five patients met the inclusion criteria. Kappa was 0.81 (95% confidence interval (CI) 0.70, 0.93) between PET/CT readers (PERCIST) and 0.67 (95% CI 0.51, 0.82) between CT readers (RECIST) when 4 response categories were used. Agreement increased amongst PET/CT readers (k=0.94; 95% CI 0.85, 1.0) for the classification of cases as either responders or non-responders. Agreement was moderate between CT readers when cases were classified as responders or non-responders (k=0.54; 95% CI 0.32, 0.76). Discordant results between CT readers were due to measurement differences in 10 cases and differences in interpretation of findings in 3 cases. Among PET/CT readers, all differences were due to differences in interpretation (n=9). **Conclusion:** In patients with metastatic breast cancer, response assessment with FDG PET/CT and PERCIST is highly reproducible and the variability of response assessment compares favorably with response assessment by RECIST.

OP245

Predictive Value of Intratumoral Metabolic Heterogeneity in terms of Disease Free Survival in Hormone Receptor Positive Invasive Ductal Carcinoma Breast

A. S. Bedmutha, N. Singh, M. Pereira, A. Nair; P.D.Hinduja National Hospital and Medical Research Center, Mumbai, INDIA.

Aim: Malignant component within solid neoplasms has distinct heterogeneity regarding cell proliferation, metabolism, angiogenesis and necrosis and this heterogeneity is represented as phenotypic and behavioural alterations of the neoplasm, including proliferative and metastatic potential which has reliably been demonstrated by F-18 FDG on autoradiography. It has been shown to correlate significantly with disease outcome in sarcomas and cervical cancer. This study was performed to evaluate the significance of intratumoral heterogeneity in predicting disease free survival of patients with hormone receptor (HR) positive invasive ductal carcinoma (IDC) breast. **Materials and methods:** Thirty female patients (age group 38-65 years) with HR positive (ER/PR positive or triple positive) local or locally advanced invasive ductal carcinoma breast, excluding multicentric/ multifocal tumours and patients with other co-existing or past malignancy, who underwent pre-treatment fluorodeoxyglucose positron emission tomography/ computed tomography (F-18 FDG PET/CT) scan were retrospectively evaluated. Maximum transaxial dimensions of primary tumours ranged from 1.3cm - 7cm. Metabolic parameters such as standardized uptake value maximum (SUVmax) and metabolic tumour volume (MTV) were noted. Intratumoral heterogeneity factor (HF) was defined as the derivative (dV/dT) of a volume threshold function from 40-80%, quantified for each primary tumour. Patients were clinically and radiologically followed up for minimum period of 3 years post completion of treatment. Events of recurrence/ metastasis were compared to PET/CT parameters by receiver operating characteristic (ROC) curve analysis. **Results:** HF ranged from 0.025 to 1.37, with mean values for recurrence and disease free group being 0.83 and 0.15 respectively. It correlated well with MTV (correlation coefficient 'r' = 0.984, $p<0.01$). ROC curve analysis demonstrated significant association of both HF and MTV with disease free survival (area under curve = 0.967 for HF and 0.955 for MTV; $p<0.001$ for both). HF was found to be higher in higher T stage tumours. Optimal cut-off values of HF >0.34 and MTV >12.03 cm^3 were found to have high sensitivity and specificity in predicting recurrence, and hence affecting prognosis. SUVmax was not found to be a reliable predictor of DFS. **Conclusion:** Intratumoral heterogeneity correlates well with MTV, and is a potentially reliable predictor of DFS in patients with hormone receptor positive local or locally advanced IDC breast. It can be evaluated as a tool to decide management strategy in selected group of patients.

OP246

Prognostic significance of FDG-PET/CT derived parameters in a first metastatic breast cancer relapse

E. Depardon[1], S. Kanoun[1], O. Humbert[1], J. Riedinger[1], I. Tal[2], J. Vrigneaud[1], M. Lasserre[1], M. Toubeau[1], A. Berriolo-Riedinger[1], I. Dygai-Cochet[1], P. Fumoleau[3], F. Brunotte[1], A. Cochet[1]; [1]Department of Nuclear Medicine, Centre Georges-François Leclerc, Dijon, FRANCE, [2]Beth Israel Deaconess Medical Center, Boston, MA, UNITED STATES, [3]Department of Medical Oncology, Centre Georges-François Leclerc, Dijon, FRANCE.

Aim: To investigate the prognostic value of fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) derived parameters (metabolic tumour volume [MTV]) in a first metastatic breast cancer recurrence (MBCR). **Methods:** From December 2006 to August 2013, 49 women with a first MBRC were retrospectively included. FDG-PET/CT was performed within one month before systemic treatment.

Three sets of MTV were calculated with Beth Israel (BI) software: based on an absolute threshold selecting voxel with standardized uptake value (SUV) >2.5 ($MTV_{2.5}$), applying a per-lesion threshold of 41% of the maximum SUV (SUV_{max}) (MTV_{41}) and using a per-patient adapted threshold based on PERCIST definition of measurable target lesion defined by SUV> 1.5-fold greater than liver SULmean + 2 standard deviations (SD) (MTV_P). Patients were also classified as mono-organ (only one organ involved) or multiorgan relapse according to PET/CT uptake. MTV analysis was dichotomised by median value and overall survival (OS) with each MTV methodology was determined by Kaplan-Meier survival curves and log rank test. Spearman rank order correlation was performed to establish the correlation between MTV_P and CA15-3 value. **Results:** Median follow-up period was 34 months (range: 8-72 months) during which 21 patients died. Median MTV value for $MTV_{2.5}$, MTV_{41} and MTV_P were respectively 24 ml (range: 0-1302), 34.5 ml (range: 1.4-876.8), 26.9ml (range: 0.38-1796.1). By log-rank analysis, a high MTV value after dichotomisation by the respective median value was able to predict OS using all methodologies ($p=0.031$, 0.027 and 0.002 respectively). Time delay longer than 5-y between initial diagnosis and recurrence (26 patients) was also predictor of OS ($p < 0.001$). When the patients were classified into four groups according to the combined factors of MTV_P and delay, MTV_P was predictive of OS in patients with a relapse time <5 years (mean survival time: 60 months versus 27 months; $p = 0.026$), but not in patients with time delay longer than 5-y. Mono-organ invasion (27 patients) predicted longer overall survival than multiorgan invasion (56 months versus 34 months; $p = 0.003$) whatever the number of metastases involved. SUVmax, initial diagnosis stage, SBR status and CA15-3 value were not predictors of OS. No statistically significant relationship was observed between MTV_P and CA15-3 value. By cox multivariate analysis, recurrence delay and mono-organ invasion remained independent predictors of survival. **Conclusion:** In a first MBCR, MTV, recurrence delay and multiorgan invasion are significant prognostic biomarkers. Recurrence delay <5 years and multiorgan recurrence being unfavourable independent prognostic biomarkers.

OP247

Reproducibility of MR-based attenuation correction maps for PET/MRI: Variations with free breathing and breath-hold protocols

S. K. Øen[1], M. L. Lassen[2], I. Rausch[2], M. O. Myrthue[3], L. Eikens[1], T. Beyer[2]; [1]Norwegian University of Science and Technology, Trondheim, NORWAY, [2]Medical University of Vienna, Vienna, AUSTRIA, [3]St. Olavs Hospital, Trondheim, NORWAY.

Objectives Combined PET/MRI systems are well-suited for long-term follow-up studies given the lowered ionizing radiation burden. Here, we investigate the variability of DIXON-based attenuation correction (AC) maps acquired in free breathing and breath-hold for longitudinal PET/MRI studies in a scan-rescan set-up. **Materials/Methods** Nine healthy volunteers (3m/6f) were included in this study. All subjects were positioned with arms-down in a whole-body PET/MRI scanner (Siemens Biograph mMR) and underwent the MRI-part for the generation of MR-based AC. AC maps of thorax were acquired during free breathing (FB) and breath-hold (BH) in a scan-rescan set-up. All scans were acquired again on a second day. Attenuation correction coefficients (ATN) in mediastinum, lungs and liver were calculated for all AC maps. Further, total lung volume and artifacts were calculated for all subjects and scans. Image artifacts were categorized into: (ASF) air misclassified as soft tissue/fat, (SFA) soft tissue/fat misclassified as air, (LSF) lung tissue misclassified as soft tissue/fat, (LA) lung tissue misclassified as air and (TI) tissue inversion of soft tissue and fat. **Results**Mean lung volumes across subjects were 2.1±0.5L (FB) and 2.3±0.6L (BH). Population based day-to-day variation in lung volume was 2.5±2.6% (FB) and 0.4±1.1% (BH). Lung ATN values were 0.0232±0.0034cm^{-1} (FB) and 0.0233 ±0.0044cm^{-1} (BH), with average day-to-day variations of 0.3% and 3.5%, respectively. Mediastinum- and liver-ATN values were 0.1cm^{-1} with no day-to-day variations. ASF, SFA and LSF misclassifications in the AC maps were observed in 36/36 scans acquired in FB. Further, LA misclassifications were reported in 12/36 and TI in 3/36 scans. For BH-protocols, ASF and SFA were reported in 36/36 scans and LSF in 16/36. LA and TI were reported in 8/36 and 3/36, respectively. **Conclusion** Day-to-day variation of- ATN values and lung volumes are very small (non-significant) on population-basis. Breath-hold acquisitions improved the quality and accuracy of the AC maps and, thus, should be used for thorax-studies.

OP248

The use of RESOLUTE brain attenuation correction in [^{18}F]-fluoro-ethyl-tyrosine (^{18}F-FET) PET/MRI of gliomas

C. N. Ladefoged, I. Law, C. Hassing, L. Højgaard, F. L. Andersen; Rigshospitalet, Copenhagen, DENMARK.

AIM: Evaluating glioma patients using [^{18}F]-fluoro-ethyl-tyrosine (^{18}F-FET) PET scanning is critically dependent on accurate and reliable tissue activity quantification. However, the vendor-provided attenuation correction (AC) maps in present PET/MRI scanners are incorrect particularly close to the skull. The glioma patients are often scanned post-operative with MRI artifacts from titanium craniotomy fixation plugs, which may also challenge atlas or template-based AC methods. The aim of this study was to determine the use of the subject-specific MR-derived AC method RESOLUTE in post-operative glioma patients. *METHODS:* We analyzed 61 postsurgical glioma patients with static PET images acquired 20-40 minutes after injection of 200 MBq [^{18}F]-FET on a PET/MRI scanner (Siemens mMR) followed by separate same day acquisition of low dose CT as "gold standard" AC . Furthermore, MRAC maps were acquired using the Dixon water fat separation sequence and ultra short echo time (UTE) sequences, and calculated using a patient specific segmentation-based method with continuous bone density values assigned - RESOLUTE (Ladefoged, PMB 2015). For each subject and AC method the tumor was segmented using an isocontour including tracer uptake above a tumor-to-brain background activity (B), ratio of 1.6. We measured B, tumor mean and maximal activity (T_{mean} ,T_{max}), and tumor volume (T_{vol}) calculating T_{mean}/B and T_{max}/B, and the Jaccard index of tumor delineation. *RESULTS:* A single patient was excluded from analyses due to disruptive signal voids from the metal plugs. The average %-difference within the tumor was for T_{mean}: -15%, -8%, and -3% for Dixon, UTE, and RESOLUTE, respectively. The absolute difference of T_{max}/B relative to CT was 0.13±0.13 for Dixon (max: 0.6), 0.07±0.09 for UTE (max: 0.4), 0.03±0.05 for RESOLUTE (max: 0.2). The absolute difference in T_{vol} was 5.2±6.2 ml for Dixon (Jaccard: 73%), 2.3 ±3.0 ml for UTE (Jaccard: 84%), and 1.6±2.0 ml for RESOLUTE (Jaccard: 87%). *CONCLUSIONS:* The AC method RESOLUTE robustly produced AC maps in postsurgical glioma patients with metal plugs. Only a single case had signal voids near the metal extending into the brain. Using RESOLUTE resulted in a large decrease in the average error in the tumor uptake. As a T_{max}/B level >2.4 is used as a cut-off to identify active tumor tissue this decrease in error (mean, SD and maximum) is instrumental for correct assessment. The accuracy of the tumor volume and delineation also increased, which indicates a potential use of the method in therapy planning.

OP249

Accuracy of a new atlas-based attenuation correction method in comparison to standard MR-based attenuation correction of the skull region in PET/MR imaging

I. Rausch[1], L. Rischka[1], C. N. Ladefoged[2], M. Fenchel[3], A. Hahn[1], R. Lanzenberger[1], T. Traub-Weidinger[1], T. Beyer[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]Rigshospitalet University Hospital, Copenhagen, DENMARK, [3]Siemens Healthcare GmbH, Magnetic Resonance, Erlangen, GERMANY.

Aim: To evaluate the influence of different attenuation correction approaches in positron emission tomography (PET)/magnetic resonance imaging (MR) on clinical evaluation of dynamic [18F]FET imaging. **Methods:** Up to date, 12 patients who underwent a 40 min (0-40 min post injection) dynamic PET/MR (Siemens Biograph mMR) examination following the injection of 250 MBq [18F]FET were included in this ongoing study. Dynamic PET data was reconstructed using an OP-OSEM algorithm (3 iterations, 21 subsets, 3mm FWHM Gaussian post filtering) into 8 frames of 2x2 min, 4x4 min and 2x10 min using four different attenuation correction methods: (A) Standard implemented Dixon-based AC, (B) Standard implemented UTE-based AC, (C) a model-based post-processing approach incorporating spatially variant bone attenuation values into the attenuation map from (A) (non-commercial prototype software by Siemens Healthcare) and (D) CT-based AC. For each reconstruction, a threshold-based volume of interest (VOI) was segmented using a threshold of 90% of the maximum pixel in the respective lesion on summed images (20-40 min). An additional spherical background VOI was placed on the contralateral side to calculate a lesion-to-background ratio (LBR). The VOIs were copied to the different timeframes to calculate the time activity curves (TAC). From the last time frame, volumes of the VOIs and LBR were extracted. An experienced reader with 5 y of experience in dynamic [18F]FET imaging assigned each TAC to two curve patterns: 1) constantly ascending or peaking followed by a plateau and 2) peaking followed by a descent. The volumes and LBRs were compared, and differences to (D) were calculated. For the TAC patterns, changes in assignments relative to the pattern found in (D) were investigated. **Results:** Extracted VOI volumes changed on average by (A): -14±29%, (B) -7±38% and (C) 0±23% relative to (D). LBR were in general similar for all AC methods with an average difference to (D) of (A): -2±2%, (B) -2±5%, and (C) 0±3%. The assignment of the TACs to the different uptake patterns changed for 2/12 cases for (A) and for (B). For (C), no change in uptake pattern assignment could be observed. **Conclusion:** The use of different AC methods in PET/MR can influence the clinical diagnosis in dynamic [18F]-FET glioma imaging. This is mainly attributed to changes in the segmentation of VOIs when using threshold-based segmentation approaches. Nevertheless, LBR seems to be comparable for all evaluated AC approaches.

OP250

Implementation of routine sequential PET/MR of the rat heart in an in-line preclinical scanner

J. M. Vrigneaud[1], P. Walker[2,3], A. Camacho[4], A. Courteau[2], A. Oudot[1], M. Guillemin[1], F. Brunotte[1,2,3]; [1]CGFL Preclinical Platform, Dijon, FRANCE, [2]Le2i-UMR CNRS 6306, Dijon, FRANCE, [3]CHU, Dijon, FRANCE, [4]MR Solutions, Guildford, UNITED KINGDOM.

Introduction: Cardiac imaging is one of the important potential applications of PET/MR studies as MRI and PET are the most accurate methods to respectively collect functional and molecular data during the same examination. Several clinical PET/MR Scanners are now marketed and permit cardiac clinical investigation but surprisingly no pre-clinical cardiac PET/MR scanner is available. The present system is made of an 8 head SiPM PET module with Dual-layer LYSO matrix and an effective axial field of view of 50.4 mm. The PET detector is clipped-on at the extremity of a 3T 17 cm bore cryogen-free superconducting magnet with 400 mT/m gradients. The bed movements and PET operation are fully integrated in the software controlling MRI. The aim of the present study is to detail the implementation of heart imaging and the first results obtained with this scanner. **Methods:** The present study comprised two steps. The first step was to adapt the PET/MR scanner to cardiac imaging of the rat. The second step was to obtain cardiac acquisitions after injection of 10-40 MBq of 18F-FDG. PET was acquired in list mode and images were reconstructed using 3D OSEM. MR images of the left ventricle were acquired in cine-MRI using 2 mm thick short- and long-axis FLASH sequences. Cardiac gating was obtained all over the PET and MR examinations using cutaneous electrodes. All the MR acquisitions were respiratory gated in expiratory position using a pneumatic cushion placed on the abdomen **Results**: The adaptation of the PET/MR scanner comprised the development of a bed Technical Support Unit adapted to anaesthesia, ECG acquisition, passage of the perfusion line with adequate shielding in order to reduce the noise in MR induced by the ECG wires. A quadrature coil was also developed with a sufficient diameter to permit the movement of the animal bed. Ten consecutive rats were imaged with 16 images per cardiac cycle acquired sequentially with each modality in less than 90 minutes**. Conclusion:** Rat heart PET/MR imaging can be easily obtained in less than 90 minutes with a temporal resolution of 16 images per heart cycle and a spatial resolution better than 1 mm. This study opens the way to routine use of PET/MR in cardiac preclinical imaging.

OP251

Impact of respiratory motion compensation in patients with solid tumors undergoing PET/MR

M. Soussan, S. Djelbani, C. Comtat, V. Brulon, B. Helal, I. Buvat; IMIV, CEA-Inserm, Univ Paris Sud, CNRS, Université Paris Saclay, Orsay, France, Orsay, FRANCE.

Objective: For chest and abdominal imaging, respiratory motion can create blurring and suboptimal quantification in PET imaging. We evaluated the impact of bellow-based respiratory compensation to mitigate motion both in MR and PET images during oncologic routine PET/MRI. Methods: Twenty patients underwent a FDG-PET/MR (Signa, GE Healthcare) (107±15 min after FDG injection, 4MBq/kg, 4-6 beds, 3-4 min/bed position, time-of-flight OSEM reconstruction, 2 iterations/28 subsets, no post reconstruction filter) for solid tumor staging. Respiratory signal was recorded using a respiratory bellow. MR sequences consisted in a Dixon sequence for attenuation correction, and a thin section (5mm) axial T2W-FRFSE, with respiratory triggering (duration ~2 min). PET data were reconstructed using 3 approaches: the entire data set (Static), the end-expiration quiescent period only (PET frame with around 50% of the counts; GE, Q-Static), and gated data set registered to a single time frame using a non-rigid technique (GE, Q-Freeze). All that were clearly distinct from adjacent lesions or surrounding background were included for analysis. Lesions were evaluated using SUVmax and SUVpeak. Noise in PET images was estimated in the liver parenchyma by drawing a region of interest (ROI) over the right hepatic lobe, using the standard deviation (SD) of SUV divided by the mean SUV in that ROI. Results: Forty-eight lesions were included in the analysis: 23 mediastinal lymph nodes (LN), 19 lung nodules and 6 abdominal lesions. The noise measurements showed that noise level was significantly higher in motion corrected PET images than in static images : 0.21+/-0.04, 0.31+/-0.09 and 0.25+/-0.04, in Static, Q-Static, and Q-Freeze images respectively ($p<0.001$). 46% (22/48) of lesions had a consistent increase in SUVpeak after motion correction with both methods: these changes were mostly related

to motion correction given that SUVpeak is little affected by noise. Among these 22 lesions, 11/22 were lung nodules (SUVpeak increase: 7+/-6.5% with Q-Static and 8+/-5% with Q-Freeze) and 9/22 were LN (SUVpeak increase: 4.1+/-3% with Q-static and 17+/-24% with Q-Freeze). Interestingly, only 27% (13/48) of lesions showed an increase in SUVmax with both Q-Static and Q-Freeze, suggesting that the impact of motion correction is not properly characterized using SUVmax. Conclusions: Respiratory triggering and motion correction methods are feasible during routine PET/MR protocols, and affect lesion quantification in about half of lesions in our cohort. Changes in SUVmax, being sensitive to the noise level that is affected by motion compensation, do not properly reflect the number of lesions benefiting from motion correction.

OP252

Validation of Zero-Echo Time PET-MR against stand-alone PET using dynamic dopamine transporter imaging

J. M. Sousa[1], L. Appel[1], S. Papadimitriou[2], D. Nyholm[2], J. Sörensen[1], T. Danfors[1], E. Larsson[1], G. Delso[3], F. Wiesinger[3], H. Ahlström[1], M. Lubberink[1]; [1]Department of Surgical Sciences, Uppsala, SWEDEN, [2]Department of Neurosciences, Uppsala, SWEDEN, [3]GE Healthcare, Zürich, SWITZERLAND.

Objectives: Zero echo time (ZTE) MR has been proposed as a skull segmentation method for MR-based attenuation correction (MRAC) which may reduce the quantitative bias of PET data. The aim of this study was to evaluate quantitative measures of dopamine transporter availability and relative cerebral blood flow based on a dynamic ^{11}C-PE2I-PET scan acquired on a PET-MR scanner using ZTE-MRAC. Data from the same subjects acquired on a stand-alone PET system with rotating ^{68}Ge rod sources for attenuation correction, considered the gold standard for quantitative brain-PET, was used as reference. **Methods:** Six patients evaluated for Parkinsonism underwent two 80-min dynamic ^{11}C-PE2I PET scans within 6 months on a stand-alone PET (ECAT HR+) and a time-of-flight integrated PET-MR (Signa PET-MR). ECAT and PET-MR scans were reconstructed using resolution-matched OSEM, with MRAC based on 2-point Dixon with ZTE as well as the standard head atlas method. Volumes of interest were defined using a probabilistic template on co-registered T1 images and transferred to the PET datasets. Binding potential (BP_{ND}), reflecting dopamine transporter availability, and relative cerebral blood flow (R_1) were estimated with a simplified reference tissue model using cerebellar cortex as reference tissue. Correlation and agreement between BP_{ND} in putamen and R_1 in anterior cortical, posterior cortical, limbic and striatal regions for both modalities were assessed using regression and Bland-Altman analysis.**Results:** High correlation (R^2 0.97) was found between BP_{ND} values for putamen based on PET-MR with ZTE-MRAC and stand-alone PET, with no significant bias. For R_1, highest correlations were observed in limbic and striatal regions (R^2 0.94 and 0.91, respectively), with somewhat lower correlations in anterior and posterior cortex (R^2 0.82 and 0.78). PET-MR R_1 values were higher in posterior cortex (bias 0.07) and lower in striatum and limbic regions (bias -0.18 and -0.05), but biases were not significant. Correlation and agreement between PET-MR and ECAT was considerably better for ZTE than for head atlas MRAC, especially in anterior and posterior cortex where head atlas showed a significant positive bias. **Conclusion:** A good correlation and agreement was found between PET-MR with ZTE-MRAC and stand-alone PET for quantitative measures of dopamine transporter availability and relative cerebral blood flow based on dynamic PET scans. Besides extension of the number of patients, further studies will have to show whether the remaining observed differences are due to MRAC only or to other factors influencing quantitative accuracy.

OP253

PET/MR in radiation oncology - how to correct for attenuation caused by flat table top?

S. Witoszynskyj[1], P. Andrzejewski[2], I. Rausch[3], M. Hacker[4], D. Georg[2], B. Knäusl[2]; [1]Div. of Nuclear Medicine, Dept. of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Vienna, AUSTRIA, [2]Dept. of Radiation Oncology, Comprehensive Cancer Center, Medical University Vienna, Vienna, AUSTRIA, [3]Center for Medical Physics and Biomedical Engineering, Medical University Vienna, Vienna, AUSTRIA, [4]Div. of Nuclear Medicine, Dept. of Biomedical Imaging and Image-guided Therapy, Medical University Vienna, Vienna, AUSTRIA.

Introduction: PET and MR provides complementary information useful in many aspects of radio-therapy (RT). The implementation of PET/MR scanners overcame issues of PET-MR image registration. However, to assure patient positioning during imaging and RT, dedicated MR-compatible flat table tops (FTT) are required. However, these FTT cause attenuation and scatter and can lead to a significant degradation of PET image quality (IQ). This study's goal was to evaluate the impact of a FTT on PET IQ and to introduce a correction method. Materials and methods: PET images of a 12l cuboid canister, a cylinder phantom and a modified NEMA body phantom (all spheres of 11.3ml volume; activity-to-background ratio of 8:1) were acquired on a Biograph TrueV PET/CT and a Biograph mMR PET/MR (Siemens). All phantoms were filled with 18F-FDG in aqueous solution containing 0.9% NaCl and 0.2mmol/l Gd-DO3A-butrol. Measurements were performed with and without FTT (X-tend ApS). A transmission scan (PET-TS) of the FTT was acquired using a GE Advance PET. MR markers visible in PET were used for co-registration. An attenuation map (μMap) was derived from PET-TS and used for PET(/MR) image reconstruction. Activities measured in the spheres of the body phantom and activity profiles in the cylinder were compared between PET/CT and PET/MR images. Canister images were evaluated by computing a uniformity index (UI) using a sliding window approach with a 5x5 voxel ROI on slice-by-slice basis. Advantages of using PET-TS were compared to standard correction methods. Results: The (MAX-MIN)/AVG ratios of the mean activities in the body phantom's spheres were as follows (without and with the FTT, respectively): PET/CT 1.7% and 6.2%; PET/MR 2.6% and 6.8%. The best IQ was found in PET/CT without FTT. Compared to these images, PET/MR images were degraded. PET/CT with FTT exhibited attenuation artifacts. In PET/MR scans, scatter and attenuation artifacts were observed. IQ was significantly improved using FTT's PET-TS μMap.Discussion: Using PET-TS derived μMap reduces artifacts in PET/MR. The deteriorated AC observed in PET/CT images is caused by the transformation from CT attenuation to PET attenuation not being valid for materials used in the FTT. This proves that CT based AC may not be sufficient to perform AC in PET/MR scanner. Although the UI measure provides an indication of IQ, it is of limited use for evaluating systematic artifacts caused by incorrect AC. Further improvements are currently explored to improve quality of the PET-TS μMap and to integrate it into image reconstruction.

OP254

PET Detection Capabilities of Siemens Biograph PET/CT and PET/MR Systems

L. B. Aasheim[1], L. Eikenes[2], **A. M. Karlberg**[1]; [1]Department of Radiology and Nuclear Medicine, St. Olavs Hospital, Trondheim, NORWAY, [2]Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, NORWAY.

Aim: With improvements in PET technology such as time-of-flight (TOF) capability, point-spread-function (PSF) modelling, reconstruction algorithms, detector design and materials, PET image quality and resolution have increased significantly, and with it the capability of detecting smaller lesions. The existing international standard for assessing PET image quality (NEMA NU 2-2012) does however not assess uptake volumes below 10 mm, even though current PET systems are more than capable of detecting lesions smaller than this. The purpose of this study was therefore to quantitatively assess, and compare the detectability of small uptake volumes in two state-of-the-art PET systems; Siemens Biograph mCT (PET/CT) and mMR (PET/MR). Furthermore, the dependence of detection capability of different reconstruction settings was evaluated. **Materials and Methods:** The PET Esser phantom with small hot spheres (inner diameters 4, 5, 6, 8, 12 and 20 mm) was used for evaluation of mCT and mMR image data. The background-to-hot-sphere activity concentration was 1:8 and 1:4. The phantom was prepared once for each concentration and scanned on both systems consecutively with clinical routine protocols. Attenuation correction was CT based in both mCT and mMR PET data. Iterative reconstruction (3D Ordered Subset Expectation Maximization (OSEM) algorithm) was employed (2-8 iterations), with/without PSF modelling and for the mCT additionally with/without TOF. Contrast-to-noise ratio (CNR) was evaluated for different reconstruction settings, and the Rose criterion (CNR≥5) was applied as a measure of detectability/visibility in phantom data. In order to validate the phantom results, a patient with lung tumours (5-9 mm) was included in the study. **Results:** For the mCT, highest CNR for small uptake volumes was found with PSF&TOF and 2-3 iterations, while for the mMR corresponding settings were PSF and 3-4 iterations. Using optimal reconstruction settings, uptake volumes down to 5 mm (1:8 activity concentration) and 8 mm (1:4 activity concentration) were visible (CNR≥5) in both mCT and mMR phantom images. For the clinical data a 5 mm lung lesion was observed in the PET images from both systems. **Conclusion:** The same uptake volumes were detected on both systems in phantom and clinical data, when using optimal reconstruction settings. Reconstruction improvements, such as TOF and PSF should be used, when available, to maximize the possibility of detecting small lesions.

Quantitative imaging of cell viability after graft in stroke rodent model with [^{18}F]-FHBG

A. SALABERT[1,2], L. Vaysse[1], M. Beaurain[1], M. Alonso[2], J. Besombes[1], I. Loubinoux[1], M. Tafani[1,2], P. Payoux[1,3]; [1]INSERM U1214, Toulouse, FRANCE, [2]University hospital, Radiopharmacy unit, Toulouse, FRANCE, [3]University hospital, Nuclear medecine unit, Toulouse, FRANCE.

Aim: Cell transplantation is an innovative therapeutic approach particularly after brain injury to compensate tissue damage and neuronal loss. However, before translation to the clinic, we need to better understand the underlying mechanisms of graft and to ensure the safety of this kind of approach. To have a real-time longitudinal monitoring of cell graft, we propose a molecular imaging approach using a gene encoding thymidine kinase (HSV1-tk) and ([^{18}F]-FHBG) as a reporter probe to image the expression of this enzyme. HSV1-tk phosphorylates the radiotracer leading to its intracellular accumulation only in cells expressing HSV1-tk. The first step of this study was to standardize the method. Material and methods: Five million of HSV1-tk stably transfected Neuro2a cells were incubated with 5,55 MBq of [^{18}F]-FHBG during 3 hours. Calibration ranges from 10 000 to 3 000 000 cells were realised and were counted in a gamma-counter or analysed by PET-camera. In parallel, we tested graft procedure in a model of rat stroke. Brain lesion was induced by stereotaxic injection of malonate toxin 3M (5μL). 15 days after the surgery; we performed a stereotaxic graft, into the lesion, with different quantity of cells. Image acquisition of rats was then performed during 15 min in PET-CT. Data analysis and quantification was performed on homemade software (Sisyphe) on co-registered image. Results: [^{18}F]-FHBG cell uptake rate was stable, around 2.61%+/-0.8 (n = 9). Calibration range analysis show no significant difference (p=0, 75, n= 6) between signal on gamma counter and PET (Bq) as a perfect correlation and reproducibility between the number of cells and the signal intensity. In vivo, we also observed a linear correlation between PET signal in brain rats and number of grafted cells (r = 0.996, p <0.00001, n =18), matching with the calibration range. Scalp attenuation was insignificant. These acquisitions also allowed the validation of stereotaxic injection quality. We noticed three types of injection variability: reflux in cisterna of CSF, cell reflux on the scalp and brain diffusion if the lesion was too small. Conclusion: We proved that molecular imaging with [^{18}F]-FHBG allows to quantify the number of grafted cells and to monitor the quality of cell injection. We plan to use this tracer to achieve a graft longitudinal follow up to quantify cell viability and biodistribution several weeks after injection. The repeated, non-invasive tracking of grafted cells will accelerate the development of effective stem cell therapy in stroke.

OP256

Reconstruction of Input Function for Rapid PET measurement of CBF, OEF, and CMRO2

N. Kudomi[1], Y. Maeda[2], H. Yamamoto[1], Y. Yamamoto[1], T. Hatakeyama[1], Y. Nishiyama[1]; [1]Faclty Of Medicine, Kagawa University, KAGAWA, JAPAN, [2]Clinical Radiology, Kagawa University Hospital, KAGAWA, JAPAN.

Objectives: CBF, OEF and $CMRO_2$ images can be quantitatively measured using ^{15}O-PET. Recently, we have developed a novel protocol allowing a short PET scan time. In that protocol, two tracers of $^{15}O_2$ and $H_2{}^{15}O$ were sequentially administrated with 10-minute interval during a single PET scan for CBF, OEF, and $CMRO_2$ (DBFM) [1]. One of problems, so far, is need for invasive arterial blood withdrawal for input function. The aim of the present study was to develop a new method for image-derived input function (IDIF) for quantitative CBF, OEF and $CMRO_2$ from the dynamic PET single scan image. **Methods:** Our technique consisted of formula based on the single tissue compartment model for expressing inputs for water and oxygen from a tissue curve with parameters of rate constants: $K_1{}^w$ and $K_1{}^o$ for water and oxygen, respectively. For multiple tissue curves extracted from brain regions in a PET dynamic image, the rate constants were estimated so as to minimize a sum of square differences for expressed inputs expressed from the tissue curves. Using the estimated rates, IDIFs were reconstructed for all applied tissue curves, and mean of reconstructed inputs was estimated as IDIF. To test validity, 20 subjects with suspected cerebrovascular disorder were studied with DBFM protocol. Arterial blood was sampled during scan time and activity concentration was determined to serve as reference measurements. The CBF, OEF and $CMRO_2$ values were computed by the IDIF and measured input functions. **Results:** The estimated IDIFs were well reproduced compare to the measured ones. The mean of calculated CBF, OEF, and $CMRO_2$ values were 0.46±0.16 and 0.46±0.16 ml/min/g by the measured and IDIF, 0.46±0.08 and 0.44±0.08, and 0.037 ±0.014 and 0.035±0.013 ml/min/g, respectively and differences were ±7.1%, ±6.7% and ±8.3% for those functions, respectively. Regression analysis showed tight correlation between IDIF and measured input methods as: r=0.97, 0.93, and 0.97, for CBF, OEF and $CMRO_2$, respectively. **Conclusion:** The presented results demonstrate that IDIF can be

estimated directly from tissue TACs extracted from dynamic PET image for DBFM method. This suggests the possibility to enable the noninvasive assessment of CBF, OEF and $CMRO_2$. [1] Kudomi et al JCBFM (2013) 33; 440-448

OP257

Healthy ageing assessed by simultaneous high-resolution TOF PET/MR brain imaging: partial-volume corrected cerebral glucose metabolism versus white matter microstructure

S. M. A. Willekens*[1], J. Ceccarini*[1], M. Koole[1], K. Goffin[1], S. Sunaert[2], K. Van Laere[1]; [1]Division of Nuclear Medicine, University Hospitals Leuven and KU Leuven, Leuven, BELGIUM, [2]Translational MRI, Devision of Radiology, University Hospitals Leuven and KU Leuven, Leuven, BELGIUM.

Aims Cognitive decline in neurodegenerative disorders such as Alzheimer's disease and frontotemporal dementia, is marked by underlying grey matter (GM) atrophy, impairment in brain metabolism and white matter (WM) integrity. To comprehensively understand the effect of healthy ageing on cerebral glucose metabolism combined with GM and WM integrity, we studied age-related changes in simultaneously acquired ^{18}F-FDG PET and diffusion tensor imaging (DTI) using high resolution time-of-flight (TOF) PET/MR. **Methods** ^{18}F-FDG PET and DTI data were acquired simultaneously in 24 cognitively healthy individuals as part of an ongoing normal dataset project, with an age range of 20 to 78 years (n=4 /decade; mean age 49.8±18.2 years, 10M, 14F). Dynamic ^{18}F-FDG brain PET data and MR sequences (volumetric T1, T2 FLAIR and DTI) were acquired for 60 minutes on a GE SIGNA PET/MR scanner. Partial volume corrected (PVC) PET images were analyzed VOI-based (Hammers atlas, PNEURO v3.6) and voxel-based (SPM12). Regional 40-60 min ^{18}F-FDG uptake values were normalized to average whole-brain activity. DTI data were analyzed using ExploreDTI. Fractional anisotropy (FA) was evaluated as diffusion tensor parameter in pre-defined WM ROIs (Johns Hopkins University WM atlas). Associations between regional ^{18}F-FDG uptake, FA and age were assessed using linear regression and voxel-wise analyses (SPM12; $p_{height}<0.005$; $K_{ext}>50$). **Results** PVC VOI-based analysis showed negative correlations between age and ^{18}F-FDG uptake in the frontal and prefrontal lobes, mainly in the middle (r=-0.50-0.54) and superior frontal gyrus p=0.007-0.01), and in the anterior cingulate gyrus (r=-0.46, p=0.03). These observations were confirmed in the voxel-based SPM analysis ($P_{FWE\text{-}corrected}<0.005$, T=5.2). Pearson correlation analysis showed a negative correlation between FA and age in the superior corona radiata and posterior thalamic radiation (r=-0.44, p=0.03). Age-related decrease in prefrontal metabolism correlated positively with WM FA decline with the age in the anterior (r=-0.43, p=0.04) and superior corona radiata (r=-0.44, p=0.03). **Conclusion** Partial volume-corrected cerebral glucose metabolism and WM FA decline with age, especially in frontal brain regions, indicating aging effects that surpass grey matter atrophy. Furthermore, prefrontal glucose metabolism decline is related to decreases in WM integrity in the anterior and superior corona radiata, demonstrating connected deterioration of frontal projection networks upon healthy ageing. The joint study of metabolism and GM/WM integrity with PET/MR can enable a more refined composite picture of the ageing healthy and diseased brain.

OP258

Evaluation of a novel quantitative metric, Volumetric Statistical Amyloid Burden (VSAB), for 18-F florbetaben PET using a probabilistic gray matter brain mask

A. Swallen, A. Nelson, **J. Piper**; MIM Software, Inc, Cleveland, OH, UNITED STATES.

PURPOSE/OBJECTIVES: Our goal is to evaluate the use of VSAB, the volume of gray matter that exceeds a z-score threshold when compared to a database of healthy controls, for distinguishing amyloid+ from amyloid- patients using a probabilistic gray matter mask (GMM) for florbetaben PET scans. MATERIALS/METHODS: MRI scans from 10 subjects were segmented using FreeSurfer into gray matter and white matter. The segmentations were transferred to corresponding florbetaben PET images for the same patients and transformed into template space using the florbetaben template registration. A mask was constructed for computing VSAB which includes only voxels which are at least 50% more likely to contain gray matter than white matter. One-hundred fourteen florbetaben PET scans acquired 90-110 minutes after injection were selected for analysis. All scans were classified as amyloid positive or negative by three expert readers and the majority read result was taken after assessment. For the quantitative analysis, MIMneuro 6.6 was used to deformably register each scan to a common template space comprised of 3 florbetaben PET templates. Z-scores were computed for every voxel, using the whole cerebellum as reference, as compared to 49 healthy controls within a probabilistic GMM. Z-score thresholds from 1.65 to 7 were considered for the computation of VSAB, defined as the percentage of voxels within the GMM that exceeded the z-score threshold. The z-score volume threshold was defined by finding the best separation of the two groups. RESULTS: Agreement with consensus reads for VSAB at z-score thresholds 1.65, 3, 4, 5, 6, 7 were kappa = 0.95, 0.95, 0.95, 0.95, 0.93, 0.86, respectively. The VSAB used were 22.65, 2.1, 0.45, 0.066, 0.007, 0.0007 %, respectively. Using z-score 3, 4, and 5 threshold the percent of patients classified correctly were 97.4%. For the visually positive cases, 60/62 (96.8%) were correctly classified and for the visually negative cases, 51/52 (98.1%) were correctly classified. CONCLUSION: VSAB using a probabilistic GMM was found to have high accuracy and excellent agreement with expert visual assessment. The level of agreement with expert visual assessment suggests that VSAB has the potential to serve as a valuable quantitative metric in the evaluation of florbetaben PET images.

OP259

Regional Visual Read Inspection of [^{18}F]Flutemetamol Brain Images from a Large Autopsy Cohort

G. Farrar[1], M. Zanette[2]; [1]GE Healthcare, Amersham, UNITED KINGDOM, [2]GE Healthcare, Boston, MA, UNITED STATES.

Introduction Visual interpretation of PET amyloid images obtained with [^{18}F]flutemetamol as normal (negative) or abnormal (positive) relies upon a systematic review of 5 brain regions (frontal, parietal, posterior cingulate & precuneus, striatum and lateral temporal lobes). For a brain to be deemed amyloid-positive there must be an elevated cortical signal in at least one of these grey-matter regions. Analysis of a 106-patient autopsy cohort was performed to examine which regions were assessed as visually positive to contribute to the overall assignment of 'amyloid positive'. **Methods** 180 end-of-life subjects were scanned following 185-370 MBq of intravenous [^{18}F]flutemetamol and 106 of these came to autopsy. PET images were read by 5 blinded readers trained using an electronic program, who independently classified as positive or negative each of the 5 regions in each of the 106 images. The majority interpretation (made by at least 3 of the 5 readers) was used as the imaging endpoint. **Results** Of the 106 images, 71 (67%) were positive and 35 (33%) were negative. Of the positive images, 54 (76%) were positive in all 5 regions and 14 (20%) were positive in 4 regions. There were 3 brains that read positive with 3, 2 or one region each. Posterior cingulate & precuneus always read positive in each of the 71 abnormal brains. **Conclusion** When interpreting PET [^{18}F]flutemetamol images the reader should systematically review each of the 5 review regions. This is particularly important when assigning a scan as negative as there can be cases with a positive PET signal restricted to one or more regions. The majority of positive [^{18}F]flutemetamol images showed positivity in 4 or 5 of the

review regions in this cohort of end-of-life subjects. In summary the methodology for the visual read of [^{18}F]flutemetamol offers a robust assessment of 5 individual cortical brain areas which potentially allows different regions to be discretely studied if required.

OP260

Agreement Between Automatic Quantification and Experienced Reviewers in the Reporting of Amyvid PET/CT Scans

D. Fakhry-Darian[1,2], S. R. Khan[2], N. H. Patel[1,2], K. S. Nijran[1,2], K. L. Wallitt[2], S. Khan[2], W. Svensson[2], T. D. Barwick[2], Z. Win[2]; [1]Radiological Sciences Unit, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM, [2]Nuclear Medicine, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Aim: Florbetapir ^{18}F (Amyvid, Eli Lilly) is a PET radiopharmaceutical used to detect the presence of β-amyloid plaques in the brain - an early stage indicator of Alzheimer's disease. The recent release of Hermes Amyvid BRASS allows for quantification of these studies by comparing SUV_r in six regions of the brain (relative to the cerebellum) against a database of 80 healthy control patients. In order to validate this software the agreement between trained reviewers and automatic quantification in BRASS was assessed. **Materials and Method:** 100 patients, age range 41-88 years, median age 68 years, were blind reported by 3 experienced reviewers with one final clinical report decided upon by all reviewers. The images were quantitatively evaluated in BRASS and the outcome was compared against the agreed clinical report. Studies were blind reported as either positive or negative and the subtype of the scan was identified amongst reviewers. The BRASS result was classed as positive if two out of the six automatic regions showed increased uptake more than 2 SD from the mean database score (z-score ≥ 2). Each patient underwent the same preparation and imaging: 370 MBq (max) florbetapir-^{18}F, imaged 40 minutes p.i. for 20 minutes, list mode acquisition, on a Siemens Biograph 64. The 20 minute study was assessed for motion visually and any frames with obvious motion were left out of the final reconstruction (OSEM 2D 4i 14s, 3 mm Gauss, 168 matrix, min. 10 minutes). **Results:** 70 patients have so far been reported by all reviewers and quantified in BRASS. Moderate to good agreement was observed between the clinical report and BRASS quantification, k = 0.66 (95% CI 0.49-0.84). The false positive rate (FRP) was 29% (11 FP results) and the false negative rate (FNR) was 3% (1 FN result). Of the 12 results that disagreed, 10 displayed significant motion or were of atypical appearance (non-subtype A). Agreement between clinical reviewers and BRASS for type A scans only (56/70) was much better, k = 0.79 (95% CI 0.63-0.95). FPR = 16%, FNR = 4%. **Conclusions:** Hermes BRASS can support clinical reporting of Amyvid studies. Scan subtype should be identified prior to BRASS quantification. In the case of scans with atypical appearance a re-evaluation of Z-scores is necessary so as not to increase the occurrence of FP results. Motion should be identified prior to the final reconstruction and only the most stable frames should be used.

OP261

Comparison of F-18 FDG Brain PET Data Acquired Sequentially on Hybrid PET/CT and PET/MR Systems

Ü. Ö. Akdemir, U. Aydos, M. Özçelik, N. &. Karabacak, L. Ö. Atay Kapucu; Gazi University Faculty of Medicine, Nuclear Medicine Department, Ankara, TURKEY.

Aim: We aimed to compare brain F-18 FDG PET data of the same patients acquired sequentially on PET/CT and hybrid PET/MR cameras in a mixed patient group of neurodegenerative diseases and epilepsy. **Materials and Methods:** Brain PET/CT imagings were done on a PET/CT system (Discovery ST PET/CT, GE) 45 minutes after injection of 0.1 mCi/kg of F-18 FDG in resting state. The acqusition time for PET emission was 12 minutes. Subsequently brain PET/MR acquisitions were done on a hybrid PET/MR system (Signa PET/MR, GE) in patients who gave informed consent and had no contraindications for MR without additional F-18 FDG administration. The PET/MR protocol consisted of a PET emission acquisition (15 minutes) and simultaneous MR imaging which included a T1w-DIXON sequence for attenuation correction of PET data. The two sets of brain F-18 FDG PET data were quantitatively compared using spm2 using a paired t-test model with $p<0.05$, *FWE*-corrected and extent-threshold of 100 voxels. Spatial normalizations of PET data were done using an institutionally created F-18 FDG PET template. **Results:** Eleven patients with neurodegenerative diseases (5 dementia and 6 parkinsonism; mean age = 65 (± 10)) and 12 patients with epilepsy (mean age = 19 (± 9)) were included. Three separate spm2 analyses were done: One for the whole group and two separately for each patient groups. In the whole group analysis PET images from the PET/MR system showed lower values in bilateral frontal-temporal and higher values in bilateral parietal and right temporal regions in comparison to PET images from the PET/CT system. In the neurodegenerative diseases group PET images from the PET/MR system showed lower values in left frontal lobe and higher values in left parietal-posterior cingulate, right frontal, right primary auditory regions and right cerebellum. In the epilepsy group PET images from the PET/MR system showed lower values in left frontal lobe, right cerebellum and higher values in left primary visual, right premotor and posterior cingulate cortical regions. **Conclusion:** We observed significant quantitative differences between paired brain F-18 FDG PET data acquired sequentially on PET/CT and PET/MR systems in a mixed clinical patient population, which might be caused by differences in spatial resolution of PET cameras and methods of attenuation correction of PET data. These results indicate that for the quantitative analysis of brain PET images a camera specific spatial normalization procedure and normal database should be used.

OP262

A PET/CT approach to spinal cord metabolism in amyotrophic lateral sclerosis

E. Pomposelli[1], A. Cistaro[2], C. Campi[3], M. Pennone[1], A. Buschiazzo[1], F. Bongioanni[1], F. Nobili[4], E. Monteverde[1], P. Gancitano[1], A. Massone[5], G. Sambuceti[1], A. Chio'[6], M. Piana[3], C. Caponnetto[7], C. Marini[8]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa and IRCCS AOU San Martino-IST, Genoa, ITALY, [2]Positron Emission Tomography Centre IRMET S.p.A., Euromedic inc., Turin, ITALY, [3]Department of Mathematics, University of Genoa, Genoa, ITALY, [4]Clinical Neurology, IRCCS AOU San Martino-IST, Genoa, ITALY, [5]CNR-SPIN Institute for Superconductors, Innovative Materials and Devices, Genoa, ITALY, [6]Department of Neuroscience "Rita Levi Montalcini", University of Turin, Turin, ITALY, [7]Department of Neuroscience, IRCCS AOU San Martino-IST, Genoa, ITALY, [8]CNR Institute of Bioimages and Molecular Physiology, Section of Genoa, Genoa, ITALY.

Aim. Amyotrophic lateral sclerosis (ALS) is fatal late-onset neurodegenerative disorder of adult life, characterized by a progressive impairment of motor function. We recently developed new software able to recognize the spinal canal and spinal cord (SC) tracer uptake on PET/CT images. Our study aims to investigate whether this method permits to identify abnormalities in SC metabolism in ALS patients. Materials and Methods. We studied 30 patients with spinal-onset ASL at different clinical stage, submitted to FDG-PET/CT following 1-36 months (median 14) after diagnosis. Obtained data were compared with corresponding findings in age and sex-matched healthy controls selected from a published normalcy database. Image analysis was performed according to a previously validated algorithm able to identify all vertebrae from the image data set and to extract the spinal canal as the non-osseous space within the spine volume. The output

of the software was therefore the extraction and the 3D-representation of spinal canal volume that served as a mask to recognize SC using a segmentation algorithm based on Hough transformation. Thereafter, mean standardize uptake value (SUV) of cervical and dorsal SC, normalized to the liver (NSUV), was evaluated in comparison with normal subjects. Results. No differences were found in SC volume between patients and controls. FDG uptake was slightly, yet significantly, higher in ALS patients in the whole SC (NSUV 0.82±0.28 vs 0.70±0.14 $p<0.05$) and in cervical segment (NSUV 0.99±0.37 vs 0.85±0.20, $p<0.05$). During follow-up 13 patients died. A potential prognostic role of SC metabolism was suggested by the observation of a higher SC_NSUV in non-survivors compared with the survivor patients (0.71±0.26 vs 0.55±0.16, $p<0.05$). Kaplan-Meyer approach confirmed the predictive value of SC-NSUV while multivariate analysis confirmed the additive nature of metabolic information (HR = 24.3, 95% CI 2.2-262.8). By contrast no association with prognosis was observed for age, ALSFRS-R score, time elapsed from diagnosis to PET scanning or presence/absence of riluzole treatment.Conclusion. Our computational approach might represent a new window to explore SC metabolism from PET/CT images. Whether confirmed in larger prospective studies, the prognostic significance of SC metabolic pattern in ALS patients might suggest a relevant role for SC inflammatory response in ALS progression.

Quantification of FDG PET/CT dual-time-point imaging in recurrent breast cancer

C. Baun[1], K. Falch[1], O. Gerke[1], J. Hansen[1], A. Alavi[2], P. F. Høilund-Carlsen[1], M. G. Hildebrandt[1]; [1]Dept. of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]Department of Radiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, UNITED STATES.

Aim: To investigate quantification measurements of whole-body dual-time-point FDG-PET/CT in patients with suspected recurrent breast cancer using semi-quantitative analysis with partial volume correction. **Material and methods:** Patients with suspected recurrent breast cancer underwent whole-body PET/CT scans 1 hour (1 h) and 3 hours (3 h) after intravenous injection of FDG. Scans were evaluated semi-quantitatively by estimating standard uptake values (SUVmax, SUVmean) in suspected malignant lesions along with lesion volume and partial volume corrected SUVmean (cSUVmean). The change in SUV from 1h to 3h was calculated, and SUVmean was compared to cSUVmean for all subgroups. Reference measurements where obtained in healthy liver tissue for all patients. Metastases were verified by biopsy, but for ethical reasons most patients had only one biopsy, and follow-up data were used to verify other metastatic sites. **Results:** Of 102 patients included in the study, 99 had data for analysis and 41 of these had recurrent disease with a total of 337 malignant lesions. Overall, SUVmax of malignant lesions increased by 28% ($p<0.0001$) from 1h to 3h imaging, i.e., SUVmax was 6.36 ±3.4 [0.9-19.7] (mean ±SD, min and max) at 1h versus 8.14±4.4 [0.7-29.7] at the 3h time point. For healthy liver reference tissue, SUVmax decreased by 11% ($p<0.0001$), i.e., from 3.32±0.67 [2.2-6.1] to 2.97±0.51 [2.1-4.2] at 1h and 3h imaging, respectively. Metastases in breast, lung, lymph nodes and bone showed significant ($p<0.0001$) increase in SUVmax between 1h and 3h by 25%, 40%, 33% and 27% respectively. Metastases in the lungs showed the highest increase%

in SUVmax, i.e., from 5.05±3.5 [1.2-15.2] at 1h to 7.05±4.8 [1.7-18.8] at 3h. Overall, partial volume correction increased SUVmean significantly at 1h by 63% with a mean factor of 2.51 [2.14 - 2.88] and at 3h by 71% with a mean factor of 3.64 [3.22 - 4.06]. The highest impact was in breast lesions at 3h, where cSUVmean increased by 87% compared to SUVmean, whereas the smallest change was noted in liver lesions at 1h, where cSUVmean was 39% higher than SUVmean. No difference was seen between cSUVmean and SUVmean in healthy liver reference tissue. **Conclusion:** Standard uptake values increased significantly between 1h and 3h in malignant lesions of recurrent breast cancer, and particularly in lung lesions. The use of partial volume correction increased these values significantly, especially in breast lesions.

OP274

Use of PET / MRI hybrid systems in cancer recurrent prostate: pioneering study in Latin America

T. M. Ionescu, T. Vitor, K. M. Martins, **S. A. Nogueira**, J. Wagner, R. H. Baroni, M. F. Barboza, M. L. Cunha, G. C. Campos Neto; Hospital Israelita Albert Einstein, São Paulo, BRAZIL.

In recent year hybrid imaging scanners have emerged, achieving superior results by combining several techniques imaging advantages. PET/CT is the most widely used hybrid imaging system in oncologic diseases, including prostate cancer. PET/CT imaging of prostate cancer has been significantly improved with the introduction of the highly specific tracer ^{68}Ga-PSMA-11. Prostate cancer is the most frequent cancer in men worldwide and relatively high rates of recurrences, however, it is often more difficult to evaluate in its early stages using PET/CT. The main drawback of CT is its poor soft-tissue resolution. Recently the emerging PET/MRI systems improve this aspect using the excellent soft-tissue contrast and resolution of MRI and less radiation exposure. The aim of this study was present the clinical relevance of PET/MRI in prostate cancer compared to PET/CT. Since the acquired and the implementation of the Biograph mMR PET/MRI scanner (Siemens Medical Solutions, Erlangen, Germany) by Hospital Albert Einstein in Brazil, images were analyzed retrospectively and compared to the PET/CT scans performed with a Biograph mCT scanner (Siemens Medical Solutions, Erlangen, Germany). The PET/CT examinations were performed 60 minutes after intravenous injection of 148-222Mbq ^{68}Ga-PSMA-11. A typical prostate whole body parameters were used for PET/CT images including: 120kV, modulated mAs, 1.5mm collimation, abdomen window, 4-5min per bed position, 200mm field-of-view (FOV), zoom 1.0, 2 interactions, 21 subsets and UltraHD PET at reconstruction method using a 3.0mm Gaussian filter. Following PET/CT the patients directly underwent PET/MRI examinations without any further intravenous injection or contrast agent. PET/MRI was acquired with attenuation correction using a dual echo VIBE Dixon sequence separating water and fat. The anatomical MRI sequences used were axial T2, axial T1 In_Out, diffusion and sagittal T2. The simultaneously acquired PET scan used following parameters: 500mm FOV, 400mm anterior-posterior FOV, 1.0 zoom, 3 interactions, 21 subsets, HD PET as reconstruction method and 2.0mm Gaussian filter. Both images were analyzed and compared retrospectively. New molecular imaging permit accurately assess the status of the disease and the progress of therapy and facilitate the selection of optimal treatment and improve patient outcomes. Our results show important advantages of PET/MRI regarding the evaluation and spatial characterization of lesions, including their expansive and invasiveness. We thereby believe that PET/MRI can achieve significant improvement in the diagnosis and therapy of recurrent prostate cancer in cases of poor resolution of soft-tissue contrast of PET/CT. In the future PET/MRI imaging should be employed in such cases.

OP275

Respiratory gated FLT and FAZA PET-CT imaging in patients with tumour motion

D. C. Vines[1], B. D. Driscoll[1], H. Keller[1], A. Lin[1], D. Glick[1], H. Raziee[1], M. Giuliani[1], A. Sun[1], D. A. Jaffray[2]; [1]Princess Margaret Cancer Centre, TORONTO, ON, CANADA, [2]Princess Margaret Cancer Centre and TECHNA Institute, TORONTO, ON, CANADA.

Objectives: Respiratory gated PET (gPET) with FDG has been shown to quantitate radioactivity more accurately in the presence of motion. Other PET radiotracers such as ^{18}F-Fluorothymidine (FLT) or ^{18}F-Fluoroazomycin arabinoside (FAZA) do not typically have the same high target-to-background ratios as FDG. The purpose of this study was to evaluate feasibility and potential benefit of using gPET for imaging lung tumors with motion using either FLT or FAZA. Methods: A retrospective study combining 10 patients (non-small cell lung cancer) with motion from 2 different PET trials was performed. Patients were imaged at 1 and 2h post-injection with either FLT or FAZA (n=6,4, respectively). Attenuation correction (AC) was performed using a helical CT (hCT) for both non-gated (NG) and gPET using 6 bins (hCT-gPET). A respiratory gated cine CT (4DCT) was then also used to reconstruct the matching phase of the gPET to create phase-matched AC gPET (PM-gPET). Scans were analyzed in patients having tumor motion greater than 5mm as assessed by 4DCT. Uptake of FLT and FAZA in the primary tumor was measured as SUVmax and SUVpeak. For both gPET methods (hCT and PM) only the exhale bin was used. To allow comparison of both gPET methods to NG data, the original 1200s NG scan was re-binned to 200s to match the gPET bin time. Evaluation of the effects of gated PET was performed by comparing SUV's for both hCT- and PM-gating methods to NG. Results: Tumour motion ranged from 5.7-26.1mm. SUVmax values for NG, hCT- and PM-gating were 3.04±1.6, 2.99±1.8, and 2.97 ±1.7, respectively, while SUVpeak values were 2.37±1.3, 2.39±1.5, and 2.36±1.4. It appears there is little difference in uptake between both gPET methods and NG, as well as for SUVmax and SUVpeak. Within FLT and FAZA there were also little differences. However, gPET showed some differences in spatial distribution of uptake in some cases. Conclusions: Both gated FLT and FAZA PET were feasible, however, the potential benefit of gating was not as evident as previous FDG data suggest. Additional data with tumor motion is required to determine if there are differences in the potential benefit of gPET using uptake metrics of SUVmax and SUVpeak. Although there seems to be little difference between quantitative results in patients with tumor motion, there may nevertheless, be differences in spatial distribution of the uptake regions within tumors among the 3 imaging methods. The impact of method on spatial distribution requires further investigation.

OP276

The diagnostic quality of 18-F-FDG PET images from the PET/MR in comparison with the PET/CT

E. Voets, **M. G. W. Visser**, F. M. Mottaghy, S. Vöö; Maastricht UMC, Maastricht, NETHERLANDS.

Aim: The purpose of this study was to compare and correlate the diagnostic quality level of PET images based on Magnetic Resonance Attenuation Correction (MRAC) from the hybrid PET/MR (Siemens Biograph mMR) with those derived from Computed Tomography Attenuation Correction (CTAC) of the PET/CT (Philips Gemini TF TOF 64) at our department. **Material and methods:** Nine consecutive oncology patients (54 years ±18.6) which were included in this research underwent a whole body 18-F-FDG PET/CT and a whole body PET/MR. The PET/MR was subsequently performed after the routine PET/CT, approximately 15 minutes later, for validation of our new PET/MR system and in order to avoid unnecessary administration of additional 18-F-FDG radioactive tracer. Visual assessment

was performed by four experienced nuclear medicine physicians and included the overall image parameters contrast-to-noise ratio (CNR), signal-to-noise ratio (SNR), and the delimitation of lesions based on a Likert scale 0-5. Quantitive assessment was determined in ROI measurements on MR/CT PET images. Volume of interest (VOI) were drawn over four normal structures (liver, spleen, mediastinal blood pool, and muscle gluteus maximus). SUV_{max} and SUV_{mean} values were determined in VOI on the MRAC and CTAC images. Between correspondent SUV_{mean} and SUV_{max} on MRAC and CTAC the difference was determined on Bland Altman plots. The study was approved by the internal ethical review board and all subjects gave written informed consent prior to inclusion in the study. **Results:** The Likert scale based analyses show a good inter observer agreement with regard to SNR and delimitation of lesions (median 0) and a good agreement for CNR (median 0.25). The Bland Altman test showed < 0.4 mean difference between SUV_{max} (MRAC-CTAC) indicating a very good agreement (SUV_{max} liver 0.04, mediastinal blood pool, 0.02 and muscle gluteus maximus 0.16) and a relatively good agreement for the spleen (SUV_{max} spleen 0.38). The same was available for the SUV_{mean} (liver 0.16, spleen -0.27, mediastinal blood pool 0.11, and muscle gluteus maximus -0.14). **Conclusions:** Our results show an overall agreement for the visual and quantitive image quality between MRAC and CTAC from the PET/MR and PET/CT. Differences observed between MRAC and CTAC derived SUV values are negotiable and may be attributed to the time-delay between the PET/CT and PET/MRI scans and biologic clearance of radiotracer. Further studies are required to assess SUV measurements when performing different MR attenuation correction techniques.

OP277

Optimisation of Time per Bed Position in ^{18}F-FDG PET/CT Lung Cancer Studies

A. List, E. Souza, N. H. Patel, J. W. Hubber, H. Tam, S. Khan, N. D. Soneji, Z. Win, K. S. Nijran; Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Aim: To find the minimum time required per bed position for a 18F-FDG PET/CT scan while maintaining diagnostic image quality, lesions detectability, and clinical diagnosis. **Methods:** Forty patients with lung cancer referred to the PET/CT imaging centre took part in the study. A standard half body protocol (eyes to mid-thigh) with three minutes per bed position, was performed on the Siemens Biograph-64 PET/CT scanner at our institute followed by an extra 10 minutes bed position over the lungs collected in list mode. The data was subsequently histogrammed to replicate bed position times of 2 min to 4 min in 30sec increments. A minimum bed position time of 2 minutes was determined from previous phantom studies which demonstrated a high confidence level for image quality when acquiring for $\geq$ 2 minutes. Transverse slices were reconstructed using attenuation and scatter-corrected iterative reconstruction 3D OSEM (4 iterations, 8 subsets, 5mm FWHM Gaussian post reconstruction filter, 168 x 168 matrix size). Reconstructed images from datasets at different time per bed position (i.e. 2 min, 2.5 min, 3 min, 3.5 min and 4 min) were independently reviewed by three Nuclear Medicine radiologists while blinded to the dataset used for image reconstruction. The number of lesions, the maximum standard uptake value (SUV_{max}), and a confidence score of diagnosis and image quality using a scale of 1 to 5 (1 indicating low confidence of diagnosis, 5 indicating high confidence in diagnosis) were collected. **Results:** For each patient, the mean SUV_{max} of all lesions and nodes between the different time per bed position was evaluated with z-statistics. The confidence scores for the different time per bed positions were evaluated with a score $\geq$4 indicating high confidence of diagnosis and image quality. Kappa analysis was performed to determine inter-observer and final report agreement. Initial results show good agreement between the observers for a 2.5 minutes bed position time. The SUV_{max} of each lesion and node, the mean SUV_{max} for all lesions and nodes, and the diagnostic confidence for each time per bed-position will be presented at the meeting. **Discussion and Conclusion:** The optimal time required per bed position for lung cancer patients from our initial findings is 2.5 minutes. We will work towards implementing an optimised protocol for lung cancer patients. Future work will look at optimising the time per bed position for different clinical applications.

OP278

First clinical experience with SUVmax cuantification by a dedecated breast PET compared to PET-CT.

R. SANCHEZ JURADO, J. FERRER REBOLLEDA, M. COZAR SANTIAGO, J. AGUILAR BARRIOS, R. BRISA VAZQUEZ, A. VICEDO GONZALEZ; ERESA MEDICAL GROUP, Valencia, SPAIN.

Methods: Twenty-five patients with invasive breast cancer (20 ductal, 3 lobular, 2 other) prior to chemotherapy and surgery, underwent both 18F-FDG breast PET/CT and MAMMI-PET in prone position with hanging breasts. PET/CT and MAMMI-PET were performed 60 min and 90 min after injection of 223 (+/- 15) MBq of FDG, respectively. Primary tumor detection was assessed and FDG uptake, expressed as maximum standardized uptake value (SUVmax) was calculated in both and compared the results. RESULTS: Twenty-five patients evaluated, and focused only in the breast imaging: 34 lesions detected by PET/CT and 42 lesions by MAMMI-PET. All lesions were confirmed by histology. Also, MAMMI-PET revealed a heterogeneity uptake of the tumor. Agreement in FDG uptake between PET/CT and MAMMI-PET was high (r=96, 97% CI 0.92-0.98). SUVmax quantification differences were observed between PET/CT and MAMMI-PET. 0.3 points of SUV higher in MAMMI-PET than PET/CT. CONCLUSION: The dedicated high-resolution breast PET (MAMMI-PET) was able to visualize all breast tumors including in its field of view (about 2 cms upper limit of pectoral muscle). Actually SUVmax values by MAMMI-PET are directly comparable to standard PET-CT. The high-resolution of MAMMI-PET provides a better visualization of tumoral heterogeneity with possible impact in the management of the patients. However, further studies will be necessary to support the use of MAMMI-PET for tumor quantification.

OP279

Amyloid brain PET: Does SUVr semi-quantitation help reader confidence including cases of suspected mixed proteinopathies?

N. Gulliver, G. Havariyoun, D. Ruiz, A. Eccles, N. Mulholland, G. Vivian; King's College Hospital, London, UNITED KINGDOM.

Introduction: Amyloid brain PET-CT is a relatively new tool for in-vivo investigation of suspected Alzheimer's disease and the availability of new amyloid-binding ligands has generated intense interest in this area. Three fluorine-18 tracers (^{18}F-florbetaben, ^{18}F-florbetapir, ^{18}F-flutemetamol) have now entered clinical use in a limited number of centres in the UK. However, since the routine clinical use of amyloid PET is not publically funded, it is rare for reporting physicians to see significant numbers of scans. Aim: We aim to describe our single scanner centre experience thus far with amyloid ligands in investigating aetiology of memory loss. In addition, we aim to assess the impact of semi-quantitation on reader confidence of amyloid brain PET scans. Clinical criteria for use of amyloid PET includes patients who satisfy a core criteria but with mixed aetiology presentation. In these cases, the clinical question is to assess degree of amyloid burden with co-existing synucleinopathies. Methods: We retrospectively reviewed patients seen within our department from February to December 2015 who were imaged with amyloid-binding PET ligands as part of their routine clinical investigation. All scans were reported visually. Images were binary read (abnormal/positive or normal/negative) using Hermes Hybrid Viewer by two reporting clinicians having received multiple ligand-specific reader training, stating a confidence level from 1 to 5 (1 = not confident at all, 5 = extremely confident). Images were then assessed by semi-quantitative

analysis using Hermes BRASS™ software with SUVr calculated for frontal, anterior cingulate, lateral temporal, precuneus, posterior cingulate and parietal brain regions with a cut-off of Z<-2.5SD from database template. Confidence scoring was with then repeated. Statistical analysis was performed using SPSS. Results: The mean age of patients was 67 (range 50-80), with 6 male and 4 female. 50% of patients had previous examinations with findings consistent with Parkinson's disease (PD) or PD"plus" syndromes. Results indicated a statistically significant increase in confidence post quantitation for both reporting physicians (p=0.005). Global amyloid findings based on ligand-specific criteria for interpretation were changed from positive to negative in four (reader 1) and two (reader 2) cases. There was a statistically significant increase in inter-observer agreement (from k=0.2 pre quantitation to k=1 post quantitation) for overall scan result. Conclusions: although a larger sample size is needed to confirm this, early indications suggest semi-quantitation with Hermes BRASS software has some benefits in improving reader confidence and inter-observer agreement including for amyloid plaque burden assessment in patients with PD.

OP280

Correlation between TNM staging and tumor metabolic parameters assessed in vivo by FDG-PET/CT in patients with lung cancer

P. Cegla[1], K. Tyczynska[2], R. Czepczynski[3], W. Cholewinski[4]; [1]Greater Poland Cancer Center, Poznan, POLAND, [2]Affidea Medical Center, Poznan, POLAND, [3]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, POLAND, [4]Chair and Department of Electroradiology, Medical University in Poznan, Poznan, POLAND.

OBJECTIVES: Lung cancer is the most common cancer in men and globally the leading cause of death in both sexes. Although CT is the primary diagnostic method that provides relevant information about the morphology and location of the tumor, the introduction of PET/CT allowed greater accuracy for determining the stage of the process and acquiring in vivo information on the biology of cancer cells. Commonly used TNM staging, despite the proven benefits has the limitations of pure morphological assessment. Several parameters of the biological activity of tumor in PET images have been introduced based on SUV and its derivatives as metabolic tumor volume (MTV) and TLG (total lesion glycolysis), calculated for primary tumor [TLG] and all foci of the cancer [TLGtotal]. The aim of the study was to compare the TNM stage of the cancer with biological parameter as MTV and TLG in patients with lung cancer. **MATERIAL AND METHODS:** The analysis was performed in 65 patients (40M,25F) aged 70±10y with a histologically confirmed lung cancer before treatment. PET scans were acquired on Gemini TF PET/CT scanner 60min after IV injection of 18F-FDG with the mean activity of 364±75MBq, with the area being examined from calvaria to half way down the thigh. The reconstructed PET images were evaluated using MIM 6 Software for MTV and TLG values. For MTV calculation a phantom study was performed for simulation of the variety of activity and volume. **RESULTS**: The analysis of the cancer stage showed stage IV-17patients, stage IA and IIIA-12 patients, stage IIA-11patients, 8 patients with stage IB, stage IIB at 5 patients. The lowest TLG values were observed in stage IA (19.05±17.5) and the highest in stage IIB (415±384). Other groups showed TLG values: stage IB (155 ±108), stage IIA (210±254), stage IIIA (278±348), stage IV (275±381). TLGtotal values were as follows: stage IA (19.5±17.2), stage IB (156 ±107), stage IIA (216v251), stage IIB (433±403), stage IIIA (299±344) and stage IV (433±464). An expected strong and significant correlation was found between the MTV and feature T but there was no correlation between the stage and both parameters of TLG and TLGtotal. **CONCLUSION:** Metabolic parameters of the tumor and proliferative process expressed with TLG values represent different from TNM staging system biological description of lung cancer, which may be important for the treatment and prognosis.

OP281

Image quality of PET ^{18}F-FDG for patients with a high body weight

J. Hagerman[1], B. Olsson[1], A. Stenvall[2], F. Hedeer[1], H. Almquist[1], J. Oddstig[2], C. Hindorf[2]; [1]Clinical Physiology and Nuclear Medicine, Lund, SWEDEN, [2]Radiation Physics, Lund, SWEDEN.

Aim The image quality for patients that undergoes ^{18}F-FDG PET examination and has a body weight over 100 kg is lower than for patients with body weight less than 100 kg. In the clinical protocol patients are administered an activity of 4 MBq/kg body weight, maximum 400 MBq, and images are acquired for 2 min/bed position. The aim of this study was to investigate whether the image quality could be improved after increasing the maximum activity to 500 MBq and prolonging the acquisition time. **Material and Methods** 23 patients were included in the study. Nine patients had a weight <100 kg (63-95 kg) and 14 patients had a weight >100 kg (108-147 kg). The patients were injected with 4 MBq/kg, maximum 500 MBq, and imaged after 60 minutes on a GE Discovery PET/CT 690. The acquisition time for patients <100 kg was 2.0 min/bed. For patients with a weight >100 kg the acquisition time per bed was prolonged: 105-125 kg, 2.5 min/bed; 126-150 kg, 3.0 min/bed. Listmode allowed studies for patients >100 kg to be truncated to correspond to acquisition of maximum 400 MBq and 2.0 min/bed. Three regions-of-interest were drawn in the liver. The SNR (signal-to-noise ratio) was calculated as the ratio of the mean value of the activity concentration (kBq/ml) and the standard deviation. Two expert readers scored the studies for image quality independently. Scores were given by a five grade image quality scale (1=unacceptable image quality and 5=very high image quality). **Results** SNR for patients <100 kg was 10.5. For patients >100 kg the SNR increased from 7.8 to 9.3 ($p<0.05$) when the maximum activity was increased to 500 MBq and the time per bed was prolonged. The SNR for patients >100 kg with the new protocol was not statistically different from patients <100 kg. The mean value of the scored image quality for patients <100 kg was 3.1. For patients >100kg the mean image quality score increased from 2.2 to 2.9 ($p<0.05$) when increasing the injected activity and prolonging the time per bed position. The image quality score increased in 9 and 10 of 14 patients, respectively, for the two readers. **Conclusions** Increasing the maximum injected activity to 500 MBq and prolonging the acquisition time for patients with a body weight over 100 kg improved the image quality to become similar to the image quality in patients with a body weight less than 100 kg.

OP282

Does cardiac ^{123}I-*m*IBG scintigraphy predict appropriate ICD-therapy in stable chronic heart failure patients?

D. O. Verschure[1,2], J. R. de Groot[1], S. Mirzaei[3], O. Gheysens[4,5], B. L. F. van Eck - Smit[1], G. A. Somsen[6], H. J. Verberne[1]; [1]Amsterdam Medical Center, Amsterdam, NETHERLANDS, [2]Zaans Medical Center, Zaandam, NETHERLANDS, [3]Wilhelminenspital, Vienna, AUSTRIA, [4]University Hospitals Leuven, Leuven, BELGIUM, [5]KU Leuven, Leuven, NETHERLANDS, [6]Cardiology Centers of the Netherlands, Amsterdam, NETHERLANDS.

Aim: Chronic heart failure (CHF) is a life-threatening disease, in part due to sudden cardiac death (SCD). Implantable cardioverter defibrillators (ICD) for primary prevention of SCD have improved overall survival of CHF patients. However, a high percentage of patients never receives appropriate ICD therapy. Moreover, ICD's are associated with malfunction, (operative) complications (e.g. infection, inappropriate ICD shocks) and high cost. Therefore, optimization of current selection criteria for

primary ICD is needed. This prospective multicenter study evaluated whether cardiac sympathetic activity assessed by planar ^{123}I-*m*IBG scintigraphy could identify high-risk CHF subjects most likely to experience appropriate ICD therapy. **Materials and Methods:** A total of 135 stable CHF subjects (age 64.5±9.3 years, 79% male, LVEF 25±6%) referred for primary prevention ICD implantation in 12 centres in Austria, Belgium and the Netherlands were enrolled. All subjects underwent planar cardiac ^{123}I-*m*IBG imaging before ICD implantation. Planar images were acquired at 15 minutes (early) and 4 hours (late) after i.v. administration of 185 MBq ^{123}I-*m*IBG. Early Heart/Mediastinum ratio (H/M), late H/M and ^{123}I-*m*IBG washout (WO) were calculated. Cross-calibrated phantom study-data were used to correct these values for differences in collimator-gamma-camera combinations. Cox proportional hazards regression was used to determine the association between ^{123}I-*m*IBG derived parameters (i.e. H/M and WO) and appropriate ICD therapy. Furthermore, the association between H/M and WO and the combined endpoint of appropriate ICD therapy, NYHA functional class progression and SCD was investigated, expressed as hazard ratio (HR) with 95%-confidence interval (95%CI). **Results:** The mean early H/M was 2.05±0.39, late H/M 1.79 ±0.38 and ^{123}I-*m*IBG WO 12.4±9.2. During a median follow-up of 29±16 months (2-64 months), 21 subjects (15.6%) experienced a cardiac event (appropriate ICD therapy [10], NYHA functional class progression [6] and SCD [5]). In multivariate analysis, WO was associated with occurrence of the combined endpoint (HR 1.063 [95%CI: 1.016-1.112], *p=0.008*). WO had an almost statistical significant association with appropriate ICD therapy (HR 1.065 [95%CI: 1.000-1.135], *p=0.051*). No association was observed between H/M and appropriate ICD therapy or combined endpoint. **Conclusion:** There is a significant association between cardiac sympathetic activity as assessed by planar ^{123}I-*m*IBG WO and the combined endpoint of appropriate ICD therapy, worsening of heart failure and SCD in stable CHF subjects with an ICD for primary prevention. Planar myocardial ^{123}I-*m*IBG scintigraphy derived WO trended toward an association with appropriate ICD therapy. Therefore, ^{123}I-*m*IBG scintigraphy seems to identify CHF subjects most likely to experience appropriate ICD therapy.

OP283

Polymorphism of SLC6A2 gene does not influence outcome of myocardial ^{123}I-*m*IBG scintigraphy in patients with chronic heart failure

D. O. Verschure[1,2], F. Baas[1], B. L. F. van Eck-Smit[1], G. A. Somsen[3], H. J. Verberne[1]; [1]Amsterdam Medical Center, Amsterdam, NETHERLANDS, [2]Zaans Medical Center, Zaandam, NETHERLANDS, [3]Cardiology Centra Netherlands, Amsterdam, NETHERLANDS.

Aim: Chronic heart failure (CHF) results in both increased cardiac sympathetic activity and myocardial inflammation. The aim of this study was to identify the relationship between severity of heart failure (i.e. NTproBNP and LVEF), cardiac sympathetic activity (^{123}I-*m*IBG scintigraphy) and markers of inflammation in subjects with stable, optimally treated CHF. In addition, the predictive value for cardiac events (ventricular arrhythmia, progression of CHF, cardiac death) of ^{123}I-*m*IBG parameters and these inflammatory markers was evaluated. **Materials and Methods:** Fifty-five CHF patients (age 66.3±8.0 years, 78% male, LVEF 22.4±6.3) referred for cardiac ^{123}I-*m*IBG imaging were included. At 15 minutes (early) and 4 hours (late) after i.v. administration of ^{123}I-*m*IBG (185 MBq), planar images were acquired. Early Heart/Mediastinum (H/M), late H/M and ^{123}I-*m*IBG washout (WO) were calculated. NT-proBNP and inflammatory markers (i.e. C-reactive protein (CRP), IL-1β, IL-6, IL-8, IL-10, IL-12p40, tumour necrosis factor-α (TNF-α), soluble (s)E-selectin, myeloperoxidase (MPO), plasminogen activator inhibitor-1 (PAI-1), tPA, tumor necrosis factor receptor 1 (TNFR1) and TNFR2) were measured in blood plasma samples, taken just before ^{123}I-*m*IBG administration. **Results:** Mean early H/M was 2.12 ± 0.39, late H/M 1.84 ± 0.40 and ^{123}I-*m*IBG WO 13.0 ± 10.9. LVEF was the only independent predictor of late H/M (adjusted R^2 = 0.100, p = 0.011). NT-proBNP was an independent predictor of ^{123}I-*m*IBG WO (adjusted R^2 = 0.090, p = 0.015). None of the inflammatory markers was related to late H/M or ^{123}I-*m*IBG WO. During a median follow-up of 31 months (2 - 58 months), 13 patients experienced a cardiac event (ventricular arrhythmia (4), progression of CHF (4) and cardiac death (5)). Univariate Cox regression analysis showed that the risk of a cardiac event was associated with CRP (HR 1.047 [95% CI: 1.013-1.081]), NT-proBNP (HR 1.141 [95% CI: 1.011-1.288]), MPO (HR 0.998 [95% CI: 0.996-1.000]) and late H/M (HR 0.182 [95% CI: 0.035-0.946]). Multivariate Cox regression analysis showed that only CRP, NT-proBNP, MPO and IL-12p40 were predictors of a cardiac event. **Conclusion:** In this specific CHF population inflammatory markers and ^{123}I-*m*IBG assessed cardiac sympathetic activity are both prognostic indicators.

OP284

Validation of the 2-year cardiac mortality risk model using I-123 meta-iodobenzylguanidine in chronic heart failure

K. Nakajima[1], T. Nakata[2], T. Doi[3], T. Kadokami[4], S. Matsuo[1], T. Konno[1], T. Yamada[5], A. Jacobson[6]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]Hakodate-Goryokaku Hospital, Hakodate, JAPAN, [3]Obihiro-Kosei Hospital, Obihiro, JAPAN, [4]Saiseikai-Futsukaichi Hospital, Tsukushino, JAPAN, [5]Osaka Prefectural General Medical Center, Osaka, JAPAN, [6]Diagram Consulting, Kihei, HI, UNITED STATES.

Purpose: A 4-parameter risk model for predicting cardiac mortality was developed based on a Japanese pooled database consisted of 1280 patients with chronic heart failure (CHF), who underwent I-123 meta-iodobenzylguanidine (MIBG) imaging (EHJ Cardiovasc Imaging 2015/12/24). This study aimed to validate this 2-year risk model in a new cohort of CHF patients. Methods: A total of 546 patients (392 males, 72%; age, 66 ± 14 years) with either suspected or definitive CHF who underwent I-123 MIBG imaging were selected retrospectively from 4 hospitals. Baseline conditions were 126 patients (23%) with NYHA class III-IV, left ventricular ejection fraction (LVEF) 39 ± 14%, and ischemic etiology in 198 (36%) patients. Late anterior imaging of the chest was performed 3-4 hours after injection of 111 MBq I-123 MIBG, and heart-to-mediastinum ratio (HMR) was calculated on-site. Since low-energy (LE) and low-medium-energy collimators were used at the participating hospitals, HMRs were adjusted to LE-collimator comparable values using institutional collimator-specific conversion coefficients as previously established. The 2-year cardiac mortality risk prediction model used was developed using 4 variables: age, New York Heart Association (NYHA) functional class, I-123-MIBG HMR and LVEF. Patients were classified into 3 risk categories using commonly acceptable threshold of 2%/y and average of the 2-year cardiac mortality risk (12%); namely 2-year cardiac mortality of low (<4%), intermediate (4-12%) and high (>12%) risk. Results: Adjusted late HMR was 1.51 ± 0.30. The average 2-year cardiac mortality risk calculated by the model was 12 ± 11%, ranging from 0.4% to 52%. Mortality risk for 2 years was estimated to be 2.4 ± 0.9% (n=85), 7.5 ± 2.2% (n=291), and 24.9 ± 11.1% (n=170) for low, intermediate and high-risk groups, with predicted numbers of cardiac deaths of 1, 22, and 42, respectively. During the 2-year follow-up, cardiac mortality occurred in 1 (2%), 24 (8%), and 82 (48%) patients in the 3 risk groups. The predicted and actual numbers of cardiac deaths were comparable for low and intermediate risk groups, but the model underestimated cardiac mortality in the high-risk group. This probably reflected more severe CHF in the validation population in a hospital versus the derivation population (2-year cardiac mortality in class III-IV: validation population 51%; derivation population 20%). Conclusion: The present results demonstrated validity of the 2-year risk model, particularly for

differentiating low and intermediate risk patients from high-risk patients. In these CHF patients, the model may have practical applications to assist in clinical management decisions.

OP285

Characteristics of gamma cameras with medium-energy-type collimators in cardiac ^{123}I-MIBG imaging: A multicenter MIBG phantom study in Japan

K. Okuda[1], K. Nakajima[2], C. Kitamura[3], M. Hori[3], Y. Kirihara[3], S. Matsuo[2], J. Taki[2], M. Hashimoto[1], S. Kinuya[2]; [1]Kanazawa Medical University, Uchinada, JAPAN, [2]Kanazawa University Hospital, Kanazawa, JAPAN, [3]FUJIFILM RI Pharma Co., Ltd., Tokyo, JAPAN.

Objectives: We have proposed a standardization method using a dedicated phantom for the determination of the ^{123}I-metaiodobenzylguanidine (MIBG) heart-to-mediastinum ratio (HMR) for the calibration of the characteristics of gamma cameras with collimators. We have been accumulating the calibration factors obtained from different combinations of gamma cameras and collimators in Japan. The purpose of this study was to characterize the calibration factors for various gamma camera with medium-energy (ME)-type collimators in a multicenter phantom study. Methods: A total of 667 planar phantom images were acquired by using gamma cameras manufactured by ADAC Laboratories (n = 28), GE Healthcare (n = 107), Philips Healthcare (n = 48), Shimadzu Medical Systems (n = 28), Siemens Healthcare (n = 262) and Toshiba Medical Systems (n = 210). The low-medium-energy general-purpose (LMEGP, n = 328), ME/MEGP/ME general-all-purpose (GAP) (n = 249) and ME low-penetration (MELP, n = 90) collimators were used in the multicenter phantom study. The mean acquisition time was 309 ± 126 s (95% range, 70-600 s). Planar images were obtained with 64 × 64 (n = 2), 128 × 128 (n = 30), 256 × 256 (n = 495) and 512 × 512 (n = 140) matrices. The calibration factor was calculated by using a dedicated software program, and defined as the conversion coefficient K. The K value shows an approximate range of 0.5 to 1.0, corresponding to low-energy to ME collimators. Results: The mean K value for all of the ME-type collimators was 0.863 ± 0.054 (95% range, 0.765-0.976). When the conversion coefficients were evaluated for each of the collimators, the mean K values for the LMEGP, ME/MEGP/MEGAP and MELP were 0.834 ± 0.043 (95% range, 0.829-0.839), 0.880 ± 0.044 (0.874-0.885) and 0.922 ± 0.046 (0.913-0.932), respectively ($P \leq 0.0001$). The mean K values for the LMEGP showed significantly higher in SIEMENS (0.845 ± 0.042, 95% range, 0.839-0.851) than Toshiba (0.822 ± 0.033, 0.816-0.829) ($P < 0.0001$). The mean K values were equivalent among the manufacturers in the ME/MEGP/MEGAP and MELP collimators. Conclusions: The characteristics of the gamma cameras and collimators could be determined by using the conversion coefficient K, derived from the multicenter phantom study. Since the K values for the LMEGP collimators differed significantly, depending on the manufacturers, we might apply cross-calibration to ^{123}I-MIBG imaging to obtain standardized HMR.

OP286

Characterization of cardiac sympathetic denervation and innervation after ischemia-reperfusion injury as assessed by a novel PET tracer [11C]Me@HAPTHI for the norepinephrine transporter

X. Li[1], M. Dumanic[1], A. Kiss[2], C. Philippe[3], N. Berroterán-Infante[4], M. Mitterhauser[4], W. Wadsak[2], B. Podesser[2], M. Hacker[2]; [1]Vienna General Hospital, Vienna, AUSTRIA, [2]Medical University of Vienna, Vienna, AUSTRIA, [3]Medical university of vienna, Vienna, AUSTRIA, [4]Medical Univiersity of Vienna, Vienna, AUSTRIA.

Background and Aim: Disorders of sympathetic nervous system was recognized as key underlying pathophysiology after myocardial ischemia reperfusion (IR). Norepinephrine transporter (NET) is located in the noradrenergic neurons and is responsible for the synaptic reuptake of extracellular norepinephrine. In this study, a novel PET tracer [11C]Me@HAPTHI with high affinity and selectivity to the NET was used to characterize sympathetic denervation and innervation after myocardial ischemia. **Method:** Myocardial uptake of [11C]Me@HAPTHI was compared [11C]-mHED which is an analogue PET tracer of the NE using PET/CT. In vivo dynamic [11C]Me@HAPTHI gated PET imaging and ex-vivo autoradiography was performed to determine rat myocardial sympathetic nerve denervation (1day, 3days, 1week, 4 weeks) following transient ischemia of 20 minutes. Tracer's biodistribution and kinetics was analysed. Specificity of tracers was evaluated by PET imaging with NET blocking agent Nisoxetine (2mg/kg). Immunohistochemical stains of H&E and Tetrazolium chloride (TTC) assay were used to determine myocardial defect area and remote region. TH staining was quantified to assess sympathetic innervation density. Region-of-interest analysis was used to determine uptake ratios for the ischemic region related to the remote area. **Results:** Significant myocardial uptake of [11C]Me@HAPTHI compared with [11C]mHED PET was observed (Fig.A). After transient ischemia, reduced [11C]Me@HAPTHI uptake was detected from day 1 to 4 weeks, which was confirmed by increased uptake ratio of ischemic area to the non-ischemic area (Fig. A), and increased uptake ratio of non-ischemic area to the blood pool. Representative time-course PET/CT images are shown in figure A. Correspondingly, in autoradiography, decreased uptake in the ischemia region with myocardial injury was observed, which was determined by histology (Fig.C); moreover, innervation in the heart was confirmed during the time course (Fig.B). In the kinetics analysis, the ratio of myocardium to blood radioactivity was reduced by the pre-injection of blockers (Fig. B) confirming the high specificity of cardiac uptake. **Conclusion:**[11C]Me@HAPTHI PET can be used for specific imaging and quantitative method for cardiac adrenergic nerve function with high specific myocardial uptake through NET. It enable in vivo monitoring dynamic repair process after transient ischemia. Further therapeutic studies with remote ischemic conditioning will be conducted at left limb of rats to achieve protection against IR injury and evaluated by [11C]Me@HAPTHI PET scan.

OP287

Abnormal cardiac adrenergic neuron activity assessed by ^{123}I-MIBG is an early marker of cardiac dysfunction in doxorubicin-induced cardiomyopathy in rats

B. Collin[1,2], A. Oudot[1], J. M. Vrigneaud[1], S. Delemasure[3], M. Guillemin[1], P. M. Walker[4,5], A. Lalande[4,5], A. Cochet[1,5], F. Brunotte[1,5]; [1]Centre Georges-François Leclerc, Dijon, FRANCE, [2]ICMUB - UMR CNRS 6302, UBFC, Dijon, FRANCE, [3]Cohiro Biotech, Dijon, FRANCE, [4]CHU François Mitterrand, Dijon, FRANCE, [5]Le2i - UMR 6306, UBFC, Dijon, FRANCE.

Aim: Several antitumor agents are well known to induce cardiac dysfunction such as anthracyclines (*e.g*: doxorubicin) and trastuzumab (Herceptin®). Thus, it is very important to identify, as early as possible, patients at risk of cardiac toxicity induced by cancer therapies, especially when combination therapies are necessary. Echocardiography and nuclear functional imaging such as Single Photon Emission Computed Tomography (SPECT) are common techniques to determine Left Ventricle (LV) functional parameters during anticancer treatment. Interestingly, SPECT could also be a valuable tool to go further, regarding its ability to assess the cardiac neurons activity within the heart with the noradrenaline analog ^{123}I-Metaiodobenzylguanidine (^{123}I-MIBG). Thus, the purpose of the present study was to follow and compare over time the evolution of cardiac function (echocardiography) and sympathetic innervation (SPECT) in a rat model of doxorubicin-induced cardiac failure. **Materials and methods:** Wistar Rats were respectively treated with doxorubicin (DOX, cumulative dose of 15 mg/kg) or with a saline solution (control, CTRL) and followed-up over a 6 weeks period. Transthoracic

micro-echocardiography (functional cardiac parameters such as Fractional shortening - FS) and ^{123}I-MIBG SPECT (cardiac sympathetic innervation) of rats was performed at baseline, two, four and six weeks. Cardiac injury biomarkers (troponin I - Tn-I and N-Terminal Pro-Brain Natriuretic Peptide - NT-proBNP) concentrations were determined in plasma by ELISA at 6 weeks. **Results:** Body weight evolution of DOX group was significantly lowered compared to CTRL group from week 2 (W2) to week 6 (W6). Echocardiography showed that DOX significantly impaired the FS at W6 (31.4±1.7% *vs* 46.1±2.1%, $p < 0.001$) whereas SPECT demonstrated a significant sympathetic denervation through the decrease of ^{123}I-MIBG uptake in DOX group as early as W2 and this effect was maintained until W6 (Heart to mediastinum ratio at W6: 3.05±0.20 *vs* 1.21±0.10, $p < 0.001$). At W6, plasma levels for both Tn-I and NT-proBNP were dramatically increased in the DOX group when compared to CTRL (respectively: 628.0±245.0 pg/mL *vs* 2.4±2.4 pg/mL, $p < 0.01$ and 463.0±236.0 pg/mL *vs* 0.0±0.0 pg/mL, $p < 0.05$). **Conclusion:** Our results suggest that ^{123}I-MIBG SPECT imaging could constitute a reliable biomarker of doxorubicin-induced-cardiomyopathy much earlier than echocardiography did with functional parameters. Thus, molecular imaging of cardiac sympathetic innervation in this cardiotoxicity model could be particularly relevant to evaluate either new cardioprotective drugs in a preclinical setting or to set up cardioprotective regimens for clinical purpose.

Standardization of dietary regimen to highlight the metabolic effect of doxorubicin administration on myocardium in mice: a microPET study

G. Ferrarazzo[1], M. Bauckneht[1], F. Pastorino[2], F. Fiz[1,3], M. Ponzoni[2], G. Bottoni[1], A. Buschiazzo[1], F. Ticconi[1], L. Emionite[4], A. Bozzano[1], A. Nieri[1], M. Pennone[1], C. Marini[5], S. Morbelli[1], G. Sambuceti[1]; [1]Nuclear Medicine Unit, IRCCS-IST San Martino, University of Genoa, Genova, ITALY, [2]Laboratory of Oncology, Istituto Giannina Gaslini, Genova, ITALY, [3]Nuclear Medicine Unit, Department of Radiology, Uni-Klinikum Tübingen, Tübingen, GERMANY, [4]Animal facility, IRCCS AOU San Martino-IST, Genova, ITALY, [5]Institute of Bioimaging and Molecular Physiology, CNR, Milan, Genoa Section, Genova, ITALY.

Aim. Several in vitro studies documented that antracycline-related cardiomyopathy is at least partially related to the capability of these drugs to impair mitochondrial function. The reduced oxidative phosphorylation rate and the consequent decrease in ATP availability accelerate glycolytic flux far before the development of contractile dysfunction. Accordingly, an increased ^{18}F-FDG uptake in the left ventricular myocardium might represent an early predictor of toxic doxorubicine (DXR) effect. However, this hypothesis has not been fully tested, since myocardial FDG uptake is profoundly influenced by dietary regimen in the days preceding the scan, despite a correct fasting period before tracer injection. The aim of the present study was to verify whether and to what degree DXR increases cardiac FDG uptake in a series of mice, exposed to the same dietary condition before microPET scanning. **Materials and Methods.** Animal experiments were reviewed and approved by the Italian Ministry of Health. Five-week-old female, athymic mice were treated once a week for 3 weeks, with DXR (5 mg/kg, n=7) or saline (n=7). Time points of PET scans were at baseline and 3 weeks after treatment beginning. FDG imaging was preceded by 6-hours fasting, with a dedicated micro-PET system (Albira, Bruker, US). After intraperitoneal administration of ketamine/xylazine (100 and 10 mg/kg, respectively), mice were weighted and serum glucose level was tested. A dose of 3-4 MBq of FDG was injected through a tail vein, while 10 minutes image acquisition was performed 40 minutes later. An operator unaware of mice treatment manually identified a volume of interest on the left ventricular myocardium and hind limb skeletal muscle (internal control). Average standardized uptake values (SUV) within both regions were thus calculated and termed LV-SUV and SM-SUV, respectively. **Results.** DXR markedly increased the ratio between LV- and SM-SUV from 2.3 ±0.5 at baseline to 4.6±1.4 at the end of the experiment ($p<0.05$). Conversely, the same ratio remained stable in control animals, starting from 2.2±0.2 and resulting 2.3±0.2 in the second PET scan (p=ns vs. baseline; $p<0.05$ vs. DXR group). **Conclusions.** Administration of high DXR doses result in increased cardiac FDG uptake in mice fed with a standardized dietary regimen. Further studies, including lipid-rich diet, are needed to clarify the potential additive value of diet regimen standardization in the early detection of myocardial metabolic injury related to DXR, especially in patients with Hodgkin Lymphoma submitted to serial ^{18}F-FDG imaging and treatment protocols encompassing DXR.

First Clinical Study of Gastroenteropancreatic Neuroendocrine Tumor (GEP-NET): Patient Dosimetry Assessment with the Somatostatin Receptor Antagonist ^{68}Ga-OPS202

S. Beykan[1], G. P. Nicolas[2], M. Fani[2], R. Mena[3], J. Kaufmann[3], H. Bouterfa[3], R. Bejot[3], D. Wild[2], M. Lassmann[1]; [1]University of Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY, [2]Division of Nuclear Medicine, University of Basel Hospital, Basel, SWITZERLAND, [3]OctreoPharm Sciences GmbH, Ipsen Group, Berlin, Germany, Berlin, GERMANY.

Aim: Radiolabeled somatostatin receptor antagonists are a promising class of radiotracers for imaging and treatment of neuroendocrine tumor patients. We report here on the biodistribution and dosimetry of ^{68}Ga-OPS202 PET/CT in gastroenteropancreatic neuroendocrine tumors (GEP-NET) in a phase I trial (ClinicalTrials.gov NCT02162446). **Materials and Methods:** In-vivo patient studies in metastatic G1/G2 GEP-NET patients (5 female, 7 male, weight: 55±19 kg) were performed with approximately 158±34 MBq ^{68}Ga-OPS202 (amount of peptide: 15μg). Biodistribution and dosimetry of ^{68}Ga-OPS202 were investigated. A series of whole-body PET/CT scans were conducted, multiple blood and urine samples were taken up to 4 hours after intravenous injection. Time-activity curves (TACs) were generated for blood and selected organs delineated on fused PET/CT images. Organ-specific time-integrated activity coefficients (TIACs) were calculated by using the NUKFIT software tool (Kletting et al., MedPhys 2013;40:102504) for the corresponding TACs. Blood- and image-based (LV2-LV4) time-activity curves were integrated to calculate the bone marrow TIACs. Based on these data, the absorbed organ dose coefficients for a 74kg patient were calculated using the OLINDA/EXM software and applying the ICPR60 weighting factors. **Results:** The highest calculated absorbed doses were registered in urinary bladder wall (1.01E-01 mGy/MBq), the kidneys (8.43E-02 mGy/MBq) and the spleen (6.02E-02 mGy/MBq). The calculated mean absorbed dose, based on imaging, for the bone marrow was 1.13E-02 mGy/MBq. None of the absorbed doses exceed organ toxicity levels. An analysis of the activity in the urine samples shows that, 8.1±2.8% of the injected activity (min: 3.3%, max: 12.4%) and 1.6±0.6% of the injected activity (min: 0.6%, max: 2.6%) are excreted 2 h and 4 h respectively after administration of the activity. The effective dose coefficient for ^{68}Ga-OPS202 is 2.4E-02 mSv/MBq which is comparable to previous studies with ^{68}Ga-DOTATATE (2.6E-02 mSv/MBq), ^{68}Ga-DOTATOC (2.2E-02 mSv/MBq), and lower than the values for ^{111}In-DTPA-octreotide (8.0E-02 mSv/MBq). The effective dose for an injection of 150 MBq ^{68}Ga-OPS202 is 3.6 mSv. **Conclusion:** ^{68}Ga-OPS202 is well tolerated and

exhibits a favorable dosimetry delivering absorbed doses to organs that are comparable to other ^{68}Ga-labeled somatostatin receptor ligands. As expected, the main pathway of excretion is the urinary tract.

OP290

^{68}Ga-Pentixafor-PET/CT in Neuroendocrine Tumors - a triple tracer approach

R. A. Werner[1], A. Weich[2], H. Wester[3], M. Scheurlen[2], **J. Brumberg**[1], T. Higuchi[4], S. Samnick[1], M. Lassmann[1], C. Blümel[1], M. Rudelius[5], A. K. Buck[1], C. Lapa[1], K. Herrmann[1]; [1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Department of Internal Medicine II, Gastroenterology, University Hospital Würzburg, Würzburg, GERMANY, [3]Pharmaceutical Radiochemistry, Technische Universität München, Munich, München, GERMANY, [4]Comprehensive Heart Failure Center, University Hospital Würzburg, Würzburg, GERMANY, [5]Institute for Pathology, University of Würzburg, Würzburg, GERMANY.

Introduction: Diagnostic imaging of neuroendocrine tumors (NETs) is the domain of somatostatin receptor (SSTR) agonists as well as FDG PET/CT in dedifferentiated tumors. SSTR also serves as target for receptor directed peptide therapy. More recently, specific ligands targeting the chemokine receptor 4 (CXCR4) were introduced potentially offering an additional theranostic option in NETs. Here we evaluated the CXCR4 expression using ^{68}Ga-Pentixafor PET/CT in NET patients in comparison to ^{68}Ga-DOTATOC and ^{18}F-FDG PET/CT. **Material and Methods:** 11 consecutive patients with histologically proven advanced NETs were retrospectively analyzed (3 female; mean age, 69±10 years; Ki67 36±36%). 5/11 (45%) suffered from pancreatic NETs, 3/11 (27%) from ileum NETs, 2/11 (18%) from cancer of unknown primary and 1/11 (9%) was classified as a gastric NET. DOTATOC, FDG and Pentixafor PET/CT were performed in all patients within 4 weeks to confirm target expression of SSTR, CXCR4 and to detect dedifferentiated tumor lesions. Image analysis was performed visually. Immunohistochemical CXCR4 expression was evaluated in biopsy samples using monoclonal anti-human anti-CXCR4 antibodies. **Results:** 7/11 (63%) initially presented with lymph node metastases, 3/11 (27%) with bone metastases, 9/11 (82%) with liver metastases, 2/11 (18%) with lung metastases and 1/11 (9%) with a brain metastasis. On visual analysis, Pentixafor was positive in 4/11 (36%), FDG in 9/11 (82%) and DOTATOC in 9/11 (82%) patients, respectively. Of the nine SSTR positive patients seven and three were also FDG- and CXCR4-positive. Two DOTATOC negative patients were FDG positive and one of them also Pentixafor positive. Three patients were positive on all three PET/CT scans. In 2/4 Pentixafor-positive patients, biopsy samples revealed intense CXCR4 expression. **Conclusions**: In this pilot study, only one third of NET patients were CXCR4 positive. However, one NET patient without SSTR expression was Pentixafor positive. Hence, CXCR4-directed radionuclide therapy can be envisioned for selected patients with SSTR-negative tumors.

OP291

11C-hydroxy-tryptophan-PET/CT of Small Intestinal Neuroendocrine Tumours

N. Casta[1], K. Fröss-Baron[2], U. Garske-Román[1], A. Sundin[1]; [1]Surgical Sciences, Dept. Radiology & Molecular Imaging, Uppsala, SWEDEN, [2]Inst. Immunology, Genetics and Pathology, Dept Oncology, Uppsala, SWEDEN.

Aim: In a retrospective study, PET/CT with the serotonine precursor 11C-hydroxy-tryptophan (5-HTP) was assessed for staging and restaging in small intestinal neuroendocrine tumour (SI-NET) patients. Materials and methods: 83 patients (48 men/35 women, median age 60 years) with a histopathological diagnosis of SI-NET underwent Whole-Body 5-HTP-PET/CT without i.v. contrast-enhancement for staging or restaging purposes. The imaging results were compared to those at diagnostic contrast-enhanced CT of the thorax and abdomen (n=76), MRI (n=3) and US (n=4) of the abdomen performed within 3 months of PET/CT. The imaging results were correlated to those at surgery, and clinical and imaging follow-up. Results: 5-HTP-PET/CT showed 47 true positive, 30 true negative, 4 false negative and 2 false positive observations and a resulting patient-based 92% sensitivity, 94% specificity, 96% positive predictive value (PPV) and 88% negative predictive value (PPV). 5-HTP-PET/CT detected 384 tumours out of a total of 398 lesions resulting in 96% lesion-based detection rate. The detection rate was 93% for liver metastases, 100% for lymph nodes metasases and peritoneal tumours, 100% for bone lesions and 91% for breast metastases. In the 12 patients who underwent surgery of the primary tumour 5-HTP-PET/CT detected 4 (33%). 5-HTP-PET/CT missed 14 small (less than 6mm) hypervascular liver metastases and 1 breast metastasis that were diagnosed by CT. Three false positive observations were a lesion in the stomach and in the duodenum, that could not be verified at follow-up, and an adrenal tumour that was found to represent a pheochromocytoma. In 5 patients 5-HTP-PET/CT correctly diagnosed 19 SI-NET metastases (12 in liver, 6 in abdominal lymph nodes, 1 ovarian metastasis) that were missed by CT. Conclusion: This first report on PET/CT with 5-HTP shows high patient based sensitvity and specificity and high lesion detection rates, consistent with previous reports on stand alone 5-HTP-PET. Especially detection of metastases in bone, lymph nodes and liver were advantageous by 5-HTP-PET/CT although small hypervascular liver metastases were missed. Consequently, contrast-enhanced CT is needed in conjunction with 5-HTP-PET/CT.

OP292

Use of ^{68}Ga-DOTATOC PET/CT in initial or recurrent ectopic Cushing's syndrome: a single centre experience

O. Bélissant Benesty, V. Nataf, J. Ohnona, M. Gauthé, L. Michaud, T. Cassou-Mounat, J. Talbot, F. Montravers; Hôpital Tenon, Paris, FRANCE.

Aim: Ectopic Cushing's syndrome (ECS) is rare, but localisation of the causative tumour is of paramount importance: treatment consists of resection of the tumour to avoid morbidity and mortality linked to chronic glucorticoid excess. Neuroendocrine tumours (NETs) of low grade are frequently involved but can be of small size, hardly seen on conventional imaging, leading to up to 20% of tumours still occult after years. ^{68}Gallium-somatostatin receptor-PET/CT (SR-PET) with different peptides (DOTATOC, DOTANOC or DOTATATE) has been shown to be promising, mainly for the detection of the primary NET, but its role in the detection of the cause of recurrence of ECS has been less often reported. In this review we share our experience with DOTATOC PET/CT in localising of the cause of ECS, for both the detection of the primary NET and for the restaging in case of recurrence. Materials and Methods: We performed a retrospective review of all patients who underwent DOTATOC PET/CT for ECS in our centre between January 2011 and March 2016. Thirteen patients (11 females, 2 males, aged from 31 to 66 years) underwent 18 examinations. Eight examinations were performed for detection of a primary NET, five for persistence or recurrence of ECS in patients who had previously surgical resection of a primary NET, without SR-PET before surgery (three lung carcinoids and one thymic NET), and five for surveillance after resection of primary or secondary NETs detected on a DOTATOC PET/CT performed in our centre, all with complete resolution of clinical symptoms and biologic anomalies after surgical removal of the tumour. Results: Among the eight examinations performed to search for primary NET, four were positive: three carcinoid lung tumours were confirmed after surgical resection and one lung focus is not confirmed yet. Four examinations were negative. Among the five examinations performed for persistence or recurrence of ECS after surgery, four were positive showing mediastinal lymph nodes, three confirmed after

surgical resection and one not confirmed yet, and one was negative. All examinations performed for surveillance after resection of NETs previously detected on a DOTATOC PET/CT were negative. Maximum Standard Uptake Values in the true positive lesions ranged from 2.9 to 8.5, with high tumour to background ratios. Conclusion: DOTATOC PET/CT seems to be a valuable tool not only for detection of the causal tumour in ECS, but also in the detection of the cause of persistence or recurrence of ECS after surgery.

OP293

Interim Results in 19 Patients on the Influence of Lanreotide on Uptake of [68Ga]-DOTATATE in Patients with Metastatic or Unresectable NET: No Evidence for Discontinuation of Lanreotide before [68Ga]-DOTATATE PET/CT

E. A. Aalbersberg, L. J. Saveur, M. E. T. Tesselaar, M. P. M. Stokkel; Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Introduction: Somatostatin receptor imaging with [68Ga]-DOTATATE PET/CT has become common practice in patients with neuroendocrine tumors (NET). Current guidelines (from both the EANM and SNMMI) recommend discontinuing treatment with somatostatin analogues before obtaining a [68Ga]-DOTATATE PET/CT scan. The assumption is that unlabeled somatostatin may lower the detectability of lesions. However, both guidelines also state that this issue is still being debated. Aim: The aim of this study is to investigate the influence of lanreotide on the uptake of [68Ga]-DOTATATE in tumor- and normal tissue. Materials and methods: Patients with metastatic or unresectable NET being treated with lanreotide and scheduled for [68Ga]-DOTATATE PET/CT are included prospectively in this study. A [68Ga]-DOTATATE PET/CT scan is made on the day before and the day after lanreotide injection in each patient. PET images were acquired 45 minutes post injection of 100 MBq [68Ga]-DOTATATE. [68Ga]-DOTATATE uptake in the primary tumor, metastasis, and normal tissue are quantified as SUV_{max}, SUV_{peak}, and $SUV_{mean50\%}$. A maximum of three target lesions per metastatic site (liver, bone, lung, peritoneal, lymph nodes, and other) were quantified in each patient. Normal tissue measurements were performed in the liver, spleen, adrenal gland, pituitary gland, thyroid gland, and parotid gland. Results: 19/34 patients have been included up to March 2016. No significant difference was seen in uptake of [68Ga]-DOTATATE in tumor lesions, neither in primary tumors or metastatic lesions, before or after injection of lanreotide. This held true for all metastatic sites investigated. Mean SUV_{max} was 21.01 before and 21.47 after lanreotide ($p=0.26$), mean SUV_{peak} was 16.62 before and 16.82 after lanreotide ($p=0.34$), and mean $SUV_{mean50\%}$ was 14.54 before and 14.64 after lanreotide ($p=0.59$). In normal tissue, the SUV_{max} of [68Ga]-DOTATATE in spleen, liver, and the thyroid gland were significantly lower after injection of lanreotide. Conclusion: The administration of lanreotide does not change the uptake of [68Ga]-DOTATATE in tumor lesions, but lowers the background uptake in the liver, spleen, and thyroid gland. This contradicts the current guidelines for [68Ga]-DOTATATE PET/CT imaging.

OP294

Comparison of ^{68}Ga-DOTA-TOC and ^{18}F-FDG-PET/CT in the follow-up of neuroendocrine tumor patients after first full PRRT cycle

B. Nilica, D. Waitz, V. Stevanovic, C. Uprimny, D. Kendler, S. Buxbaum, L. Gerardo, B. Warwitz, B. Henninger, I. Virgolini, **M. Rodrigues**; Medical University, Innsbruck, AUSTRIA.

Purpose: to determine the value of 68Ga-DOTA-TOC and 18F-FDG-PET/CT for initial and follow-up evaluation of NET patients treated with PRRT. Methods: We evaluated 66 patients who had histologically proven NET and underwent both PRRT and 3 combined 68Ga-DOTA-TOC and 18F-FDG-PET/CT studies. 68Ga-DOTA-TOC-PET/CT was performed before PRRT, 3 months after completion of PRRT and 6-9 months thereafter. 18F-FDG-PET/CT was done within 2 months of 68Ga-DOTA-TOC-PET/CT. Follow-up ranged 11.8-80.0 (mean:34.5) months. Results: All patients were 68Ga-DOTA-TOC-PET-positive initially and at follow-up after first full PRRT. Overall, 62/198 (31%) 18F-FDG-PET were true-positive in 38/66 (58%) patients. 28 patients (G1,5; G2,23 patients) were 18F-FDG-negative initially and during follow-up (group 1), 24 patients (G1,5; G2,13; G3,6 patients) were 18F-FDG-positive initially and during follow-up (group 2), 9 patients (G1,2; G2,6; G3,1 patient) were initially 18F-FDG-negative, but converted to 18F-FDG-positive during follow-up (group 3), and 5 patients (all G2) were initially 18F-FDG-positive, but converted to 18F-FDG-negative during follow-up (group 4).18F-FDG-PET showed more and/or larger metastases than 68Ga-DOTA-TOC-PET in 5 patients of group 2 and 4 patients of group 3, all with progressive disease. In 3 patients (progressive disease, died during follow-up) SUVmax of tumors increased 41-82% from first to last follow-up investigation. Conclusions: In NET patients, the presence of 18F-FDG-positive tumors correlates strongly with a higher risk of progression. Initially 18F-FDG-negative NET patients may show 18F-FDG-positive tumors during follow-up. Also G1 and G2 NET patients may have 18F-FDG-positive tumors. Therefore, 18F-FDG-PET/CT is a complementary tool to 68Ga-DOTA-TOC-PET/CT with clinical relevance for the molecular investigation.

OP295

Evaluation of System Characteristics of Next Generation Digital Photon Counting Compared to Current Photomultiplier Tube PET/CT

J. Zhang[1], K. Binzel[1], M. Miller[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Philips Healthcare, Cleveland, OH, UNITED STATES.

Purpose: To measure, evaluate and compare system physics characteristics of next generation digital photon counting (DPC) PET/CT with current photomultiplier tube (PMT) PET/CT. **Materials and Methods:** Physical characteristics of timing resolution and energy resolution as well as NEMA 2012 based spatial resolution, sensitivity, count loss and image quality were measured on both a pre-commercial release DPC PET/CT system (Vereos) (dPET) and a conventional PMT PET/CT system (Gemini TF 64) (cPET). A 1110 MBq (30 mCi) ^{18}F acquisition was performed for count loss and noise equivalent counting rate determination over ~16hours. CQIE PET uniformity was measured in a quarterly manner on both systems. Sensitivity, timing, energy and spatial resolution were characterized across the clinically relevant count rate range. Overall system characteristics were evaluated and compared on both systems regarding its potential impact in clinical applications. **Results:** The dPET system demonstrated robust system physics characteristics with <2% variability in timing resolution, ±0.4% change in energy resolution, <2% change in spatial resolution, <10% variations in detector temperature and humidity as well as <5% change of the SUV or uniformity profile over a 12 month monitoring period. NEMA 2012 testing found for dPET a spatial resolution (in mm FWHM) of 4.10 transverse / 3.96 axial at 1 cm and 5.79 / 6.20 at 20 cm compared to cPET with 4.70 / 4.71 at 1cm and 6.5 / 7.1 at 20cm. For dPET, a 325 ps timing and 11.1 % energy resolution were consistently obtained, versus 550 ps timing and 11.7% energy on cPET. While NEMA sensitivity showed a 5.7: 7.0 (in kcps/MBq) for dPET/cPET, the clinical effective sensitivity was 24.1:17.0 correspondingly. The peak

of NECR failed to exceed 250kcps at ~25kBq/mL for cPET, whereas dPET achieved > 680 kcps peak true rate (>160% improvement) even at 50 kBq/mL revealing a substantially broader dynamic range. NEMA IQ demonstrated improved hot sphere contrast (from ~62%±2% (10 mm) to ~88%±2% (22 mm)) as well as significantly better image uniformity and quality on dPET than on cPET. CQIE performance testing showed significantly improved uniformity with ~3% variances on dPET vs. ~10% variances on cPET. **Conclusion:** The digital photon counting PET/CT system demonstrated excellent system characteristics, most notably in dynamic range, clinical sensitivity and timing resolution which promise to improve clinical PET imaging compared to conventional photomultiplier tube based systems.

OP296

Comparison of SUVs based on different ROIs and VOIs definitions: a multicenter respiratory phantom study

M. L. Lambrecht[1], M. La Fontaine[2], J. Sonke[2], R. Boellaard[3], M. Verheij[2], C. W. Hurkmans[1]; [1]Catharina ziekenhuis, Eindhoven, NETHERLANDS, [2]Netherlands cancer institute, Amsterdam, NETHERLANDS, [3]University Medical Center Groningen, Groningen, NETHERLANDS.

Background: In the context of the EORTC LungTech trial, a QA procedure including a PET/CT credentialing has been developed. This procedure will ultimately allow us to pool data from 23 institutions with the overall goal of investigating the impact of tumour motion on quantification. As no standardized procedure exists under respiratory conditions, we investigated the variability of 14 SUV metrics to assess their robustness over respiratory noise. **Methods:**The customized CIRS-008A phantom was scanned at 13 institutions. This phantom consists of a 18 cm long body, a rod attached to a motion actuator, and a sphere of either 1.5 or 2.5cm diameters. Body, rods and spheres were filled with homogeneous ^{18}FDG solutions representative of activity concentrations in mediastinum, lung and tumour for a 70kg patient. Three respiratory patterns with peak-to-peak amplitudes and periods of 15mm/3sec, 15mm/6sec and 25mm/4sec were tested. Prior to scanning in respiratory condition, a 3D static PET/CT was acquired as reference. During motion, images were acquired using 3D or 4D gated PET(average image) according to institutional settings. 14 SUV(mean) metrics were obtained per acquisition varying VOI/ROI shape and location. Three ROIs and three VOIs with respective radii of 0.5, 0.6 and 0.8cm were investigated. These ROIs/VOIs were first centred on the maximum activity voxel; a second analysis was made changing the location from the voxel to the region (ROI5voxels) or the volume (VOI7voxels) with the maximum value. Two additional VOIs were defined as 3D isocontours respectively at 70% and 50% of the maximum voxel value. The SUV metrics were normalized by the corresponding 3D static SUV. Converting to recovery coefficients (RC) allowed us to pool data from all institutions, while maintaining focus solely on motion. For each RC from each motion setting we calculated the mean over institutions, we then looked at the standard deviation (Sd) and spread of each averaged RC over each motion setting (formula [1], [2], Figure1). **Results:**For the institutions visited we found that $RC_{VOI70\%}$ and $RC_{VOI50\%}$, yielded over the 14 metrics the lowest variability to motion with Sd of 0.04 and 0.03 respectively. The RCs based on ROIs/VOIs centered on a single voxel were less impacted by motion (Sd: 0.08) compared to region RCs (Sd: 0.14). The averaged Sd over the RCs based on VOIs and ROIs was 0.12 and 0.11 respectively. **Conclusion:**Quantification over breathing types depends on ROI/VOI definition. Variables based on SUV max thresholds were found the most robust against respiratory noise.

OP297

Amplitude-based respiration-gated PET and patient-specific breathing-instructed CT to improve the spatial alignment in PET/CT

C. S. van der Vos[1,2], A. P. W. Meeuwis[1], W. Grootjans[1,3], **E. P. Visser**[1], L. de Geus - Oei[1,2,3]; [1]Radboud university medical center, Nijmegen, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS, [3]Leiden University Medical Center, Leiden, NETHERLANDS.

Respiratory motion can introduce a spatial mismatch between PET and CT images during combined PET/CT imaging, possibly reducing quantitative accuracy of PET images. It is therefore important to have a good spatial alignment to obtain a correct PET interpretation. In this study, the effect of patient-specific breathing-instructed CT on the spatial alignment between CT and amplitude-based optimal respiration-gated (ORG) PET images was investigated. *Materials and Methods:* FDG PET/CT imaging was performed in 20 patients. Images were acquired using a Siemens Biograph 40 mCT PET/CT scanner. Respiratory gating was performed using ORG (HD.Chest). The respiratory signal was obtained using a pressure sensor integrated in an elastic belt placed around the patient's upper abdomen. In addition to the standard free-breathing low-dose (LD) CT (CT_{st}) an additional LD CT was made with patient-specific breathing instructions (CT_{bh}). These breathing instructions were provided using the amplitude limits of the ORG PET reconstructions. Patients were instructed to hold their breath at the same amplitude level. Lesions were segmented manually on CT images and on PET images using a fixed threshold at 40% of the maximum standardized uptake value (SUV_{max}). For both CT_{st} and CT_{bh}, the mismatch was quantified using the position differences between the lung-liver transition in PET and CT images (Δ_{LL}), the distance between PET and CT lesions' centroids (Δ_C) and the amount of overlap indicated by the Jaccard similarity coefficient (JSC). Furthermore, the effect of attenuation correction was quantified using the SUV_{max} of PET images reconstructed with both types of CT scans. Statistical analysis was performed using the Wilcoxon Signed Ranks test, statistical significance was defined for $p<0.05$. *Results:* Three out of 20 patients did not follow the breathing instructions and were excluded. The remaining 17 patients had 29 lung lesions. Regarding quantification of spatial overlap, the following values were found when comparing CT_{st} and CT_{bh}, respectively: Δ_{LL} was 5.0±7.0 and 1.4±6.7 mm (p=0.036), Δ_C was 5.7±6.7 and 3.7±2.1 mm (p=0.050), JSC was 0.32±0.16 and 0.37±0.17 (p=0.151), and SUV_{max} was 10.6±6.4 and 10.9±1.3 g/cm^3 (p=0.139). *Conclusion:* There was a significant improvement in the spatial alignment of the lung-liver transition for these 17 patients. The same trend was visible for the alignment of the lesions. The effect on SUV_{max}, however, was small. The results indicate that the breathing instructions can improve spatial alignment and possibly quantification of ORG PET and CT.

OP298

Performances comparison of five commercial 4D-PET/CT devices

J. N. BADEL[1], V. ISNARDI[1], E. SPASIC[2], D. DONNARIEIX[3], A. CHEMIN[4], J. M. VRIGNEAUD[5], T. MOGNETTI[1]; [1]LEON-BERARD, LYON, FRANCE, [2]Institut Curie, PARIS, FRANCE, [3]JEAN-PERRIN, CLERMONT-FERRAND, FRANCE, [4]Institut BERGONIE, BORDEAUX, FRANCE, [5]GEORGES-FRANCOIS LECLERC, DIJON, FRANCE.

Introduction: Use of the 4D-PET/CT technology is growing in radiotherapy planning of mobile lesions. This technique allows a reduction of breathing-related PET image degradation (underestimation of tracer uptake, overestimation of the lesion volume, etc.) and thus improves the delineation of metabolic tumor volume (MTV). Several respiratory gated 4D-PET/CT acquisition techniques have been developed by constructors. In this study, we propose a comparative study of five commercial 4D-

PET/CT gating devices for use in the context of radiotherapy applications.*Material and method:* Five commercial built-in 4D-PET/CT technologies were evaluated: Ingenuity TF (A), Gemini TF Big Bore (B), IQ (C), Discovery 710 (D) and Biograph mCT-Flow (E). The A, B and E devices use a respiratory monitoring system based on pressure sensor whereas C and D use an opto-electronic system. The 4D-PET/CT's impact on the quantification and the definition of MTV was compared among five devices. A CIRS-008A dynamic thorax phantom was used to simulate a spherical lesion's motion in the lung parenchyma. Three volumes of fillable spheres were tested: 0.5, 2 and 8 ml. To simulate the breathing motion, a cosine equation was used with 20 mm longitudinal peak-to-peak amplitude and 4 seconds breathing cycle. Three acquisitions were done with each size of spheres: a standard 3D without respiratory motion (3D reference acquisition), a standard 3D and retrospective 4D (4 and 10 phases reconstructions) with respiratory motion. The emission times per bed position were 2 and 8 minutes for 3D and 4D acquisitions respectively. The gain on the quantification provided by the five 4D technologies was estimated by calculating the SUV ratios (max and peak) between 3D and 4D acquisitions. The impact of 4D-PET/CT on the definition of MTV was measured by comparing the measured volume to the actual volume of spheres from volume recovery coefficients (VRC). The alignment between 4D-PET and 4D-CT images was tested by calculating the Dice coefficient on the spheres volume. *Results:* Differences in the quantification among systems were relatively small (max 20%). The ratio between 3D and 4D SUV ranged between 1.7 and 3.2 depending on the sphere's size and the number of phases reconstructed. The VRC ranged between 1.1 and 2.9 according to the same parameters. *Conclusion:* The 4D-PET/CT gating technology significantly improves the quantification and the MTV's definition. The five commercial systems tested offer relatively similar performances, and no technology really stands out.

OP299

Characterisation of Scatter and Attenuation in GE Discovery 530c using Monte Carlo simulations

M. Peterson, M. Ljungberg; Department of Medical Radiation Physics, Lund University, Lund, SWEDEN.

Introduction: New SPECT systems, based on CZT (Cadmium-Zink-Telluride) solid-state detectors, have been commercially introduced during the last 5-10 years. The characteristic of CZT differs significantly from common NaI(Tl)-based scintillation crystal cameras in that an electrical signal is produced directly at the photon interaction site. Effects such as recombination and charge chairing results, however, in a detector response that differ from NaI(Tl) scintillators and therefore is it important to characterize the energy spectrum to investigate, for example, the usefulness of scatter compensation methods, based on acquisition in additional energy windows. Material and Methods: The Monte Carlo code SIMIND has previously been modified to model CZT detectors. By simulations using a digital version of an elliptical torso phantom with a cardiac insert (Data Spectrum Inc) we create projections for the GE Discovery 530c system (a pinhole collimation using 19 CZT detectors in different positions with 180 degrees angular coverage). Simulated SPECT projections are then imported to the Xeleris workstation by patching a Dicom file and the clinical routine reconstruction program is used to create horizontal-axis, vertical-axis and short-axis images. Comparisons with measurements have been made to validate the simulation procedure. In addition, we have studied a) the scatter fraction in the main energy peak and in additional lower energy windows, b) the distribution of primary good events resulting from incomplete charge collections c) the effect of attenuation and d) defect contrast. Results: Comparisons between measured and simulated energy spectrum shows a good agreement even down in the lower parts of the spectrum. Visually, reconstructed images on the GE Xeleris workstation compared well with measurements, as do profiles through short-axis images. The myocardial-to-defect contrast, $[C_{max}\text{-}C_{def}]/C_{def}$, is 1.25 in measured data and 1.04 in simulated data with an overall good agreement between the two polar plots. Despite the lower energy resolution (in the order of 5% FWHM at 140 keV) the scatter-to-total fraction is about 30.5% for a 20% energy window, 25.1% for a 15% energy window and 19.2% for a 10% energy window. Conclusion: The Monte Carlo simulations of the 19 detectors pinhole GE 530c SPECT system, based on CZT detectors, have shown good agreement with measurement projections. The ability to separate the events into components of primary events, scatter, penetration event etc. makes it suitable for optimization of acquisition parameters and to understand if commonly used scatter correction method are applicable.

OP300

Initial performance evaluation of a preclinical PET scanner available as a clippable assembly in a sequential PET/MRI system

J. M. Vrigneaud[1], J. Mc Grath[2], R. Pegg[2], A. Camacho[2], G. Martin[2], N. Schramm[3], F. Brunotte[1,4]; [1]CGFL, preclinical imaging platform, Dijon, FRANCE, [2]MR Solutions, Guildford, UNITED KINGDOM, [3]Central Institute of Engineering (ZEA-2), Research Center, Juelich, GERMANY, [4]Le2i - CNRS 6306, UBFC, Dijon, FRANCE.

AIM: we evaluated the performance characteristics of a new preclinical PET scanner available as an easy clippable assembly that docks to the MRI system to perform sequential PET/MR imaging using a unified interface. **MATERIALS AND METHODS:** The single ring version of the PET system consists of 8 detectors, each of which comprises 12 × 12 SiPMs (50.2 × 50.2 mm^2) coupled with a dual layer of offset scintillation crystals to measure depth of interaction. The crystal arrays have 30 × 30 (29 × 29 for the outer layer) 6 mm long LYSO crystals (4 mm for the outer layer). The ring diameter is 119.2 mm and the axial field of view is 50.4 mm. The NEMA NU-4-2008 protocol was followed for studying the PET performance. The following tests were performed: counting-rate performance, scatter fraction, sensitivity and image quality. Image quality was assessed using the 3D-OSEM algorithm implemented in the system with one iteration and 64 subsets. FWHM and FWTM spatial resolutions in all three directions were estimated on FBP reconstructed images by fitting line profiles in each direction with a Gaussian function. To evaluate the resolution experienced in practice, a Jaszczak phantom was also acquired (0.7-1.2 mm) and reconstructed with 3D-OSEM. **RESULTS:** The peak system absolute sensitivity was 4.56% at the center of the field of view (FOV). The uniformity with the image-quality phantom was 13.6% and the spillover ratios in the images of the water and air filled chamber were 0.16 and 0.31, respectively. Recovery coefficients ranged from 0.20 to 0.76. The radial spatial resolution was nearly constant as a function of the radial offset, varying from 1.27 mm FWHM at a distance of 5 mm from the center to 1.58 mm FWHM at a distance of 25 mm from the center. The tangential spatial resolution ranged from 1.67 mm FWHM to 1.98 mm FWHM in the same conditions. The axial spatial resolution remained nearly constant (less than 2.0 mm) within a radial offset less than 15 mm from the center. Using the Jaszczak phantom, the 0.9 mm diameter rods were resolved after one iteration of the 3D-OSEM, 2-3 iterations resolved the 0.8 mm diameter. **CONCLUSION:** These first results indicate excellent spatial resolution performance of this preclinical PET system for use with animal studies. Moreover, the clippable assembly can be ugraded to accept a second ring of SiPMs modules, leading to improved sensitivity and axial coverage.

OP301

Breast-dedicated PET scanner based on partial geometry

A. Emami[1,2,3], H. Ghadiri[1,2], P. Ghafarian[4,5], P. Geramifar[6], **M. Ay**[1,2]; [1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC

OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]International Campus, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]PET/CT and cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Breast cancer is the most frequent type of cancer in women all over the world. Mammography, ultrasound (US), and magnetic resonance imaging (MRI) are employed as diagnostic tools for diagnosis of breast cancer and help raise sensitivity for several years. Molecular imaging techniques such as Positron Emission Tomography (PET), has the potential to significantly enhance the diagnostic and reflects metabolic changes that often occur before morphological. However, because of the limited resolution and partial volume effect of most whole-body PET scanners, sensitivity for detection of small tumors is generally low. To improve the visualization and quantification of primary breast tumors, several dedicated breast PET devices have been developed. Most of them consist of tightly packed discrete detector module to improve efficiency. Our aim is to assess the possibility of reducing the number of detector elements per ring. while maintaining image quality by employing compressed sensing (CS) techniques, accuracy, and lower cost compared with current screening tools. The simulation of dedicated breast PET scanners was performed using GATE (GEANT4 application for tomographic emission) for assisting, optimizing and finding the best detector configuration system. Using GATE, different detector geometries were generated assuming different numbers and width for a system polygon .The system has two detector rings that each ring consist of 10 modules. Each detector block is composed of 50 mm × 50 mm array of LYSO crystals coupled to photodiodes , with transaxial field of view (FOV) of 170 mm in diameter and 80 mm axial FOV. In order to investigate the possibility of reducing number of detectors and provide geometric flexibility in lower price, the partial geometry of dedicated breast PET scanners lead to gaps between the detector modules and result in loss of PET data during measurement. So, we applied the compressed sensing minimization method to PET image reconstructions in order to reduce the artifacts caused by gaps. Simulation results predicted a 60-100% relative increase of photon sensitivity for the proposed dedicated breast PET system geometry. Also, simulation results indicated that spatial resolution values below 4 mm were measured in most of the FOV, and the partial ring incorporating CS method could control gap artifacts, recovered the PET image with minimal error in image quantification and generated image from its partially sampled data. Decreasing the number of detector module including some advantages specially reducing the cost of scanner to make it more accessible to users, and scan time.

OP302

Design and Performance evaluation of a Novel Brain PET Geometry Based on Partial Cylindrical Detector using Monte Carlo simulation

P. Sheikhzadeh[1,2], H. Sabet[3], H. Ghadiri[1,2], P. Ghafarian[4,5], **M. Ay**[1,2]; [1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Massachusetts General Hospital, Harvard Medical School, Charlestown, MA, UNITED STATES, [4]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: The aim of this study is to introduce a novel PET system dedicated to brain imaging which we refer to as HoodPET, and evaluate its performance characteristics compared with other brain dedicated PET systems. In the conceptual design of HoodPET, we are seeking a compact, low cost, and portable design which can provide brain image(s) at different patient positions. **Materials and methods:** Our design is based on cylindrical geometry with partially populated detector modules such that the front and back of the patient head is open, and the detector modules cover the top and the sides of the patient head. We simulated different variations of this open geometry in GATE simulation code. In one design, the ring diameter is 240mm and axial FOV is 317mm. A total of 72 block detectors arranged in 6 rings of 12 blocks per ring that cover ~3/4 circumference of the cylinder. Each block comprises of an array of 2.3×2.3 mm2 LYSO crystals. For comparing the performance of our design with conventional cylindrical brain PET, a cylindrical scanner with 300 mm ring diameter and 227mm axial FOV and 72 block detector contains of 2.3×2.3 mm2 LYSO crystal array was simulated. For sensitivity evaluation in both scanners the NEMA 70cm sensitivity phantom with 1 MBq 18F activity and a 10cm radius Polymethyl methacrylate sphere was modeled as a head phantom. A spherical source with radius of 2cm that emits back to back gamma photons with activity of 1 MBq positioned in the 7cm offset in phantom to model the brain lesion. **Results:** The sensitivity of 23.61 and 36.42 kcps/MBq was calculated for NEMA and head phantoms, respectively. The mentioned sensitivities for conventional design were 17.00 and 21.58 kcps/MBq. This results show that our design has higher sensitivity than conventional cylindrical PET with the same number of block detectors. This is because of compatibility of our design with head and brain anatomy. **Conclusion:** Preliminary simulation results shows that our design for a brain-dedicated PET scanner can provide higher sensitivity than conventional cylindrical PET scanner for brain imaging. The results are very encouraging in that a non-cylindrical PET geometry can potentially provide better performance than a cylindrical PET geometry for brain imaging. We will further optimize the geometry of the HoodPET to increase the sensitivity while taking advantage of detectors with depth of interaction information which is a necessity in non-symmetric geometries with small FOV.

Radio-labeling and initial evaluation of a novel beta-secretase (BACE)-selective PET radioligand, [^{18}F]PF-06684511, in nonhuman primates

A. Takano[1], L. Chen[2], S. Nag[1], M. A. Brodney[3], N. Amini[1], C. Chang[2], R. Arakawa[1], S. Doran[2], J. Dutra[2], T. McCarthy[3], C. Nolan[3], B. O'Neil[2], A. Villalobos[3], L. Zhang[3], C. Halldin[1]; [1]Karolinska Institutet, Department of Clinical Neuroscience, STOCKHOLM, SWEDEN, [2]Pfizer Inc., Worldwide Research and Development, Groton, CT, UNITED STATES, [3]Pfizer Inc., Worldwide Research and Development, Cambridge, MA, UNITED STATES.

Aim Beta-secretase (BACE) is a key enzyme in the generation of beta-amyloid. BACE inhibitors are being developed to decrease beta-amyloid accumulation in the brain and to reduce the risk of Alzheimer disease. BACE-selective PET radioligands would enable target occupancy measurement and inform optimal dose selection in clinical trials. PF-06684511 was identified by Pfizer and has shown high specific binding in rodents. In this study, we aimed to radio-label PF-06684511 with F-18 and evaluate the

brain distribution and quantitative methods of [^{18}F]PF-06684511 as PET radioligand for BACE in nonhuman primates (NHPs). **Materials and methods** [^{18}F]PF-00684511 radiolabelling was accomplished from Boc protected precursor, PF-06816649 by a two-step synthesis, compromising a nucleophilic substitution followed by hydrolysis of the protected group. Brain PET measurements were performed for 180 min at baseline and after oral administration of 5 mg/kg of PF-06738879, a selective BACE inhibitor, in two cynomolgus monkeys. Arterial blood was collected to evaluate kinetic compartment models. Total distribution volume (V_T)(mL/cm^{-3}) was estimated from one tissue compartment model (1TC) and two tissue compartment model (2TC). The target occupancy was calculated using the Lassen plot. **Results** Radiolabeling was accomplished successfully with an incorporation radiochemical yield of 4-12% from fluorine-18 ion. The radiochemical purity was higher than 99% and the specific radioactivity was 73 ± 38 GBq/μmol at the time of administration. Whole brain uptake of [^{18}F]PF-06684511 reached peak (approximately 220%SUV) at approximately 20 minutes and thereafter decreased (approximately 100%SUV at 180 min). Pretreatment with PF-06738879 significantly blocked the brain binding of [^{18}F]PF-06684511, confirming its *in vivo* specificity. There were no radioactive metabolites showing higher lipophilicity than [^{18}F]PF-06684511. In most brain regions, 1TC and 2TC fit well to the time activity curves while 2TC fit better in some regions such as the hippocampus. V_T of two monkeys were 7.6 and 6.1 in the cerebellum and 19.5 and 13.6 in the amygdala at the baseline PET measurements. Non-displaceable distribution volumes (V_{ND}) estimated by Lassen plot were 2.7 and 3.1. The estimated BACE occupancy was greater than 90% after a single 5 mg/kg oral dose of PF-06738879. **Conclusions** [^{18}F]PF-06684511 demonstrated favorable *in vivo* binding and brain kinetics in NHPs. The target occupancy was able to be estimated using the Lassen plot. [^{18}F]PF-06684511 could be a valuable PET imaging translational tool to facilitate the clinical development of BACE inhibitors as potential treatment for Alzheimer disease. Further evaluation is expected in human subjects.

OP304

ImmunoPET of uPA/uPAR signaling: broad applicability in cancer imaging

H. Hong[1], D. Yang[1], C. A. Dougherty[1], G. W. Severin[2], D. Chen[1], A. P. Mazar[3]; [1]University of Michigan, Ann Arbor, MI, UNITED STATES, [2]Technical University of Denmark, Kongens Lyngby, DENMARK, [3]Northwestern University, Evanston, IL, UNITED STATES.

Aims: Mounting evidences have suggested that urokinase plasminogen activator (uPA) and its receptor (uPAR) play a central role in tumor cell survival, growth, migration, angiogenesis, and metastasis. The fact that uPA/uPAR can be identified in nearly all solid tumors and their confined expression pattern (almost undetectable in healthy, quiescent tissues) make them attractive targets for tumor detection. The goal of this study was to develop an ^{89}Zr-labeled, antibody-based positron emission tomography (PET) tracer for quantitative imaging of uPA/uPAR system. *Materials and Methods:* An anti-uPA monoclonal antibody named ATN-291 was conjugated to desferrioxamine via the reaction of p-SCN-Bn-Df and subsequently labeled with ^{89}Zr. Flow cytometry, microscopy studies, and competitive binding assay were conducted to validate the binding affinity and specificity of Df-ATN-291 against uPA. PET imaging with ^{89}Zr-Df-ATN-291 was carried out in six different tumors with distinct expression levels of uPA. Biodistribution and *ex vivo* histology examination were perform to validate the results from PET, while Western blot of tumor lysate was conducted to correlate the uptake of ^{89}Zr-Df-ATN-291 with uPA/uPAR expression level. *Results:* ATN-291 retained the binding affinity and specificity against uPA after Df conjugation, confirmed by flow cytometry, fluorescence microscopy, and competitive binding assay. ^{89}Zr-labeling of ATN-291 was achieved in good yield and high specific activity. Serial PET imaging demonstrated that, in most tumors (except uPA$^-$ LNCaP), the uptake of ^{89}Zr-Df-ATN-291 was higher than all other organs at 120 h post-injection, which provided excellent tumor contrast. The tumor-to-muscle ratio of ^{89}Zr-Df-ATN-291 in U87MG was as high as 45.2 ± 9.0 at 120 h p.i. (n = 4). In vivo uPA specificity of ^{89}Zr-Df-ATN-291 was confirmed by successful blocking of tumor uptake with ATN-291 in U87MG tumors. Interestingly, the tumor uptakes obtained from PET correlated with both uPA and uPAR expression in tumor measured by Western blotting. *Conclusion:* The tumor uptake of ^{89}Zr-Df-ATN-291 from PET quantification reflects tumor uPA/uPAR expression level as a whole system *in vivo*. Quantitative immunoPET imaging of uPA/uPAR in tumors can facilitate oncologists to adopt more relevant treatment planning in future clinical investigations.

OP305

The use of somatostatin receptor antagonists may provide a role for receptor-mediated nuclear imaging and therapy of breast cancer

S. U. Dalm, J. Haeck, G. N. Doeswijk, E. de Blois, C. H. M. van Deurzen, M. de Jong; Erasmus MC, Rotterdam, NETHERLANDS.

Background: Somatostatin receptor (SSTR) mediated imaging and therapy using radiolabeled SSTR agonists are successfully used for imaging and treatment of patients with neuroendocrine tumors. Recently, radiolabeled SSTR antagonists have been described that show superior tumor targeting (≥11 times higher tumor dose) compared to radiolabeled SSTR agonists. SSTRs are also expressed on breast cancer (BC) cells. Sufficient SSTR expression is a pre-requisite for successful SSTR-mediated tumor targeting, but SSTR expression on BC seems to be lower and more heterogeneous compared to neuroendocrine tumors. Since radiolabeled SSTR-antagonists proved to be more efficient for SSTR-mediated targeting of neuroendocrine tumors, the use of these antagonists might provide a role for SSTR-mediated imaging and/or treatment of BC. We therefore compared the tumor-targeting property of the radiolabeled SSTR agonist DOTA-Tyr^3-octreotate versus that of the SSTR antagonist DOTA-JR11, in BC tumor tissue and a BC xenograft mouse model. **Materials and methods:** Binding of DOTA-Tyr^3-octreotate and DOTA-JR11 to 40 primary BCs was analyzed by in vitro autoradiography. Tumors were incubated with 10^{-9} M ^{111}In-DOTA-Tyr^3-octreotate or ^{111}In-DOTA-JR11, with or without 10^{-6} M unlabeled peptide to determine specificity of binding. Radioligand binding of the radiotracers to tumor tissue was quantified and compared. Furthermore, SPECT/MR imaging was performed in an orthotopic SSTR2-expressing patient-derived xenograft mouse model, T126. When tumor size reached ±1300 mm^3, animals were injected with 20 MBq/200 pmol ^{177}Lu-DOTA-Tyr^3-octreotate or ^{177}Lu-DOTA-JR11. Four hours post injection T1 and T2 weighted MR images and focused SPECT images were acquired. After imaging, animals were euthanized and tumors were excised to determine radioactivity uptake. **Results:** Specific binding of the receptor antagonist ^{11}In-DOTA-JR11 to tumor cells was significantly higher (up to 21 times higher, $p<0.0001$) than binding of the agonist ^{111}In-DOTA-Tyr^3-octreotate. Regarding in vivo imaging of the xenograft mouse model, the T1 and T2 weighted MR images showed homogenous tissue signal intensity throughout the tumor, indicating viable tumor tissue. SPECT images showed superior tumor targeting of the receptor antagonist vs. the agonist, in agreement with the measured tumor uptake (2.3 vs. 0.9% ID/g tissue, respectively). **Conclusion:** Our findings indicate that the radiolabeled SSTR2 antagonist DOTA-JR11 is superior to the SSTR agonist DOTA-Tyr^3-Octreotate for targeting of low SSTR-expressing tumors such as BC. Therefore, the use of a radiolabeled SSTR antagonist might lead to better results than previously obtained with the agonist, shedding new light on the potential role for SSTR-mediated imaging and/or treatment of BC.

Sensitive ^{111}In-labeled SPECT/CT imaging to monitor anti-IL-22 treatment in experimental arthritis

T. van der Geest[1], D. M. Roeleveld[2], T. K. Nayak[3], C. Klein[4], B. Walgreen[2], M. M. Helsen[2], J. M. Metselaar[5,6], P. Laverman[1], M. I. Koenders[2], **O. C. Boerman**[1]; [1]Department of Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, NETHERLANDS, [2]Department of Experimental Rheumatology, Radboud university medical center, Nijmegen, NETHERLANDS, [3]Roche Pharmaceutical Research & early Development, Innovation Center, Basel, Basel, SWITZERLAND, [4]Roche pharmaceutical Research & Early Development, Innovation Center Zurich, Schlieren, SWITZERLAND, [5]Department of Experimental Molecular Imaging, University and Helmholtz Institute for Biomedical Engineering, RWTH-Aachen University, Aachen, GERMANY, [6]Department of Targeted Therapeutics, MIRA Institute, University of Twente, Enschede, NETHERLANDS.

Rheumatoid arthritis (RA) is a chronic autoimmune disease leading to progressive destruction of cartilage and bone. RA patients show elevated levels of IL-22 and IL-22-producing T helper cells that correlate to erosive disease, suggesting a role for this cytokine in the pathogenesis of RA. The purpose of this study was to determine the feasibility of ^{111}In-28H1 SPECT/CT imaging to monitor the therapeutic potential of neutralizing IL-22 during experimental arthritis. Collagen-induced arthritis (CIA) was induced in male DBA/1J mice. Mice (N=6) were treated 3 times per week with anti-IL-22 antibodies (8 mg/kg), while the control group (N=6) received rat IgG1 isotype control antibodies. To monitor the therapeutic effect after 2 weeks of treatment, SPECT/CT images were acquired 24 h after injection of ^{111}In-labeled DTPA-conjugated anti-FAP antibody, 28H1. After image acquisition, mice were euthanized and dissected. Imaging results were compared with the macroscopic arthritis score.Blocking IL-22 during CIA was a potent approach to prevent arthritis development, reaching a disease incidence of only 50%, versus 100% in the control group. Imaging showed that joint uptake was significantly ($p = 0.02$) lower in treated mice (4.3 ± 5.4 %ID/g) compared to the control group (12.8 ± 9.0 %ID/g). This was confirmed by macroscopic scores, histological scores and bone damage scores that all were lower in treated mice compared to the control group. These findings suggest that IL-22 plays an important role in the development of experimental arthritis, and targeting this cytokine seems an attractive new strategy in RA treatment. Most importantly, SPECT/CT imaging with ^{111}In-DTPA-28H1 can be used to specifically monitor response to therapy and is potentially more sensitive in disease monitoring compared to the gold standard method of macroscopic arthritis scoring.

OP307

Differentiating Cancer From Inflammation: Positron Emission Tomography With A Boron-Derived Leucine Mimic

Z. Liu, D. Kiesewetter, G. Niu, X. Chen; National Institute of Health, Chevy Chase, MD, UNITED STATES.

AIM Non-invasively differentiating tumor from inflammation is a long-standing challenge for cancer diagnosis. Therefore, a biopsy or surgery is still required in many occasions to justify the malignancy of a neoplasm. Previously, positron emission tomography (PET) with ^{18}F-FDG is the standard non-invasive technique for cancer imaging. However, FDG highlights any tissue with high energy consumption and is not tumor-specific. In addition to accumulating in fast growing tumors, FDG accumulation may be observed in a variety of healthy tissues and ones affected by various non-neoplastic pathologic conditions, such as acute and chronic inflammations and infections. Herein we report a boron-derived leucine derivative (B-Leu) to distinguish cancer from inflammation by using PET imaging. **METHOD** A boron-derived leucine derivative was synthesized to mimic Leu, of which the transportation depends on L-type amino acid transporter type one (LAT-1). ^{18}F-^{19}F isotope exchange reaction was conducted for radiolabelling and quality control was performed by both HPLC and radioTLC. The metabolic stability of ^{18}F-B-Leu was assessed both *in vitro* and *in vivo*. PET imaging and bio-distribution studies were performed in mice bearing UM22B xenografts on the right shoulder and inflammation in the left hind limb (Inflammation was introduced by intramuscular injection of turpentine 72 h prior to PET scan). **RESULT** The cellular uptake of B-Leu was found to be highly LAT-1 dependent, and a nearly linear correlation was observed between B-Leu intake and LAT-1 expression. Remarkably, ^{18}F-B-Leu exhibited superior metabolic stability over ^{11}C-labelled natural Leu, resulting in better tumor-specificity as an imaging probe. As expected, PET images showed that ^{18}F-B-Leu has intense accumulation in UM22B tumor (12.5 ± 3.1 %ID/g) and low uptake in the rest of the body (liver, 2.23 ± 0.46 %ID/g; muscle, 2.01 ± 0.53 %ID/g; and blood, 1.49 ± 0.82%ID/g). The tracer had predominant renal clearance but with low kidney retention. Comparing with ^{11}C-Leu and ^{18}F-FDG, ^{18}F-B-Leu showed higher tumor uptake in UM22B xenografts (^{18}F-B-Leu: ^{11}C-Leu: ^{18}F-FDG = 12.5 ± 3.1: 6.5 ± 2.2: 10.7 ± 2.3 %ID/g), and notably lower uptake in healthy tissues. In addition, PET images and biodistribution demonstrated that ^{18}F-B-Leu does not accumulate, but ^{18}F-FDG does accumulate, in the inflammatory lesion. **CONCLUSION** A boron-derived Leu derivative has been developed for imaging LAT-1 expression with PET. Administration of ^{18}F-B-Leu allowed for clear visualization of tumor xenografts, with almost negligible uptake in the inflammatory foci, suggesting a unique advantage over ^{18}F-FDG on distinguishing cancer from inflmmation.

OP308

Non-invasive imaging of CD146 in hepatocellular carcinoma with a dual-labeled monoclonal antibody

W. Cai, R. Hernandez, H. Sun, C. G. England, H. F. Valdovinos, T. E. Barnhart, Y. Yang; University of Wisconsin-Madison, MADISON, WI, UNITED STATES.

Objective: Overexpression of CD146 has been correlated with aggressiveness, recurrence rate, and poor overall survival in hepatocellular carcinoma (HCC) patients. The goal of this study was to develop a CD146-targeted probe for high-contrast non-invasive *in vivo* positron emission tomography (PET) and near-infrared fluorescence (NIRF) imaging of HCCs. **Methods:** *In vitro* expression levels of CD146 were characterized in two HCC cell lines, HEPG2 (CD146+) and Huh7 (CD146-) via western blot, flow cytometry, and immunofluorescent staining. YY146, an anti-CD146 monoclonal antibody, was conjugated to the zwitterionic NIRF dye ZW800-1 and to deferoxamine (Df) for radiolabeling with ^{89}Zr. Sequential PET and NIRF imaging was performed after intravenous injection of 5.6-7.4 MBq (400 pmol) of ^{89}Zr-Df-YY146-ZW800 in athymic nude mice bearing HepG2 or Huh7 subcutaneous (s.c.) xenografts. Orthotopic tumors were generated by stereotactic injection of stably luciferase-transfected HepG2 cells into the left lobe of the liver and their progression was monitored by regular bioluminescence imaging. Multimodality imaging was carried out in mice with confirmed orthotopic liver tumors using the condition described for s.c. tumors. A terminal imaging time-point was acquired at 168 h post-injection (p.i.) of the tracer, after which tissues were collected for *ex vivo* NIRF imaging, biodistribution, and histological studies. **Results:** *In vitro* assays revealed high and low CD146 expression levels in HepG2 and Huh7 cells, respectively. Flow cytometry showed similar CD146-binding affinity between the native and conjugated YY146 mAb. PET and NIRF imaging unveiled a prominent and persistent uptake of ^{89}Zr-Df-YY146-ZW800 in HepG2 tumors that peaked at 31.7±7.2 %ID/g (n=4) at 72 h p.i. Owing to such marked accumulation, the detection of orthotopic HepG2 tumors was successful, despite the relatively high liver background. CD146-negative Huh7 and CD146-blocked HepG2 tumors exhibited

significantly lower ^{89}Zr-Df-YY146-ZW800 accretion (6.1±0.5 and 8.1 ±1.0 %ID/g at 72 h p.i., respectively; n=4), demonstrating CD146-specificity of the tracer *in vivo*. *Ex vivo* biodistribution and immunofluorescent staining corroborated the accuracy of the imaging data and correlated ^{89}Zr-Df-YY146-ZW800 uptake with in situ CD146 expression. **Conclusion:** ^{89}Zr-Df-YY146-ZW800 showed excellent properties as a PET/NIRF imaging agent, including high *in vivo* affinity and specificity for CD146-expressing HCC. CD146-targeted molecular imaging using dual-labeled YY146 has great potential for early detection, prognosis, and image-guided surgical resection of liver malignancies. Currently, we are devoting efforts to improve imaging by using antibody fragments that can allow for faster imaging and enhanced liver contrast, and to assess the potential of YY146 as a targeted therapeutic agent.

OP309

Dual Isotope Labeled Multimeric PSMA Ligands

A. Wurzer[1], C. Seidl[2], A. Morgenstern[3], F. Bruchertseifer[3], H. Wester[1], **J. Notni**[1]; [1]Pharmaceutical Radiochemistry, TU Munich, Garching, GERMANY, [2]Department of Nuclear Medicine, TU Munich, Garching, GERMANY, [3]Institute for Transuranium Elements, Karlsruhe, GERMANY.

Exact quantification of biodistribution and tumor uptake of endoradiotherapeutics is highly desirable for therapy optimization. Currently, therapy planning for radiometallated compounds (e.g., sst2- or PSMA-ligands labeled with Y-90, Lu-177, or Bi-213) often relies on the respective Ga-68 PET tracers, thus lacking precision because pharmacokinetics of the structurally different diagnostics and therapeutics are not identical. Dual-isotope labeled tracers could circumvent this problem by allowing for direct PET-based dosimetry. *Methods:* Phosphinate chelators with selectivity for Ga-68 (TRAP) and lanthanides (DOTPI) were tethered together and further equipped with 3 copies of DBCO-Ahx-KuE or PA-Ahx-KuE (DBCO = 5-aza-1,3-dibenzocyclooctyne, Ahx = 6-aminohexanoic acid, KuE = Glu-urea-Lys, PA = 4-pentynoic acid), employing Cu(I)-catalyzed (CuAAC) as well as strain-promoted click chemistry (SPAAC). The TRAP chelating site of the resulting constructs DOTPI(PA-Ahx-KuE)$_3$(TRAP) (*1*) and DOTPI(DBCO-Ahx-KuE)$_3$(TRAP) (*2*) was selectively saturated with cold Ga(III) by reaction with excess Ga(III) and subsequent by removal of DOTPI-bound Ga(III) with Na_2EDTA, followed by manual labeling with Lu-177 and Bi-213. Likewise, the compounds containing cold Lu(III) or Bi(III) in the DOTPI cage, obtained by M(III) complexation and subsequent treatment with Na_3DTPA, were labeled with Ga-68 in a standard automated procedure. Lu-177 and Ga-68-labeled compounds were used for biodistribution studies and PET imaging, respectively, in LNCaP-xenografted SCID mice. *Results:* For DOTPI-TRAP conjugates *1* and *2*, the complementary chelation selectivity of DOTPI (lanthanides and large trivalent metal ions) and TRAP (trivalent gallium) enabled site-specific complexation of the respective (radio)metal ions and thus, chemoselective radiolabeling with two independent radionuclides. The nonradioactive compounds, [^{nat}Bi][^{nat}Ga]-*1*, *2*, and [^{nat}Lu][^{nat}Ga]-*2* exhibited comparably high PSMA affinities (IC_{50} = 2.5 ± 0.2, 1.8 ± 0.4 and 2.8 ± 0.3 nM, respectively). Presence of the DBCO moieties effected a less pronounced hydrophilicity of [^{nat}Lu][^{68}Ga]-2 (logD = -3.8 ± 0.1) compared to [^{nat}Bi][^{68}Ga]-1 (-4.4 ± 0.1). Bi-213 labeling of [^{nat}Ga]-*1* required lower concentration than DOTA, pointing at a higher Bi-213 labeling efficiency of DOTPI than DOTA. Comparable PET imaging results were obtained for [^{nat}Bi][^{68}Ga]-*1* and [^{nat}Lu][^{68}Ga]-*2* for which a ROI-based tumor uptake of 3.35 ± 0.17 %ID/g (60 min p.i., n =4) was found. *Conclusions:* DOTPI-TRAP conjugates allow for preparation of theranostic pairs consisting of a Ga-68-PET tracer and a radiometallated therapeutic with indentical chemical structure. Their co-injection enables exact PET-based dosimetry, which is particularly attractive for combinations of Ga-68- and Bi-213-labeled compounds due to comparable nuclide half lives (68 and 43 min, respectively) and the lack of other imaging possibilities for Bi-213.

OP310

In Vivo Evaluation of [^{18}F]PF-06445974, a Novel Phosphodiesterase 4D Sparing PET Radioligand for the Phosphodiesterase 4 Enzyme, In Nonhuman Primates

L. Chen[1], K. Zasadny[1], E. M. Beck[1], C. Chang[1], T. Chappie[2], R. V. Coelho[1], S. Doran[1], K. Fan[1], K. Kuszpit[1], M. B. Skaddan[1], A. Villalobos[2], J. M. Young[1], L. Zhang[2]; [1]Worldwide Research & Development, Pfizer Inc., Groton, CT, UNITED STATES, [2]Worldwide Research & Development, Pfizer Inc., Cambridge, MA, UNITED STATES.

Aim: Phosphodiesterase 4 (PDE4) is a major regulator of cyclic adenosine monophosphate and consists of multiple subtypes such as PDE4A, PDE4B, PDE4C and PDE4D. PDE4D-sparing PDE4 inhibitors, with low affinity to PDE4D and high affinity to other subtypes, were hypothesized to be as effective as non-selective PDE4 inhibitors for treating diseases such as psychosis but without emesis side effects. [^{18}F]PF-06445974 is a novel PDE4D-sparing PDE4 PET radioligand. In this study, we aimed to evaluate the brain distribution and the baseline test-retest variability (TRV) of the total volume of distribution (V_T) by [^{18}F]PF-06445974 in nonhuman primates (NHPs). In addition, [^{18}F]PF-06445974 was applied to measure the target occupancy (TO) of a PDE4D-sparing PDE4 inhibitor ABI-4 in NHPs. **Materials and methods:** Three cynomolgus monkeys were scanned with [^{18}F]PF-06445974 (IV, 37 MBq/kg) PET for 180 minutes at baseline twice to measure the TRV. Four doses (0.005, 0.025, 0.01, and 0.1 mg/kg, IV, 30 minute pretreatment time) of ABI-4 were tested to measure the TO. Arterial and venous blood samples were collected to measure the percent parent and ABI-4 concentration in plasma respectively. Time-activity curves (TACs) were generated for various brain regions. V_T was calculated with the one tissue (1T), two-tissues (2T) and MA1 kinetic models. TO was estimated using Lassen plots. An Emax model was fitted between the TO and the mean plasma ABI-4 exposure.**Results:** The percent parent of [^{18}F]PF-06445974 in plasma decreased gradually and reached about 67% at 180 minutes. [^{18}F]PF-06445974 showed the highest uptake in thalamus, followed by putamen and caudate, various cortical regions and lower uptake in cerebellum and hippocampus. The baseline TACs reached peak concentration (SUV ~1.5-3.5) in less than 30 minutes post tracer injection at all brain regions. The 2T model fit the data the best, though the MA1 and 1T models produced a more robust estimate of V_T. The mean TRV of baseline V_T were 9.5%, 6.6% and 7.7% for 2T, 1T and MA1 models respectively. Significant blockade of the brain uptake of [^{18}F]PF06445974 was achieved with the pretreatment of ABI-4. The measured TO (36.2% to 93.7%, MA1) and the plasma ABI-4 exposure were fitted nicely with an Emax model, with an estimated free plasma EC50 of 2.24 nM. **Conclusions:** [^{18}F]PF-06445974 demonstrated favorable in vivo binding and brain kinetics and good baseline TRV in NHPs. It could be a valuable PET radioligand for measuring the TO of PDE4D-sparing PDE4 inhibitors upon further evaluation in human subjects.

OP311

Feasibility of in vivo imaging of VEGFR2 expression using high affinity antagonistic biparatopic affibody construct Z_{VEGFR2}-Bp_2

B. Mitran[1], R. Güler[2], E. Lindström[1], F. Fleetwood[2], V. Tolmachev[1], S. Ståhl[2], A. Orlova[1], J. Löfblom[2]; [1]Uppsala University, Uppsala, SWEDEN, [2]KTH Royal Institute of Technology, Stockholm, SWEDEN.

Aim: Vascular endothelial growth factor receptor 2 (VEGFR2) is a key mediator of angiogenesis. Therefore it has emerged as a promising target in a wide variety of malignancies and several ophthalmological disorders. Molecular imaging of VEGFR2 expression may enable patient stratification for therapies targeting VEGF-VEGFR signaling axis. Z_{VEGFR2}-Bp_2 is an antagonistic biparatopic affibody construct (14.4 kDa) with equally high affinity to human and murine VEGFR2. The aim of this study was to

develop an imaging probe for in vivo visualization of VEGFR2 expression in tumors using the Z_{VEGFR2}-Bp_2 derivative. **Materials and methods:** Maleimido derivative of NODAGA was site-specifically conjugated to a unique cysteine at C-terminus of HEHEHE-Z_{VEGFR2}-Bp_2. HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA was radiolabeled with ^{111}In. In vitro specificity, binding affinity and cellular processing were investigated using VEGFR2-expressing MS1 murine endothelial cell line. The biodistribution of ^{111}In-HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA was studied in BALB/c nu/nu mice bearing MS1 xenografts. Experimental imaging was performed using SPECT/CT for small rodents. **Results:** HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA was radiolabeled with ^{111}In with >98% radiochemical yield and the specific activity of 15 GBq/μmol. ^{111}In-HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA demonstrated specific binding to VEGFR2-expressing MS1 cells. The internalized fraction was 58% of cell-associated radioactivity after 24h. The dissociation constant (K_D) of ^{111}In-HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA binding to MS1 cells was 33±18 pM. Tumor targeting and biodistribution studies showed specific dose-dependent uptake in tumors (3.1±0.7 %ID/g for 1 μg, 2.4±1.3 %ID/g for 4 μg, 0.8±0.1 %ID/g for 20 μg at 2 h p.i.). Uptake in liver, spleen and lungs was also saturable, indicating VEGFR2-mediated accumulation. Variation in tumor uptake over time was negligible up to 24 h (1.9±0.2 %ID/g at 6h p.i., 1.9±0.4 %ID/g at 24h p.i.). At 6 h p.i., lung uptake decreased by approximately 60% compared to 2 h p.i. There was no statistically significant decrease of ^{111}In-HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA in other organs. The tumor-to-organ ratios at 6 h p.i. were 9.1±0.6, 4.7±0.4, 27±2, for blood, muscle and brain, respectively. MS1 xenografts were visualized using ^{111}In-HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA. **Conclusion:** ^{111}In-HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA was able to specifically target VEGFR2 in vivo. Tumor-to-blood ratio for anti-VEGFR2 affibody construct was higher than for other anti-VEGFR2 imaging probes. While the high uptake in major metastatic sites such as liver, lungs and bones limit the diagnostic potential in most cancers, ^{111}In-HEHEHE-Z_{VEGFR2}-Bp_2-NODAGA could be a promising probe for imaging of VEGFR2 expression in glioblastoma.

Imaging synaptic density in the living human brain using positron emission tomography

S. J. Finnema[1], N. B. Nabulsi[1], T. Eid[2], K. Detyniecki[3], S. Lin[1], M. Chen[1], R. Dhaher[2], E. Baum[1], D. Holden[1], D. D. Spencer[4], J. Mercier[5], J. Hannestad[5], Y. Huang[1], R. E. Carson[1]; [1]Yale PET Center, New Haven, CT, UNITED STATES, [2]Yale University, Department of Laboratory Medicine, New Haven, CT, UNITED STATES, [3]Yale University, Department of Neurology, New Haven, CT, UNITED STATES, [4]Yale University, Department of Neurosurgery, New Haven, CT, UNITED STATES, [5]UCB Biopharma, Braine-l'Alleud, BELGIUM.

Aim: Synaptic changes are associated with numerous brain disorders, including epilepsy and Alzheimer's disease. However, quantification of synaptic density in living patients has been limited to studies of surgically resected or post-mortem tissues. Here, we validated positron emission tomography (PET) imaging with the synaptic vesicle glycoprotein 2A (SV2A) radioligand ^{11}C-UCB-J as a novel approach for the quantification of synaptic density in the living primate brain. **Materials and methods:** In a validation study, one baboon was studied with ^{11}C-UCB-J. After completion of the PET scan, the baboon was euthanized and the brain harvested. Tissue samples from 12 brain regions were analyzed with western blot analyses (for SV2A and synaptophysin (SYN)) and SV2A homogenate binding assays. Regional V_T values were estimated with arterial input functions using the one-tissue compartment model. Furthermore, three patients (3 men, 52±6 years of age) with temporal lobe epilepsy (TLE) and mesial temporal sclerosis (MTS) were examined in the HRRT PET system after injection of ^{11}C-UCB-J. Parametric binding potential (BP_{ND}) maps were generated with the simplified reference tissue model 2 using the centrum semiovale as a reference region for non-displaceable binding. **Results:** Western blot analyses demonstrated strong and specific SV2A and SYN signals in all gray matter regions, and weak/absent signals in the white matter (centrum semiovale). The correlation between SV2A and SYN was linear across all gray matter regions examined. In the homogenate binding assays, the regional SV2A density ranged between 2.1-20.6 pmol/mg protein. There was a good correlation between regional *in vitro* B_{max} values and the corresponding SV2A optical density as well as with the *in vivo* V_T values measured with PET. In all three epilepsy patients, there was a large unilateral decrease in hippocampus binding ipsilateral to the MTS seen on MRI. The unilateral uptake of ^{11}C-UCB-J was region specific, with no asymmetry observed in the fusiform. Regional asymmetry indices were much higher in the hippocampus (52±13% vs. -9.6±5.4%, 3 patients) and amygdala (47±13% vs. -8.4±15%, 2 patients) of epilepsy patients than in 5 previously examined healthy subjects. **Conclusion:** Validation studies confirmed that SV2A is a valid alternative synaptic density marker to SYN. PET studies in TLE patients confirmed that ^{11}C-UCB-J binding is sensitive to synaptic loss. Thus, ^{11}C-UCB-J PET imaging is a promising biomarker approach for *in vivo* quantification of synaptic density with several potential applications in diagnosis and therapeutic monitoring of neurological and psychiatric disorders.

OP313

Complete hearing loss changes activity pattern and inhibitory neurotransmission in the auditory system of rodents detected with PET

M. Mamach[1,2,3], **M. Kessler**[1,2], J. P. Bankstahl[1], T. L. Ross[1], L. Geworski[3], F. M. Bengel[1], G. Berding[1,2], S. Kurt[2,4]; [1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Cluster of Excellence Hearing4all, Hannover, GERMANY, [3]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [4]Department of Otolaryngology, Hannover Medical School, Hannover, GERMANY.

Aim: In inferior colliculus (IC), medial geniculate body (MGB) and auditory cortex (AC), F-18-Fluorodeoxyglucose (FDG) enables detection of activation in the auditory system and F-18-Flumazenil (FMZ) quantification of inhibitory $GABA_A$ receptors. Ex-vivo studies provided evidence that the GABAergic system is involved in adaptive/plastic changes after hearing loss. The present longitudinal study aims to detect such changes before/after induction of complete hearing loss *in vivo*. **Methods:** Six Sprague Dawley rats were studied before (PRE) and after (POST1: 1-7days, POST2: 29-36days) inducing complete hearing loss by either cochlear ablation or noise trauma. After trauma all animals showed a complete loss of the hearing thresholds. 12-20MBq FMZ or 18-22MBq FDG were injected intravenously during isoflurane anesthesia. Imaging was performed dynamically for 45min after injection of FMZ and after injection of FDG plus 40min of acoustic stimulation by laboratory background noise of 55dB (BG) for 30min using an Inveon PET system (Siemens). Data were analyzed using PMOD3.6 software and Schwarz´s VOI atlas to match changes to anatomical locations. Non-displaceable binding potentials (BPnd) of $GABA_A$ receptors were determined based on Logan's reference tissue method (using the pons as a reference). Changes of activity in auditory regions during BG from PRE to POST conditions were assessed after proportional scaling. All parameters were determined at all time points in the somatosensory cortex (SC) as well as control for unspecific changes in the brain. **Results:** Compared to PRE the activity during BG decreased significantly ($p<0.05$) in the IC (POST1 -19%, POST2 -18%) and the AC (POST1 -9%, POST2 -7%). No significant change was observed in the MGB. Significant changes ($p<0.05$) in $GABA_A$ receptor BPnd compared to PRE were detected in AC (BPnd PRE = 1.24±0.15) at POST2 (decrease: -0.14±0.05) and MGB (BPnd PRE = 0.69±0.09) at POST1 (increase: +0.09 ±0.03) as well as POST2 (increase: +0.09±0.03). No significant change in

BPnd could be observed in the IC. The control region (SC) did neither show differences in activity during BG condition nor changes in $GABA_A$ receptor BPnd between the given time points. **Conclusions:** We demonstrated reduced activity in IC and AC but not in MGB in rats with complete hearing loss. $GABA_A$ receptor binding in AC decreased significantly for the later time point. Conversely, the region without change in activity (MGB) showed an increase in BPnd. The present data provide first-time an evidence for the involvement of the inhibitory GABAergic system in adaptive/plastic changes *in vivo* after complete hearing loss.

OP314

Differential cerebral plasticity after bilateral audio-vestibular damage in a rat model: A comparative [^{18}F]FDG-μPET behavioral analysis

E. Eilles[1], L. Günther[1], G. Xiong[1], R. Oos[2], A. Zwergal[3], P. Bartenstein[2], R. Beck[1]; [1]German Center for Vertigo and Balance Disorders, University Hospital of Munich, Department for Nuclear Medicine, Munich, GERMANY, [2]University Hospital of Munich, Department for Nuclear Medicine, Munich, GERMANY, [3]German Center for Vertigo and Balance Disorders, University Hospital of Munich, Munich, GERMANY.

Aim: The aim of the study was to analyse the regeneration of balance control after a bilateral audio-vestibular inner ear damage by behavioral testing and to correlate the results with changes of the regional glucose metabolism (rCMRglu) in the cerebral audio-vestibular system. Methodology: 7 SD rats underwent a bilateral chemical labyrinthectomy (BL) by transtympanale injection of bupivacain/arsenilat in the inner ear. For control (Sham) 0.9% NaCl solution was applied to 8 other rats. On day 1,2,3,7,15,30 and 60 post Op behavioral testing was carried out with all animals (apparative gait analysis (catwalk), apparative movement analysis (open-field)). In addition, behavioral testing was followed by serial cerebral [^{18}F]FDG-μPET-scans on the respective days. Results: All BL-animals showed a pronounced stance and gait ataxia as well as a hearing decrease, which persisted up to day 60 after surgery. Corresponding serial [^{18}F]FDG-μPET-scans showed a permanent bilateral reduction of the rCMRglu in the *colliculi inferiores* compared to the Sham-animals. The gait analysis of the directed walk in the catwalk system revealed an assimilation of gait parameters after day 15 post surgery. Accordingly a bilateral reduction of the rCMRglu in the *nuclei vestibulares* was visible in the [^{18}F]FDG-μPET just up to day 15 post BL. The movement analysis in the open-field showed a permanently hyperlocomotion up to day 60 post BL compared to the Sham-animals. Referring to this, indicated the rCMRglu of the BL-animals an activation of limbic regions.Conclusions: Using the [^{18}F]FDG-μPET differential cerebral plasticity after bilateral audio-vestibular damage could be visualised. The findings of the [^{18}F]FDG-μPET correspond with the results of behavioral testing. While no relevant change appeared in the central audiological system a vestibular compensation could be proved in the central vestibular system. The hippocampal system showed a persistent activation.

OP315

Inhibition of P-gp and BCRP-mediated efflux transport of [^{11}C]erlotinib at the non-human primate blood-brain barrier

N. Tournier[1], S. Goutal[1], S. Auvity[1], A. Traxl[2], S. Mairinger[2], T. Wanek[2], I. Buvat[1], M. Soussan[1], F. Caillé[1], O. Langer[2]; [1]CEA, Orsay, FRANCE, [2]Austrian Institute of Technology, Seibersdorf, AUSTRIA.

Aims: The epidermal growth factor receptor (EGFR) targeting tyrosine kinase inhibitor erlotinib poorly penetrates the blood-brain barrier (BBB) due to efflux transport by P-glycoprotein (P-gp) and breast cancer resistance protein (BCRP) thereby limiting its utility in the treatment of non-small cell lung cancer brain metastases. Pharmacological strategies to inhibit P-gp/BCRP-mediated efflux transport at the BBB have been successfully developed in rodents, but it remains unclear if these can be translated to humans given pronounced species differences in BCRP/P-gp expression ratios at the BBB. We assessed the efficacy of two different P-gp/BCRP inhibitors (elacridar and high-dose erlotinib) to enhance brain distribution of [^{11}C]erlotinib in non-human primates as a model of the human BBB. Methods: Three adult male *Papio anubis* baboons underwent arterial blood sampling and PET scans of the brain following i.v. injection of [^{11}C]erlotinib under baseline conditions ($n = 4$), during i.v. infusion of high-dose erlotinib (10 mg/kg/h, $n = 4$) and during i.v. infusion of elacridar (12 mg/kg/h, $n = 3$). Brain distribution of [^{11}C]erlotinib was expressed as total volume of distribution (V_T) estimated with Logan plot analysis using an arterial plasma input function. Data were statistically compared using an ANOVA with Tukey's *post-hoc* test. Results: Under baseline conditions, [^{11}C]erlotinib distribution to the brain ($V_T = 0.23 \pm 0.015$ mL/cm^3) was markedly lower ($P < 0.001$) than its distribution to muscle tissue surrounding the skull ($V_T = 0.86 \pm 0.10$ mL/cm^3). Elacridar infusion resulted in a 3.7-fold increase in [^{11}C]erlotinib distribution to the brain ($V_T = 0.81 \pm 0.21$ mL/cm^3, $P < 0.01$), reaching comparable levels as in muscle tissue, without changing [^{11}C]erlotinib plasma pharmacokinetics. During high-dose erlotinib infusion [^{11}C]erlotinib brain distribution was also significantly (1.7-fold) increased ($V_T = 0.38 \pm 0.033$ mL/cm^3, $P < 0.05$) with a concomitant increase in [^{11}C]erlotinib plasma exposure. The 3-7-fold increase in [^{11}C]erlotinib brain distribution in non-human primates following P-gp/BCRP inhibition with elacridar was remarkably similar to a previously performed mouse study (5.3-fold increase). Conclusion: We successfully translated P-gp/BCRP inhibition protocols from rodents to non-human primates resulting in pronounced increases in distribution of [^{11}C]erlotinib to the non-human primate brain. Such inhibition protocols may ultimately find application for a more effective treatment of patients with brain tumors using drugs that undergo efflux transport at the BBB.

OP316

Target occupancy of PF-06663195 measured with a beta-secretase (BACE) PET radioligand [^{18}F]PF-06684511 in non-human primates

R. Arakawa[1], L. Chen[2], A. Takano[1], M. A. Brodney[3], S. Nag[1], C. Chang[2], N. Amini[1], S. Doran[2], T. McCarthy[3], C. Nolan[3], L. Zhang[3], C. Halldin[1]; [1]Center for Psychiatric Research, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, SWEDEN, [2]Worldwide Research & Development, Pfizer Inc., Groton, CT, UNITED STATES, [3]Worldwide Research & Development, Pfizer Inc., Cambridge, MA, UNITED STATES.

Aim PF-06684511 is a promising PET ligand lead identified by Pfizer that has shown high specific binding in rodents to beta-secretase (BACE). To further evaluate its potential as a BACE selective PET ligand, PF-06684511 was successfully radio-labeled with F-18 and evaluated with a baseline/blocking study in non-human primates (NHPs) with PET imaging. [^{18}F]PF-06684511 showed high brain uptake in NHPs and the brain uptake was significantly reduced by a high dose of a BACE inhibitor PF-06738879, demonstrating high target binding specificity. To further develop [^{18}F]PF-06684511 into a clinically usable PET radioligand, we assessed the relationship between BACE target occupancy in the brain and the plasma exposure for a BACE inhibitor, PF-06663195, in NHPs. *Materials and methods* Four cynomolgus monkeys were used in this study. Brain PET measurements for 120 min were performed three times in each NHP, one at baseline and two after intravenous administration of one of four different doses of PF-06663195. Total distribution volume (V_T) by two tissue compartment (2TC) model with metabolite corrected plasma radioactivity as the input function was calculated. The target occupancy was estimated by Lassen plot as there was no good reference region for BACE binding observed in NHPs. The relationship between average plasma concentration of PF-06663195 determined by area under the curve during 120min PET scan and the brain occupancy was estimated by an E_{max} model with the following equation: Occupancy (%) = $C/(EC_{50}+C)\times E_{max}$, as C is the plasma concentration of PF-06663195, EC_{50} is the plasma concentration required to achieve 50% of the maximum occupancy, and E_{max} is the maximum occupancy. *Results* The uptake of [^{18}F]PF-06684511 decreased in all brain regions with

administration of PF-06663195. 2TC model was fitted well to estimate the V_Ts. The target occupancy estimated using Lassen plot was 39.5% - 98.1%, as showing at a dose dependent manner. Exposure-occupancy curve was well fitted with an E_{max} model. EC_{50} was estimated to be 3.75 ng/mL. *Conclusions* These data suggest that PF-06663195 might fully block the target enzyme, BACE. [^{18}F]PF-06684511 can estimate the BACE activity specifically in NHP brain in vivo and may be a promising PET radioligand for estimating BACE activity in human brain upon further evaluation.

OP317

Microglia, Amyloidosis and TREM2 Progress in Parallel during the Life Course of PS2APP Mice

M. Brendel[1], A. Jaworska[2], S. Lindner[1], F. Gildehaus[1], N. Albert[1], R. Beck[1], P. Bartenstein[1], J. Herms[2], G. Kleinberger[2], C. Haass[2], A. Rominger[1]; [1]University of Munich, Munich, GERMANY, [2]DZNE, Munich, GERMANY.

Aims: TREM2 as an innate immune receptor on myeloid cells has a potential impact on the linkage between neuroinflammation and amyloidosis. Therefore we aimed to investigate amyloid and TSPO μPET estimates together with TREM2 levels at different stages of age in PS2APP mice, an Alzheimer's disease model with severe amyloid pathology. The main focus was on regional mapping of microglia activation and amyloidosis during the life course of the animals tracked by dual small animal PET in a cross-sectional design. Materials and Methods: Groups (N=8) of PS2APP and C57Bl/6 wild-type mice of four ages (5-16 months of age) were examined *in vivo* by F-18-GE180 (microglial activity) and F-18-florbetaben (amyloidosis) μPET, followed by biochemical quantification of TREM2 *post mortem*. μPET data was analysed voxel-wise by statistical parametric mapping including (all FDR-corrected; $p<0.05$). Pathology affected brain regions were compared between tracers (dice similarity coefficients) and pseudo-longitudinally. μPET results of both tracers were correlated with terminal TREM2 levels. Results: Microglial activation was already elevated at early ages of PS2APP mice in large parts of the brain (5mo: 11% brain volume; 8mo: 32% brain volume; versus WT) where fibrillary amyloidosis only occurred punctually (≤ 3% brain volume, dice similarity ≤ 12%). Both neuropathological hallmarks consecutively reinforced each other during the advancing life course. Finally at 16 months of age neuroinflammation and amyloidosis indicated an overlap in 37% of the total brain volume (dice similarity 67%). Dual *in vivo* μPET data and *post mortem* TREM2 levels were closely associated with each other ($R=0.86$; $p<0.001$) and progressed in parallel during the life course of PS2APP mice. Conclusion: The study reveals a strongly correlated and age-dependent progression of microglial activation and amyloidosis together with TREM2, allowing interventional designs to detect interdependence of each other. Especially early anti-inflammatory treatment and its effect on amyloidogenesis is of highest interest.

OP318

PET in vivo imaging of 18kDa TSPO expression in a mouse model of temporal lobe epilepsy using [18F]DPA-714

D. NGUYEN, C. WIMBERLEY, I. BUVAT, R. BOISGARD, V. BOUILLERET; CEA/I2BM/Service Hospitalier Frédéric Joliot, Gif sur Yvette, FRANCE.

Introduction: Mesial temporal lobe epilepsy (MTLE) is the most common type of epilepsy. Several studies in animal models showed a high neuroinflammatory signal using PET with 18kDa TSPO tracer during the constitution of the seizures. In rat models of epilepsy previously established, the disease-related signal decreases and even disappears at later time points, whereas it persists in the human. The intrahippocampal kainate injection mouse model reproduces the pattern of hippocampal sclerosis and the persistent life-time of spontaneous recurrent seizures of MTLE better than the rat model. We studied whether [^{18}F]DPA-714 PET of 18kDa TSPO was a good marker of neuroinflammation to investigate the disease process in the mouse model. *Methods:* The model was induced by unilateral injection of kainic acid (KA) into the right dorsal hippocampus of male C57/Bl6 mice. Sham mice were also prepared by injecting saline at the same location. To investigate the epileptic process, 60 minutes dynamic [^{18}F]DPA-714 PET/CT scanning were performed at 2 different groups (i) during the constitution of the epileptic process at 7 days and (ii) during the recurrence of the seizures 1 and 6 months after injection. Brain PET/CT images were reconstructed using OSEM 2D algorithm including attenuation correction. These images were then coregistered to a MRI atlas in PMOD 3.6 to identify regions of interest. The uptake within the right and left hippocampus reported here were normalized to the cerebellum uptake. *Results:* For the first group (5 KA and 5 sham mice), 7 days after the injection, an increased uptake was observed in both hippocampi, predominant in the injected hippocampus compared to the sham mice (right: 1.06±0.04 *vs* 0.88±0.03, $p<0.0001$; left: 0.96±0.03 *vs* 0.83±0.02, $p<0.0001$). For the second group (5 KA and 5 sham mice), one month after the KA injection the TSPO uptake decreased but remained always higher than in sham (right: 0.94±0.03 *vs* 0.79±0.03, $p<0.0001$; left: 0.82±0.03 *vs* 0.74±0.05, $p=0.0154$), and persisted even 6 months after injection (right: 0.93 ±0.04 *vs* 0.82±0.01, $p=0.0003$ and left: 0.85±0.03 *vs* 0.77±0.02, $p=0.0011$). *Conclusion:* For the first time, we showed that [^{18}F]DPA-714 PET could detect the inflammatory process in a mouse model of MTLE *in vivo* up to 6 months after the induction of a lesion. More sophisticated processing and quantification should help precisely characterize TSPO expression in longitudinal studies in the hippocampus and in other brain regions. *Acknowledgement:* This work was supported by the EU FP7 INMiND (Grant agreement no. 278850)

Evaluation of Logan's graphical method with reference tissue input as a simplified approach for quantification of $GABA_A$ receptor binding in rats

M. Kessler[1,2], M. Mamach[1,2,3], J. P. Bankstahl[1], T. L. Ross[1], F. Wilke[3], L. Geworski[3], F. M. Bengel[1], S. Kurt[2,4], G. Berding[1,2]; [1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Cluster of Excellence Hearing4all, Hannover, GERMANY, [3]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [4]Department of Otolaryngology, Hannover Medical School, Hannover, GERMANY.

Aim: In rodent models for hearing loss $GABA_A$ receptors have been demonstrated to play a key role in adaptive/plastic changes in the auditory system. Therefore we aimed to implement a simplified approach for measurements of $GABA_A$ receptor non-displaceable binding potentials (BPnd) in rats using F-18-flumazenil (FMZ) PET. Methods: 12-20MBq FMZ were injected via the tail veins of 6 normal-hearing female Sprague Dawley rats under isoflurane anesthesia. Simultaneously a 45min list-mode acquisition was started employing an Inveon PET (Siemens) system. Data were reconstructed iteratively into 31 time consecutive frames (5x2s, 4x5s, 3x10s, 8x30s, 5x60s, 5x5min, 1x10min) including Co-57-transmission-source-based attenuation-correction. Analyses were performed using PMOD3.6 software. Three bio-kinetic models were applied: (i) a 2-tissue-compartment-model with an image derived input function not corrected for metabolites (2T), (ii) a 2-tissue-compartment-model with an image derived input function including metabolite correction based on data from literature (2T-corr) and (iii) a Logan-plot with a reference tissue input function obtained from the pons (Logan). The values of BPnd for auditory cortex (AC), inferior colliculus (IC), mediate geniculate body (MGB) and somatosensory cortex (SC) were calculated with the pons as a reference region based on a standard VOI atlas. Results: Using the 2T-corr procedure, BPnd was 1.53±0.26 for AC,

1.47±0.21 for IC, 0.81±0.15 for MGB and 1.38±0.30 for SC. Pairwise t-test between bio-kinetic models revealed significant difference in BPnd with a hierarchy of values 2T-corr > Logan > 2T for all regions. In the AC 2T-corr showed the highest difference of +35% to 2T ($p<0.001$) and +12% to Logan ($p<0.05$), while Logan was 23% higher than 2T ($p<0.001$). Linear regression analyses revealed highly significant ($p\leq0.001$)correlation between BP values determined using 2T-corr and Logan for all regions, i.e. $R^2=0.9970$ for AC, $R^2=0.9873$ for IC, $R^2=0.9444$ for MGB and for SC $R^2=0.9956$. Conclusion: Considering 2T-corr as a gold standard, omitting metabolite correction (2T) produced distinctly lower values. Employing Logan's reference tissue model partly compensated for this effect and resulted in only moderately lower absolute BPnd values which strongly correlate to BPnd values determined by 2T-corr. Therefore our data indicate that using the simpler Logan approach seems to be adequate for analysis of data from one research center. However, if absolute values of BPnd should be compared to other centers' values or to other methodological approaches 2T-corr would be preferable. Furthermore, the relatively low BPnd values determined for MGB might be explained by partial volume effects related to this anatomically small structure.

223Ra-dichloride treatment: the Europen Institute of Oncology experience

M. Colandrea, Jr., S. M. Baio, S. L. V. Fracassi, L. Gilardi, L. L. Travaini, P. A. Rocca, M. Cossu Rocca, A. Gaetano, D. Cullurà, E. Verri, S. Papi, A. Carollo, F. Nolè, C. M. Grana; IEO, Milan, ITALY.

Introduction: 223Ra-dichloride is a novel radiopharmaceutical approved for the treatment of bone metastases of castration resistant prostate cancer (mCRPC). Its chemical affinity with calcium and the high dose delivered, make Ra-223 dichloride a relevant radiopharmaceutical for targeting areas of increased bone turnover. **Aim**: To present the IEO single-centre experience with 223Ra-dichloride in the treatment of patients with mCRPC, in terms of evaluation of feasibility, efficacy and management of a multidisciplinary patient. **Methods**: Nine progressive and symptomatic patients with multiple bone metastases without involvement of any other organ (age 62±9.3 yrs,

medium PSA 150.8 ng/mL) are under treatment; they are receiving 223Ra-dichloride 50 kBq/kg i.v. on day 1 every 28 days for a maximum of 6 cycles. So far 3 patients have completed the treatment, and we are planning to present the complete report during the congress. Pretreatment evaluation was performed with CT scan and bone scan. Patients have been evaluated at every cycle with complete blood chemistry and pain scale and QoL evaluations. A multidisciplinary team followed patients during both screening and treatment period. **Results:** No problems in vial manipulation, dose preparation, administration and radiation protection isseus occurred. Therapy was well tolerated in all patients and none presented acute side effects. No cycles were delayed due to blood toxicity, and no patient discontinued the treatment. Most of patients had bone pain relief and reduced pain drugs intake, also during the tratment. No patient presented anorexia; only one case of diarrhoea was observed during the first 4 cycles. At the current timepoint our patients received 33 cycles of 223Ra-dichloride. Three patients have already completed the treatment: we found G3 anemia in 1 patient; G2 neutropenia and G2 thrombocytopenia in 1 patient. Biomarkers response showed different results: 1 patient with increase in ALP and 1 with decline, 1 patient with a stable value. We have no significative data on PSA. At the first CT and bone scan evaluations, the three patients presented bone stable disease and one patient presented visceral metastases. **Conclusion**: our single-centre experience shows the feasibility of radiometabolic therapy with 223Radium-dichloride in patients with mCRPC in a multidisciplinary team. Palliative effect allows decreasing pain drugs consume with a mild toxicity profile (at this first evaluation), allowing the use of 223Ra-dichloride in combination with other treatments. We are planning to compare the ALP, PSA and bone scintigraphy results before and after treatment.

OP333

Two Years Of Experience Of 223Ra-Dichloride In Clinical Practice: Have We Started Treating At Earlier Stage Of Bone Disease?

S. Dizdarevic[1,2], M. Jessop[1], P. Begley[1], M. Aplin[1], A. Hosur[1], A. Nikapota[1], A. Robinson[1]; [1]Brighton and Sussex University Hospital NHS Trust, BRIGHTON, UNITED KINGDOM, [2]Brighton and Sussex Medical School, Brighton, UNITED KINGDOM.

Background: Extent of bone disease as assessed by pre-treatment bone scintigraphy is a predictive imaging biomarker of the overall survival of patients with castrate resistant prostate cancer (CRPC) treated with 223Ra-dichloride. However very often those patients were referred to Nuclear Medicine (NM) department at very late stage with severe metastatic bone burden.Aim: Aim of this study was to demonstrate a change in the pattern of referrals for 223Ra-dichloride treatments in our clinical practice in the second year in comparison with the first year of service and further to implementation of strong collaborative Uro-Oncology/NM multidisciplinary referrals pathways. Methods: All patients treated in period March 2014 to March 2016 were included. Extent of bone disease (EOBD) was categorised from a pre-treatment bone scan in accordance with Alsympca trial (EOBD1 = less than 6 metastases, EOBD2 = 6-20, EOBD3 >20, EOBD4 = superscan). Data from the first year of service were compared with the second year. Overall survival was defined as the time from first clinic visit to the date of death, regardless of cause. A log-rank test was applied to Kaplan-Meier survival analysis.Results: Fifty two patients underwent 223Radium-dichloride treatments from March 2014 to March 2016; in the first year 26 patients were treated and in the second year 24 patients completed their treatment and two are on their sixth cycle. The percentage of patients referred in each EOBD group in the first year versus the second year was: EOBD1 (4% vs. 23%), EOBD2 (35% vs. 27%), EOBD3 (23% vs. 35%), EOBD4 (38% vs. 15%). All patients with EOBD 1 completed their treatment with 6 cycles and no patient from group EOBD1 died. Patients in EOBD2 underwent an average of 4.6 cycles [SD: ±1.5]; EOBD3, 4.3 cycles [±1.9]; EOBD4, 3.1 cycles [±2.1]. In addition, we have previously demonstrated a statistically significant difference in survival between EOBD2/3 and EOBD4 (p < 0.03 and p < 0.05, respectively), but no significant difference between EOBD2 and EOBD3. Conclusion: In the 2nd year of 223Ra service we have noticed reverse pattern in EOBD1 and EOBD4 referrals with 19 % increase in EOBD1 and 23% decrease in EOBD4 treatments. We continue treating EOBD2/3 with similar rate. Treating more patients with lower bone burden subsequently has resulted in significantly better overall outcomes. Coherent uro-oncology/NM interface with increased confidence of referring clinicians for earlier intervention is a key for successful treatment with 223 Ra-dichloride.

OP334

Pain Response and Acute Hematologic Toxicity in Castration-Resistant Prostate Cancer (CRPC) patients (pts) treated with ^{223}Ra-dichloride: a Single-Center Clinical Series

G. A. Follacchio, V. Frantellizzi, M. Liberatore, F. Monteleone, G. De Vincentis; Sapienza University, Dept of Radiology, Oncology and Human Pathology, Rome, ITALY.

Aim. Alpha-emitter ^{223}Ra-dichloride has been recently approved for treatment in mCRPC pts with symptomatic bone metastases due to its significant impact on OS associated to a low hematologic toxicity profile. Since its approval, 59 pts have been referred to our center to undergo ^{223}Ra treatment, currently consisting in 50 kBq/kg IV q4wks for 6 cycles. This interim retrospective analysis was conducted to evaluate pain response and occurrence of acute hematologic toxicity in our series. **Methods.** Complete blood counts were recorded at baseline and before each ^{223}Ra administration. Pain score was assessed through Brief Pain Inventory-Short Form at baseline and after each ^{223}Ra infusion. To further evaluate pain response, EORTC questionnaires QLQ-C30 and QLQ-BM22 were submitted to pts at baseline and after each treatment and analyzed according to published guidelines. Data were retrospectively collected and summarized using descriptive statistics. **Results.** 206 ^{223}Ra cycles were delivered to 59 pts (mean age 74y, mean Gleason Score 8, mean ECOG Performance Status 1.3, no known visceral metastases). Skeletal tumor burden evaluated at baseline bone scan was classified as low (0-6 mets) in 8% of pts, intermediate (6-20 mets) in 80% pts and high (>20 mets) in 12% pts. 49% of pts received prior docetaxel. Baseline pain was mild in 27% of pts, moderate in 46%, severe in 27%. During ^{223}Ra treatment, 3 out of 59 pts developed G3/4 thrombocytopenia, while 6/59 pts received blood transfusions during the course of treatment due to G3 anemia. Discontinuation rate of ^{223}Ra treatment was 22% (13/59) due to disease progression (46%), bone marrow failure (23%) and death (31%). Prior docetaxel use was associated to a higher discontinuation rate (66% vs 34%). 54% of pts experienced an improvement of bone pain, 39% had no changes in pain scale and 7% reported worsening bone pain. **Conclusions.** This interim analysis confirmed ^{223}Ra favorable hematologic toxicity profile. Bone pain response was not correlated to baseline hematologic status in our series. ^{223}Ra was effective in pain relief in the majority of pts. Notably, all pts with high tumor burden at baseline experienced an improvement in bone pain. Prior docetaxel use was associated to a higher discontinuation rate; this should support the opinion that ^{223}Ra treatment should be delivered in an upfront therapeutic setting in mCRPC patients.

OP335

Response Evaluation to Radium-223-Dichloride in Castration-Resistant Metastatic Prostate Cancer using 11C-choline PET/CT and Bone Scintigraphy

P. Ghedini[1], T. Graziani[1], E. Lodi Rizzini[1], G. M. Lima[1], A. Matti[1], I. Bossert[1], F. Ceci[1], G. C. Montini[1], F. Monari[2], A. Morganti[3], P. Castellucci[1], S. Fanti[1]; [1]Nuclear Medicine Department, University Hospital S.Orsola-Malpighi, Bologna, ITALY, [2]OU Radiotherapy, University Hospital S.Orsola-Malpighi, Bologna, ITALY, [3]OU Radiotherapy, University Hospital S.Orsola-Malpighi, Bologna, ITALY.

Aim: our purpose was to investigate the response to Radium-223-Dichloride therapy using 11C-choline PET/CT in comparison with Bone Scintigraphy in patients with bone metastasis in castration-resistant prostate cancer (mCRPC). **Material and Methods**: 11 patients were retrospectively enrolled (age mean 75.4 yr, range 58-86). Our inclusion criteria were 1) symptomatic bone metastasis in mCRPC; 2) 6 months treatment with Radium-223-Dichloride; 3) Bone scintighraphy and 11C-choline-PET/CT performed before (SCI1; PET1) and two months after withdrawal of therapy (SCI2; PET2). PSA and Alkaline phosphatase (ALP) values were measured before (PSA1; ALP1) and after the end of treatment (PSA2; ALP2). PET2 and SCI2 were reported as complete response (CR), partial response (PR), or stable disease (SD). The appearance of a new lesion at PET2 or SCI2 was considered progression disease (PD). Clinical, radiological and laboratory follow-up were performed within 3 months. We measured the SUVmax of the detectable lesions, ΔSUV values between PET1 and PET2 and SUVmax of bone marrow in both scans. Limitations of our study are the small number of patients and the short duration of follow up. **Results**: the 72.7% (8/11) of patients showed PR at PET2; 27.3% (3/11) showed a CR of bone metastasis. Considering the 8 patients with PR, the 75% (6/8) showed increasing PSA-trend while considering the 3 patients with CR at PET2, the 66.6% (2/3) showed increasing PSA-trend. 100% of patients of both groups showed a significant decrease of ALP (mean reduction of 44.1%). 81.8% (9/11) of patients showed PR at SCI2; 18,2% (2/11) of patients showed PD at SCI2. PET2 and SCI2 were accordant in 7 patients, while 4 patients obtained a discordant result (2 PET2 classified as CR showed a PR at SCI2; 1 CR PET2 demonstrated a PD at SCI2; 1 PET2 reported as PR was classified as PD at SCI2). All patients with PD at PET2/SCI2 were confirmed by clinical or radiological follow-up. The mean SUVmax reduction (ΔSUV) in PR patients at PET2 was 56.7%; in CR patients SUVmax of the lesions at PET2 was <1,5. All patients showed an increased SUVmax of bone marrow at PET2. **Conclusion**: to better evaluate the real state of the disease in discordant patients a prolonged follow up is needed. PSA trend don't seem able to foresee PET or SCI outcome. Furthermore, ALP trend demonstrate the efficacy of the treatment on bone lesions, without any implications in the final outcome.

OP336

Lesion dosimetry for ^{223}Ra therapy of bone metastases from castration-resistant prostate cancer: patients eligibility criterion and update of dosimetric assessments

M. Pacilio[1], **B. Cassano**[2], G. De Vincentis[3], G. Ventroni[4], V. Frantellizzi[3], G. A. Follacchio[3], R. Pellegrini[5], E. Di Castro[3], P. Ialongo[6], L. Mango[4], R. Pani[7]; [1]Department of Medical Physics, Azienda Ospedaliera San Camillo Forlanini, Rome, ITALY, [2]"Sapienza" University of Rome, Rome, ITALY, [3]Department of Radiological, Oncological and Anatomo Pathological Sciences, Rome, ITALY, [4]Department of Nuclear Medicine, Azienda Ospedaliera San Camillo Forlanini, Rome, ITALY, [5]Department of Molecular Medicine, " Sapienza" University of Rome, Rome, ITALY, [6]Department of Radiology, Azienda Ospedaliera San Camillo Forlanini, Rome, ITALY, [7]Department of Medico-surgical Sciences and Biotecnologies, "Sapienza" University of Rome, Rome, ITALY.

AIM: Dosimetry of bone metastases from castration-resistant prostate cancer in ^{223}Ra-dichloride therapy, by in-vivo quantitative planar imaging, was recently demonstrated to be feasible, obtaining preliminary values of absorbed dose (AD) to lesions using exclusively the MIRD S factor of ^{223}Ra. The aim of this study were: to assess an eligibility criterion for patient dosimetry; to evaluate more reliable ADs, considering the S factors of all ^{223}Ra decay daughters.**Materials and methods:** The study included 36 patients, treated with 6 injections of 50 kBq per kg. For a subgroup of 25 patients (69 lesions), the visibility of lesions (with area>900 mm^2) on ^{223}Ra images at t=24 h from the administration was described by ROC curve, using the lesion/soft tissue ^{99m}Tc-MDP whole-body contrast ratio as score value. The lesions visibility was examined independently in anterior and posterior views, so obtaining a group of 138 data. Gamma-camera calibrations for ^{223}Ra included measurements of sensitivity and transmission curves. After the first injection, patients were statically imaged for 30 min, using a MEGP collimator, double-peak acquisition, and Wiener filtering to improve the image quality. For most patients, three serial acquisitions were performed: between 18-24 h, 48-60 h and 7-10 days. Lesions were delineated on ^{99m}Tc-MDP whole-body images, and the ROIs superimposed on the ^{223}Ra images (if lesions were visible) after image coregistration. The overall number of patients resulting eligible for dosimetry was 20 (38 lesions). The activity was quantified with background, attenuation, and scatter corrections. ADs were assessed from the OLINDA/EXM S factors for soft-tissue spheres of ^{223}Ra and decay daughters, evaluating the lesion mass by CT images delineation and 1.4 g/cm^3 density. D_{RBE} values were calculated multiplying ADs by the cycles number (6) and alpha particles RBE (5).**Results:** The ROC analysis yielded: AUC=0.972; optimal threshold=10 (accuracy of about 92%). The mean effective half-life of ^{223}Ra (mean [range]) was 7.7 [4.2-11.4] days. The AD was 3.6 [0.8-9.7] Gy, D_{RBE}/A_{adm} was 4.5 [1.1-12.1] Gy/MBq, and D_{RBE} was 108 [24-291] Gy.**Conclusion:** In-vivo quantitative imaging and lesions dosimetry in ^{223}Ra therapy resulted feasible if the lesion/soft tissue ^{99m}Tc contrast ratio is higher than 10. The D_{RBE} to lesions was much higher than that of other bone-seeking radiopharmaceuticals. Further studies are ongoing to evaluate the dose-response correlation in a clinical context.

OP337

Early bone SPECT/CT for prediction of prognosis in patients with castration resistant prostate cancer treated with 223 Ra

G. Paone, L. Ceriani, T. Ruberto, G. Treglia, L. Giovanella; Oncology Institute of Southern Switzerland, Lugano, SWITZERLAND.

Aim: The purpose of this study was to assess the prognostic value of early Bone-SPECT/CT (BS), using treatment-related changes in skeletal tumor burden (active tumor volume) compared with visual assessment, in patients with metastatic castration resistant prostate cancer (mCRPC) treated with 223-Ra dichloride (223-Ra). **Materials and Methods:** Eleven patients with a mCRPC underwent bone SPECT/CT before and after 3 cycles of 223-Ra therapy for evaluation of skeletal metastatic disease. In order to determine skeletal tumor Burden semi-automatic isocontour ROIs, normalized to highest normal bone uptake, were performed on pre-treatment and post 3-cycle BS. A 1-cm spherical VOI was placed on right femur to compute the maximum normal bone uptake (NBup) and threshold defined was > 4NBup. Active tumor volume (ATV) and maximum metastatic bone uptake (MBup) on base line BS and their changes post 3-cycle BS were recorded and compared with visual analysis for predicting event-free survival (EFS), in terms of no treatment discontinuation and absence of skeletal related events (SRE), using receiver-operating-characteristic (ROC) analysis. Survival curves were estimated with Kaplan-Meyer analysis. A correlation with treatment-related changes in prostate-specific antigen (PSA) and alkaline phosphatase (ALP) was assessed. **Results:** With visual analysis, the accuracy of early BS to predict EFS was 64%. An optimal cutoff value of 47% ATV reduction from baseline to mid-therapy obtained from ROC analysis ($p< 0.0001$; 95% CI 0,715 to 1,000) yielded an accuracy of 91%. EFS was 17% in patients with ATV reduction ≤ 47% (Mean 7,1 months; 95% CI 4,496 to 9,837) compared with 80% (Mean 11,8 months; 95%CI 9,696 to 13,904) in those with reduction > 47% (p 0,0485). Corresponding ALP levels reduction was more evident (66,7%) in the group α ATV > 47% . No good correlation was found with the heterogeneous variation of PSA. **Conclusion:** These data suggest that quantitative assessment on 3-cycles bone scan during 223-Ra therapy could be considered as predictive biomarker improving the prognostic value, in terms of no treatment discontinuation and absence of skeletal related events (SRE), compared with visual analysis in mCRPC. Further studies are needed to support these conclusions.

OP338

Re-treatment of Radium-223 From an International, Multicenter, Prospective, Single-Arm Trial in Patients With Castration-Resistant Prostate Cancer and Bone Metastases

A. Schwartz[1], O. Sartor[2], N. Mariados[3], J. A. Vallejo Casas[4], C. Thellenberg Karlsson[5], A. Peer[6], G. Procopio[7], S. J. Frank[8], K. Pulkkanen[9], S. Severi[10], J. M. Trigo Perez[11], R. Li[12], J. Garcia-Vargas[12], D. Keizman[1]; [1]Meir Medical Center, Kfar-Saba, ISRAEL, [2]Tulane Cancer Center, New Orleans, LA, UNITED STATES, [3]Associated Medical Professionals of New York, PLLC, Syracuse, NY, UNITED STATES, [4]Hospital Universitario Reina Sofía, Cordoba, SPAIN, [5]Cancer Center Norrlands University, Umeå, SWEDEN, [6]Rambam Medical Center, Haifa, ISRAEL, [7]Foundation IRCCS National Cancer Institute, Milan, ITALY, [8]Hadassah Hebrew University Medical Center, Jerusalem, ISRAEL, [9]Kuopio University Hospital, Kuopio, FINLAND, [10]Romagnolo Scientific Institute for the Study and Care of Cancer—IRST IRCCS, Meldola, ITALY, [11]Hospital Universitario Virgen de la Victoria, Málaga, SPAIN, [12]Pharmaceuticals Division of Bayer, Whippany, NJ, UNITED STATES.

Aim: Given the acceptable safety profile in phase 3 ALSYMPCA, re-treatment with radium-223 may be well tolerated after initial exposure and provide added benefit to patients who had disease progression following an initial course of 6 radium-223 injections. In addition, recent revision of US National Institute of Standards and Technology (NIST) standardization and its impact on radium-223 dosing is clinically important for nuclear medicine physicians. Reported here are safety and efficacy findings of radium-223 re-treatment from an international prospective open-label trial (NCT01934790) and updated radium-223 labeling based on a new NIST standardization requirement. **Materials and Methods:** Eligible patients had bone-metastatic castration-resistant prostate cancer and 6 radium-223 injections with no bone progression during initial treatment. Eligible patients had clinical or radiologic bone progression after prior exposure to radium-223 treatment, and adequate hematologic values. Concomitant agents were allowed at investigator discretion, excluding initiation of new abiraterone or enzalutamide, and cytotoxic treatment. Primary end point was safety; exploratory end points included time to radiographic bone progression and radiographic progression-free survival (rPFS) based on MRI/CT and bone scans every 3 months. Dose labeling was updated based on NIST revision of radium-223 primary standardization (Zimmerman et al. *J Res NIST.* 2015). **Results:** Radium-223 re-treatment was based on a 50-kBq/kg dose (55 kBq/kg following NIST update). The NIST update does not change the amount of radioactivity administered, but translates to a labeled increase from 1000 to 1100 kBq/mL in the 6-mL vial, as of April 18, 2016. Of 44 radium-223 re-treatment patients, 29 (66%) received all 6 injections. At baseline, 18 (41%) patients had <6 bone metastases, 15 (34%) had 6-20, 6 (14%) had >20, and 5 (11%) had superscan. Median time from last dose of initial radium-223 treatment was 6 months. There were no marked alterations in treatment-emergent adverse event (TEAE) incidence compared with ALSYMPCA. No grade 4 or 5 hematologic TEAEs were reported; 3 (7%) patients had grade 3 or 4 treatment-related TEAEs. Maximum follow-up time for radiographic bone progression and rPFS was 12.8 months. Only 1 patient had radiographic bone progression. Median rPFS was 9.9 months. **Conclusions:** Re-treatment with radium-223 was well tolerated with minimal hematologic toxicity and provided continued control of disease progression in this small dataset. Radium-223 labeling was recently updated following NIST standardization; 50 kBq/kg is now 55 kBq/kg. However, the amount of radioactivity administered has not changed from that in ALSYMPCA.

OP339

Effect of ^{153}Samarium Ethylene Diamine Tetra Methylene Phosphonate therapy on pain and analgesic requirement in patients with multiple skeletal metastases

K. Reddy, Dr. Dhanapathi. H, Dr. Madhusudhanan. P, Dr. Gunaseelan. K, Dr. Biswajit. D.; Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, INDIA.

Aim: This study was aimed to assess the effect of Sm-153 EDTMP therapy on pain and analgesic requirement in patients with painful multiple skeletal metastases. **Materials and Methods:** *Study design*: Prospective observational study *Sample population*: The patients who attended to Nuclear Medicine OPD of JIPMER for bone pain palliation during the period September 2013 to July 2015. *Methods:* Patients with multiple painful bone metastasis documented on bone scan within last 8 weeks were included. Pain and performance were assessed using the visual analog scale, Karnofsky performance scale, mobility score and analgesic score. The dose of Samarium-153 EDTMP administered was 37 MBq/kg (1mCi/kg) body weight, by intravenous route on an outpatient basis. Whole body scan was done after 2 hours to see the radiopharmaceutical distribution. The patients were followed up at 4, 8 and 12 weeks after therapy with recording of complaints, blood investigations, VAS pain score, analgesic-score, mobility score and Karnofsky performance scores. **Results:** 45 patients were recruited for the study. 24 out of 45 patients completed the 12-week follow up and all of them responded to Samarium-153 EDTMP therapy. Eight (33.3%) patients showed complete response to therapy. After therapy, pain scores (VAS scale) were significantly reduced ($P < 0.001$). Maximum reduction of pain was seen around 4-8 weeks in most of the patients. Analgesic scores were not changed significantly after the therapy. There was a significant difference in the class of analgesic used after Samarium-153 EDTMP therapy ($P< 0.01$). No statistically significant change was seen in Karnofsky scores pre- and post-therapy. Statistically significant ($P< 0.002$) change was seen in mobility scores before and after therapy. Only 3/24 patients showed grade III anaemia, 8/24 patients showed grade II anemia, 4/24 patients showed grade II leucopenia and 2/24 patients showed grade III and IV thrombocytopenia. No other significant side effects were seen immediately after the administration and during the study period. **Conclusion:** Multimodality approach is needed to relieve bone pain in patients with multiple skeletal metastases. Sm-153 EDTMP is an effective adjuvant in relieving skeletal metastatic pain. Most of the patients show good response to therapy that lasts for a long duration. It helps in decreasing the use of more potent opioids that produce side effects. Temporary myelosupression can be seen after the therapy, but recovery occurs in most of the patients.

[^{68}Ga]NeoBOMB1, a new candidate in the diagnosis of breast cancer: First results in GRPR-expressing cells and animal models

T. Maina-Nock[1], A. Kaloudi[1], A. Giarika[1], E. Lymperis[1], S. U. Dalm[2], F. Orlandi[3], D. Barbato[3], M. Tedesco[3], M. de Jong[2], B. A. Nock[1]; [1]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, ATHENS, GREECE, [2]Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [3]Advanced Accelerator Applications, Collereto Giacosa, ITALY.

Aim: The gastrin releasing peptide receptor (GRPR) is a promising molecular target for diagnosis and therapy of prostate and breast cancer. We have recently introduced NeoBOMB1, a potent GRPR-antagonist coupled to DOTA at the N-terminus (DOTA-*p*-aminomethylaniline-

diglycolic acid-DPhe-Gln-Trp-Ala-Val-Gly-His-NH-CH[CH_2-$CH(CH_3)_2$]$_2$) for facile labeling with diagnostic and therapeutic radiometals. The respective [$^{67/68}$Ga/^{111}In/^{177}Lu]NeoBOMB1 radioligands have shown excellent theranostic properties at the preclinical level for application in prostate cancer. In the present work, we have investigated the potential impact of [^{68}Ga]NeoBOMB1 in the diagnosis of breast cancer, using [^{67}Ga]NeoBOMB1 as a surrogate and GRPR-positive T-47D cells and animal models. **Materials and Methods**: The affinity of NeoBOMB1 and [^{nat}Ga]NeoBOMB1 for the GRPR was studied during competition binding assays against [^{125}I-Tyr^4]BBN in T-47D cell membranes. The internalization of [^{67}Ga]NeoBOMB1 at 37°C in T-47D cells was studied over time (15 min - 2 h intervals). Mouse blood collected 5 and 30 min post-injection (pi) of [^{67}Ga]NeoBOMB1 was analyzed by HPLC to assess in vivo stability. Biodistribution was performed at 1, 4 and 24 h pi of [^{67}Ga]NeoBOMB1 (100 μL bolus, 37 kBq, 200 pmol total peptide) in female SCID mice bearing subcutaneousT-47D xenografts; for in vivo GRPR-blockade an additional 4-h animal group received 40 nmol NeoBOMB1 together with the radioligand. **Results:** NeoBOMB1 and [^{nat}Ga]NeoBOMB1 showed identical affinity for the GRPR (IC_{50}s of 2.2±0.2 nM and 2.5±0.2 nM, respectively). At 37°C [^{67}Ga]NeoBOMB1 strongly and specifically bound to the cell-membrane of T-47D cells (45.8±0.4% at 2 h) with only a small portion internalizing (up to 10% at 2 h), as consistent to a radioantagonist profile. [^{67}Ga]NeoBOMB1 was found more than 90% intact in peripheral mouse blood at 30 min pi. In mice bearing T-47D xenografts, [^{67}Ga]NeoBOMB1 rapidly and specifically localized in the tumor (8.68 ±2.9%ID/g *vs*. 0.6±0.1%ID/g in GRPR-blocked at 4 h pi). Interestingly, tumor values remained unchanged between 1 and 24 h pi. **Conclusions**: This study has revealed the potential of [$^{67/68}$Ga]NeoBOMB1 to target GRPR-positive breast cancer with excellent prospects for clinical translation.

Biodistribution, radiation dosimetry and first preliminary results of a novel ^{18}F-fluoroethyl triazole [Tyr^3] octreotate analogue for PET imaging in locally advanced and metastatic Neuroendocrine tumour patients

S. R. DUBASH[1], n. Keat[2], P. Mapelli[1], F. Twyman[1], L. Carroll[1], K. Kozlowski[1], A. Al-Nahhas[1], A. Saleem[2], m. Huiban[2], A. Frilling[3], T. Barwick[1], A. Rockall[1], R. Sharma[4], E. O. Aboagye[1]; [1]department of surgery and cancer , Imperial College, LONDON, UNITED KINGDOM, [2]Imanova centre for imaging studies, LONDON, UNITED KINGDOM, [3]Department of Surgery, Imperial College Healthcare NHS Trust, LONDON, UNITED KINGDOM, [4]Department of medicine, Imperial College, LONDON, UNITED KINGDOM.

Background Despite advances, detection and quantification of neuroendocrine tumour activity by imaging remains a challenge. We present results of the first in-man study of ^{18}F-fluoroethyl triazole [Tyr^3] octreotate (^{18}F-FET-βAG TOCA) in NET patients to evaluate biodistribution, dosimetry, and safety and the preliminary results of comparison between ^{18}F-FET-βAG TOCA versus ^{68}Ga-DOTATATE PET/CT. **Materials and methods** ^{18}F-FET-βAG TOCA was synthesized via the click reaction (*Iddon L et al, 2011*). Fourteen patients with histologically confirmed NET were evaluated. Cohort 1 (biodistribution and dosimetry), nine patients (6 female, 3 male) were enrolled into study. Eight patients with sporadic NET and 1 MEN1 syndrome. Patients underwent whole body PET-CT multi-bed scanning over 4 h and venous blood samples were taken at intervals to measure ^{18}F radioactivity concentration in blood and plasma. Regions of interest were drawn, to derive individual and mean organ residence times; effective dose (ED) was calculated with OLINDA 1.1. Comparison of ^{18}F-FET-βAG TOCA versus ^{68}Ga-DOTATATE was assessed in all patients. Images were reviewed by 2 independent radiologists and patient data was blinded. SUV_{max} in all patients was assessed by a lesion-by-lesion analysis. SUV measurements were performed side-by-side on corresponding lesions on fused image datasets and obtained by outlining whole tumour volumes. In regions of >5 lesions, 5 target lesions all ≥2cm were chosen. **Results** All patients tolerated ^{18}F-FET-βAG TOCA with no adverse events. Over 60% parent tracer was present in plasma at 60 minutes. High tracer uptake was observed in tumours (primary and metastases). Physiological uptake was seen in pituitary, salivary, thyroid and spleen, with low background uptake in liver, an organ where metastases commonly occur. The organs receiving highest absorbed dose were gallbladder, spleen, stomach, liver, kidneys and bladder. The calculated ED over all subjects was 0.029mSv/MBq (SD ± 0.004). There was high tumour to background ratio with both ^{18}F-FET-βAG-TOCA and ^{68}Ga-DOTATATE. The ^{18}F-FET-βAG-TOCA and ^{68}Ga-DOTATATE PET/CT were both positive in 12 (86%) and negative in 2 (14%) patients. In those negative on ^{68}Ga-DOTATATE and ^{18}F-FET-βAG-TOCA, both patients were confirmed as having high grade (G3) NET. **Conclusion** We present the first in-man study of ^{18}F-FET-βAG-TOCA. The favourable safety, imaging and dosimetric profile makes it a valuable candidate in staging and management of NETs. Head to head comparison of ^{18}F-FET-βAG-TOCA versus ^{68}Ga-DOTATATE show comparable accuracy in detection of lesions. Clinical studies in an expanded cohort are ongoing to clinically qualify ^{18}F-FET-βAG-TOCA.

OP342

CCK-2 Receptor Targeting by Tc-99m-Demogastrin in Patients with Medullary Thyroid Carcinoma

A. C. Fröberg[1], M. de Jong[1], T. Maina[2], R. Valkema[1], F. van Nederveen[3], M. W. Vernooij[1], B. A. Nock[2], J. W. A. Burger[4], W. W. de Herder[5]; [1]Erasmus MC, Department of Radiology & Nuclear Medicine, ROTTERDAM, NETHERLANDS, [2]Molecular Radiopharmacy, INRASTES, NCSR "Demokritos", Athens, GREECE, [3]Laboratorium voor pathologie, Dordrecht, NETHERLANDS, [4]Erasmus MC, Department of Surgery, ROTTERDAM, NETHERLANDS, [5]Erasmus MC, Department of Internal Medicine, ROTTERDAM, NETHERLANDS.

Aim: In medullary thyroid carcinoma (MTC), surgery is still the only curative therapy. No well tolerable, effective systemic therapy exists. Unfortunately, conventional imaging modalities (such as ultrasound or CT/MRI) often fail to localize metastatic lesions, both preoperatively and in suspected recurrent MTC. Therefore, there is a need for more sensitive imaging, to enable local treatment of local recurrences and/or oligometastatic disease. As > 90% of MTC show overexpression of cholecystokinin-2 receptors (CCK2R), these may represent excellent targets for peptide receptor radionuclide scintigraphy. After first promising results of ^{99m}Tc-N_4-Gly-(D)Glu-$(Glu)_5$-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH_2 (^{99m}Tc-Demogastrin 2), patients with a diagnostic challenge have been referred for CCK2R-scintigraphy. In the present study, we give an overview of the results of all (first) ^{99m}Tc-Demogastrin 2 scans. Patients and methods: 42 patients (28 f. 16-76 y, calcitonin range 0.27-823 (median 83) times the upper reference value) were included; 9 patients were scanned prior to planned neck surgery, the others after surgery; 11 had ≥1 known tumour lesion and 22 patients had elevated serum calcitonin levels but earlier conventional imaging had not detected tumour. Imaging was performed at 4, 8 and 24 h post injection of 800 MBq ^{99m}Tc-Demogastrin 2. Positive and equivocal findings were correlated with CT, MRI and/or ultrasound, already available or directed by scintigraphic results. If feasible, fine needle aspiration cytology of neck lesions was performed. Results: Side-effects were minor and as expected similar to those of Pentagastrin® tests. Scintigraphy was positive in 28 pts, false positive in 1, negative in 7 and "false negative" (tumour discovered < 6 months) in 3 pts. In 1 patient not yet confirmed. Two scans were true negative (serum calcitonin elevation at referral, no elevation nor tumour in follow up). In the subgroup of 21 pts in whom earlier conventional imaging was

negative, 10 scans were positive; in 9 of these, lesions were confirmed. Seven patients underwent local therapy. Two patients with distant metastases could not be treated. For 1 lesion follow up is needed. Of scans made prior to surgery, 2 showed clear uptake in the primary tumour, 3 in primary tumour and neck metastases and 3 in primary tumour, neck and distant metastases. One scan was false negative. Conclusion: Our results suggest CCK2R scintigraphy to be a very promising diagnostic tool in MTC, both preoperatively and in case of recurrent tumour. Because of the clear clinical need for better treatment of MTC, further investigation to optimize CCK2R scintigraphy is imperative.

A direct comparison of four ^{68}Ga-labelled RGD peptides to image $\alpha_v\beta_3$ integrin expression in a human tumour xenograft mouse model

D. Lobeek[1], G. M. Franssen[1], J. D. M. Molkenboer-Kuenen[1], A. Eek[1], M. Rijpkema[1], M. T. Ma[2], H. Wester[3], C. Decristoforo[4], S. Y. A. Terry[2], W. J. G. Oyen[1,5], O. C. Boerman[1]; [1]Department of Radiology and Nuclear Medicine, Radboud University Medical Center Nijmegen, Nijmegen, NETHERLANDS, [2]Department of Imaging Chemistry and Biology, King's College London, London, UNITED KINGDOM, [3]Lehrstuhl für Pharmazeutische Radiochemie, Technische Universität München, Garching, GERMANY, [4]Department of Nuclear Medicine, Medical University Innsbruck, Innsbruck, AUSTRIA, [5]Institute of Cancer Research, Royal Marsden NHS Trust, London, UNITED KINGDOM.

Introduction: Angiogenesis plays an important role in tumour proliferation and tumour cell migration. During angiogenesis, $\alpha_v\beta_3$ integrin is overexpressed on newly formed blood vessels. A series of radiolabelled cyclic RGD analogues with a high affinity for $\alpha_v\beta_3$ integrin has been developed. Dimeric and trimeric RGD analogues have shown enhanced accumulation in $\alpha_v\beta_3$ integrin expressing tumours as compared to their monomeric counterparts. In the current study four multimeric cyclic RGD-based radiotracers were selected: ^{68}Ga-DOTA-E-[c(RGDfK)]$_2$, ^{68}Ga-TRAP-(RGD)$_3$, ^{68}Ga-fusarinine-C-(RGD)$_3$, and ^{68}Ga-THP-(RGD)$_3$, and the *in vitro* and *in vivo* $\alpha_v\beta_3$ integrin targeting characteristics of each tracer were determined under standardized conditions. *Methods*: DOTA-E-[c(RGDfK)]$_2$ and TRAP-(RGD)$_3$, were labelled with fractionated eluted ^{68}Ga in HEPES buffer at pH 3.8. Fusarinine-C-(RGD)$_3$, and THP-(RGD)$_3$ were labelled in NaOAc buffer at pH 5. The IC_{50}-values of the RGD analogues were determined in a solid phase $\alpha_v\beta_3$ integrin binding assay. The *in vivo* $\alpha_v\beta_3$ targeting properties of the four tracers (i.v. injection of 0.5 nmol, 10 MBq per mouse) were determined in mice with s.c. $\alpha_v\beta_3$ integrin expressing SK-RC-52 xenografts using microPET/CT and biodistribution studies at 1 hour post injection. *Results:* ^{68}Ga-DOTA-E-[c(RGDfK)]$_2$, ^{68}Ga-TRAP-(RGD)$_3$, ^{68}Ga-fusarinine-C-(RGD)$_3$, and ^{68}Ga-THP-(RGD)$_3$ were produced with specific activities ranging from 40-48 MBq/nmol and a radiochemical yield of >95%, as determined by RP-HPLC and ITLC. IC_{50}-values of DOTA-E-[c(RGDfK)]$_2$, TRAP-(RGD)$_3$, fusarinine-C-(RGD)$_3$, and THP-(RGD)$_3$, were : 3.79 ± 0.65 nM, 10.0 ± 1.81 nM, 9.02 ± 1.61 nM, and 11.38 ± 1.88 nM, respectively. Tracer accumulation in the SK-RC-52 tumours was 5.1 ± 2.7 %ID/g, 4.3 ± 0.8 %ID/g, 8.5 ± 1.4 %ID/g, and 5.3 ± 0.6 %ID/g for ^{68}Ga-DOTA-E-[c(RGDfK)]$_2$, ^{68}Ga-TRAP-(RGD)$_3$, ^{68}Ga-fusarinine-C-(RGD)$_3$, and ^{68}Ga-THP-(RGD)$_3$, respectively. Mice with ^{68}Ga-fusarinine-C-(RGD)$_3$ and ^{68}Ga-THP-(RGD)$_3$ showed a higher concentration of the tracer in non-tumour tissues. ^{68}Ga-fusarinine-C-(RGD)$_3$ resulted in a high blood level, possibly due to interaction with plasma proteins. Consequently, tumour-to-blood ratios of ^{68}Ga-DOTA-E-[c(RGDfK)]$_2$ (17.81 ± 9.39), ^{68}Ga-TRAP-(RGD)$_3$ (31.46 ± 15.79), and ^{68}Ga-THP-(RGD)$_3$ (13.47 ± 1.54) were higher than those of ^{68}Ga-fusarinine-C-(RGD)$_3$ (4.24 ± 1.83). *Conclusion:* In this model, all tracers allowed *in vivo* visualization of the tumour and showed IC_{50}-values in the same nM range. ^{68}Ga-DOTA-E-[c(RGDfK)]$_2$ and ^{68}Ga-TRAP-(RGD)$_3$ showed optimal *in vivo* $\alpha_v\beta_3$ integrin targeting properties, due to higher tumour-to-blood ratios and lower tracer uptake in non-tumour tissue, compared to ^{68}Ga-fusarinine-C-(RGD)$_3$ and ^{68}Ga-THP-(RGD)$_3$.

OP344

Design and validation of a 68Ga-radiolabelled PET imaging agent for in vivo evaluation of angiomotin expression

A. Moyon[1], P. Garrigue[1], P. Brige[2], J. Stalin[1], S. Fernandez[2], M. Blot-Chabaud[1], F. Dignat-George[1], B. Guillet[1]; [1]UMR_S1076 VRCM, Marseille, FRANCE, [2]CERIMED, Marseille, FRANCE.

This study aimed to develop a ^{68}Ga-radiolabelled PET imaging agent for assessing tissular angiomotin (AMOT) expression, as a regulator of angiogenic processes in ischemic tissues. On that basis, we developed in this work an AMOT-targeting ^{68}Ga-radiolabled radiotracer, ^{68}Ga-NODAGA-AM007, and performed the first *in vivo* evaluation on a hindlimb ischemia model in mice. Hindlimb ischemia was induced by ligature and resection of the right femoral artery in mice and limb perfusion evaluated by LASER-Doppler imaging up to 30 days after surgery. AMOT expression was evaluated by histology on gastrocnemius muscle. NODAGA-conjugates of AM007 were synthetized and radiolabeled with ^{68}Ga (25°C for 15 minutes). Gallium was obtained in $^{68}Ga^{3+}$ form using a commercial TiO_2-based ^{68}Ge/^{68}Ga generator (Obninsk). ^{68}Ga-NODAGA-AM007 (8-14MBq) PET imaging was performed on SHAM and ischemic mice 1, 2, 5, 10, 15 and 21 days after surgery using μPET/CT (nanoPET/CT®, Mediso). We demonstrated by immunohistochemistry a significant overexpression of AMOT from Day 1 up to Day 21 after hindlimb ischemia in mice (ipsi=444±102μm^2; contro=18.7±4.7 μm^2, P<0.0001, on day 5) whose intensity was significantly correlated with post-ischemic reperfusion. Mean ^{68}Ga-NODAGA-AM007 radiochemical purity was 93.1%±2.0 (n=10) and stability in serum evaluated up to 2 hours at 90 ±1.5%. In mice, ^{68}Ga-NODAGA-AM007 showed a rapid plasmatic clearance (6.0±2.0min) and a pharmacokinetic profile compatible with PET imaging. In hindlimb ischemia model, ipsi- to contralateral hindlimb (i/c) ratio of ^{68}Ga-NODAGA-AM007 uptake 40min after injection showed a specific radiotracer uptake in ischemic hindlimb from day 1 (i/c=1.85±0.6; n=11; P<0.05) up to day 30 (i/c=1.13±0.1; n=7), peaking on day 5 (i/c=2.67±1.1; n=7; P<0.001) confirming our previous observations of AMOT expression time profile. Moreover, we also observed a significant positive i/c ratio assessed by μPET on Day 15 and the ischemic hindlimb reperfusion assessed by LASER-Doppler on day 28 (R^2=0.77; n=8, P=0.009). Based on the increased AMOT expression after hindlimb ischemia in mice, we developed an AMOT-targeting imaging agent, ^{68}Ga-NODAGA-AM007, and showed that ^{68}Ga-NODAGA-AM007 presented a specific uptake in ischemic hindlimb up to 21 days using μPET imaging. Correlation of post-ischemic ^{68}Ga-NODAGA-AM007 uptake with delayed hindlimb perfusion recovery allows us to postulate that ^{68}Ga-NODAGA-AM007 could represent a promising and innovative radiotracer for tissue angiogenesis assessment.

OP345

A comparison of ^{68}Ga and ^{89}Zr labelled minigastrin bioconjugates in animal imaging

D. Summer[1], G. Franssen[2], P. Laverman[2], H. Haas[3], E. von Guggenberg[1], C. Decristoforo[1]; [1]Department of Nuclear Medicine, Medical University, Innsbruck, AUSTRIA, [2]Department of Nuclear Medicine, Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]Division of Molecular Biology/Biocenter, Medical University, Innsbruck, AUSTRIA.

Background: Over the last 5 years ^{89}Zr has attracted tremendous interest as radionuclide for PET applications. Due to a relatively long half-life

(3.2d) compared to the well-established ^{68}Ga (67.6 min.), ^{89}Zr seems to be the right choice for tracers with slow pharmacokinetics or when late time point imaging is needed. Recently our working group showed that Fusarinine C - a hexadentate bifunctional chelator - is suitable for labelling tetravalent ^{89}Zr without being fully coordinated. Introducing an additional charge and its influence on imaging abilities as well as the direct comparison to ^{68}Ga-labelled counterparts was the matter of this study. **Methods:** Mono- and multimeric compounds were synthesized by utilizing Fusarinine C (FSC) from fungal culture followed by coupling of minigastrin (MG11) peptides via maleimide chemistry. Radiotracers were labelled with ^{68}Ga as well as with ^{89}Zr following standard radiolabeling protocol and labelling efficiency was monitored by radio-HPLC for ^{68}Ga and radio-ITLC for ^{89}Zr respectively. Small animal imaging (μPET/CT) was carried out in tumour xenograft bearing balb/c nude mice. Static imaging was made after one and two hours for ^{68}Ga-labelled tracers and after one, four and 24 hours for ^{89}Zr-labelled counterparts. Furthermore dynamic imaging was performed with a few selected derivatives over a period of one hour. **Results:** First of all ^{68}Ga as well as ^{89}Zr-labelled radiotracers showed no significant release of radionuclide when imaging was performed, this indicating excellent complex stability. ^{68}Ga-labelled multimeric conjugates showed higher tumour uptake but kidney retention also increased severely compared to the monomeric tracer. This effect could be confirmed by comparing the dynamic imaging of ^{68}Ga-labelled monomer with the trimeric conjugate. Comparing ^{89}Zr-labelled compounds the monomer showed fast tumour wash out after four and 24 hours respectively whereas multimeric radiotracers showed better uptake. In comparison to their ^{68}Ga-labelled counterparts overall tumour uptake was lower at early time points i.e. one hour but increased retention in tumour tissue was observed at late time points. Furthermore kidney retention was more intense; this may be related to the additional charge of not fully coordinated ^{89}Zr.**Conclusion:** In summary we could show that ^{68}Ga-labelled mono and multimeric minigastrin bioconjugates showed a similar behaviour compared to their ^{89}Zr-labelled counterparts including slight variations in tumour uptake at early stages and overall kidney retention.

OP346

Preclinical Characterization of Ga-68-Avebehexin, a Specific Probe for the "Cancer Integrin" αvβ6

J. Notni[1], K. Steiger[2], C. Mendler[3], D. Reich[1], O. V. Maltsev[4], T. G. Kapp[4], F. Hoffmann[1], W. Weichert[2], H. Kessler[4], M. Schwaiger[5], H. Wester[1]; [1]Pharmaceutical Radiochemistry, TU Munich, Garching, GERMANY, [2]Institute for Pathology, TU Munich, Munich, GERMANY, [3]Department of Nuclear Medicine, TU Munich, Garching, GERMANY, [4]Center for Integrated Protein Science, TU Munich, Garching, GERMANY, [5]Department of Nuclear Medicine, TU Munich, Munich, GERMANY.

αvβ6-integrin expression is restricted to epithelial cells and is upregulated by carcinomas (epithelial cancers), particularly in connection with tumor invasion and metastasis. For many cancers, for example pancreatic, ovarian and gastric carcinoma, it has thus been recognized as a prognostic marker, associated with poor survival. Hence, αvβ6-integrin imaging could primarily be useful for prognosis and tumor staging, but also for imaging of idiopathic pulmonary fibrosis (IPF) where αvβ6-integrin has been shown to play a role as well. *Methods:* Avebehexin was obtained by conjugation of TRAP (triazacyclononane-triphosphinate) to the cyclic nonapeptide c(FRGDLAFp(NMe)K(pentynoic acid)) on the pentynoic acid-functionalized lysine side chain by means of click chemistry (CuAAC). Fully automated Ga-68-labeling (HEPES-buffered eluate of an IThemba generator, pH 2, followed by SPE cartridge purification) delivered Ga-68-Avebehexin, which was used for biodistribution studies and dynamic as well as static αvβ6-integrin PET imaging in H2009 (human lung adenocarcinoma) and FaDu (human squamous cell carcinoma) tumor xenografted mice. αvβ6-integrin affinities were determined by ELISA on immobilized integrins. Expression density of of αv- und β6-integrin chains were analyzed by immunohistochemistry (IHC) in paraffin slices of tumors and other tissues (αv: LS-Bio 6179; β6: clone 442.5C4, Calbiochem 407317). *Results:* Ga-68-Avebehexin possesses high αvβ6-integrin affinity (260±17 pM) and pronounced hydrophilicity (logD: -3.7). Biodistribution studies in H2009 mice showed moderate tumor uptake (0.65±0.04 %ID/g) but also significant uptakes in lung (0.41±0.01 %ID/g) and stomach (0.52±0.04 %ID/g), all of which were blockable by co-injection of 100 μg nat-Ga-Avebehexin. Virtually no uptake was observed in the pancreas (0.07 %ID/g), giving rise to a tumor/pancreas ratio of ~10. β6-integrin levels determined by IHC were found to correlate with these data, in particular, confirming only moderate β6 expression in tumor tissue. Dynamic 68Ga-PET showed fast renal clearance and low background, enabling clear delineation even of tumors with moderate αvβ6-integrin expression densities. *Conclusion:* Ga-68-Avebehexin enables high-contrast PET imaging of αvβ6-integrin expression, suggesting applicability for imaging of various carcinomas as well as fibrosis. Particularly the good tumor/pancreas ratio rises high expectations for diagnosis and staging of pancreatic carcinoma.

Detection of prostate cancer with the [^{68}Ga]-labeled bombesin antagonist RM2 in patients undergoing radical prostatectomy - a Phase I/II study

M. Beheshti[1], P. Taimen[2], J. Kemppainen[3], A. Mueller[4], G. Broinger[5], W. Loidl[6], E. Kaehkoenen[7], M. Kaekelae[3], M. Berndt[4], A. W. Stephens[4], H. Minn[8], W. Langsteger[1]; [1]PET-CT Center Linz, Department of Nuclear Medicine & Endocrinology, St. Vincent's Hospital, Linz, AUSTRIA, [2]Department of Pathology, Turku University Hospital, Turku, FINLAND, [3]Turku PET Centre, University of Turku and Turku University Hospital, Turku, FINLAND, [4]Piramal Imaging GmbH, Berlin, GERMANY, [5]Department of Pathology, Krankenhaus der barmherzigen Schwestern, Linz, AUSTRIA, [6]Department of Urology, Krankenhaus der barmherzigen Schwestern, Linz, AUSTRIA, [7]Department of Surgery, Division of Urology, Turku University Hospital, Turku, FINLAND, [8]Department of Oncology and Radiotherapy, Turku University Hospital, Turku, FINLAND.

Background: Gastrin-releasing-peptide receptor (GRPr) is overexpressed in prostate carcinoma (PCa) and offer new means to detect prostate cancer foci. The bombesin derivative RM2 (DOTA-4-amino-1-carboxy-methyl-piperidine-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH2) is a GRPr antagonist with strong binding affinity (Kd 3 nM). Based on promising results from a first-in-man study on PCa detection in patients with local disease, a Phase I/II study was initiated. **Methods:** A Phase I/II study was performed with a pre-specified interim analysis after 30 biopsy-positive PCa subjects had been enrolled, stratified into high, intermediate and low pretreatment risk of prostate Ca recurrence as defined by NCCN criteria. All enrolled subjects had documented PCa by transrectal needle biopsy and were scheduled to undergo prostatectomy with pelvic lymph node (LN) dissection in intermediate and high risk patients. The patients received an intravenous dose of 140 MBq of [^{68}Ga]RM2 followed by imaging for at least 20 min at 60 min p.i. Twenty-five (25/30) subjects had concomitant [^{18}F]-fluoromethycholine

([^{18}F]FCH) PET/CT imaging. All intra-prostatic and pelvic nodal PET/CT findings were correlated with histopathologic results. **Results:** High uptake of [^{68}Ga]RM2 is seen in pancreas and the urinary system with very low background in the rest of the abdomen or thorax. Despite of high bladder activity, focal intraprostatic uptakes were well detectable. Lesion-based analysis of [^{68}Ga]RM2 PET/CT revealed 35 true-positive tumor lesions, 6 false-positive lesions, and 8 false-negative lesions resulting in a sensitivity of 81%. Five (5/6) false-positive intraprostatic lesions were determined to be BPH or inflammation based on whole-mount prostatectomy sections. [^{68}Ga]RM2 PET/CT successfully detected the index lesions in 20 of 24 subjects (83%). Lesion-based analysis of [^{18}F]FCH PET/CT revealed 27 true-positive tumor lesions, 11 false-positive lesions, and 13 false-negative lesions resulting in a sensitivity of 68%. Eight (8/11) false-positive intraprostatic lesions were determined to be BPH or inflammation based on whole-mount prostatectomy sections. [^{18}F]FCH PET/CT successfully detected 17 index lesions in 21 subjects (81%). There was no difference in sensitivity or index lesion detection between the NCCN risk groups with either agent. [^{68}Ga]RM2 PET/CT correctly detected 2 histopathologically verified LN metastases in 2 high risk patients, while [^{18}F]FCH PET/CT only identified the LN lesion in 1 patient. **Conclusion:** [^{68}Ga]RM2 is a promising new tracer with a high detection rate for intraprostatic and extracapsular PCa. Although the index lesion detection rate is similar, [^{68}Ga]RM2 performs notably better than [^{18}F]FCH in the detection of intraprostatic lesions largely because of improved specificity for cancer vs. BPH.

OP349

^{11}C-choline (CHOL) PET/CT outcome prevented potential toxic local salvage therapy in 47% of men with radio-recurrent prostate cancer

M. S. Vallinga[1], J. Pruim[1,2], M. Rybalov[3], A. J. Breeuwsma[4], I. J. de Jong[1]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Univeristy of Stellenbosch, Stellenbosch, SOUTH AFRICA, [3]Pavlov Saint-Petersburg State Medical University, Saint-Petersburg, RUSSIAN FEDERATION, [4]Elisabeth-TweeSteden Ziekenhuis, Tilburg, NETHERLANDS.

Aim: So far studies on ^{11}C-choline (CHOL) PET/CT for restaging patients with recurrent prostate cancer, involved a heterogeneous population or patients with concomitant androgen deprivation use. There is no data on the clinical impact of restaging with CHOL PET/CT on selection for and outcome of local salvage therapy in a homogeneous post-radiotherapy population. We studied the clinical impact of screening with CHOL PET/CT to exclude patients with extra prostatic activity and thus avoid a potential toxic salvage cryoablation. Secondary we aimed to reveal the outcome of salvage therapy after screening with CHOL PET/CT, without distorted results due to simultaneous androgen deprivation use. Materials and Methods: A total of 116 patients with biochemical recurrence after radiotherapy (Phoenix definition: PSA nadir + 2 ng/mL) were retrospectively studied. All patients were restaged with a CHOL PET/CT and prostate biopsies. Patients received 200 MBq ^{11}C-choline and were scanned with an mCT Siemens Biograph system, 5 minutes post-injection. Patients with equivocal lesions on CHOL PET/CT underwent additional imaging, biopsy or lymph node dissection for histological confirmation. Clinical impact of CHOL PET/CT outcome on therapy was rated as major (no salvage cryoablation because of metastases or lack of local recurrence on PET/CT), minor (local salvage treatment, but different technique or after additional diagnostics) or none (salvage cryoablation). The outcome of salvage cryoablation was measured by biochemical failure (phoenix definition) and clinical progression to metastasis or start of hormonal therapy. Results: Of 116 patients who were restaged with CHOL PET/CT, 59 (51%) underwent cryoablation, 3 underwent other local salvage treatment and 5 patients could be actively surveillanced after a negative scan. In 42 % (49/116) treatment changed from cryoablation to delayed hormonal therapy because extra-prostatic tumor activity was seen. Impact of CHOL PET/CT outcome on therapy was rated as major, minor and none in respectively 46%, 23% and 31%. After salvage cryoablation, the biochemical recurrence free rate was 66% with a mean follow-up post-scan of 38 months (range 6-71). 12.5 % did not show a PSA response after cryoablation. Clinical progression to metastasis and start of hormonal therapy, was seen in respectively 15% and 17% of patients post-cryoablation. Conclusion. ^{11}C-choline PET/CT showed a significant clinical impact on therapy choice for salvage cryoablation. A potential toxic salvage cryoablation could be abandoned in almost half of men. Outcomes of salvage cryoablation were encouraging with few men with clinical progression and a long biochemical recurrence free survival.

OP350

Observer Agreement of Treatment Responses on Planar Bone Scintigraphy in Prostate Cancer Patients: Importance of the Lesion Assessment Method

R. F. Fonager[1], H. D. Zacho[1,2], S. Albertsen[3], J. Fledelius[4], J. A. Ejlersen[4], M. H. Christensen[5], R. Aleksyniene[1], J. A. Biurrun Manresa[6], L. J. Petersen[1,2]; [1]Dept. of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, [2]Dept. of Clinical Medicine, Aalborg University, Aalborg, DENMARK, [3]Dept. of Urology, Aalborg University Hospital, Aalborg, DENMARK, [4]Dept. of Nuclear Medicine, Herning Hospital, Herning, DENMARK, [5]Dept. of Clinical Physiology, Viborg Regional Hospital, Viborg, DENMARK, [6]Dept. of Health Science and Technology, Aalborg University, Aalborg, DENMARK.

Aim: The aim of this study was to assess observer agreement in the evaluation of treatment responses of bone metastases using three different scoring methods in prostate cancer patients. **Materials and methods:** A total of sixty-three paired bone scans (BSs) were selected from prostate cancer patients with two or more BSs within twelve month at Aalborg University Hospital from January 2009 to November 2014. BS was performed before initiation of a therapy and minimum twelve weeks within treatment. Experienced nuclear medicine physicians, blinded to clinical and laboratory data, evaluated the whole-body BS by three different methods, A) standard clinical assessment (improved, stable, or worse), B) MD Anderson criteria (complete response, partial response, stable disease, or progression), and C) Prostate Cancer Working Group 2 criteria (non-progression versus progression, defined as two or more new lesions). Individual BS were evaluated for presence (M1) or absence (M0) of bone metastases, superscan (absent/present), and number of lesions per region. Observer agreement was assessed by Cohen's kappa and reported by Landis & Koch strength of agreement terminology. **Results:** There was substantial agreement on bone response when using Prostate Cancer Working Group 2 criteria (Cohen's kappa at 0.84, 95% CI 0.69-0.99). Cohen's kappa for standard clinical assessment and MD Anderson criteria were 0.52 (95% CI 0.36-0.69) and 0.56 (95% CI 0.40-0.71), respectively, corresponding to moderate agreement. However, the latter methods have more response categories and this is known to affect agreement negatively. Excellent agreement was demonstrated with regards to M0/M1 (Cohen's kappa 0.94, 95% CI 0.82-1.00), and substantial agreement was found in assessment of superscan (Cohen's kappa 0.78, 95% CI 0.49-1.00). Bland-Altman analysis showed a large variation in the assessment of number of lesions per region, e.g. in columna, which showed the largest variation, limits of agreement (Bland Altman analysis) ranged from -14 to 15, with median number of lesions of 7 (range 0 to >20). The average difference in number of lesions between readers though was low, maximum 1.0 in all regions, meaning that no reader assessed the number of lesions systematically higher or lower than another. **Conclusion:** Variations in BS response assessment strongly depended on the method of analysis. Separate counting of lesions on repeated BSs without access to prior scans cannot be recommended. Furthermore, variation in classification of progression versus non-progression might have significant impact on clinical decision-making, emphasizing the need for a uniform approach in bone response monitoring.

OP351

PET imaging of prostate cancer using the GRPr-targeting ligand Sarabesin 3 prior to radical prostatectomy

I. L. Bakker[1], A. C. Fröberg[1], M. B. Busstra[1], J. F. Verzijlbergen[1], I. Schoots[1], G. J. L. H. van Leenders[1], E. de Blois[1], J. Veenland[1], W. M. van Weerden[1], T. Maina[2], B. A. Nock[2], M. de Jong[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]NCSR "Demokritos", Athens, GREECE.

Aim: Even though [^{68}Ga]PSMA-PET shows impressive results in the detection of prostate carcinoma (PCa) metastases, still a selection of lesions are missed. Gastrin releasing peptide receptor (GRPr) targeting tracers may improve the detection of PC. We selected the gallium-68-labelled GRPr-antagonist Sarabesin 3 ([^{68}Ga]SB3) for further clinical investigation because of its excellent results in (pre)clinical pilot studies. The aim of the study was to assess safety and to investigate the diagnostic potential of [^{68}Ga]SB3 PET-CT imaging in prostate carcinoma. To enable correlation with gold standard histopathology, this pilot study was performed in therapy-naive PCa patients prior to prostatectomy. **Materials & Methods:** Nine therapy-naive patients with biopsy-proven PCa scheduled for curative prostatectomy were included in the study. [^{68}Ga]SB3 (178±91 MBq, 40±5μg) was administered, followed by an extensive scan protocol. To enable optimal imaging of the prostatic region, the bladder was flushed continuously. Scans were separately interpreted by two experienced nuclear physicians who reached consensus. After prostatectomy, the pathologist determined tumour localisations and Gleason Scores (GS). In vitro autoradiography was performed to investigate GRPr expression. Available multiparametric MRI scans were matched to PET-CT. Results were evaluated per patient and per lesion. **Results:** [^{68}Ga]SB3 administration did not induce side-effects, though the urinary catheter caused some discomfort. Up to now, 7 patients have been evaluated. In all of them tumour lesion(s) were visible on [^{68}Ga]SB3 PET-CT-scans. All positive lesions on scintigraphy that were analysed showed GRPr overexpression. Eleven of 12 tumour lesions (5xGS6, 5xGS7, 2xGS8) were identified on scintigraphy. In one patient a lesion of <2 mm was missed (sensitivity 92%), unfortunately in-vitro autoradiography was not possible of this lesion. Two lesions judged positive on scintigraphy showed no histologic confirmation and are considered false positive (specificity 85%). Correlation with MR showed concordance of correct PCa detection in 3 patients; concordance of underestimation in 1 patient; in 1 patient MR showed an underestimation, tumour was correctly assessed by PET-CT; a false positive lesion on PET-CT was correctly not detected by MR in 1 patient; in the last patient number of lesions was overestimated on PET-CT, MR was false negative. The GRPr-expressing pancreas showed high physiological uptake. We observed fast renal excretion and very low radioactivity in liver. Diffuse, low tracer uptake was visible in the gastrointestinal tract, lower oesophageal and rectal sphincters. **Conclusion:** This data shows that [^{68}Ga]SB3 PET-CT is a promising diagnostic tool in the imaging of prostate carcinoma and might be helpful in PCa.

OP352

Fluciclovine (^{18}F) for the Characterisation and Detection of Primary and Recurrent Prostate Cancer: Results of a Single-Centre Experience

F. Willoch[1], W. Picker[2], J. Kieboom[2], A. Chau[3], P. Ward[3]; [1]University of Oslo, Oslo, NORWAY, [2]Aleris Helse AS, Oslo, NORWAY, [3]Blue Earth Diagnostics Ltd., Oxford, UNITED KINGDOM.

Aims: To evaluate the ability of the amino acid analogue PET radiotracer, fluciclovine (^{18}F) to detect recurrent prostate cancer according to PSA values in a biochemical relapse (BR) cohort, and to characterise primary prostate cancer. **Materials and Methods:** Data were obtained from a single-centre in Norway from patients with either BR of prostate cancer or biopsy-confirmed high-risk primary prostate cancer who underwent fluciclovine (^{18}F) PET/CT scanning. These data are part of a retrospective observational study (BED001) designed to analyse results across multiple research sites in Norway, Italy and USA. Scans were acquired on a GE 690 PET/CT in 3D mode using a 3.5 MBq/kg fluciclovine (^{18}F) dose. A 15 minute dynamic scan was acquired centred over the prostate beginning immediately after injection, followed by a whole body acquisition using 2.5 min/bed. Detection rate (DR) in the BR cohort was analysed according to baseline PSA; the diagnostic performance in primary disease was evaluated versus histology. **Results:** 146 BR patients (mean [SD] age: 65.1 [7.2] years; Gleason score: 8.0 [1.1]; baseline PSA: 4.9 [7.9] ng/mL; 26.7% D'Amico high risk) and 51 primary patients (mean [SD] age: 66.1 [9.1] years; Gleason score: 8.0 [1.0]; baseline PSA: 16.9 [19.3] ng/mL; 62.7% D'Amico high risk) were included. In the BR cohort, the DR according to baseline PSA (ng/mL) at the subject level was: ≤0.2, 3/9 (33.3%); >0.2-0.5, 16/22 (72.7%); >0.5-1.0, 9/11 (81.8%); >1.0-2.0, 12/14 (85.7%); >2.0-5.0, 19/22 (86.4%); >5.0, 30/32 (93.8%). The DR in the prostate/bed was: ≤0.2, 0/9 (0%); >0.2-0.5, 5/23 (21.7%); >0.5-1.0, 2/8 (25.0%); >1.0-2.0, 6/16 (37.5%); >2.0-5.0, 13/22 (59.1%); >5.0, 19/29 (65.5%). The DR in the extra-prostatic region was: ≤0.2, 3/10 (30.0%); >0.2-0.5, 12/21 (57.1%); >0.5-1.0, 9/11 (81.8%); >1.0-2.0, 9/13 (69.2%); >2.0-5.0, 10/20 (50.0%); >5.0, 21/29 (72.4%). In patients with primary prostate cancer, fluciclovine (^{18}F) was true positive in all patients (N=32) at prostate level (100% sensitivity and positive predictive value (PPV)) and had 50% sensitivity, 73% specificity, 67% PPV and 58% NPV for disease detection in the extra-prostatic region (N=31). **Conclusions:** Fluciclovine (^{18}F) is effective for visualising locations of prostate cancer relapse across a wide range of PSA values in BR; DR was proportional to PSA. Fluciclovine (^{18}F) may also be used to assist pre-treatment staging of patients with high-risk primary prostate cancer, in particular for extra-prostatic disease detection.

OP353

18F-Choline PET/CT and multiparametric MRI for the detection of local recurrence of prostate cancer initially treated by radiotherapy: comparison with systematic transperineal mapping biopsy

S. Kanoun[1,2,3], P. Walker[1,2], J. Vrigneaud[3], E. Depardon[3], V. Barbier[4], O. Humbert[1,3], M. Moulin[4], G. Créhange[3], L. Cormier[4], R. Loffroy[4], F. Brunotte[1,3,2], A. Cochet[1,3,2]; [1]Le2i CNRS UMR 6306, Dijon, FRANCE, [2]CHU Dijon, MRI unit, Dijon, FRANCE, [3]Centre Georges Francois Leclerc, Dijon, FRANCE, [4]CHU Dijon, Dijon, FRANCE.

Purpose: To compare the diagnostic performance of ^{18}F-Fluorocholine PET/CT (FCH PET/CT), multiparametric prostate MRI (mpMRI) and combination of both techniques for the detection of local recurrence of prostate cancer initially treated by radiotherapy. **Methods:** This was a retrospective single-institution study of 32 patients with suspicion of prostate cancer recurrence, who underwent both FCH PET/CT and 3T mpMRI (T2-weighted, diffusion-weighted and dynamic contrast-enhanced sequences) for detection of recurrence within 3 months. All included patients had to be cleared for a metastatic recurrence. The reference standard was systematic transperineal prostate biopsies for the final assessment of local recurrence. Both imaging modalities were analyzed blindly of clinical data by two experienced readers. FCH PET/CT was considered positive for a local recurrence in case of a focal uptake in the prostate, and mpMRI in case of concordant abnormalities in at least two MRI sequences. The analysis was made per-patient and per-segment using a 4-segments model. **Results:** The median PSA at the time of imaging was 2.92ng/mL. The mean PSA doubling time was 14 months. Of the 32 patients, 31 had a positive transperineal mapping biopsy for a local relapse. On a patient-based analysis, detection rate was 71% (22/31) for mpMRI and 74% (23/31) for FCH PET/CT. On a segment-based analysis, the sensitivity and specificity were 32% and 87% for mpMRI, 34% and 87% for FCH PET/CT, and 43% and 83% for the combined

analysis of both techniques. Accuracy was 64, 65 and 66% respectively. Seven segments on 128 were discordant between FCH PET/CT and mpMRI procedure (Kappa=0.84). The inter-observer agreement was kappa=0.92 for FCH PET/CT and kappa=0.74 for mpMRI. **Conclusion:** Both mpMRI and FCH PET/CT shows limited sensitivity but good specificity for the detection of local cancer recurrence after radiotherapy, when compared with transperineal mapping biopsy. Prostate biopsy still appears mandatory to diagnose a local relapse and select patients who could benefit for a local salvage therapy.

OP354

Diagnostic performance of ^{18}F-FACBC PET/CT, PET/MRI and MRI in primary prostate cancer

J. Kemppainen[1], I. Jambor[2,3], A. Kuisma[4], M. Kim[1], S. Ramadan[4], O. Eskola[5], H. J. Aronen[2], E. Kähkönen[6], P. Taimen[7], H. Minn[4,3]; [1]Turku University Hospital, Turku PET Centre, TURKU, FINLAND, [2]Department of Radiology, Turku University Hospital, TURKU, FINLAND, [3]Turku University Hospital, Turku PET Centre, Turku, FINLAND, [4]Department of Oncology and Radiotherapy, Turku University Hospital, TURKU, FINLAND, [5]Turku PET Centre, Radiopharmaceutical Chemistry Laboratory, University of Turku, TURKU, FINLAND, [6]Department of Surgery, Division of Urology, Turku University Hospital, TURKU, FINLAND, [7]Department of Pathology, Turku University Hospital, TURKU, FINLAND.

Purpose: Uptake of [1]1-amino-3-fluorocyclobu- tane-1-carboxylic acid (^{18}F-FACBC) tracer depicts amino acid transportation, which has shown to be elevated in PCa cells. The diagnostic accuracy of ^{18}F-FACBC PET/CT, PET/MRI and MRI for the detection of primary prostate cancer (PCa) was prospectively evaluated in this study. Materials and Methods: Twenty-six patients with histologically confirmed PCa who were scheduled for radical prostatectomy underwent dynamic and static ^{18}F-FACBC PET/CT examination followed by PET/MRI. Multiparametric MRI scan consisted of T2-weighted, diffusion weighted (DWI), second order rotating frame (RAFF) imaging, T2 mapping and contrast enhanced imaging. Presence of PCa was assessed in 12 prostatic regions with histopathological reference. Sensitivity, specificity, accuracy and area under the curve (AUC) values were determined for each imaging modality. Results: Altogether 41 tumor foci larger than 0.5 cm^3 were identified. In the region-based analysis, 164 (53%, 164/312) regions contained PCa. The sensitivity, specificity and accuracy were 88%, 56% and 72% respectively for PET/CT, 79%, 93% and 86% for PET/MRI and 78%, 99%, and 88% for multiparametric MRI. AUCs of both PET/MRI and MRI were significantly ($p<0.01$) higher (0.85 and 0.88, respectively) than that of PET/CT (0.72) while no significant differences were present between PET/MRI and MRI. Conclusion: ^{18}F-FACBC PET/CT had the highest sensitivity but lacked specificity in PCa detection. Combined PET/MRI has significantly higher specificity than PET/CT. This highlights the importance of adding MRI rather than CT with PET for PCa imaging. However, ^{18}F-FACBC together with PET/CT or PET/MRI provided limited added value to multiparametric MRI imaging of prostate cancer.

OP355

Impact of 11C-CHOLINE PET-CT in the management of prostate cancer patients candidate to Radiation Therapy

E. Lopci[1], G. D'Agostino[1], C. Iftode[1], C. Franzese[1], M. Rodari[1], E. Villa[2], M. Scorsetti[1], A. Chiti[3]; [1]Humanitas Clinical and Research Hospital, Milano, ITALY, [2]Humanitas Gavazzeni, Bergamo, ITALY, [3]Humanitas University, Milano, ITALY.

Purpose: The aim of the present study was to verify the impact of Choline PET imaging in treatment planning of prostate cancer (PCa) patients eligible for radiotherapy (RT). **Materials and Methods**: From September 2011 to April 2016, 135 consecutive patients (median age 69 years, range 53-89) referred to our Institution and investigated with 11C-choline PET prior to radiotherapy, were enrolled. The planned therapy was with radical intent (n=29), adjuvant to surgery (n=13), salvage therapy (n=50), re-irradiation (n=18) or palliative treatment of distant metastases (n=25). Clinical-tumor volumes (CTV), planning-tumor volumes (PTV) and organs at risk (OAR) were outlined on CT slices with Eclipse Varian Medical System software, whereas gross tumor volume (GTV) was defined on 11C-choline PET using a PETVCAR software on Advantage GE workstation. Patients were monitored for a median period of 41.1 months. **Results**: The indication to RT was modified in a total of 65 cases (48.2%) on the basis of PET results. The median PSA before and after treatment in this subgroup of patients was 35.2ng/ml (range 0.19-387) and 3.46ng/ml (range 0.01-337), respectively. Among the 29 patients evaluated before radical RT, 11 received an additional boost on positive nodes, while 1 patient presented with metastatic disease and was treated according to the new stage. Adjuvant or salvage therapy was planned in 63 patients: 23 patients (36.5%) received a boost on positive nodes, 3 oligometastatic patients received RT on visible lesions, while the remaining patients presented multiple metastases. Out of 18 patients candidate to re-irradiation: 3 were upstaged for distant metastases and excluded, 5 were excluded because of a negative scan. Out of 25 patients scheduled for target RT on metastatic lesions, 12 had a change in their treatment plan (48%). Overall, 11C-choline PET influenced RT planning in 41.4% of patients candidate to radical RT, 52.4% of patients undergoing adjuvant or salvage RT, 46.5% of patients with relapsed or metastatic disease. **Conclusion**: Choline PET confirmed to have a significant impact on RT planning of patients affected from prostate cancer, determining a change in the treatment management in 48.2% of cases.

Towards fast 123I/99mTc-sestaMIBI parathyroid imaging with CZT camera : a preliminary study

Y. R. PETEGNIEF, M. VERSTRAETE, R. SABBAH, C. DROUET, H. BOULAHDOUR; CHRU Jean Minjoz, BESANCON, FRANCE.

Introduction : Cadmium-Zinc-Telluride (CZT) detectors have recently emerged as an alternative to conventional NaI(Tl)-based Anger cameras for cardiac and breast imaging. It is likely to improve sensitivity and resolution and limits crosstalk between isotopes for dual isotope 99mTc MIBI/123I parathyroid SPECT. This study focuses on the evaluation of a new method for simultaneous reconstruction of subtracted 99mTc and 123I clinical data using a dedicated cardiac CZT system in comparison with conventional Anger cameras imaging . **Material :** Stationary projections (600 s) obtained with pin-hole collimators and the 123I energy window (159 keV, 18 keV width) were adaptively weighted and then subtracted from the 99mTc projections (141 keV,15 keV width) in order to simulate a 'scatter-like' additional window for MIBI correction during MAP OSEM OSL reconstructions. Image reconstructions were repeated with the 99mTc and 123I raw projections and the subtracted ones. We adaptively varied the coefficient of correction of 99mTc projections C till achieving optimal visualization of parathyroid adenoma. Resulting images were reoriented and simultaneously reviewed with 123I thyroid images to localise the lesions and were compared to SPECT Anger iterative reconstructions (A-SPECT) for localisation of primary parathyroid adenomas. **Results :** The 123I / 99mTc ratio of counts in anterior projection at the thyroid location varied from 0,4 to 1 in CZT studies. Ratios in the reconstructed slices (range 0.15-1.9) were not correlated with A-SPECT ratios. With weighted 123I projections (C varying from 0.25 to

1 - step 0.25) , higher C demonstrated artifactual patterns of activity around the thyroid location whereas lower coefficients gave an homogeneous activity level within the parenchyma of the thyroid affecting detection of lower activity foci. For C=0.5, the parathyroid to thyroid ratio (PTTR) of counts showed huge variations from one patient to the other (range 0.4-36) in comparison to the raw Tc99m slices (PTTR 0.13-1.3) and A-SPECT (0.37-1.45) . **Conclusion :** CZT imaging demonstrated very promising preliminary results for high contrast fast parathyroid imaging. OSEM MAP OSL improved contrast of adenomas with preprocessed 99mTc projections. Further work is required for automatic dual-isotope processing and comprehensive evaluation of the technique with regards to the established Anger camera protocols.

OP357

SPECT image quality parameters for lesion detection task

K. Kacperski, D. Świtlik; Centre of Oncology - Institute, Warsaw, POLAND.

Clinical task-based image quality assessment is regarded the most relevant in the context of medical imaging. However, such approach, involving evaluation of series of simulated or experimentally generated images by human observers is usually time consuming and often impractical, when many combinations of scanning, reconstruction and post-processing parameters are to be tested for optimal performance. In this paper we search for an easily computable parameter of the type of contrast-to-noise ratio, which could predict the results of a human observer experiment of hot lesion detection on reconstructed SPECT images. Materials & Methods: We used cylindrical numerical phantoms of the diameter 42 cm filled uniformly with water solution of 200 MBq 99mTc. Spherical hot lesions of diameters from 4.2 mm to 50 mm, and contrasts from 1:2 up to 1:15 have been placed randomly within the phantom. SPECT scans have been simulated for a range of parallel hole collimators form ultra high resolution to high sensitivity and different scanning times. The images were reconstructed using ML-EM/OSEM iterative algorithms with different number of iterations, subsets and inter-iteration filters. Depending on the lesion type and scanning/reconstruction parameters, images with lesions clearly visible to hardly detectable have been obtained. Sets of 60 images (30 with lesions and 30 lesion free) were evaluated by several human observers in free-choice ROC (FROC) studies with the task to mark all the lesions and rate the level of confidence on a 5-point scale. Average Jafroc figures of merit (JFOM) have been used as a gold standard quantifying the performance of human observers. On the other hand, several types of contrast-to-noise ratio (CNR) parameters have been computed on the evaluated sets as well as on ensembles of images with fixed lesion position. Correlations between the JFOM and the corresponding CNRs nave been computed. Results: The CNRs correlate relatively well with the JFOMs for a wide range of image qualities, however, several significant outliers can also be noticed for the fixed lesion based CNRs. Those values display lower variance for a given number of sample images, but their predictive value is lower. CNRs computed on images with random lesions, although of higher variance, are better correlated with lesion detectability. CNR type parameters are well correlated with the FROC figures of merit and are good predictors of human observer studies on SPECT images, provided they are computed on a population of reconstructed images with randomly placed lesions of the same type.

OP358

The use of fast acquisition SPECT/CT for the assessment of suspected bone metastases

H. D. Zacho[1,2], J. B. Manresa[3], J. A. Ejlersen[4], J. Fledelius[4], R. Aleksyniene[1], H. Bertelsen[1], L. J. Petersen[1,2]; [1]Dept of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, [2]Department of Clinical Medicine, Aalborg University, Aalborg, DENMARK, [3]Department of Health Science and Technology, Aalborg University, Aalborg, DENMARK, [4]Department of Nuclear Medicine, Herning Hospital, Herning, DENMARK.

Aim: To assess whether standard SPECT/CT used as an 'add-on' to whole body bone scintigraphy (WB-BS) can be replaced by a fast acquisition SPECT/CT for the investigation of bone metastases. **Materials & Methods:** Consecutive cancer patients referred for WB-BS were included in the study if SPECT/CT was conducted as 'add-on' due to suspicious or equivocal findings of bone metastasis on WB-BS or if the patients had localized cancer-suspicious pain despite the findings on WB-BS. A standard SPECT, a fast acquisition SPECT and a low-dose CT was performed. Standard SPECT-parameters: Matrix 128x128, zoom factor 1, 20 seconds per view (32 views), 180 degrees detector rotation (non-circular orbit, step and shoot), flash 3D iterative reconstruction (four iterations, eight subsets) with scatter correction applied. Fast acquisition SPECT had identical parameters except for 10 s per view using 16 views. A low-dose CT (25 mA, 130 keV, scan time 13.55 s, 30 mAs, slice thickness 0.6 mm) was acquired and used for both standard and fast acquisition SPECT. Four nuclear medicine physicians participated in the evaluation. A three category scale was used in the evaluation: M0 for no bone metastases, M1 for bone metastases, and Me for equivocal findings. A diagnosis was reached in consensus by two observers for each set of images (WB-BS + standard SPECT/CT and WB-BS + fast acquisition SPECT/CT). Images were evaluated in random order with at least four weeks between evaluations. Agreement between acquisition methods was assessed by Cohen's Kappa. **Results:** A total of 104 patients were included in the study, the majority were diagnosed with prostate cancer (n=71). According to WB-BS + standard SPECT/CT, 71 (68%) patients had M0, 19 (18%) had M1, whereas 14 (14%) patients had Me. Agreement between WB-BS + standard SPECT/CT and WB-BS + fast acquisition SPECT/CT using the three category-scale was: unweighted Cohen's Kappa=0.86 (95% CI 0.76-0.96), linear weighted Cohen's Kappa =0.91 (95% CI 0.84 - 0.97), and quadratic weighted Cohen's Kappa=0.94 (95% CI 0.90-0.99). This corresponds to excellent agreement between the two SPECT/CT acquisition-methods. The use of fast acquisition SPECT versus standard SPECT reduced SPECT-acquisition time from 16 to 4 minutes. The use of SPECT/CT provided a definitive classification in 90 of 104 cases in which the WB-BS was not entirely diagnostic. **Conclusion:** Investigation for bone metastases can be conducted using a fast acquisition SPECT/CT as 'add-on' to WB-BS without compromising the diagnostic confidence and with notable reduction in acquisition time.

OP359

Keel- versus Knife-Edge Slit-Hole Collimation in Small-Animal SPECT: a GATE Monte Carlo Study

H. Mahani[1,2], G. Raisali[2], A. Kamali-Asl[3], **M. Ay**[4,1]; [1]Research Center for Molecular and Cellular Imaging (RCMCI), Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Radiation Application Research School, Nuclear Science and Technology Research Institute (NSTRI), Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiation Medicine Engineering Department, Shahid Beheshti University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Performance of knife-edge SPECT collimators is usually limited by a considerable edge penetration, leading to inferior spatial resolution. The problem is severe in slit-hole collimation where there is a long narrow aperture. In this research, we were aiming at making a comparison between imaging performance of a keel- and a knife-edge slit-hole collimator, a novel collimation offering a high detection efficiency. **Materials and Methods**: The slit-hole is a single slit aperture extended across long-axis of scanner's head, allowing to collect much more photons. To meet

the data-sufficiency condition, the collimator has to spin around its central-axis at each regular SPECT angle. To doing so, HiReSPECT camera, a dedicated small-animal SPECT scanner developed in our department, benefiting from the slit-hole collimator was modeled within the GATE. Slit's edges differed in channel height ranging from 0 (knife-edge) to 1.2 mm (full-keel), and slit width was 0.6 mm. Percentage edge-penetration (normalized to that of the knife-edge), full-width-at-tenth-maximum (FWTM) of the reconstructed point-source images, and system sensitivity were evaluated. The channel height was then optimized for two common collimator materials: lead and tungsten. The silt-hole collimation data were iteratively reconstructed using a dedicated in-house 3D MLEM algorithm. **Results**: Edge-penetration exponentially falls off as channel height raises, for both lead and tungsten. A 6 mm channel height results in a decreased percentage edge-penetration by a factor of 1.49 and 2.25 for lead and tungsten, respectively. A 1.2 mm height outcomes a decreased reconstructed FWTM of 1.35 and 1.57 times which observed with a knife-edge geometry, for lead and tungsten, respectively. Increasing channel height also simultaneously improves spatial resolution and mitigates image background. In contrast, sensitivity drops when channel height increases. A 6 mm channel height tungsten collimation gives rise to a decreased background-subtracted system sensitivity of 7.46 cps/μCi compared to 8.18 cps/μCi obtained by a knife-edge one, all at a 30 mm distance. The gains in percentage edge-penetration and FWTM obtained by increasing channel height also compromises filed-of-view of the camera. Therefore, a tungsten keel-edge slit-hole collimation benefited from a 0.6 mm channel height provides the best compromise for technetium-99m molecular imaging using the HiReSPECT system. **Conclusion**: The results highlight that there is a trade-off among spatial resolution, edge-penetration, sensitivity, and FOV for slit aperture design. As a conclusion, a keel-edge collimator offers SPECT image quality superior to a knife-edge one.

OP360

Design Optimisation of 3D Printed Parallel-Hole Tungsten Collimators for High Activity I-131 Imaging

J. Gear, G. Flux; Royal Marsedn NHSFT, Sutton, UNITED KINGDOM.

Introduction: With the advent of power bed laser melting (3D printing) the clinical introduction of tungsten based collimators could soon be realised. This could have a significant impact on quantitative imaging for I-131 dosimetry. I-131 imaging is affected by several factors including scatter, septal-penetration, system resolution and camera dead-time. Commercial high-energy lead collimators are designed for diagnostic imaging and optimised for detection efficiency. High activity administrations of therapeutic I-131 do not suffer from a lack of counts and tungsten collimators could therefore be designed to reduce system deadtime and to improve image quality. **Method:** Designs for lead and tungsten parallel-hole collimators were optimised by iteratively solving analytical formulae for penetration, efficiency and resolution. A cost-function to determine the optimal septal length, thickness and hole-size was reduced using benchmarking inputs for the desired collimator characteristic. Optimised collimator geometries were then used as input into the Monte Carlo program SIMIND to demonstrate the improvement in I-131 image quality that could be achieved. Simulated images for each collimator were used to generate NEMA system characteristics. Comparisons with physical measurements for commercial collimators were also made. **Results:** A good agreement between physical and simulated measurements was observed for commercial lead collimators. For the optimised collimators NEMA system-sensitivity was reduced by a factor of 5 compared to commercial alternatives. However, sensitivity also includes scattered and penetrating photons which were reduced from 30% to 10%. Spatial resolution improved from 14 mm to 6 mm FWHM. A simulation of a thyroid remnant demonstrated clearer foci with the optimised collimator with peak counts only 50% less than commercial lead HEGP, indicating that such collimators may also be suitable for general use. Estimations of costs and collimator mass indicate that tungsten collimators would weigh approximately 170 kg and have material cost 35 times that of current lead alternatives. However, 3D printing options of tungsten offset the expensive machining costs required for lead and therefore such collimators are becoming financially viable.

OP361

A Qualitative and Quantitative Comparison of Step-and-shoot, Acquire-during-step and Continuous SPECT Acquisition Modes

N. A. Bebbington[1], H. B. Joergensen[2], V. Ovtchinnikova[2], J. B. Medhus[2], P. C. Holdgaard[2]; [1]Siemens Healthcare A/S, Aarhus, DENMARK, [2]Nuclear Medicine Department, Vejle Sygehus, Vejle, DENMARK.

AIMS: Time savings of >3 minutes/acquisition or dose reduction for equivalent time can be made with continuous or acquire-during-step (ADS) acquisitions, compared with step-and-shoot (SS). Comparisons made ≥20 years ago favoured continuous acquisition mode due to greater angular sampling, despite a small increase in image blurring, yet clinically, SS is most common. However, given the improved image quality with modern SPECT reconstruction techniques, an up-to-date comparison is necessary. This study provides thorough qualitative and quantitative comparisons of images acquired with continuous, ADS and SS modes under clinically realistic conditions. MATERIALS AND METHODS: SPECT-CT studies of a Tc-99m-filled NEMA-IEC image quality phantom were acquired on a Siemens Symbia Intevo 6, with different settings used clinically (LEAP/LEHR collimator; 128/256 matrix, 60/120 projections; 5, 10, 20 minutes scan time) under four tracer conditions (high contrast (8:1) hot spheres with high and low activities; low contrast (7:2) hot spheres with low activity; medium contrast (1:6) cold spheres with high activity). Flash3D (resolution recovery) reconstructions were made with optimal iterations and Gaussian filter for the given conditions (consistent between acquisition mode) and CT attenuation correction. Five experienced observers blind-scored confidence in uptake from 0 (no uptake) to 5 (certain significant uptake) for each sphere (10-37mm) in 90 datasets (30 per mode). Contrast-to-noise ratios (CNR) were also measured under the four conditions. Results for were plotted on a curve (sphere size (mm) vs confidence; sphere size (mm) vs CNR) and AUC compared by acquisition mode. RESULTS: High contrast hot spheres: ADS gave highest CNR at high activities (AUC: ADS 366; cont 320, SS 270) but confidence scores were comparable (AUC: ADS 109.9; SS 109.2; cont 107.2). Yet, at low activities ADS gave lowest CNR whilst SS and continuous were comparable (AUC: SS 260; cont 259; ADS 179), and continuous gave greatest confidence in lesion detectability (AUC: cont 94.5; ADS 88.0; SS 85.7). Low contrast hot spheres: CNR and confidence scores were greatest for SS (CNR AUC: SS 91; ADS 83; cont 63; confidence AUC: SS 62.0; cont 52.7; ADS 51.4). Cold spheres: CNR and confidence scores were most favourable for continuous mode (CNR AUC: cont -121; ADS -92; SS-82; confidence AUC: cont 70.8; SS 68.6; ADS 67.5). CONCLUSIONS: For equivalent counts and reduced time to SS, continuous mode acquisitions showed favourable qualitative and quantitative results in assessing high contrast hot lesions and cold defects, although it was considered inferior to SS for low contrast hot lesions.

OP362

A Comparative Phantom Study: Digital-CZT vs Analog SPECT

E. Goshen[1], L. Beilin[2], R. Goldkorn[1], S. Ben-Haim[1]; [1]Chaim Sheba Medical Center, Ramat Gan, ISRAEL, [2]Molecular Dynamics, Caesarea, ISRAEL.

Purpose We have assessed the performance of a novel digital SPECT camera with multiple pixelated cadmium zinc telluride (CZT) detectors and high sensitivity collimators (Digital SPECT; Valiance X12 prototype,

Molecular Dynamics). The system's architecture enables gantry rotation, as well as radial and swivel detector motion, providing multiple degrees of freedom for the scanning pattern. These features are used to minimize the patient-detector distance, providing patient-tailored imaging. **Materials and Methods** Images of both Tc-99m filled Hoffman 3-D Brain phantom, and Tc-99m filled Jaszczak phantom with cold rod and solid sphere inserts (rod diameter 4.8-12.7 mm, spheres 9.5-31.8 mm) , were compared to images acquired on a standard NaI based analog (Anger) SPECT system. The images acquired on the digital SPECT camera with high sensitivity collimators (Valiance X12) were compared to the images obtained on the analog SPECT system fitted with high resolution collimators (Discovery NM/CT 670, GE). All images (digital and analog SPECT) were iteratively reconstructed and evaluated visually for resolution. Contrast was calculated using standard methodology. **Results** The digital SPECT images of Hoffman Brain phantom displayed improved resolution compared to the analog SPECT images. The contrast calculated in the region corresponding to the anatomic site of basal ganglia was higher in digital SPECT compared to the analog system (72% vs. 26% respectively). Digital SPECT of Jaszczak phantom demonstrated cold rods in reconstructed transaxial slices of 5 segments with rod diameters of 12.7, 11.1, 9.5, 7.9, 6.4 mm, and in five external rows in the sixth segment (diameter 4.8 mm). Analog SPECT demonstrated rods in 4 segments and in part of the 5th (down to 6.4mm). Spheres were resolved on digital SPECT with contrast of 92.9%, 87.8%, 82.7%, 68.2%, 66.3% and 51.7% (for sphere diameters measuring 31.8, 25.4, 19.1, 15.9, 12.7 and 9.5 mm, respectively). Analog SPECT yielded contrast of 63.5%, 52.8%, 44.4%, 39.3%, 26.4%, and 18.6% for the same spheres, respectively. See fig. 1: Top - Jaszczak phantom cold rods section: Left - Valiance X12 prototype; Right - NaI based analog SPECT system. Center and Bottom - Transaxial slices of Hoffman 3-D Brain phantom with horizontal profile plots through section corresponding to anatomical site of basal ganglia: Left - Valiance X12 prototype; Right - NaI based analog SPECT system. **Figure Conclusion** Contrast and resolution of digital SPECT consistently surpassed standard analog SPECT performance in the phantom studies reported. The superior image quality will likely prove useful in clinical settings.

OP363

Optimization of Preclinical I^{125} SPECT in Conventional and CZT Cameras using Universal Image Quality Indices

J. A. Kennedy[1,2], M. Weiler-Sagie[1], R. Lugassi[1], Z. Gil[1], M. Amit[1]; [1]Rambam - Health Care Campus, HAIFA, ISRAEL, [2]Technion - Israel Institute of Technology, Haifa, ISRAEL.

Purpose: To optimize preclinical imaging of iodine-125 (I^{125}) in conventional and solid-state CZT cameras according to indices relevant to the human visual system (HVS). Method: SPECT images were obtained of a small 33 mL phantom with an activity of 36.7 MBq of I^{125} solution on conventional (Discovery 670 SPECT/CT) and CZT cardiac (Discovery 570c SPECT/CT) cameras for durations of 30 and 15 min respectively. For image quality (IQ) comparison, Poisson resampling and list mode provided virtual acquisitions at 1/8, 1/4, and 1/2 of the full acquisition time. SPECT with energy windows of ±13.5%, ±27% and ±54% centered at 27.5 keV were compared to SPECT at the monochromatic γ-peak (35.5 keV ±15%). Metrics for IQ comparison were contrast, contrast-to-noise ratio, mean-squared error (MSE), and the structural similarity index (SSIM) reflecting known HVS characteristics, with higher SSIM or lower MSE values indicating superior IQ. Optimized acquisition parameters were used to obtain SPECT images of 3 mice at 36 hours post-injection of 11 MBq I^{125} solution. These were an euthyroidic C57BL/6, one athyroidic C57BL/6 and an athyroidic athymic nude mouse with a human papillary thyroid cancer (PTC) flank xenograft, the latter two being thyroidectomized one day prior to the study and treated with thyrotropin-alpha. The PTC case was sacrificed at 8 hours post-I^{125} injection to see total body distribution. Results: Of the evaluated IQ metrics, SSIM improved monotonically with increased acquisition time, a known IQ determinant. For the CZT camera, the ±54% energy window gave the best SSIM (0.398) compared to the ±27% and ±13.5% cases (0.388 and 0.363 respectively) or to the monochromatic γ-peak case (0.274), with MSE giving comparable results (6.85 vs. 7.00, 7.39 and 10.44 respectively). The conventional camera IQ indices were also superior for the ±54% energy window (0.409 vs. 0.406, 0.395 and 0.349 respectively for SSIM, and 7.54 vs. 7.72, 7.58 and 8.34 respectively for MSE). With both cameras, the thyroid was clearly visible in the euthyroidic case as was stomach uptake in the athyroidic case. The total body distribution was well delineated in both studies for the PTC case. Conclusion: I^{125} SPECT performed on conventional and CZT cameras provides a good imaging tool for preclinical research and should be performed with a wide energy window. The CZT camera provided similar IQ as the conventional camera in half the acquisition time. Using SSIM to model HVS provides an effective index for IQ optimization.

Effect of glycemic control on exendin-based beta-cell mass quantification

M. Buitinga, W. A. Eter, C. Frielink, L. Claessens-Joosten, D. Bos, M. Brom, M. Gotthardt; RadboudUMC, Nijmegen, NETHERLANDS.

Background and aim: Targeting of the glucagon-like peptide-1 receptor (GLP-1R) with radiolabeled exendin, a GLP-1R agonist, is an attractive approach to determine the beta-cell mass (BCM) (1-3), which is of high interest in diabetes research. Hence, the effect of metabolic status/chronic hyperglycemia on GLP-1R expression and exendin uptake remains to be elucidated. Here, we investigated the effect of chronic hyperglycemia on ^{111}In-exendin uptake in diabetic mice with intramuscular islet transplants. **Materials and methods:** Syngeneic transplantations of 200 islets were performed in the calf muscle of alloxan-induced diabetic C3H mice (n=6). Glycemic state was regulated using insulin pellets. Three groups of glycemic state were analyzed; 4 weeks of hyperglycemia (HG, blood glucose levels >25mM, n=6), 4 weeks of normoglycemia (NG, blood glucose levels <10mM, n=6), and 2 weeks of normoglycemia followed by four weeks of hyperglycemia (NGHG, n=6). Mice were injected intravenously with 15 MBq of ^{111}In-exendin and SPECT was acquired 1h post-injection. Exendin uptake was determined by autoradiography and was normalized for insulin area (determined by immunohistochemistry). **Results:** Islet grafts were clearly visualized by SPECT in all recipient groups. Tracer uptake was significantly influenced by glycemic state with an accumulation of 19.0 ± 1.6 counts/insulin area for the NG mice and 7.5 ± 2.0 and 9.1 ± 1.3 for the HG and NGHG mice, respectively ($p<0.01$, ANOVA with a bonferroni correction for multiple group comparisons). Despite this two-fold reduction in tracer accumulation, tracer uptake linearly correlated with insulin area (Pearson's Correlation Coefficient r for NG= 0.86, HG= 0.95 and NGHG=0.63). **Conclusion:** Our results indicate that exendin uptake is influenced by glycemic control. The observation that tracer uptake linearly correlates with insulin area, even under chronic hyperglycemia, indicates that BCM quantification using exendin is a valid technique provided that tracer uptake will be corrected for the glycemic state of the subject. These results have significant clinical implications for the interpretation of exendin scans in subjects with diabetes.

Imaging beta cell mass with ^{68}Ga-exendin PET in patients with remission of type 2 diabetes mellitus (T2DM) after Roux-en-Y gastric bypass (RYGB) surgery

L. N. Deden[1], M. Boss[2], E. O. Aarts[1], H. de Boer[1], M. Buitinga[2], I. M. C. Janssen[1], M. Brom[2], F. J. Berends[1], M. Gotthardt[2]; [1]Rijnstate, Arnhem, NETHERLANDS, [2]Radboud University Medical Center, Nijmegen, NETHERLANDS.

Background In more than 60% of T2DM patients, diabetes remission is seen after Roux-en-Y Gastric Bypass (RYGB) surgery, he underlying mechanisms is not completely understood. Possibly, preoperative beta cell activity (BCA) or mass (BCM) play a role and have a predictive value for T2DM remission. BCM could be measured *in vivo* using the radiolabeled glucagon-like peptide-1, exendin, which specifically accumulates in the islets of Langerhans. In this study the difference in pancreatic ^{68}Ga-exendin uptake, as measure for BMC, in patients with and without complete T2DM remission after RYGB is evaluated in PET. **Methods** In 24 T2DM patients ^{68}Ga-exendin PET will be performed at least one year after RYGB, 12 patients with complete T2DM remission (responders) and 12 patients without complete T2DM remission (non-responders). Pancreatic uptake corrected for injected dose (kBq/MBq) was quantified by delineation of the pancreas in PET images and compared between responders and non-responders (student's T-test). BCA was measured by arginine stimulation and oral glucose tolerance test (OGTT). Additionally, optimal acquisition moment and time were determined based on the first six patients. PET was acquired one and two hours after injection of 100 MBq ^{68}Ga-exendin in list mode with 10 minutes per bed position (reconstructions for 2, 5, 7 and 10 minutes per bed position). Optimal acquisition was based on image quality, pancreatic and kidney uptake and activity distribution within the scans. **Results** So far, three responders and three non-responders have completed the study. Preoperative and weight loss parameters were comparable, only fasting c-peptide was lower in non-responders compared to responders (0.4 versus 0.8nmol/l, P=0.049). Pancreatic uptake was 36% lower in non-responders (2.2±0.42kBq/MBq) compared to responders (3.5±1.9kBq), although this is not a significant difference (P=0.3). Pancreas volume was smaller in non-responders (42±1 ml) compared to responders (74±7ml; P=0.089). BCA was impaired in non-responders compared to responders; stimulated c-peptide was 0.8 versus 1.8 nmol/l and during OGTT maximum c-peptide was 1.3 versus 4.2 nmol/l, with largest glucose levels in non-responders. Pancreatic and kidney uptake, corrected for decay, and activity distribution were similar one and two hours after injection. Image quality was best one hour after injection. Pancreatic uptake was similar for increasing acquisition time, but image quality increased for acquisition time of 7 and 10 minutes. **Conclusion** Preliminary results suggest that pancreatic uptake of ^{68}Ga-exendin is lower in non-responders compared to responders after RYGB. Optimal acquisition is performed is one hour after injection with seven minutes per bed position.

OP366

Obesity-associated alterations of glucose metabolism are ameliorated after chronic stimulation of abdominal vagus nerve

C. Malbert[1], M. Genissel[1], J. Georges[1], F. Legouevec[1], J. Divoux[2], C. Picq[2], L. Guillemetz[2], C. Henry[3]; [1]INRA, Saint-Gilles, FRANCE, [2]Axonic, Vallauris, FRANCE, [3]LivaNova, Clamar, FRANCE.

Obesity alters glucose metabolism with specific reference to insulin resistance. We have previously demonstrated that chronic stimulation of abdominal vagus nerve (VNS) was able to restore insulin sensitivity in obese animals (Malbert et al, Obesity facts, 2015). The aim of this study is to evaluate the capability of vagal stimulation to recover the altered glucose metabolism induced by obesity. 15 adults age-matched minipigs were divided into three groups: lean (33±1.6 kg), obese (49±1.1 kg) and obese with VNS (47±1.3 kg). Obesity was induced by 3 months of obesogenic diet. Once obese, the obese and obese-stimulated groups were fitted with cuff electrodes around the abdominal vagi using laparoscopy. VNS was applied in obese-stimulated group only. Obese and obese-stimulated groups were tested after 5 months of obesogenic diet whereas lean group remained on normal diet. Oxidative and non oxidative glucose metabolism were evaluated using indirect calorimetry coupled with euglycemic clamp. Brain, hepatic and skeletal muscle metabolism were quantified as insulin-mediated glucose uptake using FDG dynamic PET imaging coupled with continuous arterial input function measurement also during clamp. Brain glucose uptake was obtained by kinetic modeling of PET and arterial data whereas hepatic and skeletal muscle glucose uptake were calculated using Patlak method. Glucose oxidative metabolism was unchanged in lean, obese and obese-stimulated animals ($p > 0.05$). On the contrary, non oxidative glucose metabolism was significantly reduced by obesity and partially restored by VNS (4.5±0.65, 2.9±0.26 and 4.1±0.19 mg/kg/min for lean, obese and obese stimulated, $p<0.01$). Whole brain glucose metabolism was also reduced by obesity, a feature restored by VNS to lean condition. ROI based analysis showed that this pattern was similar in all brain areas. Liver and skeletal muscle glucose metabolism followed the same trend. Chronic vagal stimulation was able to restore whole body glucose metabolism altered by obesity. This restoration was equally effective on the main organs involved in glucose metabolism e.g. brain, liver and skeletal muscle demonstrating that restoration of insulin sensitivity by VNS was organ independent.

OP367

Gelofusine inhibits the renal uptake of ^{111}Indium-labeled exendin in humans

M. Buitinga[1], M. Boss[1], M. Behe[2], M. Brom[1], M. Gotthardt[1]; [1]RadboudUMC, Nijmegen, NETHERLANDS, [2]Paul Scherrer Institut, Villigen, SWITZERLAND.

Background and aim: Targeting of the glucagon-like peptide-1 receptor (GLP-1R) with radiolabeled exendin, a GLP-1R agonist, is an attractive approach to determine the beta-cell mass (BCM) (*1-3*). However, the high kidney uptake is hampering SPECT-based quantification of pancreatic uptake. It has been demonstrated in rats that the renal reabsorption of ^{111}In-exendin can be reduced by co-infusion of succinylated gelatin (Gelofusine, Braun) (*4*). Here, we studied the effects of a low-dose Gelofusine infusion on the renal uptake of ^{111}In-exendin in humans. ***Materials and methods:*** Ten healthy volunteers, 5 men and 5 women, were given 50MBq ^{111}In-exendin, in combination with normal saline or Gelofusine (bolus of 1mL/kg body mass during 10 minutes followed by 0.02mL/kg/min for 3 hours). SPECT images were obtained after 24 hours. After a period of three weeks, the procedure was repeated; participants who received normal saline during the first session, were given Gelofusine, and vice versa. Blood and urine samples were taken to monitor radioactivity concentrations. Uptake of ^{111}In-exendin was determined by drawing regions of interest around the kidneys and in the pancreas. **Results:** Normal saline or Gelofusine injections did not induce any changes in blood pressure or heart rate and did not cause any other clinical side effects. Analysis of the scans of the first 5 patients showed that a low dose of Gelofusine is able to effectively reduce the kidney retention. The observed reduction in kidney uptake varied between 14% and 53% with a mean reduction of 27%. Assessment with t-test for paired data showed that this reduction was significant (p=0.013). Gelofusine injections did not alter the uptake of ^{111}In-exendin in the pancreas (paired t-test, p=0. 41). ^{111}In-exendin was rapidly cleared from the blood. When gelofusine was administered, the excretion of ^{111}In-exendin in the urine was increased from 2.0%ID to 3.2%ID in 24 hours. **Conclusion:** The present study shows that a low-dose Gelofusine infusion effectively reduces the renal uptake of ^{111}In-exendin, without any side effects. This decrease in kidney uptake does not only reduce the radiation exposure, but

also the kidney:pancreas ratio. 1. M. Brom *et al.*, *Diabetologia. 57,* 950-959 (2014) 2. M. Brom *et al. Diabetes*. 64, 1324-1328 (2015). 3. I. van der Kroon *et al. J. Nucl. Med.*, 1-24 (2016). 4. E. Vegt *et al.Eur. J. Nucl. Med. Mol. Imaging*. 37, 226-34 (2010).

Increased Proliferative Activity in Parathyroid Scan in Hyperplastic Parathyroid Glands, measured by PCNA and Ki-67 Expression: Impact on specific surgical treatment

S. Dugonjic, Sr., S. Cerovic, M. Sisic, B. Ajdinovic; Military Medical Academy, Belgrade, SERBIA.

Background. Improvement of sensitivity of parathyroid scintigraphy (PS) for hyperplasic parathyroid glands (HPG) visualization requires determination of many factors which influence intensity of Tc99m-MIBI uptake. **Aim.**The aim of this study was to correlate the degree of PS Tc99m-MIBI uptake with proliferative activity of hyperplastic PG, measured by PCNA and Ki-67 expression. **Methods.**Twenty-seven patients with primary/secondary parathyroid hyperplasia underwent PS before surgery. Static scintigrams of neck/chest were performed, 15 minutes and 2 h after *iv.* inj. of 740 MBq of Tc99m-MIBI. Four hours later, after *iv.* inj. of 185 MBq Tc99m, thyroid scintigraphy was performed. After normalization and motion correction, subtraction was done. Scintigraphic results were graded from 1-5, depending on the intensity of Tc99m-MIBI uptake. PS graded 3, 4 and 5 were considered positive. Commercial mice monoclonal anti-human antibody DAKO: PCNA and Ki-67 were used. Visualization system, EnVisionTM DAKO kit and chromogen DAKO DAB liquid, was used. As a positive immunohistochemical (IMH) response, exclusively nuclear immunoreactivity, using standard formula for the number of cells (1000 cells) and proliferative parameters at high microscopic magnification were established. Positive control for the IMH method represented by samples from 10 PG, removed incidentally at normocalaemic patients (during thyroidectomy), and negative control, IMH procedure using buffer instead of antibodies. Proliferative activity was determined as positive and negative, by the expression of PCNA and Ki-67 antibody, at standard preparations. **Results.**PS localized 51 from 73 HPG, 60 nodular hyperplastic (NHPG), 13 diffuse hyperplastic PG (DHPG), with sensitivity of 70%. From HPG, 92% were PCNA positive, while 15% were Ki-67 positive. Control PG (50 PG) were 98% PCNA and 100% Ki-67 negative. Significant statistical difference was found between HPG and control PG comparing PCNA and Ki-67 expression, $p \leq 0.0001$. PCNA expression was positive in 100% DHPG and in 90% NHPG with statistically not significant difference. Ki-67 expression was negative in all DHPG, and positive in 18.3% NHPG, with statistically important difference, $p \leq 0.0001$, between two groups. Between PS and PCNA expression significant positive correlation was found, $p \leq 0.0001$. Significant negative correlation was found between scintigraphic and Ki-67 positivity, $p \leq 0.0001$. **Conclusion.** Increased proliferative activity of HPG was demonstrated, with high sensitivity of PCNA, and high specificity of Ki-67. Increased proliferative activity is one of the factors responsible for higher Tc99m-MIBI uptake in hyperplastic parathyroid glands. Finding that scintigraphic negative HPG have less pronounced proliferative activity, imply that these HPG are PG of choice whose remnant should be left during subtotal parathyroidectomy.

OP369

^{75}SeHCAT in the diagnosis of bile acid malabsorption in patients with crohn´s disease. correlation with pathologic study and treatment

P. TALAVERA RUBIO, M. BELLÓN GUARDIA, P. OLIVENCIA PALOMAR, N. DISOTUAR RUÍZ, E. DE LA SANTA BELDA, V. POBLETE GARCÍA, G. JIMENEZ LONDOÑO, M. TELLO GALÁN, A. GARCÍA VICENTE, J. CORDERO GARCÍA, A. SORIANO CASTREJÓN; HGUCR-SESCAM, CIUDAD REAL, SPAIN.

Aim: To study the diagnosis with ^{75}SeHCAT scintigraphy in bile acid malabsorption (BAM) in patients with Crohn´s disease (CD) and its possible correlation with the severity of the disease, indicated by histological study, and treatment received. Material and Methods: We analyzed the studies that we have performed on patients diagnosed with Crohn´s disease, to assess the existence of BAM etiology associated with the persistence of diarrhea despite the treatment received (surgical/immunotherapy). The images of abdominal region were acquired at 3 hours and 7 days after administration of a capsule containing 0.01 mCi of ^{75}SeHCAT (previous fasting). Background images were also obtained immediately before and after the acquisition of patient´s images, at 3 h and 7 days. The study was considered pathological when the retention rate was ≤ 10%. The results of the technique were correlated with pathological alteration detected by endoscopic biopsy (normal-mild/moderate-severe) and previous treatment administered to the patient (medical/surgical resection) Results: We performed a total of 32 studies (15 women and 17 men, age range: 21-77 years). 23 of them had a pathological retention rate in ^{75}SeHCAT scintigraphy (72%). 11/32 patients had been treated with ileal surgery and 21/32 not (^{75}SeHCAT scintigraphy was pathological in 8 and 15 of them, respectively). 19/32 patients had received medical treatment and 13 not (^{75}SeHCAT scintigraphy was pathological in 13 and 10 of them, respectively). 5 patients of the 9 with ^{75}SeHCAT scintigraphy normal and 10 of 23 with pathological scintigraphy showed moderate-severe damage in the endoscopic study. No statistically significant correlation between the result of the technique and the variables analyzed (disease severity and prior treatment)was found. Conclusion: We found a high association between BAM and Crohn's disease (nearly 3/4 of patients), but no correlations with the severity of the disease, nor the type of prior treatment received.

OP370

Diagnostic Accuracy Of ^{99m} Tc MAA Whole Body Shunt Scintigraphy In Patients With Suspected Hepatopulmonary Syndrome

P. Shanmuga Sundaram, S. Padma; Amrita School of Medicine, Amrita Institute of Medical Sciences, COCHIN, INDIA.

Aim: Hepatopulmonary syndrome (HPS), a severe complication of cirrhosis is associated with poor survival. It is characterized by hypoxaemia due to pulmonary vasodilatation and shunting (i.e Pulmonary atriovenous fistula PAVF formation). Pts are managed conservatively or by liver transplant. 2D transthoracic contrast echocardiogram (CE) is accurate and an established imaging modality in HPS. ^{99m}Tc MAA Whole body shunt scintigraphy (MAA scan) is less commonly used. This study was designed i) to assess the diagnostic accuracy of MAA scan in suspected HPS patients in comparison to CE (ii) to evaluate the clinical significance of semiquantitative analysis of shunts as assessed by both techniques. Materials & Methods: Prospective study was conducted in 22 consecutive cirrhotic patients with portal hypertension (all males, age 17 to 59 yrs, Jan 2013 to 16) planned for liver transplant. All underwent clinical evaluation, pulse oximetry, MAA scan and CE. Presence of PAVF (interatrial shunt) is depicted by extrapulmonary MAA distribution followed by shunt percentage calculation. Semiquantitative analysis of shunt severity was also performed by CE in all (Grade 0 no bubbles; 1 occasional filling with less than 20 bubbles; 2 moderate filling; 3 complete opacification). Results: Dyspnoea, digital clubbing, cyanosis and spider angiomas were present in all. Hypoxemia was documented in all. 20/22 pts (91%) had positive CE and MAA scan. In 2 pts CE was erroneous. MAA shunt of more than 6% was observed in all patients, except 2 who were negative for shunt. Grade of shunt severity by CE was found to be equivalent to that of MAA shunt calculation. MAA shunt was grade 3 (more than 25%) in 6 pts, grade 2 (more than 15%) in 5 pts & grade 1 (6 to 15 %) in 9 pts. A significant correlation was found between CE and MAA shunt grading (*P* less than 0.0001). A χ^2 test for linear trend showed significant association

between CE & MAA shunt grading, *P* less than 0.0001. Conclusion: Wholebody MAA shunt scintigraphy is an effective modality to assess and grade HPS in cirrhotic liver patients. Presence of HPS indicates a worse prognosis thus early initiation of therapy is imperative.The grade of shunt severity as assessed by CE is equivalent to MAA shunt percentage calculation. Thus MAA shunt scintigraphy is a reliable, reproducible investigation with excellent diagnostic accuracy and can be used at par with CE in identifying and prognosticating HPS pts scheduled for liver transplant.

OP371

Ectopic gastric mucosa scintigraphy: retrospective review of a series

M. R. Victor, A. Prata, S. Carmona, J. G. Santos, J. A. Sequeira, A. I. Santos; Hospital Garcia de Orta, Almada, PORTUGAL.

Introduction: Ectopic gastric mucosa scintigraphy (EGMS) is a simple nuclear medicine procedure indicated in Meckel's Diverticulum (MD) suspicion. The radiopharmaceutical used, ^{99m}Tc-pertechnetate, is taken up and excreted by the mucus-secreting gastric cells, present superficially in all different types of gastric glands. Aim: To review our series of EGMS regarding presenting symptoms, referral data, scan results and clinical follow-up. Material and methods: Retrospective analysis of referrals for EGMS between July 1998 and December 2015, characterizing age, clinical referral, symptoms, scintigraphic results, surgery and corresponding histological findings. Results: A total of 105 EGMS were performed to a population of 99 patients, 78 children with median age and interquartile range of 6 [2,5;12] years; and 21 adults with median age and interquartile interval of 39 [28;47,5] years. In the pediatric patients, the majority of the referrals came from pediatric surgery (30%) and pediatric emergency ward (25%). The adult patients were mainly referred from gastroenterology appointments (52%). The most prevalent presenting symptoms were lower gastro-intestinal bleeding (49% children and 67% adults) and abdominal pain (29% children and 14% adults). A total of 16% of patients were asymptomatic (20% pediatric and 5% adult), electively studied after incidental MD finding during abdominal or pelvic surgery, and all of them had a negative EGMS. In 6 (5,7%) EGMS there was scintigraphic evidence of ectopic gastric mucosa (positive result), being 5 children and 1 adult; they underwent surgery and all had histologic confirmation of gastric mucosa. Within the population with negative EGMS, 5 patients were operated, one of which had a MD resection with histological confirmation of presence of gastric mucosa. The remaining four had a different final diagnosis (gastric duplication, appendicitis, enteric herniation and peptic ulcer, respectively). Conclusions: The most frequent symptom for referral was gastrointestinal bleeding, in accordance with the literature. There were no false positive results, in agreement with the known high specificity of this diagnostic procedure. The only false negative case raises the need of further data on mass/volume and type of gastric cells present on the ectopic mucosa, in order to understand the limitations of the exam.The low prevalence of positive results indicates that there is a possible need for better referral criteria definition. All the asymptomatic patients who were referred after incidental intraoperative finding of MD had a negative EGMS, questioning the appropriateness of this indication.

GLP-1 Analog Raises Glucose Transport Capacity of Blood-Brain Barrier in Alzheimer's disease

A. Gjedde[1], M. Gejl[2], J. Rungby[1], B. Brock[2]; [1]University of Copenhagen, Copenhagen N, DENMARK, [2]Aarhus University, Aarhus, DENMARK.

Introduction: Glucose enters the brain tissue from plasma by facilitated diffusion across the two membranes of the endothelium of the blood-brain barrier (BBB), mediated by the glucose transporter 1 (GLUT1). There is evidence in Alzheimer's disease (AD) of reduction of glucose transport across the blood-brain barrier, due to diminished GLUT1 translocation and expression at the BBB. Reduced BBB GLUT1 expression is known to aggravate AD pathology and further impair cognitive function, implying that GLUT1 may be a potential target of therapy directed towards AD neurovascular dysfunction and degeneration. The incretin hormone GLP-1 prevents the decline of the cerebral metabolic rate of glucose that signifies cognitive impairment, synaptic dysfunction, and disease evolution in AD, and GLP-1 may directly activate GLUT1 transport in brain capillary endothelium. For this reason, we here claim that the GLP-1 analog liraglutide may prevent the decline of blood-brain glucose transfer in AD. Methods: In this 26-week test of the hypothesis, we randomized 38 patients with AD to treatment with the GLP-1 analog liraglutide (n=18) or placebo (n=20). We determined blood-brain glucose transport capacity (Tmax) with [18F]FDG (FDG) (ClinicalTrials.gov NCT01469351). Results: Unlike the placebo treatment, the GLP-1 analog treatment significantly (P<0.0001) raised Tmax in cerebral cortex as a whole from 0.72 to 1.1 mmol/hg/min, a 50% increase (2-way ANOVA of qui-squared). Conclusion: The results are consistent with the claim that GLP-1 analog treatment raises GLUT1 activity in the BBB and hence may represent a therapeutic target for neurovascular dysfunction and degeneration in AD.

Aims. Owing to its easy measurability, education is one of the most straightforward used proxies for Cognitive Reserve (CR). We hypothesized that the link between education and cognitive meta-skills needed to maintain daily functioning against the AD-related damage may be influenced by the educational gradient of the elderly at different latitudes across Europe. **Methods.** 62 patients with

prodromal (p)AD (34 female, age 72.3±8.2 years, baseline 27.0±1.5 mmse) and 109 controls (57 females, age 66.8±6.5, MMSE 29.3±1.0) were recruited from EADC centers in Italy, the Netherlands, France, and Germany. All subjects underwent 18F-FDG PET at baseline. Patients were divided into two groups according to the educational gradient of their country of belonging: 1 higher educational gradient (Germany and The Netherlands; HEG) and 2 lower educational gradient (Italy and France; LEG). To confirm the effect of education as RC proxy, the whole CTR group was first compared with pAD subgroups divided into highly (high-educ) and poorly educated (low-educ pAD) according to their individual educational level (lower or higher than median years of education; 11 years). Then CTR were independently compared with high-educ and low-educ pAD belonging to HEG and LEG countries, respectively. Finally high-educ and low-educ HEG pAD were compared with education matched LEG pAD (significance: $p<0.001$ uncorrected at peak and FDR-corrected at cluster level). pAD subgroups were not different with respect to age and baseline MMSE score; however age, sex, MMSE score and center of belonging were included as nuisance. **Results.** The effect of CR was present in the whole group of pAD. In low-educ pAD hypometabolism was evident only in bilateral posterior cingulate and parietal cortex while in high-educ pAD a larger cluster of hypometabolism involved also temporal cortex bilaterally and left dorso-lateral frontal cortex. When subgroups of pAD where independently compared with CTR, HEG-poorly-educated pAD showed hypometabolism in posterior cingulate while LEG-poorly-educated pAD showed a larger area of hypometabolism involving also left posterior parietal cortex. Finally, LEG poorly educated pAD showed more marked hypometabolism with respect to HEG poorly educated pAD in bilateral temporo-lateral cortex. **Conclusions.** Poorly educated pAD from European countries with lower educational gradient have higher CR with respect to pAD patients belonging to countries with higher educational gradient with the same years of formal education. This finding suggests that relevance of education and hence its influence on clinical expression of dementia varies with latitude across Europe.

OP374

Role of 18F-FDG-PET and amyloid-PET imaging on patient management in mild cognitive impairment or dementia

Llinares-Tello[1], A. Pons-Escoda[6], C. Majós-Torro[6], C. Aguilera-Grijalvo[6]; [1]PET Unit. Nuclear Medicine Department. IDI. H. de Bellvitge-IDIBELL., L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN, [2]Neurology Department. Hospital de Bellvitge-IDIBELL, L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN, [3]Neurology Department. H. de Bellvitge-IDIBELL., L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN, [4]Neurology Medicine Department. H. de Bellvitge-IDIBELL., L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN, [5]Psychiatry Department. H. de Bellvitge-IDIBELL., L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN, [6]RM Unit. IDI. H. de Bellvitge-IDIBELL., L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN.

Aim: To evaluate the role of FDG-PET and amyloid-PET on patient management and outcomes in mild cognitive impairment or dementia. **Material and Methods:** Prospective study including 142 patients (77 women) with mean age of 68 years old (range: 50-82), with cognitive impairment where Alzheimer Disease (AD) was considered as a possible cause. Patients underwent brain FDG-PET and 18F-Florbetapir-PET scans, CT or MRI and a battery of laboratory and neuropsychological tests. History of depression, hypothyroidism and diabetes and the standardized Mini-Mental State Examination (SMMSE) were recorded. The APOE genotype and cerebrospinal fluid biomarkers for AD were available in 43 and 10 patients, respectively. The FDG-PET brain analysis was visual and quantitative (CortexID-GE Healthcare) and scans were classified in 2 patterns: AD (temporoparietal hypometabolism) and non-AD (others). The amyloid-PET images were classified as positive or negative by visual interpretation, using additional fusion with MRI in cases with cerebral atrophy. The FDG-PET and amyloid-PET results were compared between them and correlated with final probable clinical diagnosis. **Results:** Most patients (132/142) presented a recent history of significant memory problems and the remaining patients showed other predominant symptoms as depression, incontinence, aphasia, aggressive behaviour or agorafobia. FDG-PET studies were abnormal in 77/142 patients (54%): 52 AD (52/52 positive amyloid-PET) and 25 non-AD (4/25 positive and 21/25 negative amyloid-PET, on of them with primary progressive aphasia). FDG-PET scans were normal in 65/142 patients (66%), but 33 of them had a positive amyloid-PET (15 APOE of risk). Amyloid-PET studies were positive in 82/142 patients (58%). The SMMSE were significantly lower in patients with abnormal FDG-PET compared with the normal scans (mean: 19 vs 26) but no statistical differences were founded between patients with positive amyloid-PET and those with negative scans (mean: 22 vs 23). **Conclusions:** Brain PET is a useful diagnostic tool in patients with cognitive impairment, where FDG and amyloid provide different and complementary information. FDG-PET helps to identify typical patterns of AD and frontotemporal dementia. Amyloid-PET may have a major impact in patients with negative or abnormal FDG-PET with non-AD pattern, when negative to exclude AD (psychiatric scenarios) or when positive to confirm AD in younger patients (< 70 years old).

OP375

PET-amyloid (18F-Florbetaben) and CSF: biomarkers agreement for Alzheimer disease diagnosis

N. Testart Dardel[1,2], E. Triviño-Ibáñez[1,2], R. Sánchez Vañó[3], A. González Jiménez[1,2], C. Carnero-Pardo[1], A. Rodríguez-Fernández[1,2], M. Gómez-Río[1,2], J. Llamas-Elvira[1,2]; [1]Complejo Hospitalario Universitario de Granada, Granada, SPAIN, [2]IBS, Granada, SPAIN, [3]Hospital 9 de Octubre, Valencia, SPAIN.

OBJECTIVES:The development of reliable biomarkers in Alzheimer's disease (AD) has become one of the main areas of interest, because of the enormous impact that would have its diagnosis and treatment. The **aim** of this work is to study the relationship of CSF biomarkers (CSFb) and molecular imaging by amyloid-PET 18F-Florbetaben (FBB-PET).**METHODS:**A preliminary series of patients with mild cognitive impairment fulfilling clinical criteria for FBB-PET (early and/or atypical onset cognitive impairment) were included. In all patients data of demographic, clinical and biochemical determination of CSFb (beta-amyloid, total and phosphorylated tau protein) were collected. FBB-PET protocol: Siemens Biograph 16. CT: Low-Dose: 50mAs; 120kV. Slow injection, dose: 300 mBq; acquisition: 90 min p.i.; 3D; 30 min ($1,5x10^6$ trues accumulated). Reconstruction: OSEM-OM: 168x168; 4 it/24 sub; zoom=2; FWHM=3.CSFb were considered quantitatively and as positive/ negative. FBB-PET was evaluated according visual and semiquantitative analysis. ROIs were established at cerebellar white matter, anterior pole of the temporal lobe, frontal cortex and posterior cingulate, in both hemispheres, estimating the ratio between the SUVmax at each ROI and the cerebellum (reference region). **Results:**Ten patients were included (3 women / 7 men, mean age of 58.7 ± 9.1 years). Amyloid PET was considered positive in 7/10 patients and negative in 3/10 patients. CSFb were positive in 6/10 and negative in 4/10 patients. Only one patient had discordant findings between CSFb and PET, with positive FBB-PET, positive beta-amyloid and negatives CSF, total tau (t-tau) and phosphorylated tau (p-tau). The rest of cases (positve and negative) were concordant.The mean values of beta amyloid, t-tau and p-tau levels at CSF were significantly higher in the positive PET amyloid patients than in negative subgroup (779,3 ± 37,5 vs 364,7 ± 113.5

ng/L; 126.3 ± 2.3 vs 338.4 ± 165.9 ng/mL; 24.0 ± 1.7 vs 50.0 ± 21.3 ng/L, $p < 0.05$ respectively). The uptake ratio from all ROIs showed a positive correlation with the CSF levels of beta amyloid, t-tau and p-tau. **CONCLUSIONS:** Our preliminary results showed a high agreement between the diagnostic classification on basis CSFb and FBB-PET and suggesting a positive correlation between absolute value of CSFb and the uptake index at target ROIs.

OP376

Conversion of aMCI subjects to AD in relation to [^{18}F]flutemetamol Amyloid status, white matter hyper-intensities and hippocampal volume in a phase III longitudinal study

C. J. Buckley[1], M. Zanette[2], **A. Cherubini**[3]; [1]GE Healthcare, Amersham, UNITED KINGDOM, [2]GE Healthcare, Marlborough, MA, UNITED STATES, [3]Institute of Molecular Bioimaging and Physiology (IBFM-CNR), National Research Council, Catanzaro, ITALY.

Introduction Previously, GE Healthcare conducted a three-year outcome study in which 232 patients with amnestic mild cognitive impairment (aMCI) underwent baseline amyloid PET imaging with [^{18}F]flutemetamol to determine time to conversion to dementia in relation to baseline amyloid status. Conversion was determined by an independent clinical adjudication committee, which reviewed the results of 6-monthly neuropsychiatric testing for up to 36 months. While amyloid positivity was a significant and independent predictor of conversion, a fraction (23%) of the amyloid-negative subjects also converted while 77% did not convert in the three year study window. In this post-hoc analysis, we determined the association of hippocampal atrophy and white-matter lesion load with conversion to dementia with the ultimate aim of improving conversion prediction. **Methods** Baseline MRI scans from the study cohort were analysed quantitatively for hippocampal volume and white-matter lesion load in a post-hoc analysis. ANOVA was used to compare hippocampal volume by conversion to dementia status and amyloid status by dichotomous [^{18}F]flutemetamol PET image visual read. A similar model included white matter lesion load as the dependent variable. **Results** Among amyloid-negative patients, converters had both a significantly higher white matter lesion load ($p=0.0033$) and a significantly lower hippocampal volume ($p<0.0001$) than non-converters. For amyloid-positive patients, converters had a significantly lower hippocampal volume than non-converters ($p=0.0140$) but the difference between converters and non-converters in white-matter load was not statistically significant. **Discussion** Subjects who are amyloid-negative by [^{18}F]flutemetamol at baseline are less likely to progress in the short term to dementia than those with a positive scan. The results above provide evidence that amyloid-negative aMCI subjects who converted to dementia had significant levels of either a white-matter lesion load or hippocampal atrophy as compared to the amyloid-negative non-converters. This presentation elucidates the relationship between the assessment of amyloid PET and MRI biomarkers which can be combined to predict conversion from aMCI to symptomatic dementia.

OP377

Effects of scanner and acquisition-time on brain amyloid PET evaluation: possible impact on the follow-up

J. Arbizu[1], A. Danilenko[2], **E. F. Guillen**[1], E. Prieto[1], L. Imaz[1], B. Garcia-Garcia[1], M. Riverol[1], J. M. Martí-Climent[1]; [1]University of Navarra Clinic, PAMPLONA, SPAIN, [2]Centre Léon Bérard. CHU, QUÉBEC, QC, CANADA.

Objectives : To investigate the impact on visual and quantitative evaluation of 18F-Florbetapir PET/CT performed on new generation or standard scanners and at different acquisition times. Methods : Two consecutive studies were conducted using Biograph PET/CT scanners (Siemens): DUO using OSEM reconstruction, and mCT using OSEM reconstruction with PSF and TOF (sequence was selected randomly). A Hoffman 2-D Multi-Compartment Brain Phantom™ was filled with 18F simulating different ratios between grey and white-matter (1:1, 2:1, 4:1). We included 20 patients (57 to 89 y.o.; MMSE: 23 to 29): 4 probable AD, 2 possible AD, 7 amnestic MCI, and 7 MCI plus. Additionally, 9 patients (58 to 74 y.o.; MMSE: 17 to 29; 8 MCI, 1 possible AD) were studied in the mCT scanner using list mode acquisition between 40 to 70 minutes after injection. Images were evaluated visually (positive or negative), and quantitatively using the SUVR. Agreement between visual readings, and concordance (exchangeability and agreement) between SUVR values were analysed. Results : An overestimation of phantom ratios was measured using DUO or overfiltered mCT images. Visual reading agreement between scanners exhibited a kappa of 0.83. Three out20 patients were classified as doubtful in the DUO and negative in the mCT. SUVR values exhibited significant differences between visual categories using both scanners ($p<0.001$). A systematic bias of higher DUO SUVR values was found. Bland-Altman LOA showed mild agreement between scanners, although SUVR average differences were almost significant ($p=0.054$), but there was not clear exchangeability between SUVR values (some Lin´s Concordance Coefficient were lower than 0.9). White-Matter/Cerebellum values were higher when images were acquired firstly than when acquired secondly in the sequence ($p<0.01$). When SUVR mean of 9 patients (5 positive, 4 negative) were plotted against acquisition times (40, 50 and 60 minutes after injection), both increases and decreases were observed (unrelated to amyloid load condition). Within subject SD ranges from 0.01 to 0.06 (mean: 0.03). All regional SUV decrease slopes were homogeneous along time. Conclusions : Clinical Amyloid-PET reading is not significantly affected by the type of the scanner, although new scanners reduce the number of possible doubtful cases and estimate more precisely quantitative values. Fluctuations on the SUV decrease slopes along time have possible major impact on SUVR values. Consequently, amyloid-PET studies should be acquired at a similar uptake-time and scanner during the follow-up of patients with cognitive impairment.

OP378

Scan time-windows and diagnostic performance of florbetaben amyloid PET imaging

H. Barthel[1], A. Jovalekic[2], S. Bullich[2], S. DeSanti[2], N. Koglin[2], A. Stephens[2], S. Dresel[3], P. Bartenstein[4], J. Seibyl[5], O. Sabri[1]; [1]Leipzig University, Leipzig, GERMANY, [2]Piramal Imaging, Berlin, GERMANY, [3]Helios Hospital Berlin-Buch, Berlin, GERMANY, [4]Ludwig-Maximilian University, Munich, GERMANY, [5]Institute for Neurodegenerative Disorders, New Haven, CT, UNITED STATES.

Introduction: [^{18}F]florbetaben (FBB) is approved in the European Union, the USA, and South Korea for clinical use to image beta-amyloid plaques. Depending on the marketing authorization, different PET acquisition time windows are possible. In a phase 2A study, following FBB administration the accuracy of the visual read for earlier acquired PET images (45-60min p.i.) did not differ compared to later acquired PET images (90-110min p.i. and 110-130min p.i.) (Barthel et al., Lancet Neurol 2011). The analysis presented here aimed to further investigate the diagnostic properties of earlier FBB images analysed quantitatively. **Methods:** The FBB Phase 2A study was carried out in 18 centres on 3 continents. The present analysis examined the FBB PET data of 77 patients with probable Alzheimer's disease (AD, age 55 years or older, mini-mental state examination [MMSE] score=18-26, clinical dementia rating [CDR]=0.5-2.0) and of 69 age-matched healthy controls (HCs, MMSE ≥28, CDR=0). Volumes of interest (modified AAL template, PMOD) were defined to calculate neocortical composite SUV ratios (cSUVRs) using the cerebellar cortex as the reference region. Clinical diagnosis served as the Standard of Truth. **Results:** cSUVRs were significantly higher for the AD patients vs. HCs in all three time-windows

($p<0.0001$, Cohen's effect sizes=1.54, 1.37, and 1.44). Receiver-operating characteristics curve derived cSUVR thresholds resulted in sensitivities/specificities of 78%/93%, 74%/94%, and 75%/91% for the three time-windows. For the AD patients, the binary cSUVR readouts at 45-60min p.i. showed 86% and 88% concordance with those of the 90-110min p.i. and 110-130min p.i. images, respectively. For the HCs, the concordance was 99% and 97%, respectively. **Conclusion:** Diagnostic accuracy is not compromised when quantitatively analysing FBB PET data at the 45-60min time-window. As this time-window has not yet reached steady state of the FBB cSUVR time-activity curve, further research is needed to address the question whether the use of this time-window could influence the analysis in longitudinal studies. Research support: Piramal Imaging, Berlin, Germany

Alzheimer's disease in Down Syndrome: a FDG and Amyloid PET study

V. Camacho[1], A. Fernandez-Leon[1], F. Sampedro[2], M. Carmona-Iragui[3,4,5], D. Lopez[1], E. Vilaplana[3,5], J. Fortea[3,4,5], S. Videla[4], A. Lleó[3,5], R. Blesa[3,5], I. Carrió[1]; [1]Nuclear Medicine Department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [2]Faculty of Medicine. Autonomous University of Barcelona, Barcelona, SPAIN, [3]Memory Unit, Neurology Department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [4]Down Medical Centre. Fundació Catalana Síndrome de Down, Barcelona, SPAIN, [5]Centre of Biomedical Investigation Network for Neurodegenerative Diseases (CIBERNED), Barcelona, SPAIN.

Most patients with Down's syndrome (DS) develop young onset Alzheimer disease (AD). However, the natural history of AD in DS remains unclear. The objective of this study was to evaluate the use of 18F-Florbetapir PET and 18F-FDG PET in DS patients with prodromal AD. Material and methods: we included 16 consecutive DS patients (10 without cognitive decline and 6 with prodromal AD) who underwent 18F-Florbetapir PET-CT and 18F-FDG PET-CT studies. The studies were evaluated visually and quantitatively. The quantitative analysis for FDG and Florbetapir studies was performed according to the Alzheimer's Disease Neuroimaging Initiative methodology, obtaining SUVr values in AD-related regions of interest. Results: The FDG visual analysis showed that all patients without cognitive decline presented preserved brain metabolism in FDG studies, while 2 of 6 patients with prodromal AD showed hypometabolism in parietotemporal regions. The Florbetapir visual analysis showed cortical Florbetapir uptake in 2 of 10 subjects without cognitive decline, and in all patients with prodromal AD. These results were supported by quantitative FDG and Florbetapir analysis: patients with prodromal AD showed a significant decrease in FDG SUVr values (1.36+/- 0.08 vs 1.22+/- 0.1; $p=0.012$), and a significant increase in Florbetapir SUVr values (1.02+/- 0.08 vs 1.19+/-0.1; $p=0.003$). Conclusion: FDG and Florbetapir studies may be both useful in clinical diagnostic of dementia in DS patients and might give complementary information. Florbetapir uptake starts in the preclinical phase of the disease and is present in all presimptomatic patients, while hypometabolism observed in the FDG starts later in the symptomatic phase of the disease.

Absorbed kidney doses in patients treated with different activities of Lu-177-octreotate - results of the first 100 patients treated in the Helsinki University Hospital

V. Reijonen, J. Heikkonen, H. Mäenpää; Helsinki University Hospital Cancer Center, Helsinki, FINLAND.

Aim: The routine activity of 7.4 GBq in ^{177}Lu-octreotate treatment is often reduced by 25% or 50% for clinical reasons. The effect of this reduction on absorbed kidney doses is studied. **Materials and methods:** Between February 2011 and December 2015, 100 patients had received 3.3 to 8.8 GBq of ^{177}Lu-octreotate with protecting amino acid solution. The standard protocol was to administer 7.4 GBq four times at eight week interval, but the activity was reduced to either 75% or 50% due to older age, previous chemotherapy, diabetes, hypertension, fragility, or signs of bone marrow toxicity sustained during earlier treatment cycles. The kidney region of the patients was imaged using either Symbia T2 or Intevo T6 SPECT/CT (Siemens Healthcare) at 24 hours after each treatment and also at 168 hours after the first and third treatment. The first 58 patients were scanned at 1, 72 and/or 120 hours in addition to the later standard 24 and 168 hours after each treatment to establish the method for estimating the absorbed dose to the kidneys. The activities in the left and right kidney were determined from SPECT images and the kidney volumes were defined from the axial CT slices. Also a small volume (SV) of interest (4 cm^3) was selected from the volume of maximal counts in the kidney region to estimate the maximum absorbed dose for the kidney. **Results:** We divided the treatments into three groups according to the administered activity: group 1 (n=38, range 3283-4266 MBq), group 2 (n=55, range 4600-6432 MBq), and group 3 (n=244, range 6600-8790 MBq). In group 1, the median whole kidney dose was 1.8 Gy (range 0.9-4.9 Gy) and median SV dose 3.1 Gy (range 1.4-8.4 Gy), while in group 2 and group 3, the median whole kidney doses were 3.5 Gy (range 1.0-7.6 Gy) and 3.2 Gy (range 1.0-9.2 Gy), and the median SV doses 5.6 Gy (range 1.8-19.7 Gy) and 5.5 Gy (range 1.4-16.3 Gy), respectively. The median whole kidney and SV doses were significantly smaller in group 1 than in groups 2 and 3 (Mann-Whitney, $p<0.05$), while there was no significant difference between groups 2 and 3 ($p=0.976$ and $p=0.778$). **Conclusion**: In our patient cohort, kidney doses were significantly smaller when the administered activity was reduced to about 50% of the standard protocol. However, when the administered activity was reduced to 75% of the standard protocol, the kidney doses did not scale down accordingly.

OP391

Characterisation of a planar dosimetry method estimating the absorbed dose to the bone marrow during ^{177}Lu-DOTATATE treatment

L. Hagmarker[1], J. Svensson[2], T. Magnander[1], J. Hemmingsson[1], P. Gjertsson[3], P. Bernhardt[1]; [1]Department of Radiation Physics, Sahlgrenska Academy, University of Gothenburg, Göteborg, SWEDEN, [2]Department of Oncology, Sahlgrenska Academy, University of Gothenburg, Göteborg, SWEDEN, [3]Department of Clinical Physiology, Sahlgrenska University Hospital, Göteborg, SWEDEN.

Aim: An image based method for bone marrow dosimetry, earlier presented by our research group, has shown a significant correlation between the absorbed dose to the bone marrow and haematological toxicity in ^{177}Lu-DOTATATE treatment. The aim of this study was to further evaluate and optimise the method. Materials and Methods: 46 patients with advanced neuroendocrine tumours were treated with ^{177}Lu -DOTATATE on 2-6 occasions. The patients were evaluated using the 4 planar gamma camera images collected at 2, 24, 48 and 168 hours after injection. The whole body was divided into a high- and a low uptake compartment, using a threshold based segmentation tool in the image platform PhONSAi, developed in-house. The segmentation tool starts by including the highest uptake focus and then gradually includes foci with lower and lower uptakes until a threshold is reached where the number of foci escalates. The threshold determines the proportion of the foci that is included in the two compartments. Visual inspection was used to determine the threshold value where all high uptake tissues (i.e. kidney, spleen, liver and tumours) were included in the high uptake compartment. For thresholds around this value the activity in the two compartments was determined by the conjugate view method and the bone marrow dose was calculated as a sum of the self and cross dose in the low uptake compartment and the cross dose from the high uptake compartment. Results: The visual analysis implies a threshold value of 10 % of the maximum number of foci. A correlation was found between the absorbed bone marrow dose and haematological toxicity with p-values ranging from 0.001 to 0.02 for thresholds between 2 % and 25 %, the strongest correlation was found at 15 %. The mean absorbed bone marrow dose were 0.20-0.22 Gy per 7.4 GBq for threshold values between 10-25 %, and increased to 0.28 Gy for the lower values. No significant difference was observed in coefficient of variation (8.2-8.7 %) for the individual mean absorbed doses when varying the threshold value. Conclusion: The individual variation in absorbed dose is maintained at a low level when varying the threshold value for the determination of the compartment sizes. This implies that the method is stable for estimation of bone marrow doses and its correlation to haematological toxicity.

OP392

Simulation study to determine an optimal sampling schedule for dynamic PET measurements for treatment planning in peptide-receptor radionuclide therapy

D. Hardiansyah[1,2], A. A. Attarwala[1,2], L. D. Jimenez[1,2], P. Kletting[3], F. M. Mottaghy[4,5], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Radiation Oncology, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Department of Nuclear Medicine, University Hospital Ulm, Ulm, GERMANY, [4]Klinik für Nuklearmedizin, University Hospital, RWTH Aachen University, Aachen, GERMANY, [5]Department of Nuclear Medicine, Maastricht University Medical Center (MUMC+), Maastricht, NETHERLANDS.

Aim: To determine the optimal sampling schedule for dynamic PET measurements to obtain an accurate prediction of time-integrated activity coefficients (TIACs) in peptide-receptor radionuclide therapy (PRRT). **Methods**: Parameters of a physiologically based pharmacokinetic (PBPK) model were individually fitted to the biokinetic data of 15 patients after injection of ^{111}In-DTPAOC. True mathematical patient phantoms (true MPPs) were build using the fitted parameters from the PBPK model. Dynamic PET simulations with two bed positions were performed after i.v. injection of 150 MBq of ^{68}Ga-DOTATATE (25 μg total peptide amount) for 3 different sampling schedules (SS), i.e. SS1 consisting of 1 dynamic PET scan at approximately 30 min, SS2 consisting of 1 dynamic PET scan at approximately 4 h, and SS3 which is a combination of SS1 and SS2. Four frames, with duration of 5 min each, were collected for each bed position. Organ activities of the kidneys, liver and spleen were taken from the first bed position (first 4 frames), while the tumor activities were taken from the second bed position. A PET noise model was used to add noise to the simulated data. The PBPK model was fitted again to the simulated noisy PET data using Bayesian information calculated as the mean and SD of the population. The fitted parameters were used to build the PET-predicted MPPs. A therapeutic injection of 5 GBq of ^{90}Y-DOTATATE in a 30 min infusion was simulated in both the true and the PET-predicted MPPs followed by the calculation of their TIACs. Relative variability values (v) between the therapeutic TIACs of the true and the PET-predicted MPPs for the tumor, kidneys, liver, spleen and whole body (WB) were calculated and analyzed. **Results**: Relative

variability values from the SS1 were accurate enough to predict TIACs of the organs at risk during PRRT, i.e. $v_{kidneys}$=(3.5±1.8)%, v_{liver}=(2.9 ±1.3)%, v_{spleen}=(3.5±1.6)%, and v_{WB}=(3.9±1.9)%. The variability values from SS2 and SS3 presented small differences when compared to the SS1 variabilities, i.e. for SS2 $v_{kidneys}$=(2.6±1.7)%, v_{liver}=(2.6±1.8)%, v_{spleen}=(2.6±1.8)%, and v_{WB}=(3.8±3.4)%; and for SS3 $v_{kidneys}$=(1.6 ±0.9)%, v_{liver}=(1.1±0.5)%, v_{spleen}=(1.6±0.9)%, and v_{WB}=(0.5±0.3)%. However, variabilities of predicted TIACs in the tumor showed inaccurate results for all protocols, e.g. SS1 v_{tumor}=(19.1±12.6)%, SS3 v_{tumor}=(16.1 ±13.4)% and SS3 v_{tumor}=(17.2±7.7)%. **Conclusions**: Dynamic PET scans at approximately 30 min or 4 hours p. i. in combination with the use of a PBPK model with population-based Bayesian parameters may allow both simplifying the treatment planning workflow in PRRT and improving the accuracy of predicted TIACs.

OP393

Definition of a reference organ for lesion thresholding on ^{68}Ga-DOTATATE PET/CT

G. Marin[1,2], H. Levillain[1], B. Vanderlinden[1], T. Guiot[1], I. Karfis[1], Z. Wimana[1], S. Vandenberghe[2], P. Flamen[1]; [1]Institut Jules Bordet, ULB, Bruxelles, BELGIUM, [2]MEDISIP, Ghent University, Ghent, BELGIUM.

Aim: ^{68}Ga-DOTATATE has become the radiopeptide of choice for well-differentiated neuroendocrine tumors diagnosis and follow-up. Still, there are no established guidelines for lesion segmentation. The aim of this work was to define a reference organ for lesion thresholding, assessed by their inter- and intra-patient variability. **Materials and methods:** Twelve patients from the LuMen trial underwent 3-5 ^{68}Ga-DOTATATE PET/CT every 3 months preceding each ^{177}Lu-DOTATATE administration. Long acting somatostatin analogs were discontinued 4 weeks prior to ^{68}Ga-DOTATATE PET/CT. A mean±SD activity of 1.91±0.32 MBq/kg was administered. Whole body images were acquired 63.5±9.5 minutes after injection on a Discovery 690 PET/CT (GE-Healthcare) with 10 bed positions of 2.5-3 minutes. Images were reconstructed with 3D OSEM algorithm (18 iterations, 3 subsets, 6.8 mm Gaussian post filtering, time of flight and resolution recovery corrections). Healthy kidneys, spleen and liver mean SUVs (normalized for body weight) were determined from three spherical volumes of interest (2 cm diameter) placed in each organ. Inferior left/right and superior left kidney cortex areas were considered, thus avoiding liver activity spill-in. Two larger volumes of interest were drawn in left and right buttocks. Additionally, mean and maximum SUVs were measured in a sphere centered on the pituitary. Inter-patient coefficient of variation (CoV) of mean SUVs was computed for each organ based on the baseline ^{68}Ga-DOTATATE PET/CT of each patient. Intra-patient CoV of mean SUVs was computed for each organ of each patient from the acquisitions. Median and interquartile range (IQR) of CoVs were then calculated for each organ. The same methodology was also applied to the different considered areas in the kidneys. **Results:** Regarding inter-patient variability, the kidneys had the smallest CoV (20 % versus 25, 27, 46, 32 and 36 % respectively for mean spleen, liver, buttocks, pituitary SUV and maximum pituitary SUV). No difference was noticed between the considered kidneys areas. Intra-patient CoV results were more balanced with median[IQR] equal to 12[9], 13[16], 17[11], 11[16], 16[26] and 25[25] % respectively for mean kidneys, spleen, liver, buttocks, pituitary SUV and maximum pituitary SUV. For the kidneys, the best results were found for the right kidney (12[5] % versus 16[12] and 13[15] % for the superior and inferior left). **Conclusion:** These results indicate that kidneys are the organs with the smallest inter- and intra-patient variability on ^{68}Ga-DOTATATE PET/CT and could therefore be used as a reference for lesion thresholding.

OP394

NETTER-1 Phase III in Patients with Midgut Neuroendocrine Tumors Treated with 177Lu-Dotatate: Efficacy and Safety Results

J. Strosberg[1], E. Wolin[2], B. Chasen[3], M. Kulke[4], D. Bushnell[5], M. Caplin[6], R. P. Baum[7], P. Kunz[8], T. Hobday[9], A. Hendifar[10], K. Oberg[11], M. Lopera Sierra[12], D. Kwekkeboom[13], P. Ruszniewski[14], E. Krenning[15]; [1]H. Lee Moffitt Cancer Center, Tampa, FL, UNITED STATES, [2]Markey Cancer Center, University of Kentucky, Lexington, KY, UNITED STATES, [3]Univesity of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES, [4]Dana-Farber Cancer Institute, Boston, MA, UNITED STATES, [5]University of Iowa, Iowa City, IA, UNITED STATES, [6]Royal Free Hospital, London, UNITED KINGDOM, [7]Zentralklinik, Bad Berska, GERMANY, [8]Stanford University Medical Center, Standford, CA, UNITED STATES, [9]Mayo Clinic College of Medicine, Rochester, Rochester, MN, UNITED STATES, [10]Cedars Sinai Medical Center, Los Angeles, CA, UNITED STATES, [11]University Hospital, Uppsala, Uppsala, SWEDEN, [12]Advanced Accelerator Applications, New York, NY, UNITED STATES, [13]Erasmus Medical Center, Rotterdam, NETHERLANDS, [14]Hopital Beaujon, Clichy, Clichy, FRANCE, [15]Erasmus Medical Center, Rotterdam, Rotterdam, NETHERLANDS.

Background: Currently, there are limited therapeutic options for patients with advanced midgut neuroendocrine tumors progressing on first-line somatostatin analog therapy. **Methods:** NETTER-1 is the first phase III multicentric, randomized, controlled trial evaluating ^{177}Lu-DOTA^{0}-Tyr^{3}-Octreotate (Lutathera®) in patients with inoperable, progressive, somatostatin receptor positive midgut NETs. 230 patients with grade 1-2 metastatic midgut NETs were randomized to receive Lutathera 7.4 GBq every 8 weeks (x4 administrations) versus Octreotide LAR 60 mg every 4 weeks. The primary endpoint was PFS (RECIST 1.1), with tumor assessment every 12 weeks. Secondary objectives included ORR, OS, toxicity, and quality of life (QoL) based upon EORTC QLQ-C30 and QLQ-G.I.NET21 questionnaires. **Results:** The centrally confirmed disease progressions or deaths were 23 in the Lutathera arm and 68 in the Octreotide LAR 60 mg arm. The median PFS was not reached for Lutathera and 8.4 months with control, p<0.0001, HR 0.21. The number of CR+PR was 18 (18%) with Lutathera and 3 (3%) with control (p=0.0008; n=201). At the time of the NDA submission, interim OS analysis (14 deaths in Lutathera group and 26 in control group; p=0.0043) suggests an improvement in OS. The median TTP was not reached for Lutathera and 8.7 months with control, p<0.0001, HR 0.17. Among patients treated with Lutathera, only 5% (6 patients) experienced dose modifying toxicity. Adverse events, grade 3 or 4 neutropenia, thrombocytopenia and lymphopenia occurred in 1%, 2% and 9% of patients in Lutathera arm vs. none in controls. Health related QoL surveys indicated a slight improvement in the global health status under Lutathera treatment, demonstrating that the treatment benefit of Lutathera is not offset by a negative impact on patient quality of life. **Conclusions:** The phase III NETTER-1 trial provides evidence for a clinically meaningful and statistically significant increase in PFS, TTP and ORR, and suggests an OS benefit in patients with advanced midgut NETs treated with Lutathera. The Lutathera safety and QoL profile was found to be favorable.

OP395

Tandem peptide radionuclide therapy with ^{90}Y/^{177}Lu-DOTATATE clinical results and long term side effect - 10 years' experience

J. Kunikowska[1], D. Pawlak[2], M. Bak[3], B. Kos-Kudla[4], R. Mikolajczak[2], L. Krolicki[1]; [1]Nuclear Medicine Department, Medical University of Warsaw, Warszawa, POLAND, [2]National Centre for Nuclear Research, Radioisotope Centre POLATOM, Otwock-Swierk, POLAND, [3]Department of Gastroenterology and Internal Medicine,Medical University of Warsaw, Warszawa, POLAND, [4]Division of

Endocrinology, Department of Pathophysiology and Endocrinology, Medical University of Silesia, Katowice, POLAND.

PRRT with ^{90}Y and ^{177}Lu is a form of molecular targeted therapy for the inoperable/or disseminated neuroendocrine tumors (NEN). De Jong was the first one, who described the use of combination treatment consisting of 50% 177Lu-DOTATATE and 50% 90Y-DOTATOC in rats; which demonstrated 3 times longer survival rates. It was confirm in human in our previous trial. The aim of the study was to evaluate clinical results and long term side effects of combination treatment - tandem ^{90}Y /^{177}Lu-DOTATATE in patients with disseminated neuroendocrine tumors. **Materials and methods:** 59 patients with disseminated NEN were included in the study prospectively. Therapy protocol was based on combined 1:1 90Y/177Lu-DOTATATE with activity 3.7 GBq/m2 body surface area in 3-5 cycles. Blood tests for hematology, kidney and liver function, and chromogranin A (CgA) were evaluated before therapy. All patients underwent CT scans and somatostatin receptor imaging(SRI; ^{99m}Tc-HYNICTATE or ^{68}Ga-DOTATATE). Mixed amino-acids infusion over 8 hours was used for the kidney protection. **Results:** At the time of treatment all patients showed progressive disease confirmed by CT, SRI and/or increasing CgA level. Ki-67 of primary tumours in examined group was below 20%. Clinical response defined as increase in clinical symptoms (diarrhoea, flushes, wheezing, hypoglycemia or dyspnea) was observed in 97 % patients with hormone-related syndromes before PRRT. During a median follow up of 75.8 months (range 11-121 months) the observed PFS was 32.2 months and OS was 82 months, 25 patients died. The observed 5-years overall survival was 63% and 2-years risk of progression was 39.4%. At the time of restaging 3 patient died. Treatment response according to RECIST 1.1 criteria consisted of complete response 2%, partial response in 22%, stable disease in 65% and progressive disease in 6% patients. The disease control rate was 89%. Objective Response Rate (ORR), defined as proportion of patients achieving partial (PR) or complete response (CR), was 24%. PRRT was well tolerated by all patients . One patients (2%) revealed MDS five years, after receiving after total activity 29.6 GBq. No other hematological grade 3 and 4 was observed. Renal toxicity grade 3 was observed in one patient (2%), no grade 4 was observed. **Conclusions:** The tandem ^{90}Y/^{177}Lu DOTATATE therapy is effective and safety treatment option for patients with disseminated or inoperable neuroendocrine tumors. Long term follow up revealed high disease control rate and long PFS with small number of side effects.

OP396

Correlation Between Somatostatin Receptor Expression and Molecular Response to Peptide Receptor Radionuclide Therapy in Head and Neck Paragangliomas evaluated by ^{68}Ga-DOTANOC

G. Ferreira, I. L. Sampaio, L. Sobral Violante, J. P. Teixeira, H. Duarte; Instituto Português de Oncologia Francisco Gentil, Porto, PORTUGAL.

Aim: To correlate pre-treatment somatostatin receptor expression with molecular response after completion of three peptide receptor radionuclide therapy (PRRNT) cycles, using ^{68}Ga-DOTANOC PET/CT in patients with head and neck paraganglioma (HNPGL). **Materials and methods:** Twenty-one patients (3 men and 18 women; mean age±SD, 59.0 years±13.5) with HNPGL evaluated between 2011 and 2015 were included. All patients performed two ^{68}Ga-DOTANOC PET/CT studies, one at baseline and another after completion of three PRRNT cycles with ^{177}Lu-DOTATATE. Median time between baseline ^{68}Ga-DOTANOC PET/CT and first PRRNT cycle was 2.2 months (IQR1.2) and between PRRNT completion and post treatment ^{68}Ga-DOTANOC PET/CT was 6.1 months (IQR 2.2). The median inter-scan period was 14.4 months (IQR3.1). Somatostatin receptor expression was assessed using 2 measures of standardized uptake value (SUV): maximum SUV (SUV_{max}) and tumor-to-spleen SUV ratio ($SUV_{T/S}$). SUV_{max} variation (ΔSUV_{max}) percentage and $SUV_{T/S}$ variation ($\Delta SUV_{T/S}$) percentage were used to define four categories of molecular response, based on European Organization for Research and Treatment of Cancer Criteria: Complete Metabolic Response (CMR), Partial Metabolic Response (PMR), Stable Metabolic Response (SMR) and Progressive Disease (PD). According to metabolic response, patients were divided in responders (CMR and PMR) and non-responders (SMR and PD). Wilcoxon-Mann-Whitney for independent samples tests and Spearman rank correlation tests were used ($P<0.05$). **Results:** SUV variation percentage after PRRT was highly asymmetrical in both evaluation methods, ΔSUV_{max} (mean±SD, -16.0% ±40.3, min -78.1%, max 83.5%) and $\Delta SUV_{T/S}$ (mean±SD, -7.0%±42.3, min -69.8%, max 102.5%). Metabolic responses based on ΔSUV_{max} percentage were: 10 PMR, 8 SMR, 3 PD and 0 CMR. Baseline SUV_{max} did not correlate significantly to ΔSUV_{max} percentage after PRRNT (ρ=-0.34, P=0.134). Although responders (PMR) registered a higher baseline median SUV_{max} compared to non-responders, the difference was not statistically significant (13.0 vs. 9.2, P=0.159). Metabolic responses based on $\Delta SUV_{T/S}$ were: 9 PMR, 9 SMR, 3 PD, 0 CMR. A statistically significant correlation between baseline $SUV_{T/S}$ and $\Delta SUV_{T/S}$ percentage after PRRNT was found (ρ=-0.44, P=0,022). Responders (PMR) had statistically significant higher median baseline $SUV_{T/S}$ than non-responders (14.89 vs. 8.08, P=0.012). **Conclusion:** Initial 68Ga-DOTANOC PET/CT uptake values may contribute usefully to select HNPGL patients for PRRNT. We found a statistically significant correlation between baseline $SUV_{T/S}$ and $\Delta SUV_{T/S}$ percentage (ρ=-0.44, P=0.022). Also, responders had statistically significant higher median baseline $SUV_{T/S}$ than non-responders (14.89 vs. 8.08, P=0.012). Baseline $SUV_{T/S}$ value was therefore superior to SUV_{max} for predicting molecular response to PRRNT. Clinical correlations remain to be assessed.

A Novel and Rapid [^{11}C]CO_2 to [^{11}C]CO Conversion Methodology *via* Disilane Species

C. Taddei, S. Bongarzone, A. D. Gee; King's College London, London, UNITED KINGDOM.

Introduction: Carbon-11 carbon monoxide ([^{11}C]CO) is used to produce functionalised [^{11}C]molecules, such as amides, esters and ketones.[1] [^{11}C]CO is traditionally produced by gas-phase reduction of [^{11}C]CO_2 at elevated temperatures.[2] We recently reported a novel chemical conversion of [^{11}C]CO_2 to [^{11}C]CO *via* [^{11}C]silacarboxylic acids.[3] This methodology avoids the use of high temperatures by implementing a simple and readily available set-up. It does, however, require the careful preparation of silane lithium derivatives and the addition of an activator to trigger the release of [^{11}C]CO. A recent synthetic chemistry publication reported the use of disilanes as CO releasing agents in the presence of fluoride sources.[4] Herein, we show the application of disilane species to carbon-11 chemistry. This approach obviates time consuming preparation of reagents and simplifies the experimental set-up needed. Furthermore, the generated [^{11}C]CO is transferred to a second vial containing carbonylation reagents to yield ^{11}C-labelled products of interest. Method and Results: A simple two-vial reaction set-up on an Eckert & Ziegler Modular-Lab system was used. In a first vial, a disilane species and catalytic amount of a fluoride source were dissolved in a dry aprotic solvent. [^{11}C]CO_2 was delivered from the cyclotron by a helium stream and instantaneously converted to [^{11}C]CO at 20 °C by a fluoride activated disilane carboxylate species. The released [^{11}C]CO was transferred to a second vial where a palladium-mediated carbonylation reaction was performed. The transfer of the produced [^{11}C]CO to a second vial was time-monitored. As model reactions, [^{11}C]*N*-benzylbenzamide and [^{11}C]*tert*-butyl acrylate were obtained in high radiochemical purity (≥ 85%) and short synthesis time (≤ 10 min from EOB). Conclusion: The development of a new [^{11}C]CO_2 to [^{11}C]CO conversion methodology *via*

disilanes was successfully achieved. This methodology yields [^{11}C]CO in up to 35% under very mild and rapid reaction conditions, with no time-consuming reagent preparation or complex automation required. Moreover, it represents an attractive route to synthesise [^{11}C]carbonyl-containing molecules avoiding the need for traditional high temperature gas-phase infrastructure. Research Support: This work was supported by European Commission, FP7-PEOPLE-2012-ITN (316882, RADIOMI), Medical Research Council (MRC, MR/K022733/1) and Biomedical Research Centre award to Guy's&St Thomas' NHS Foundation Trust. OP398

Novel Chemoselective [^{18}F]-Radiolabeling of Thiol-Containing Biomolecules under Mild Aqueous Conditions

A. Chiotellis[1], F. Sladojevich[2], L. Mu[2], A. Mueller-Herde[2], I. E. Valverde[3], V. Tolmachev[4], R. Schibli[2], S. M. Ametamey[2], T. L. Mindt[2]; [1]University of Nottingham, Nottingham, UNITED KINGDOM, [2]ETH Zurich, Zurich, SWITZERLAND, [3]University Hospital of Basel, Basel, SWITZERLAND, [4]Uppsala University, Uppsala, SWEDEN.

Aim: Although prosthetic groups based on maleimide chemistry are established tools for the selective and controlled introduction of an [^{18}F] label into thiol-containing (bio)molecules, there are certain limitations. These mainly include susceptibility of the addition product to hydrolysis or exchange reactions with biologically relevant reactive thiols and the formation of racemic mixtures. Recently it was reported that 2-(methylsulfonyl)-5-phenyl-1,3,4-oxadiazole reacts rapidly and specifically with thiols of biomolecules with excellent chemoselectivity at biological pH to provide conjugates with superior stability compared to the corresponding maleimide-based analogues.[1] Herein, we report a novel prosthetic group based on this oxadiazole scaffold, termed [^{18}F]FPOS (fluoroethoxyphenyloxadiazole methylsulfone), and its utility for the [^{18}F]-radiolabeling of thiol containing molecules. **Methods:** A nosylate precursor for labeling and non-radioactive reference FPOS were synthesized from methyl-4-hydroxybenzoate in a total of 6 steps and good overall yield. FPOS was conjugated with two model thiols (dodecylthiol, methyl acetyl-L-cysteinate) and two single-cysteine containing tumor targeting biomolecules; bombesin analogue AcCys(βAla)$_3$[Nle^{14}]BBN (7-14)NH$_2$, a high affinity peptide for the gastrin-releasing peptide receptor and affibody $Z_{HER2:2395}$-Cys which effectively targets the human epidermal growth factor receptor-2 (HER-2). The corresponding [^{18}F]-labeled molecules were synthesized by a two-step procedure; (i) aliphatic nucleophilic substitution of the nosylate precursor with [^{18}F] and (ii) subsequent coupling with the corresponding thiols. *In vivo* PET imaging was performed with [^{18}F]$Z_{HER2:2395}$-Cys using CD1 nude mice bearing HER2-positive SCOV3 xenografts. Nude mice with HER2-negative RAMOS xenografts were used as control. **Results:** Prosthetic group [^{18}F]FPOS was efficiently prepared within 60 min in good radiochemical yield (27±6%, d.c.) with an activity of 6-16 GBq after HPLC purification. [^{18}F]FPOS readily reacted with the two model thiols within 15 min at 37 °C to give quantitatively the corresponding [^{18}F]-labeled compounds. Reaction of [^{18}F]FPOS with AcCys(βAla)$_3$[Nle^{14}]BBN(7-14)NH$_2$ at 3.5 mM in PBS, quantitatively yielded the [^{18}F]-labeled peptide at 37 °C after 15 min with a specific activity of 54 GBq/μmol. [^{18}F]FPOS reacted with $Z_{HER2:2395}$-Cys in PBS (50 °C, 15 min) to give [^{18}F]$Z_{HER2:2395}$-Cys with 40% conversion and 17 GBq/μmol specific activity. PET imaging of the [^{18}F]-labeled affibody showed substantial accumulation of radioactivity in the SCOV3 xenografts with excellent tumor-to-background ratio whereas negligible uptake was observed in the RAMOS tumors. **Conclusion:** The novel prosthetic group based on the oxadiazole scaffold, [^{18}F]FPOS, meets all criteria for the effective and chemoselective radiolabeling of thiol containing (bio)molecules and thus represents a true alternative to the maleimide-based approaches. OP399

From [^{11}C]CO_2 To [^{11}C]Amides And [^{11}C]Ureas: A Rapid One-Pot Mitsunobu Reaction

S. Bongarzone, A. Runser, C. Taddei, A. Haji Dheere, A. D. Gee; Division of Imaging Sciences and Biomedical Engineering, King's College London, London, UNITED KINGDOM.

Background The existence of reliable chemical methods for labeling organic molecules such as ureas and amides with ^{11}C are key to the production of novel radiotracers intended for PET imaging studies. A rapid single-pot radiosynthetic approach for the production of [^{11}C]amides and [^{11}C]ureas starting from cyclotron-produced [^{11}C]CO_2 is presented. **Materials and Methods** A vial containing a solution of an amine and 1,8-Diazabicycloundec-7-ene (DBU) in acetonitrile (ACN) was placed on an Eckert & Ziegler Modular-Lab automatic system. [^{11}C]CO_2 was bubbled through the solution producing the corresponding [^{11}C]carbamate derivative. Mitsunobu reagents, tributylphosphine (Bu_3P) and di-tert-butyl azodicarboxylate (DBAD), were added to activate the [^{11}C]carbamate derivative and subsequently reacted with either a) an amine[1,2] or b) a Grignard reagent to give the corresponding [^{11}C]ureas or [^{11}C]amides respectively. The reactions were quenched with H_2O and the crude product was analysed by radio-HPLC. **Key Results** A novel strategy for radiolabeling ureas and amides starting from cyclotron-produced [^{11}C]CO_2 is presented. [^{11}C]amides and [^{11}C]ureas are obtained in moderate to excellent radiochemical purity (30-90 %) in short synthesis times (2 - 5 mins from end of [^{11}C]CO_2 delivery). This strategy was applied to radiolabel [^{11}C]melatonin with good radiochemical yield (36%) within 2 mins from end of [^{11}C]CO_2 delivery. **Conclusion** A rapid method to radiolabel ureas and amides starting from [^{11}C]CO_2 has been developed. This strategy has been successfully applied to radiolabel melatonin, a biologically relevant amide derivative. **References** [1] Haji Dheere AK, Yusuf N, Gee A (2013). ^{68}Ga in vivo chelation with tris(hydroxypyridinone) ligands

C. Imberti, S. Y. A. Terry, S. Nawaz, J. Baguña Torres, M. T. Ma, J. D. Young, S. Karagiannis, P. J. Blower; King's College London, London, UNITED KINGDOM.

Aim: Gallium uptake in several cancers is well documented and has been extensively exploited in Ga-67 citrate scans[1]. In healthy individuals Ga^{3+} accumulates in the bones, liver and spleen while slowly clearing from the blood renally[2]. In order to increase image contrast, chelation of non-tissue associated gallium might be advantageous. *Tris*(hydroxypyridinone) ligands (THP) are promising chelators for $^{68/67}$Ga owing to their ability to rapidly chelate Ga^{3+} under unusually mild conditions (neutral pH, room temperature)[3]. Here we investigate the ability of THP chelators to radiolabel with ^{68}Ga in biological systems: *in vitro,* by testing their ability of binding $^{68/67}$Ga in presence of serum and gallium-avid cancer cells and *in vivo,* by investigating the effect of THP on ^{68}Ga biodistribution in

healthy mice. **Methods:** ^{68}Ga acetate or ^{67}Ga citrate was incubated with serum, THP (10-30 μM) was then added. Speciation pre- and post-addition of THP was determined by size exclusion chromatography. A375 melanoma cells were incubated for 30 minutes with THP (1-100 μM) or PBS, followed by ^{68}Ga acetate addition and further 30 minutes incubation. Percentage cellular uptake of ^{68}Ga was measured by γ-counting. The experiment was repeated in reverse order, i.e. ^{68}Ga first followed by THP. Balb/c mice (female, 7-8 weeks) were anaesthetised, and intravenously injected with acetate buffered ^{68}Ga for dynamic nanoPET/CT scanning. THP (1-20 μg) or saline (control group) were injected at different time points after ^{68}Ga injection. Upon procedure completion, animals were sacrificed and biodistribution assessed by γ-counting. **Results:** THP is able to decrease ^{68}Ga binding to serum proteins and A375 melanoma cells when added either before or after ^{68}Ga incubation. Intravenous injection of THP (≤20 μg/mouse) resulted in a sudden change of ^{68}Ga biodistribution in healthy mice, clearly visible in the PET scans. Biodistribution data confirmed a significant increase in ^{68}Ga renal clearance (from 4.9±1.2 ID/g to 30.3±6.6 ID/g measured in kidney) and decreased bone uptake (from 6.1±1.1 ID/g to 2.8±0.2 ID/g measured in femur). HPLC analysis of the urine confirms formation of the radiolabelled THP complex. **Conclusions:** This study shows the potential of *tris*(hydroxypyridinone) chelators for ^{68}Ga-labelling in biological systems, at low concentrations, successfully dealing with competing ligands. $^{68/67}$Ga *in vivo* chelation is a useful tool to control biodistribution and excretion of ligand-free gallium in molecular imaging. **References:** 1.Larson, S.M., Seminars in Nuclear Medicine, 1978, **8**(3), 93-203. 2.Sohn, M.H. OP401

A 3D Printed Automated Synthesizer for the Rapid production of C-11 Fatty Acids

A. Amor-Coarasa, J. M. Kelly, P. Kothari, W. Qu, D. Kim, J. W. Babich; Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, NY, UNITED STATES.

Aim: Swift, robust and reliable synthesis of C-11 tracers is vital in clinical and research settings. Here we present a fully 3D printed automated synthesis unit (ASU) that exploits the advantages of solid phase fatty acid (FA) synthesis and different trapping materials for CH_3-$(CH_2)_n$-COOH of chain length, n=0 to 14. *Methods*: A fully automated FA ASU (approximately 25h×25w×15d cm) was designed using AutoCAD and all components were manufactured exclusively using a 3D printer. Moving parts for turning valves and syringe pumping were printed in nylon while the rest of the primary structure was printed in acrylonitrile butadiene styrene (ABS). High torque motors and linear actuators were used for valve turning and syringe loading/dispending, respectively. A 24 channel USB servo controller was used for control while Maestro© software controlled sequenced automation. A 13X zeolite cartridge was coupled to a 5 port DMSO-resistant manifold containing a Grignard reagent, washing and elution solutions, and a compressed gas line for assisting liquid transfers. $^{11}CO_2$ was trapped on zeolite with the box in "loading mode". Once $^{11}CO_2$ is trapped, the automated sequence is activated, lasting 5.5 - 8.5 min (depending on the fatty acid) and yielding a radiolabeled product with final formulation dependent on chain length and solubility. *Results:* The synthesizer was mainly used to synthesize ^{11}C-acetate, ^{11}C-propionate and ^{11}C-palmitate. A total of 22 sequential syntheses were performed without mechanical failure. Short target bombardments (5 min for investigational study and 15 min for pre-clinical dose preparation) were sufficient for FA production. Using a 5 min bombardment, up to 0.59 GBq ^{11}C-acetate (96.7% RCP), 2.12 GBq (65% RCP) ^{11}C-propionate and 2.98 GBq ^{11}C-palmitate (94% RCP) were obtained preformulation. Following the 15 min bombardments 1.16 GBq (97.5% RCP) ^{11}C-acetate, 0.45 GBq (99.7%) ^{11}C-propionate and 1.06 GBq (96.7% RCP) ^{11}C-palmitate were obtained in a final formulation suitable for injection. The chemical identity of each FA product was confirmed by comparison with known standards. *Conclusions:* A 3D printed ASU was designed, manufactured and shown to be robust and reliable in a pre-clinical research environment. Furthermore, it was compatible with high starting activities comparable to clinical syntheses and overcomes high internal pressures without leakage of liquids or radioactivity. On this basis, the 3D printed ASU is a practical, lower cost alternative to commercially available ASUs for the pre-clinical and clinical synthesis of fatty acids labeled with carbon-11.

OP402

Intrinsically ^{89}Zr-Labeled Self-Destructing Mesoporous Silica Nanostructures for In Vivo Tumor Vasculature Targeting

W. Cai, S. Goel, F. Chen, S. Shi, H. F. Valdovinos, T. E. Barnhart; University of Wisconsin-Madison, MADISON, WI, UNITED STATES.

Objective: We present a systematic study of in vitro/in vivo behavior of biodegradable mesoporous silica nanoparticle (**bMSN**), designed to carry multiple cargos (both small and macromolecular drugs) and subsequently self-destruct over time after drug release. Chelator-free labeling of bMSNs with ^{89}Zr ($t_{1/2}$=72.8 h) was used to track their in vivo pharmacokinetics and CD105 targeting capability via PET imaging. **Methods:** Multi-generational bMSNs with tunable pore diameters were synthesized using a bi-phase stratification approach and thoroughly characterized. In vitro degradation and dual drug loading and release studies were carried out in simulated body fluid (SBF) for 14 days and assessed using standard techniques. bMSNs were intrinsically radiolabeled with oxophilic radionuclide ^{89}Zr, followed by conjugation with polyethylene glycol (PEG) and TRC105 (an antibody specific for CD105) to form (^{89}Zr)bMSN-PEG-TRC105 for in vivo PET imaging in 4T1 breast cancer model. Comprehensive in vitro/in vivo/ex vivo experiments were carried out to evaluate the stability, pharmacokinetics, and tumor vasculature targeting of the nanoconjugates. **Results:** Degradation of nanocarriers into biocompatible and non-toxic byproducts presents a favorable prospect for their clinical translation. We engineered dendritic bMSNs with spoke-like radiating bimodal mesoporous channels. The hierarchically structured large pore size (5.4 nm and 12 nm) of bMSNs resulted in rapid and complete degradation in SBF within 21 days, while solid silica and mesoporous silica (with smaller pore size) controls showed marginal degradation. The mesostructure further allowed greater co-encapsulation and gradual pH-dependent release of small and large biomolecular drugs. Excellent ^{89}Zr-labeling yield (~98% within 2 h) and radiostability (>95% up to 72 h) were observed. CD105 specificity of (^{89}Zr)bMSN-PEG-TRC105 was confirmed in vivo with PET imaging showing significantly enhanced tumor uptake (4.5 ±0.6, 11.2±2.1, 11.5±1.3 and 11.2±0.9 %ID/g at 0.5, 6, 24 and 48 h post-injection; n=4), compared to non-targeted and blocking controls. CD105 specificity was further confirmed with ex vivo biodistribution and histological examination. **Conclusion:** We report the first systematic in vivo study of intrinsically ^{89}Zr-labeled bMSNs, targeting CD105 that is overexpressed on tumor neovasculature. The simple, versatile and readily tunable approach shows great potential for bench-to-bedside transition of personalized nanomedicine. The nanoconjugates can be readily tailored to (i) label a plethora of diagnostic/therapeutic radioisotopes without the need for tiresome specific chelator chemistries, (ii) carry small molecule and large biomolecular drugs concurrently for combination therapy, (iii) target multiple tumor types since CD105 is overexpressed on most solid tumor neovasculature, and (iv) auto-destruct and excrete from the body overtime.

OP403

How to gain higher specific radioactivity? A Quality Control (QC) approach

L. Nics[1], B. Steiner[1], E. Klebermass[1], M. Hacker[1], M. Mitterhauser[2], W. Wadsak[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]Ludwig Bolzmann Institute for Applied Diagnostics, Vienna, AUSTRIA.

Aim: Time is the limiting factor regarding preparation of radiopharmaceuticals labeled with short-lived radionuclides (e.g. carbon-11, nitrogen-13, gallium-68), especially when both high radioactive yield and specific radioactivity are desired. It is well known, that radioactive decay starts immediately after end of bombardment - even before delivery of the radionuclide to the synthesis unit. After quality control (QC) and final release of the product there is no more influence from the lab's side. Concerning in-vivo applications, it is of utmost importance for radiotracers binding to saturable targets such as receptors and transporters that for high occupancy at the binding sites, high specific radioactivity is crucial. Optimization of the chemical synthesis process as well as the subsequent purification can lead to a significant time reduction. So far, QC procedures are not considered to its full extent in that regard. When determining specific radioactivity and radiochemical purity, high performance liquid chromatography (HPLC) is mostly the method of choice. Knowing, that HPLC is the most time consuming step in QC process, aim of present work was to implement an ultra-HPLC ((U)HPLC) method[1] for different carbon-11 based radiotracers such as (+)-[^{11}C]PHNO[2], [^{11}C]Harmine, [^{11}C]mHED and [^{11}C]Erlotinib to shorten this HPLC-based QK-step and enhance specific radioactivity. **Methods**: HPLC analyses were performed on an (U)HPLC Agilent 1260 system equipped with: quaternary pump/multi-wavelength UV-detector/manual injector/radio-detector/Elysia-Raytest software. HPLC column: Waters X-Bridge BEH Shield RP-18 (4.6x50mm, 2.5µm, 130Å); mobile phase: (A) 100mM ammonia-phosphate-buffer, pH 2.1 including 5mM sodium-1-octasulfonate; (B) 90% ACN/10% aquadest. (v/v); (C) Aqua purificata (HPLC grade); (D) 50mM ammonia-phosphate-buffer, pH 9.3. HPLC conditions: (+)-[^{11}C]PHNO: 33%A/20%B/14%C/33%D, flow rate 1.6mL/min (0-30"), then 1.0mL/min, wavelenght 280nm; [^{11}C]Harmine: 44%B/56%D, flow rate 1.7mL/min (0-15"), then 1.0mL/min, wavelenght 246nm; [^{11}C]mHED: 34,5%A/11%B/20%C/34,5%D, flow rate 1.6mL/min (0-45"), then 1.0mL/min, wavelenght 275nm; [^{11}C]Erlotinib: 25%A/36%B/39%C, flow rate 1.7mL/min (0-17"), then 1.5mL/min (17"-35"), then1.0 mL/min, wavelength 334nm. **Results**: Retention times for precursors/products/total HPLC runtimes (rt): (+)-HNO 23sec, (+)-PHNO 41sec,rt 1.0min; Harmol 20sec, Harmine 39sec, rt 55sec; Metaraminol 56sec, mHED 1min18sec, rt 1min35sec; 6-O-desmethyl-erlotinib 25sec, Erlotinib 46sec, rt 1min5sec. **Conclusion**: The present work demonstrates the importance of shortening the QC process especially time consuming HPLC analyses when working with short-lived radiopharmaceuticals. The resulting increase in specific radioactivity of up to 15% for all tested compounds ((+)-[^{11}C]PHNO, [^{11}C]Harmine, [^{11}C]mHED and [^{11}C]Erlotinib) suggests an implementation of these optimized chromatographic protocols into routine QC. Prospective non-invasive evaluation of CXCR4 expression for diagnosis of MALT lymphoma using ^{68}Ga-Pentixafor PET/MRI- initial experience

A. Leisser[1], M. Raderer[2], M. Mayerhöfer[3], W. Wadsak[1], M. Mitterhauser[1], M. Hartenbach[1], S. Pfaff[1], S. Kropf[4], M. Hacker[1], A. R. Haug[1]; [1]Medical University of Vienna, Division of Nuclear Medicine, Vienna, AUSTRIA, [2]Medical University of Vienna, Department of Internal Medicine I, Vienna, AUSTRIA, [3]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Vienna, AUSTRIA, [4]Scintomics GmbH, Fuerstenfeldbruck, GERMANY.

Aim: MALT lymphomas are a challenge for non-invasive diagnosis. So far, biopsy is still needed for staging and re-staging. MALT lymphoma express the chemokine receptor CXCR4 on a regular basis, and ^{68}Ga-Pentixafor has shown to quantify CXCR4 expression non-invasively (1-4). Based on these findings, we evaluated for the first time ^{68}Ga-Pentixafor PET/MRI for non-invasive diagnosis of MALT lymphoma. Materials and methods: We prospectively included 10 patients with MALT lymphoma in this pilot study (5 male, mean age 67). Localisations were stomach (n=3), lung (n=3), kidney (n=2), palatine tonsil and orbita (n=1). Precursor for ^{68}Ga-Pentixafor synthesis was provided by Scintomics in GMP grade. 60 minutes after application of 172 MBq ^{68}Ga-Pentixafor whole-body PET images were acquired with 5 minutes per bed position. Simultaneously the following MRI sequences were acquired: axial T1 vibe Dixon, coronal T2 haste, axial diffusion weighted images (ADC, b_50, b_800). We evaluated the uptake (SUVmax, SUVmean, SUVpeak) and volume in MALT lymphoma and the SUVmax in the liver as background. All MALT lymphomas were verified by biopsy. Results: In all patients the MALT lymphoma showed increased uptake of ^{68}Ga-Pentixafor. Mean SUVmax was 12.3 (range 4.1-25.4), SUVmean 6.0 (range 2.9-10.2), and SUVpeak 7.3 (range 7.1-22.7; 2 patients with low tumor volume were not evaluable). The mean SUVmax of the liver was 1.8. The tumor-to-background ratio was excellent with mean 7.1 (range 2.4-14.9). The mean tumor volume was 90 ml (range 3.4-306). Conclusion: In this pilot study all MALT lymphoma had high 68Ga-Pentixafor uptake with excellent tumor-to-background ratios and, therefore, enabling non-invasive detection. 1. Prognosis value of baseline total metabolic tumor volume (TMTV) in advanced Hodgkin lymphoma (HL) : Ancillary study of AHL2011 LYSA trial

S. Kanoun[1,2,3], A. Berriolo-Riedinger[2], I. Tal[4], V. Edeline[5], A. Cottereau[6], P. Brice[7], R. Bouabdallah[8], G. Salles[9], A. Stamatoullas[10], J. Dupuis[6], M. Andre[11], N. Mounier[12], C. Ferme[13], M. Meignan[6], R. Casasnovas[14]; [1]LE2I, UMR CNRS 6306, Dijon, FRANCE, [2]Centre Georges Francois Leclerc, Dijon, FRANCE, [3]CHU Dijon, Dijon, FRANCE, [4]Beth Israel Deaconess Medical Center, Boston, MA, UNITED STATES, [5]Institut Curie, Paris, FRANCE, [6]Hopital H. Mondor, Creteil, FRANCE, [7]AP-HP at Saint-Louis Hospital, Paris Diderot- Sorbonne University, Paris, FRANCE, [8]Cancer Center Institut Paoli-Calmettes, Marseille, FRANCE, [9]University De Lyon, Hospices Civils De Lyon, Lyon, FRANCE, [10]Centre Henri Becquerel, Rouen, FRANCE, [11]Centre Hospitalier Universitaire Mont-Godinne, Dinant, BELGIUM, [12]CHU l'Archet, Nice, FRANCE, [13]Institut Gustave Roussy, Villejuif, FRANCE, [14]Hôpital Le Bocage, Dijon, FRANCE.

Aim: The TMTV assessed on the baseline FDG-PET is a novel approach of tumor burden measurement. It has been reported to influence HL outcome in a retrospective series (Kanoun, EJNM 2014). We designed a study evaluating the TMTV prognosis value in patients (pts) prospectively

enrolled in a phase III randomized trial testing a treatment strategy driven by PET, compared to a standard treatment not monitored by PET. Methods: Eligible pts had to be enrolled in the AHL2011 trial (NCT01358747) and to have a baseline PET (PET0) available for central review and TMTV calculation. Pts were 16-60 y, with a previously untreated advanced HL (Ann-Arbor stage III, IV or high risk IIB) and were randomly assigned to a treatment strategy driven by PET after 2 escalated BEACOPP (BEA) cycles (PET2), delivering 4 cycles of ABVD for PET2- pts and 4 cycles of BEA for PET2+ pts or a standard treatment not monitored by PET and delivering 6 cycles of BEA. PET2 were centrally reviewed and interpreted according to Deauville criteria. TMTV was computed on PET0 by summing the metabolic volumes of the individual lesions using the 41% SUVmax thresholding method already described in lymphoma.Results: 392 pts with a median age of 30 y were included: 64% were male, 89% had stage III/IV, and 59% an IPS≥3. Median TMTV was 200 ml (23 - 2149). Using a X-tile method a 350 ml cut off value was identified from a training set (n = 262) and confirmed in a validation set (n = 130) of pts obtained from the whole series. With a 16 months median follow up, 2y-PFS was 81% vs 93% in pts with high and low TMTV respectively in the whole population (p = 0.0015; HR = 3). PET2 positivity was also related to a lower 2y-PFS compared to PET2- pts (76% vs 92%; p<0.0001). Then 3 groups could be identified: pts with either [high TMTV and PET2+ (n = 23; 6%)], or [high TMTV and PET2-, or low TMTV and PET2+ (n = 103; 27%)], or [low TMTV and PET2- (n = 261; 67%)] had a 61%, 88%, 94% 2y-PFS respectively (p<0.0001). Conclusions: TMTV predicts the outcome of young advanced HL pts independently of the early metabolic response to treatment. The combination of TMTV and PET2 allows identifying 3 subsets of HL pts with significantly different outcome that may help clinician to better tailor therapy.

OP407

FDG-PET/CT at Relapse Predicts Survival in Multiple Myeloma

B. JAMET, 44000, C. Bailly, L. Planche, T. Carlier, T. Eugene, C. Touzeau, C. Ansquer, P. Moreau, F. Kraeber-Bodéré, C. Bodet-Milin; University Hospital, Nantes, FRANCE.

AIM: Multiple myeloma (MM) is a B-cell neoplasm characterized by aberrant expansion of plasma cells, typically within the bone marrow but with increased extramedullary sites with disease relapse/progression, which arises inevitably. At relapse, recommended imaging includes skeletal survey and MRI and interest of FDG-PET/CT should be confirmed. This retrospective study evaluated the benefit of FDG-PET/CT to predict the survival of MM patients, at suspected or biochemical proved relapse. **MATERIALS AND METHODS**: 45 patients with a history of MM have been included, all initially treated as recommended by the IMWG's guidelines (median time from diagnosis to suspected or biochemical proved relapse: 42 months (range, 5 to 169)). All patients were examined with FDG-PET/CT. Visual focal lesions (FLs), bone marrow involvement (BMI), extra-medullary disease (EMD)) and quantitative PET parameters (SUVmax, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of hottest lesions, whole-body MTV (MTVT)) were evaluated. Kaplan-Meier method, Logrank tests, univariate and multivariate Cox analyses were used to analyze whether PET and usual international prognostic parameters (International staging system score (ISS), cytogenetic abnormalities (FISH analysis of del(13q), t (4;14), del(17p)) could predict free-progression survival (PFS) and overall survival (OS). **RESULTS**: The median age at diagnosis was 61 years (range, 33 to 80) and median follow-up after PET/CT was 18 months (range, 1 to 64) for living and 19 months (range, 7 to 28) for dead patients. 34/45 patients had a positive FDG-PET/CT, including 6/11 (54,5%) without abnormality of electrophoresis or free light chain level (FLC). The first multivariate analysis performed in the entire cohort showed that positive FDG-PET/CT affected PFS, (P=0.02) whereas ISS and cytogenetic abnormalities did not. Univariate analysis realised in positive FDG-PET/CT patients showed that presence of ≥2 EMD lesions was correlated with shorter OS (P<0.001) and presence of ≥17FLs (P=0.003), ≥4FLs in the appendicular skeleton (P=0.0057), SUVmax (P=0.04) and TLG≤24.22 (P=0.01) predicted shorter PFS. MTVT, ISS, cytogenetic abnormalities were not predictive for PFS or OS. Multivariate analysis performed in this subgroup of positive FDG-PET/CT patients highlighted that only presence of ≥17FLs (P=0.03) was an independent variable adversely affecting PFS whereas presence of ≥2 EMD had a limit prognostic value for OS (P=0.06). **CONCLUSION:** Our study showed interest of FDG-PET/CT in MM patients with suspected relapse, especially in patients with normal electrophoresis and FLC. Positive FDG-PET/CT predicted PFS and number of FLs, SUVmax, TLG, and presence of EMD lesions showed prognostic value.

OP408

Chronic Lymphocytic Leukemia: Computational analysis of PET/CT images as new window for evaluating disease clinical course

R. Piva[1], F. Fiz[1,2], S. Matis[3], A. Ibatici[4], M. Miglino[4], C. Neumaier[5], A. Nieri[1], M. Bauckneht[1], S. Morbelli[1], A. Orengo[1], M. Piana[6], G. Cutrona[3], G. Sambuceti[1], F. Fais[7], C. Marini[8]; [1]Chair of Nuclear Medicine, Genoa University, IRCCS San Martino-IST, Genoa, Italy, Genoa, ITALY, [2]Nuclear Medicine Unit, Department of Radiology, Uni-Klinikum Tübingen, Germany, Tubingen, GERMANY, [3]Molecular Pathology Unit, Genoa University, IRCCS San Martino-IST, Genoa, Italy, Genoa, ITALY, [4]Department of Haematology and Bone Marrow Transplants, IRCCS Martino-IST, Genoa, Italy, Genoa, ITALY, [5]Department of Radiology, Genoa University, IRCCS San Martino-IST, Genoa, Italy, Genoa, ITALY, [6]Department of Mathematics, University of Genoa, Italy, Genoa, ITALY, [7]Department Experimental Medicine, University of Genoa, Genoa, Italy, Genoa, ITALY, [8]CNR Institute of Molecular Bioimaging and Physiology, Milan, Section of Genoa, Genoa, Italy, Genoa, ITALY.

Aim. Chronic Lymphocytic Leukemia (CLL) is a heterogeneous disease, characterized by low-grade proliferation of immature B-cell clone. Existing evidence indicates that interaction between neoplastic clone and bone marrow (BM) environment is key in disease progression. The present study utilized a computational application to quantify bone alterations and metabolic changes in a cohort of patients, with different disease stages, submitted to whole-body FDG-PET/CT. **Materials and Methods**. FDG-PET/CT images of 33 CLL patients (12 Binet A, 13 Binet B and 8 Binet C, mean age 70±11 years) were analyzed. The algorithm measured the ratio between trabecular and total bone volume (IBV/SV). Active "red" BM volume, defined as all intrabone voxels with SUV>1.11 according to our previously published normalcy data-base, was normalized for ideal body weight (IBW). Data in the whole skeleton and on axial/appendicular districts were compared with corresponding findings in 36 sex/age-matched controls. **Results** IBV/SV ratio was markedly increased in CLL patients with respect to controls (39±4% vs. 30±6%, p<0.001), signaling presence of cortical bone erosion in these subjects. This phenomenon was particularly pronounced in Binet C patients (42.7±5.6%, p<0.01 vs. Binet A/B) and equally involved axial and appendicular skeleton. Likewise, CLL was associated with an expansion of active BM (10.4±3.4 vs. 7.4±3.2 ml/Kg IBW, p<0.05) whose normalized value reached its maximum Binet C stage (13.8±3.7, p =0.01 vs. Binet A/B). Similarly, CLL progression was paralleled by an acceleration in glucose metabolism of hematopoietic tissue whose mean SUV was significantly higher in stage C patients with respect to A/B ones, both in total (1.9±0.5 vs 1.66±0.12, p=0.01 vs A/B) and in axial body skeleton (2.0±0.5 vs 1.7±0.14, p<0.001 vs A/B). **Conclusions.** CLL is associated with bone erosion and increased glucose consumption of active BM. Degree of these manifestations is stage-dependent. Computational analysis of PET/CT images might represent a new window for evaluating the CLL clinical course.

OP409

Computational-Based PET/CT Evaluation Can Detect and Stage the Metabolic Changes, Linked to the RANKL/RANK Loop, in Chronic Lymphocytic Leukemia

F. Fiz[1], R. Piva[1], S. Matis[2], A. Nieri[1], S. Bruno[2], G. Ferrarazzo[1], P. Giannoni[3], D. De Totero[2], M. Bauckneht[1], S. Morbelli[1], A. Orengo[1], G. Cutrona[2], F. Fais[2], G. Sambuceti[1], C. Marini[4]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY, [2]Molecular Pathology Unit, University of Genoa, Genoa, ITALY, [3]Department of Experimental Medicine, University of Genoa, Genoa, ITALY, [4]National Council of Research, IBFM, Genoa, ITALY.

Aim. Chronic Lymphocytic Leukemia (CLL) is a heterogeneous disease, characterized by progressive insensitivity to apoptotic signals and to cytotoxic treatments. In CLL, overexpression of surface receptor associated with nuclear-factor kB and its ligand (RANK/RANKL) share the capability to bolster clonal proliferation and to prevent apoptosis. Furthermore, they can disrupt the niche environment via osteoclast activation. Both clone activation and skeletal erosion can potentially be detected by PET/CT. Accordingly, we recently reported that bone-erosion, detected at X-ray CT, is a strong predictor of disease outcome. This study aimed to verify the correlation between cellular expression of RANKL/RANK and bone marrow metabolism (as an index of CLL cells proliferation) as well as between RANKL expression and skeletal alterations. Materials and Methods. We applied dedicated software to estimate total (TBV) trabecular (IBV) and compact bone volumes (CBV) as well as total active bone marrow asset, in 30 prospectively enrolled CLL patients submitted to ^{18}F-fluoro-deoxyglucose PET/CT imaging. Before tracer injection, blood was sampled to evaluate expression of RANK/RANKL and CD38%. Whole-body FDG imaging was performed according to the standard procedure while SUV of intrabone volume was normalized for blood-pool (N-SUV). Results. Skeletal erosion was confirmed in this population with IBV/TBV displaying a progressive increase from Binet A to Binet C stage. Bone erosion was more pronounced in patients with >20% CD38+ cells with respect to the remaining ones (37±4% vs. 41 ±4%, respectively, $p<0.05$). Percentage of cells positive for both markers significantly and progressively increased from Binet A to Binet C stage (9.8%±0.5% vs. 19%±3.5%, respectively, $p<0.05$). Bone marrow N-SUV in the whole skeleton significantly correlated with double positive cells ($R=0.61$, $p<0.01$). This relationship was reproduced in the axial bone segments while it was relatively less pronounced in the appendicular ones. Conclusion. Our imaging study documents that RANK/RANKL loop contributes to bone marrow involvement by CLL. Integrated analysis of PET/CT images can improve accuracy of CLL staging.

OP410

11C-Methionine PET/CT in Multiple Myeloma: Comparison with 18FDG PET/CT and Diagnostic Value through Clinical and Biological Parameters

B. Garcia, M. Morales, E. F. Guillen, R. Figueroa, M. Marcos, V. Moran, R. Ramos, J. San-Miguel, M. J. Garcia-Velloso, J. A. Richter; Clinica Universidad de Navarra, Pamplona, SPAIN.

AIM Multiple Myeloma (MM) remains as incurable hematologic malignancy arising from clonal plasma cells. The purposes of this study were to analyse the diagnostic accuracy of PET/CT performed with ^{11}C-methionine (MET) as a radiolabelled amino acid tracer compared with ^{18}FDG, to correlate the results with clinical and biological parameters, and to evaluate the clinical usefulness of the aforementioned radiotracers by studying their diagnostic yield. **MATERIALS AND METHODS** The study group comprised 26 patients (53% women, ranged 32-73 years) with plasma cells malignancy (4 solitary plasmacytomas, 3 smoldering myelomas, and 19 MM) who underwent both MET- and ^{18}FDG-PET/CT for staging or restaging the disease. Tracer uptake in focal lesions (FL) was evaluated, and the number of FL and the standard uptake values (SUV) were interrelated with clinical/biological parameters of disease activity. **RESULTS** Concerning the definite diagnosis per patient, the accuracy values of MET (Sensitivity=100%, Specificity=88%, Positive-Predictive-Value=95%, Negative-Predictive-Value=100%) seemed to be superior to those reached with ^{18}FDG (Sensitivity=94%, Specificity=75%, Positive-Predictive-Value=89%, Negative-Predictive-Value=86%). MET detected FL in 16/26 subjects (61%) and ^{18}FDG in 17/26 (65%). The number of FL observed with MET was higher than that with ^{18}FDG in 56% of these patients (mean=4 in the subjects who presented <20FL) markedly in the cranial vault. Only in 2 patients ^{18}FDG revealed FL that were negative with MET, one of which was demonstrated by biopsy as non-malignant; the other one was considered as a false-positive result of ^{18}FDG in the definite diagnosis using standard clinical criteria. SUV was calculated in 46 FL and the values with MET were significantly higher than those obtained with ^{18}FDG [median (IQR)= 4.96 (2.05 - 6.71) *vs* 1.86 (1.32 - 3.03); $p<0.001$]. Cohen's kappa coefficient between both radiotracers (0.81) showed a very good agreement ($p<0.001$). The levels of M-component and the kappa/lambda ratio were associated with a significant increase in the SUV only with MET PET/CT ($p<0.05$) and not with ^{18}FDG PET/CT. **CONCLUSION** Uptake of MET tended to be higher than that of ^{18}FDG, and an equal or greater number of FL per patient was mostly depicted by MET, particularly shown in the cranial vault. The data also suggested that MET is a more accurate tracer of tumour burden and disease activity than ^{18}FDG.

OP411

^{18}F-FDG PET/CT in diagnosis of Plasma cell disorders: From MGUS to Multiple Myeloma - correlation with histopathology

A. S. Manglunia, A. D. Puranik, S. D. Vitalkar, T. V. Dhote, N. R. Thaker; Bombay Hospital & Medical Research Centre, Mumbai, INDIA.

Introduction: Multiple myeloma is a malignant disorder of plasma cells, which is characterized by infiltration of bone marrow and excess production of monoclonal immunoglobulins. The disease classification varies widely from monoclonal gammopathy of undetermined significance (MGUS) to symptomatic multiple myeloma (MM). Usual investigations include serum protein electrophoresis, bone marrow aspirate (BMA) and biopsy (BMB), x-ray skeletal survey, CT or MRI. The role of imaging in multiple myeloma is crucial - in the initial staging of the disease, to assess complications, and in the evaluation of treatment response. However, there is a lack of standardized imaging protocol for both recently diagnosed patients and patients on follow-up. Our study was aimed to assess the role of F18-FDG PET-CT in the patients with suspected multiple myeloma. Materials and Methods: We carried out prospective study of the patients clinically suspected to have multiple myeloma and referred to PET/CT department of our hospital. 39 patients, comprising of 21 males and 18 females underwent whole body PET/CT with intravenous contrast. SUV max was documented for every lesion. CT imaging features were also considered. Mean age of the patients was 62.5 years (SD 10.2 years). Most common presenting symptom was backache and the median symptomatic period was 2 months. Out of 39 patients, 17 patients were eventually diagnosed with Multiple Myeloma based on the BMB, 5 were diagnosed with plasmacytoma and 4 were classified as MGUS. Rest 13 patients were diagnosed with other medical conditions. Results: For multiple myeloma, the sensitivity of whole body FDG PET/CT was 94.12% (16/17) and specificity was 84.62%. SUV max of MM patients ranged from 6.5 to 28.0 (mean 13.35). PET-CT correctly diagnosed 4 out of 5 patients with solitary plasmacytoma. In the 4 patients diagnosed with MGUS, PET-CT study showed no

metabolically active disease or lesion, thus corroborating with the biochemical diagnosis. Conclusion: The results showed that PET/CT is a valuable tool to confirm MM in cases of clinical suspicion. In addition, quantitative parameter of SUV max can help differentiate between active myeloma and MGUS. Multiplicity of lesions helps in differentiating between MM and plasmacytoma. Overall, PET/CT with its metabolic dimension and morphological features has been shown to have high sensitivity and specificity in patients clinically suspected of multiple myeloma.

OP412

Use of 99m-Tc labeled Zolendronic acid in Myeloma patients

V. Y. Sukhov[1], **K. Zaplatnikow**[2]; [1]ARCEM n/a A.M.Nikiforov of MES Russia, St. Petersburg, RUSSIAN FEDERATION, [2]MÄZ, Department for Nuclear Medicine, NÜRNBERG, GERMANY.

OBJECTIVES: Resistant to cleavage by bisphosphonates (BPs) - synthetic analogues of natural bone matrix pyrophosphates, were shown to be effective in treatment of patients with different malignant tumors, incliding primary diagnosed or relapsed multiple myeloma (MM). Zolendronic acid (ZdA) most strongly inhibits osteoclasts activity, since it has unique ability to block synthesis of mevalonate, which is basic substance in formation and upkeep of osteoclasts activity. However, recently there was no possibility of direct prediction of BFs action and evaluation of their effectiveness. Introduction of new tracer labeled ZdA allowed visualization of BFs accumulation in bone. METHODS: Study included 37 patients with newly diagnosed MM, average age of 62 (29-79) y.o., 16 men and 21 women with radiographic evidence of osteolytic lesions. Besides of other diagnostics methods algorithm also included Whole-body Bone Scan (WbBS) with 99m-Tc-ZdA. As a treatment posology 90 mg of pamidronate or 4 mg of ZdA were additionally prescribed to 9 and 29 patients, respectively, as i.v. infusions every 3-4 weeks. All patients underwent repeated WbBS procedures after BFs each treatment. RESULTS: 99m-Tc-ZdA was successful in finding of known osteolytic lesions in 32 patients, while equivocal results were in 5 cases. BFs therapeutic procedures (range 1 to 6) were prescribed upon WbBS resuults of ZdA focal uptake. Majority of patients with high 99m-Tc ZdA uptake at WbBS showed good response to BFs therapy. Partial response (PR) was achieved in 86% of cases (32 of 37 patients) from ZdA-group, noted by reduction number of lesions and/or decrease of 99m-Tc-ZdA uptake and also lowering levels of biochemical markers of bone metabolism. In 1 patient treated with ZdA and all pamidronate-treated patients no PR was observed (registered progression of disease), which necessitated use of other therapeutic schemes. CONCLUSION: Study showed that WbBS with a labeled analogue of a therapeutic agent 99m-Tc-ZdA is a feasible and affective diagnostic procedure. We can suggest prediction of response to treatment with BPs and evaluation its effectiveness. Level of response depends on tracer uptake in MM pathological foci. This information is greatly valuable for correct agent choice from available spectrum of BPs to prevent further progression of disease and obtain therapeutic effect. WbBS with ZdA contributes to correct pathogenetic understanding of specific disease stages that helps identifying choice of therapeutic regimens and use of definite BF. It helps to determine various forms and stages of MM that require different therapeutic modes and schemes of BFs use.

Combined ^{18}F-fluorocholine PET and MR imaging of vulnerable atherosclerotic plaques: prospective study with immunohistochemical validation

S. Vöö[1], R. Kwee[1], J. Sluimer[1], F. Schreuder[1], R. Wierts[1], R. van Oostenbrugge[1], M. J. Daemen[2], F. M. Mottaghy[1], M. E. Kooi[1]; [1]Maastricht University Medical Center, Maastricht, NETHERLANDS, [2]Amsterdam Medical Center, Amsterdam, NETHERLANDS.

Purpose: ^{18}F-fluorocholine (^{18}F-FCH) emerges as a possible molecular tracer for positron emission tomography (PET) in assessing macrophage infiltration and detecting active inflammation. We hypothesized that ^{18}F-FCH PET is a valuable imaging tool for the identification of vulnerable plaques and associated intraplaque inflammation. **Methods and Materials:** Ten consecutive stroke patients (90% men, median age 66.0 years, range 51.7-77.4) with ipsilateral >70% carotid artery stenosis and who underwent carotid endarterectomy (CEA) were included. Prior to CEA, all patients underwent PET+MRI to assess maximum ^{18}F-FCH uptake in ipsilateral symptomatic carotid plaques and contralateral asymptomatic carotid arteries (given as maximum target-to-background ratio, TBRmax) and plaque components. Macrophage content was assessed in all CEA specimens as percentage of $CD68^+$-staining per whole plaque area ($CD68^+$) and as maximum $CD68^+$ percentage (CD68max) in the most inflamed section/plaque. **Results:** Dynamic PET imaging demonstrated that an interval of 10 minutes between ^{18}F-FCH injection and PET acquisition is appropriate for carotid plaque imaging. TBRmax in ipsilateral symptomatic carotid plaques correlated significantly with $CD68^+$ (ρ=0.648, p=0.043) and CD68max (ρ=0.721, p=0.019). TBRmax was significantly higher in symptomatic carotid plaques compared to the asymptomatic carotid arteries (median of 2.0, interquartile range [IQR], 1.6-2.6 versus median of 1.2, IQR 1.1-1.5, p=0.047). In univariate linear regression, TBRmax was not significantly related to carotid artery stenosis grade. TBRmax correlated significantly with the percentage of plaque lipid-rich necrotic core on MR ($p<0.05$), but not with the degree of plaque calcifications. **Conclusion:** ^{18}F-FCH uptake in human carotid atherosclerotic plaques correlated strongly with the degree of intraplaque inflammation and recent symptoms. Therefore, ^{18}F-FCH PET is a promising tool for the evaluation of vulnerable carotid plaques.

OP417

Non-invasive assessment of atherosclerotic carotid plaques by 18F-FDG positron emission tomography/computed tomography (PET/CT) imaging and microwave radiometry (MWR): validation with histopathological and immunohistochemical findings

A. Georgakopoulos[1], I. Koutagiar[2], N. Pianou[1], G. Benetos[2], E. Athanasiadis[3], G. Agrogiannis[4], K. Filis[5], N. Bessias[6], C. Klonaris[7], G. Spyrou[3], E. Tsiamis[2], E. Siores[8], D. Tousoulis[9], K. Toutouzas[2], **C. D. Anagnostopoulos**[1]; [1]Biomedical Research Foundation of the Academy

of Athens, Center for Clinical Research, Experimental Surgery and Translational Research, Athens, GREECE, [2]Athens Medical School, Hippokration Hospital, Athens, GREECE, [3]Center of Systems Biology, Biomedical Research Foundation of the Academy of Athens, Athens, GREECE, [4]Department of Pathology, Athens Medical School, Athens, GREECE, [5]First Department of Cardiology, Hippokration Hospital, Athens, GREECE, [6]Department of Vascular Surgery, General Hospital "Korgialenio-Benakio National Red Cross", Athens, GREECE, [7]University of Athens, Laiko Hospital, Department of Propedeutic Surgery, Athens, GREECE, [8]University of Bolton, Centre for Materials, Research and Innovation, Bolton, UNITED KINGDOM, [9]Athens University Medical School, Athens, GREECE.

Background and aim: ^{18}F-Flurodeoxyglucose (^{18}F-FDG) PET/CT imaging is a robust technique for atherosclerosis assessment, however high cost and patient exposure to radiation limit its use in everyday practice as a screening tool for evaluation of plaque inflammation. Microwave Radiometry (MWR) is a low cost non-invasive and safe diagnostic modality allowing in vivo evaluation of carotid inflammation by measuring internal temperatures of tissues. In this study, we explore the relationship between temperature measurements and carotid ^{18}F-FDG uptake and assess their association with histological and immunohistochemistry findings in patients with high-grade carotid artery (CA) stenosis. Materials and Methods: Twenty one consecutive patients scheduled to undergo carotid endarterectomy due to high grade asymptomatic carotid artery stenosis were included. ^{18}F-FDG uptake was evaluated as target-to blood ratio (TBR) across each CA, by obtaining measurements in consecutive axial slices 2cm below to 2cm above the carotid bifurcation. Temperature difference (ΔT) was assigned as the maximum-minimum measurements over the corresponding carotid segments. Degree of calcification, extent of lipid core and expression of CD68 were evaluated semi-quantitatively. Results: There was a significant positive correlation between ^{18}F-FDG uptake and ΔT values for the total carotid arteries (R=0.40 p=0.01). In contrast, no correlation was demonstrated between TBR or ΔT and the percentage of luminal stenosis (R=-0.28, p=0.86 and R= -0.02, p=0.91, respectively). TBR values were lower in patients with specimens containing increased calcification compared to those with limited calcification (p=0.003). Conversely, there was a trend for higher TBR values in patients with plaques containing an extended lipid core (p=0.06). In contrast, there was no difference in ΔT values between specimens with increased extension and specimens with low extension of lipid core (p=0.45). Similarly, there was no difference in ΔT values of specimens with high and low extension of calcification (p=0.95). Specimens with high CD68 expression had higher ΔT and TBR values compared to those with low CD68 count (p=0.04 and p=0.005, respectively). Conclusions: Inflammatory process within carotid atheromatic plaques is not correlated with structural changes, as reflected by luminal stenosis, illustrating the different pathobiological processes taking part in atherosclerosis. MWR values are correlated with ^{18}F-FDG PET/CT measurements and with immunohistochemical findings suggesting that both techniques can be used for an indirect detection of plaque inflammatory activation in vivo. However, ^{18}F-FDG PET/CT parameters are also influenced by histological plaque features too, indicating that PET/CT is a more accurate technique than MWR for plaque characterisation.

OP418

Evaluation of carotid atherosclerotic plaques using a simple semi-quantitative score based on FDG PET and CT angiography

N. Mikail[1], E. Meseguer[2], M. Mazighi[3], C. Guidoux[2], L. Cabrejo[2], A. Touati[1], G. Lesèche[4], D. Le Guludec[1], P. Amarenco[2], F. Hyafil[1]; [1]Department of Nuclear Medicine, Bichat Hospital, AP-HP, PARIS, FRANCE, [2]Department of Neurology, Bichat Hospital, AP-HP, PARIS, FRANCE, [3]Department of Neurology, Lariboisière Hospital, AP-HP, PARIS, FRANCE, [4]Department of Vascular Surgery, Bichat Hospital, AP-HP, PARIS, FRANCE.

Background. There is currently a lack of imaging criteria to define high-risk plaques with FDG-PET imaging. **Objective.** Our aim in this study as to developed a simple semi-quantitative score for the classification of carotid plaques based on morphological and functional imaging criteria extracted from FDG-PET and CT angiography, respectively. Material and methods. A total of 54 patients with carotid plaques were imaged with PET 2 hours after injection of 4 MBq/ kg of FDG followed by CTA of the supra-aortic trunks. Carotid plaques were evaluated in the region with the highest degree of luminal stenosis and graded using a semi-quantitative CT score based on plaque morphology (maximal score = 6) and a PET score based on the intensity of FDG uptake (maximal score = 4). A combined score was calculated for each carotid artery by summing the CT and PET scores (maximal score = 10). The combined score was first tested in 23 patients undergoing carotid endarterectomy. Plaque obtained after carotid endarterectomy was classified as complicated (thrombus, plaque rupture or intraplaque haemorrhage) or non-complicated. The combined score was then evaluated in a cohort of asymptomatic patients with carotid stenosis > 50 % followed for occurrence of clinical events. Results. 54 patients with carotid stenosis > 50 % (31 symptomatic; 23 asymptomatic) were imaged in this study. Among the 29 atherosclerotic plaques obtained from carotid endarterectomy, 23 plaques were classified macroscopically as complicated. Combined score measured in complicated vs. non-complicated plaques was 6.1 ± 1.9 vs. 3.7 ± 2.0 ($p < 0.05$). A combined score ≥ 4 identified complicated plaques with a sensitivity of 90 % and a specificity of 67 % (accuracy 83%). This threshold value of combined score was then tested in a cohort of asymptomatic patients with carotid stenosis > 50 % (n = 16). During a mean follow-up of 13 ± 9 months, 5 patients (1 acute ischemic cerebral event, 4 carotid endartectomy with complicated plaques) met the primary endpoint: 4 patients in the group with combined score ≥ 4 and 1 in the group of a combined score < 4 (odds ratio = 3,9 for a combined score ≥ 4). Conclusions. A simple semi-quantitative score based on combined FDG-PET-CTA imaging can help for the identification of complicated carotid plaques in symptomatic patients and helped to stratify the risk of clinical events in a small cohort of asymptomatic patients with carotid stenosis.

OP419

Detection of culprit non-stenotic plaques with FDG PET CT angiography in patients with unknown cause of ischemic stroke

N. Mikail[1], M. Mazighi[2], E. Meseguer[3], C. Guidoux[4], L. Cabrejo[4], I. Klein[5], D. Le Guludec[6], P. Amarenco[4], F. Hyafil[6]; [1]Department of Nuclear Medicine, Beaujon Hospital, AP-HP, PARIS, FRANCE, [2]Department of Neurology, Lariboisière Hospital, AP-HP, PARIS, FRANCE, [3]Department of Neurology Bichat Hospital, AP-HP, PARIS, FRANCE, [4]Department of Neurology, Bichat Hospital, AP-HP, PARIS, FRANCE, [5]Department of Radiology, Bichat Hospital, AP-HP, PARIS, FRANCE, [6]Department of Nuclear Medicine, Bichat Hospital, AP-HP, PARIS, FRANCE.

Background. Non-stenotic carotid can rupture and cause ischemic stroke but are difficult to identify owing to the high prevalence of carotid stenosis < 50 % in the population. CT angiography (CTA) and 18F-fluorodeoxyglucose positron emission tomography (18F-FDG PET) imaging allows for the detection of specific morphological and functional features associated with complicated carotid plaques. Objective. The aim of this study was to investigate the prevalence of features of complicated plaques using FDG-PET-CTA in non-stenotic plaques of patients with ischemic stroke of unknown origin. Methods. 37 patients with ischemic stroke of unknown origin < 14 days were evaluated in this study. PET imaging of carotid arteries was acquired 2 hours after injection of 4 MBq/kg of FDG and followed by CTA of the supra-aortic trunks. The presence of hypodense areas (< 30 Hounsfield units) and its extent were identified on CTA. The intensity of FDG uptake was quantified using tissue to background ratio (TBR) with PET on 3 adjacent slices centered on each plaque (TBR max.) and on 12 axial slices along each carotid artery (TBR

mean). Results. Patients (mean age: 63 ± 27; 38% female) were imaged 7 days (1-12 days) after ischemic stroke. A total of 34 non-stenotic plaques were identified in the carotid artery ipsilateral to stroke and 7 in the artery contralateral to the stroke. The prevalence of hypodense plaques was significantly higher in the carotid artery ipsilateral vs. contralateral to the stroke (47 % vs. 16 %; respectively, $p < 0.05$) but maximal hypodense area in plaques did not differ significantly (1.5 ± 1.5 mm^2 vs. 1.1 ± 1.5 mm^2; $p = 0.53$). Maximal and mean TBR were significantly higher in ipsilateral vs. contralateral carotid artery (2.75 ± 1.18 vs. 2.05 ± 0.55 and 2.20 ± 0.95 vs. 1.65 ± 0.52 respectively); $p < 0.05$ for both). Non-stenotic plaques combining hypodense area and TBR max. > 1.80 were found significantly more frequently in the ipsilateral carotid artery vs contralateral to the stroke (71% vs. 34%, $p < 0.05$, respectively). Conclusions. In this study, we found an increased prevalence of non-stenotic plaques combining hypodense area on CTA and high FDG uptake on PET in carotid arteries ipsilateral to the stroke suggesting a causal role for these plaques in patients with unknown cause of stroke and a role for FDG-PET-CTA for their more specific detection.

OP420

Higher arterial wall inflammation in familial combined hyperlipidemia (FCH) compared to heterozygous familial hypercholesterolemia (hFH): insights from a pilot ^{18} F-FDG PET/CT study

N. Pianou[1], K. Toutouzas[2], I. Koutagiar[2], A. Georgakopoulos[1], J. Skoumas[2], G. Benetos[2], P. Kafouris[3], S. Galanakos[2], M. Metaxas[1], A. Rigatou[2], G. Spyrou[3], A. Peters[4], D. Tousoulis[2], C. D. Anagnostopoulos1[1]; [1]Biomedical Research Foundation of the Academy of Athens, Center for Clinical Research, Experimental Surgery and Translational Research, Athens, GREECE, [2]Hippokration General Hospital, First Department of Cardiology, Athens, GREECE, [3]Center of Systems Biology, Biomedical Research Foundation of the Academy of Athens, Athens, GREECE, [4]Division of Clinical and Laboratory Investigation, Brighton and Sussex Medical School, Brighton, UNITED KINGDOM.

Background and aims: Familial hyperlipidemia (FH) of either heterozygous (hFH) or combined (FCH) type is the most common atherogenic disorder of lipid metabolism leading to accelerated atherogenesis and increased cardiovascular risk. It is usually characterized by LDL receptors deficiency or increased production of very low density lipoproteins (VLDL)/apolipoprotein B in the liver driving a pro-atherothrombotic lipid profile and systemic inflammatory activation. VLDL production depends on the amount of fat accumulated in the liver resulting in non-alcoholic fatty liver disease in up to 76% of individuals with FH. The aim of this study was to investigate the effect of hFH and FCH on inflammation of the arterial wall and liver using 18F-FDG PET/CT. Methods: Twenty patients (6 female) with hFH (n=10) or FCH (n=10) with no difference in age, blood glucose levels, smoking, hypertension or family history of cardiovascular disease and free of statin therapy for at least 6 months, and 10 non dyslipidaemic individuals (3 female) of similar age were included. FDG uptake was evaluated in the wall of the ascending aorta (AA) in axial slices every 5mm as target-to blood ratio (TBR) by dividing SUVmax with the superior vena cava blood mean SUV to correct the arterial FDG uptake for blood pool activity. FDG uptake was also assessed in the liver by dividing SUVmean with the mean SUV of the left ventricular cavity. Lipid profile was obtained in all patients. Results: FH patients had higher TBR values in AA compared to controls ($p<0.001$) and FCH patients exhibited higher TBR values than those with hFH (2.3 ±0.2 vs. 2±0.3, p=0.03). However, liver FDG uptake did not reach statistically significant difference between controls and FH patients (2.08±0.48 vs. 2.11±0.42 vs.2.54±0.76, for controls, hFH and FCH patients respectively, p=0.18). Total cholesterol and low density lipoprotein (LDL) values were higher in hFH patients (338±43 vs. 282±46 mg/dL, $p<0.01$ and 249±41 vs. 175±29 mg/dL, p=0.001, respectively), but triglyceride levels were higher (347 ±172 vs. 108 ±33 mg/dL, p=0.002) in FCH patients. Conclusions: Increased vascular inflammation as assessed by ^{18}F-FDG PET/CT imaging was observed in FH patients. In particular, we have demonstrated for the first time that FCH patients are characterized by higher arterial wall inflammation compared with hFH, likely reflecting different pathophysiological substrate of the atherosclerotic process. We have observed no differences in FDG liver uptake between patients and controls in this pilot study, but this needs further assessment in a larger sample size.

OP421

Metabolic interplay between arterial plaques and trabecular bone osteoblastic activity: an insight into mineral metabolism in atherosclerosis, based on ^{18}F-NaF PET/CT Data

F. Fiz[1], M. Bauckneht[1], C. Campi[2], A. Nieri[1], G. Ferrarazzo[1], R. Piva[1], V. Ceriani[1], E. Pomposelli[1], N. Artom[3], S. Morbelli[1], P. Ameri[3], M. Canepa[4], M. Piana[2], C. Marini[5], G. Sambuceti[1]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY, [2]Department of Mathematics, University of Genoa, Genoa, ITALY, [3]Department of Internal Medicine, University of Genoa, Genoa, ITALY, [4]Department of Cardiology, University of Genoa, Genoa, ITALY, [5]National Council of Research, IBFM, Genoa, ITALY.

Rationale: Atherosclerosis progression is linked to osteoblast-like cells, contributing to calcium deposition within the arterial plaque (AP): this phenomenon can be exploited to quantify plaque metabolism using ^{18}F-Natrium Fluoride (18F-NaF) PET/CT. There is accumulating evidence hinting that atherosclerosis is part of a systemic alteration of mineral metabolism. To test this hypothesis, we analyzed the correlation of average density and 18F-NaF uptake between AP and trabecular bone, as this latter tissue constitutes the physiologic calcium reserve. Patients and Methods: Seventy-nine 18F-NaF PET/CT, from prostate cancer patients, were retrospectively analyzed. After visual identification, a VOI was constructed on every aortic AP, using a region-growing algorithm, with lower bound set at 130 Hounsfield Units. From each VOI, mean plaque density (pHU) and blood-pool normalized activity (target-to-background ratio, pTBR) were calculated. Likewise, mean density and activity were extracted from trabecular bone (bHU and bTBR, respectively), using a segmentation program based on edge recognition. In the skeletal analysis, a segment that was consistently free from metastases (MTS) was selected (i.e. femoral diaphysis). The lumbar vertebrae were analyzed if no MTS were detectable (N=35) and the entire skeleton was considered if the patient was free from disease localizations (N=19) Results: An inverse correlation between pHU and bHU was observed (R=0,3, $p<0,01$); this correlation was more evident when considering lumbar vertebrae (R=0,33) or MTS-free patients only (R=0,39). There was a positive correlation between pTBR and bTBR (R=0,31, $p<0,01$), even more evident in patients whose lumbar segment was MTS-free (R=0,59, $p<0,001$). Finally, in patients with both pHU and pTBR above the median value, levels of bTBR were significantly higher with respect to those with pTBR below the median value ($p<0,01$). Conclusion: Our data highlighted an inverse correlation between calcification density and trabecular bone thickness, suggesting the existence of systemic signaling mechanisms, misdirecting calcium deposition from bones to the growing plaques. Functional data support this hypothesis as NaF uptake, as a marker of mineral turnover, correlated in the two districts. Conversely, patients presenting plaques with high density and low activity (as seen in aged, stable calcifications) had the lowest bone TBR. These data can lay the path for understanding the causes and mechanisms underlying the development of a “pro-calcifications environment”.

OP422

In vivo molecular imaging of glutamate carboxypeptidase II expression in re-endothelialisation after percutaneous balloon denudation in a rat model

F. M. Mottaghy[1], **H. Endepols**[2], S. Simsekyilmaz[3], J. Bucerius[4], F. Vogt[5], O. Winz[1], R. Richarz[2], P. Krapf[2], B. Neumaier[2], B. D. Zlatopolskiy[2], A. Morgenroth[1]; [1]Dept. Nuclear Medicine, University Hospital, RWTH Aachen, Aachen, GERMANY, [2]Institute of Radiochemistry and Experimental Molecular Imaging, Koeln, GERMANY, [3]Institute for Molecular Cardiovascular Research, University Hospital, RWTH Aachen, Aachen, GERMANY, [4]Cardiovascular Research Institute Maastricht, MUMC+, Maastricht, NETHERLANDS, [5]Dept. Cardiology, Pneumology, Angiology, and Internal Intensive Care Medicine, University Hospital, RWTH Aachen, Aachen, GERMANY.

The short- and longterm success of intravascular stents is dependent on a proper re-endothelialisation after the intervention-induced endothelial denudation. The aim of this preclinical study was to evaluate the potential of in vivo molecular imaging of glutamate carboxypeptidase II (GCPII) expression as a marker of re-endothelialisation. Angioplasty of the common carotid artery was performed under isoflurane anaesthesia in eight Sprague Dawley rats. The external carotid artery was tied off distally, and via transverse arteriotomy, a balloon dilatation catheter (2.0 x 8.0mm) guided by a flexible angioplasty wire was advanced into the common carotid artery (CCA) by 1 cm. Complete and uniform endothelial denudation was achieved by expanding the balloon for 5 seconds with a pressure of 12 bar. Molecular imaging using a fluorinated GCPII inhibitor (F-GCPII) was performed at two time intervals, 5-8d and 11-13d post intervention, additional immunostaining was performed. The contralateral CCA served as a reference. Semiquantitative analyses of CCA F-GCPII uptake revealed significantly higher values for treated CCA (0.0305 ± 0.0245 vs. 0.0165 ± 0.014, $p = 0.018$). At late time point, uptake values in treated CCA remained higher but reached no significance (0.0142 ± 0.0067 vs. 0.0106 ± 0.0074, $p = 0.068$). By immunohistochemistry, specific expression of GCPII in treated CCA was confirmed. In conclusion, by using a molecular imaging marker of GCPII expression, we provide the first non-invasive in vivo delineation of re-endothelialisation after angioplasty.

OP423

Targeting mannose receptor (MR) expressed on macrophages for imaging of atherosclerosis in a murine model using tilmanocept

Z. Varasteh[1], F. Hyafil[2], D. Diallo[3], R. Aid[4], N. Anizan[3], M. Mohring[1], J. Vigne[2], S. Nekolla[1], J. Fabre[2], D. Le Guludec[2], D. Vera[5], M. Schwaiger[1]; [1]Klinikum rechts der Isar der Technischen Universität München, München, GERMANY, [2]Department of Nuclear Medicine, Hôpital Bichat, Paris, FRANCE, [3]Fédération de Recherche en Imagerie Multimodale, Université Paris Diderot, Paris, FRANCE, [4]Hôpital Bichat, Paris, FRANCE, [5]Moores UCSD Cancer Center University of California, San Diego, CA, UNITED STATES.

Atherosclerosis, which was previously considered as a cholesterol storage disease, has come to be regarded as a chronic inflammatory disorder of the vessel wall. Despite the significant advances in the diagnosis and management of atherosclerosis-related diseases, they remain common health problems worldwide. Primary plaque rupture prevention was reported to modify the course of disease. Therefore, imaging of atherosclerosis may help to identify plaques at risk of rupture and apply early the therapies aimed at plaque stabilization. Monocyte-derived macrophage infiltration is the main characteristic of vulnerable plaques. Besides classically activated M1-macrophages, the presence of alternatively activated M2-subset is reported for human atherosclerotic plaques. Therefore it is reasonable to target mannose receptor (MR, CD206), which is an M2-macrophage marker, for plaque imaging.In this study our aim was to use diethylene triaminepentaacetic acid (DTPA)-mannosyl-dextran (tilmanocept) for in-vivo detection of atherosclerotic plaques in Apolipoprotein E-knockout (ApoE-KO) mouse model. Tilmanocept is a MR-targeting molecule, with molecular weight of 17 kDa and molecular diameter of 7 nm. ^{99m}Tc-tilmanocept with a trade name of Lymphoseek, is the first FDA approved receptor targeted lymphatic mapping radiopharmaceutical. **Methods:** Tilmanocept was labeled with ^{111}In at room temperature. The labeling stability and biodistribution of the tracer were checked in control mice (C57BL/6). The binding specificity of tilmanocept to receptor-positive organs was tested in controls. For in-vivo as well as ex-vivo imaging studies, ^{111}In-tilmanocept was injected into ApoE-KO mice and controls intravenously and scanned 90 minutes p.i. using nanoSPECT-CT. To test the specificity of ^{111}In-tilmanocept uptake in plaques, a group of mice was co-injected with excess amount of non-labeled tilmanocept. Upon imaging, the whole aortas were excised free from adventitial tissue for autoradiography. **Results:** The radiochemical yield was greater than 97% and the tracer was used for all the studies without further purification. In biodistribution studies, high liver, spleen and kidney uptake was observed. However, only low residual blood radioactivity was detected (0.18±0.02 %ID/g, 1 h p.i.). The specific uptake was detected in MR$^+$ organs, i.e. liver and spleen. The focal signal could be also detected in atherosclerotic plaques. SPECT signals from the lesions in the far end of abdominal aorta were well matched with the signals observed in ex-vivo autoradiography. **Conclusion:** The feasibility of ^{111}In-tilmanocept to image small dimension atherosclerotic plaques was presented in ApoE-KO mouse model. ^{111}In-tilmanocept may accumulate in high-risk vulnerable plaques (which are rich in CD206 expressing macrophages) and allow to identify them from low-risk stable lesions.

Development and Validation of a PGJ2 Induced Rat Model of Parkinson's Disease

A. Nikolopoulou[1,2], C. Corwin[3], Y. Kang[1], P. Kothari[2], W. Qu[2], M. Nunez-Santos[3], D. Kim[2], S. Vallabhajosula[1], M. E. Figueiredo-Pereira[3], J. W. Babich[1,2]; [1]Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, NY, UNITED STATES, [2]Citigroup Biomedical Imaging Center, Weill Cornell Medicine, New York, NY, UNITED STATES, [3]Department of Biological Sciences, Hunter College and the Graduate Center, CUNY, New York, NY, UNITED STATES.

Aim: Our earlier efforts to develop a mouse model of neuroinflammation (NI) revealed that repeated microinjections of prostaglandin J2 (PGJ2) into the substantia nigra (SN) led to Parkinsonian-like pathology with reduction of dopaminergic neurons in SNpc, activation of microglia/astrocytes and impaired gait and balance. To improve our ability to perform longitudinal quantitative imaging with μPET, we sought to establish a similar NI model in rats with the ultimate intent of studying therapeutic interventions. We report here our initial findings in rats unilaterally lesioned with PGJ2 using μPET imaging to characterize microglial activation and pre- and post-synaptic dopaminergic neuronal loss. Methods: Adult male SD rats received treatment of two unilateral injections (a week apart) of 2 μL PGJ2 (33.4 μg in DMSO/PBS) or vehicle (DMSO/PBS) into the right SN. The intact contralateral side served as internal control. Dynamic 60-min scans with [^{11}C](R)PK11195 (PK) (42±5 MBq) were performed 4 and 8 weeks post treatment. PK-μPET images were analyzed using the Logan plot and vena cava IDIF. Dynamic 90-min dopamine transporter (DAT) imaging

with [^{11}C]PE2i (PE2i) (32±2 MBq) and 60-min dopamine D_2 receptor imaging with [^{11}C]Raclopride (RAC) (26±7 MBq) were performed 14 weeks post treatment. Binding potentials (BP_{ND}) for PE2i and RAC were estimated with SRTM with cerebellum as reference. Results: At week 4 post treatment, the lesioned side of rat brains showed significantly higher PK uptake than the contralateral side with average V_T ratio of 1.55±0.10 for PGJ2 and 1.23±0.16 for vehicle (P=0.01). At week 8 post treatment, the PK average V_T ratio dropped to 1.37 ±0.15 for PGJ2 (P=0.02) while vehicle returned to baseline. At week 14 post treatment, PE2i BP_{ND} ratios were 0.81 ± 0.05 for PGJ2 and 0.97 ± 0.04 for vehicle (P=0.02) while no PGJ2 related alterations in RAC binding were found (BP_{ND} ratios: 1.00 ± 0.10 for PGJ2 and 0.95 ± 0.11 for vehicle). Conclusion: We have developed a Parkinsonian-like rat model of neuroinflammation. Our data reveal sustained microglial activation with subsequent moderate loss of pre-synaptic dopaminergic neurons in response to PGJ2 detected with PK-μPET and PE2i-μPET, respectively. NI persisted in the PGJ2 rats beyond the sham (vehicle) injection which returned to control (contralateral) levels by 8 weeks post treatment. No loss of post-synaptic neurons was detected by RAC-μPET. Long-term dopaminergic degeneration in PGJ2 lesioned rats is still under investigation. This model will be used to test pharmacological interventions for reversal of NI.

OP425

18F-THK5351 PET in Patients with Clinically Diagnosed PSP

A. Rominger, M. Brendel, S. Schonecker, G. Höglinger, S. Lindner, A. Danek, J. Levin, P. Bartenstein, N. Okamura; University of Munich, Munich, GERMANY.

Background: The pathophysiology of progressive supranuclear palsy (PSP) is characterized by deposition of fibrillar aggregates of 4-repeat tau protein in neurons. These deposits are a key finding leading to the neuropathological diagnosis of "definite PSP", which is usually established *post mortem*. The diagnosis of PSP *in vivo* according to current criteria does not take tau pathology into consideration. In light of future intervention trials biomarkers to establish a molecular diagnosis and also as potential markers of disease progression become increasingly important. 18F-THK5351 as a novel Tau-PET ligand may allow *in vivo* visualization and quantification of tau deposits, therefore the aim of the study is to investigate characteristics of 18F-THK5351 binding in patients with clinically diagnosed PSP and correlate tau-tracer uptake with clinical findings. Methods: Ten patients with probable PSP according to current criteria underwent 18F-THK5351 PET scanning. PET scans were acquired 30-70 min p. i. and were coregistered to the individual MRI. Standardized uptake value ratio (SUVR) in predefined brain regions were generated using the cerebellar cortex as reference region. Additionally disease severity measured by the PSP Rating Scale (PSPRS), functional independence measured by Schwab and England Activities of Daily Living scale (SEADL) and disease duration were assessed and correlated with PET findings. Results: In 9/10 patients significantly increased 18F-THK5351 binding was found predominantly in midbrain (SUVR 2.8-3.9), compared to a historical subject with AD (SUVR 2.2). 40-60 min p.i. time window revealed robust quantitation. One subject with a PSPRS of 33/100 and additional innate hydrocephalus did not show an elevated midbrain uptake (SUVR 2.1), suggesting no underlying tauopathy responsible for the clinical presentation. Midbrain uptake correlated significantly with PSPRS (R=0.58; p<0.05). Conclusions: 18F-THK5351 binding patterns correlated well with the known distribution of tau-pathology at autopsy in PSP and with clinical severity. 18F-THK5351 seems to be a useful biomarker of tau deposition and may therefore facilitate earlier and more reliable diagnosis of PSP.

OP426

Human brain PET imaging of PDE10A in Parkinson's disease and progressive supranuclear palsy

R. Ahmad[1], **M. Koole**[1], J. Ceccarini[1], S. Bourgeois[1], H. Hudyana[1], M. Schmidt[2], G. Bormans[1], W. Vandenberghe[1], K. Van Laere[1]; [1]KU Leuven, Leuven, BELGIUM, [2]Janssen Pharmaceutica NV, Beerse, BELGIUM.

Objective: Phosphodiesterase 10A (PDE10A) hydrolyzes cAMP and cGMP and is strongly enriched in striatal medium spiny neurons (MSNs), regulating the responsiveness of MSNs which is of particular importance in movement disorders and several neuropsychiatric diseases. In this study, we have used ^{18}F-JNJ42259152 and PET to evaluate PDE10A binding in patients with Parkinson's disease (PD) and progressive supranuclear palsy (PSP), compared to healthy controls. **Methods:** Ten patients with PD (age 69.0 ± 7.5; 8M/2F; Unified Parkinson Disease Rating Score (UPDRS) III 10-38, mean 23; Hoehn and Yahr range 1-3, mean 1.7) and 5 PSP patients (age 73.8 ± 3.1; 2M/3F; PSP rating scale 26-44, mean 35) were included and compared to 6 healthy controls (CON) (age 61.1 ± 9.1; 2M/4F). Subjects received a bolus of 167 ± 11 MBq ^{18}F-JNJ42259152, and underwent dynamic PET scanning for 90 minutes. A volume of interest (VOI) analysis was performed using individual volumetric T1-weighted MRI. Partial volume correction was applied and the frontal cortex was used as reference region.Left and Right Putamen (LPT - RPT) and left and right caudate nucleus (LCNc - RCNc) PDE10A binding potential (BP_{ND}) was calculated using a Multilinear Reference Tissue Model (MRTM). **Results:** BP_{ND} was significantly decreased in PSP compared to CON both in CNc and PT ($p_{HC\ vs\ PSP} < 0.05$). For PD, BP_{ND} values were also lower than CON, but showed only a trend for CNc (p=0.08). For both PSP and PD however, the average CNc/PT ratio was decreased compared to CON (p=0.01 and p=0.03, respectively). There was no significant difference between PD and PSP. Taking clinically affected side into account for PD did not alter the findings. BP_{ND} values were not correlated to UPDRS III motor scores for PD. For the PSP group, a Pearson correlation showed a trend towards a negative correlation with PSPRS (gait and midline) (r = - 0.83; p = 0.08). Discriminant analysis did not allow to separate PD and PSP. **Conclusions:** Striatal PDE10A expression is decreased in both PD and PSP patients compared to CON. However, VOI-based analysis of PDE10A PET using 18F-JNJ42259152 does not allow to distinguish PD from PSP patients.

OP427

Value of ^{123}I-ioflupane DaT SPECT quantification in the assessment of patients with movement disorders or dementia

J. Booij[1], D. Pryma[2], J. Dubroff[3], J. Yu[4], R. Agarwal[5], P. Lakhani[6], P. Kuo[7]; [1]University of Amsterdam, Academic Medical Center, Amsterdam, NETHERLANDS, [2]University of Pennsylvania School of Medicine, Philadelphia, PA, UNITED STATES, [3]University of Pennsylvania Medical School, Philadelphia, PA, UNITED STATES, [4]Fox Chase Cancer Centre, Philadelphia, PA, UNITED STATES, [5]University of Pennsylvania Health System, Philadelphia, PA, UNITED STATES, [6]Thomas Jefferson University Hospital, Philadelphia, PA, UNITED STATES, [7]Banner University Medical Center, Tuscon, AZ, UNITED STATES.

The visual assessment of the striatal dopamine transporter with ^{123}I-ioflupane SPECT is well-established for the differentiation of degenerative parkinsonian syndromes (PS) from essential tremor (ET) and probable dementia with Lewy bodies (pDLB) from Alzheimer's disease (AD). This study investigated the impact of image quantification on accuracy and reader confidence compared to visual interpretation alone. Striatal binding ratios were determined with the DaTQUANT™ software in 304 ^{123}I-ioflupane SPECT (DaTscan™) images from 3 multi-center, Phase 3/4 trials, enrolling subjects with a clinical diagnosis of PS, non-PS, pDLB and AD

established after a minimum follow-up of 12 months. Images were assessed by five blinded Nuclear Medicine physicians who had limited prior clinical experience of ^{123}I-ioflupane interpretation (i.e. between 5 and 50 prior assessments). In two reads, with at least a 1 month interval, readers were presented with either visual only or combined (i.e. visual plus quantitative) data. Readers were asked to rate confidence of image interpretation (from 1 - very challenging to 5 - very easy) and judge scans as easy or difficult to read. Accuracy, positive percent agreement (PPA) and negative percent agreement (NPA) were also determined. Compared to the visual read, the combined analysis showed a small, non-significant increase of mean NPA (87.9% vs 89.9%) and equivalent PPA (80.1% vs 80.2%). Readers who initially read in the combined analysis had significantly greater accuracy (85.8% vs 79.2%, p=0.0178) and were closer to the accuracy of the expert readers in the original studies (range 83.3% to 87.2%). Mean confidence of image interpretation was high for both read methodologies but was significantly greater for the combined analysis (i.e. 4.25 visual vs 4.37 combined, p<0.0001). In difficult to read cases, PPA remained high for both visual and combined assessment while NPA in the combined read trended to increase relative to the visual assessment as levels of difficulty increased. Intra- and inter-reader agreement was very high (kappa>0.85). The combined read improved the percentage of agreement among all readers from 82.8% (visual) to 89.9% (combined) and kappa values from 0.85 to 0.91. The addition of quantification allowed readers with limited experience of ^{123}I-ioflupane SPECT to perform as well as the more experienced readers used for the original clinical studies. We observed minor but consistent improvements in diagnostic accuracy while offering an increase in reader confidence that may result in fewer scans being considered difficult to read.

OP428

Striatal dopamine depletion in young onset versus late onset Parkinson's disease

A. Damian[1], C. Pascovich[1], D. Muñoz[1], M. Langhain[1], I. Amorin[2], A. Lescano[2], J. Higgie[2], R. Buzó[2], R. Ferrando[1]; [1]Nuclear Medicine and Molecular Imaging Centre, Clinical Hospital, University of the Republic, Montevideo, URUGUAY, [2]Neurology Institute, Clinical Hospital, University of the Republic, Montevideo, URUGUAY.

Even though many studies have described differences in clinical presentation and treatment response between patients with young onset Parkinson's disease (<50 years old) and late onset Parkinson´s disease (LOPD), the underlying pathophysiology of these differences and the corresponding manifestation in presynaptic dopamine imaging is still a matter of discussion. Therefore, the aim of this study is to assess the differences in dopamine depletion between these two subtypes of PD at a similar time of disease duration. Material and methods: Retrospective study of 54 PD patients, 17 with young onset Parkinson's disease (YOPD, 36.2 ± 11 years old, 6 women) and 37 with LOPD (61.1 ± 6 years old, 23 women) matched for disease duration (7.1 ± 4.7 years) that underwent 99mTc-TRODAT-1 SPECT scan between 2011 and 2015. Specific putaminal, striatal and caudate nucleus binding uptake ratios (SUR, striatal mean counts - occipital mean counts/occipital mean counts) and asymmetry index (2 x [(ipsilateral SUR - contralateral UR)/(ipsilateral SUR + contralateral SUR)] x 100) were quantified, and Hoehn and Yahr scale (HYS) of disease severity was compared in both groups. The correlation between SUR, age of disease onset and time of duration in all patients was explored using multiple lineal regression. P<0,05 was considered significant. Results: Patients with YOPD showed higher HYS score in comparison with LOPD (2.5 ± 1.2 and 1.75 ± 0.8 respectively, p=0.02). Asymmetry index was 0.42 ± 0.3 in YOPD and 0.24 ± 0.2 in LOPD (p=0.023). Although putaminal SUR was lower in YOPD (0.27 ± 0.17) in comparison with LOPD (0.38 ± 0.23) this finding did not reach statistical significance (p= 0.1). Putaminal SUR showed a significant negative correlation with time of disease duration (p=0.017, correlation coefficient -0.009) but not with the age of onset (p=0.119, correlation coefficient -0.002). Conclusion: Patients with YOPD showed more severe clinical presentation than LOPD with a similar progression time and more asymmetrical dopamine deficit. Although putaminal dopamine impairment was lower in YOPD, it did not reach statistical significance. We could not find a correlation between age of onset of PD and absolute dopamine depletion measured with 99mTc-TRODAT-1.

OP429

Clinical impact of 18F - FDOPA PET for parkinsonian syndromes management

A. SCHIAZZA, C. ZWARTHOED, D. BENISVY, N. SAPIN, M. BORG, J. DARCOURT; CENTRE A. LACASSAGNE, NICE, FRANCE.

Introduction: The diagnosis of parkinsonian syndromes (PS) remains a challenge in various clinical situations. Unlike DAT SPECT the clinical utility of 18F-FDOPA PET has not been investigated yet. The aim of our study was to perform this evaluation through a prospective survey sent to the referring physicians. Materials and methods: During a six month period, for all patients referred to our department for 18F-FDOPA PET for movement disorder evaluation, a survey was sent out to the ordering neurologist (n=192). The survey included 3 types of questions. The first addressed the indication and purpose of the study. The second concerned the diagnosis (pre-PET clinical diagnostic hypothesis, post-PET final diagnosis and correlations between clinical examination and PET results). The third evaluated the practical impact on the diagnosis, the management and the follow-up of patients with PS. 18F-FDOPA PET consisted in a 10 min static PET-CT acquisition 90 min post injection of 2 MBq/kg of 18F-FDOPA (mCT-Siemens; OSEM 5 it and 24 subsets). Each study was analyzed visually by 2 observers. The final diagnosis of the referring neurologist served as reference for the 18F-FDOPA PET performances evaluation. Results: We obtain 91 answers for 91 patients with PS (mean age: 71.4). The response rate was 47%. Clinical examination of the neurologist and PET results were considered coherent in 78% of the cases (n=71/91). 18F-FDOPA PET induced a change in the final diagnostic in 33% of the cases when a Parkinson Disease (PD) was suspected and in 50% when another PS was suspected. 18F-FDOPA PET improved physician confidence in the initial diagnosis in 71.4% of the cases. It induced changes in the intended management in 57% of the patients. These changes were a therapeutic modification in 73% of the cases. Sensitivity of 18F-FDOPA PET was 78% and specificity 98%. Conclusion: These results demonstrate that 18F-FDOPA PET is feasible in routine clinical evaluation with good performances. The results change significantly the diagnosis (more in other PS than in PD). They also induce changes in the patient management in more than 50% of the cases.

OP430

Relationship between brain metabolism and cognitive/behavioral functioning in ALS-FTD

J. Evens*[1], **S. M. A. Willekens***[2], D. Van Weehaeghe[2], P. Van Damme[1], K. Van Laere[2]; [1]Division of Neurology, University Hospitals Leuven and KU Leuven, Leuven, BELGIUM, [2]Division of Nuclear Medicine, University Hospitals Leuven and KU Leuven, Leuven, BELGIUM.

Aims Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease characterized by progressive death of motor neurons, leading to progressive muscle weakness and death within 3-5 years. ALS shows significant clinical, pathological and genetic overlap with frontotemporal dementia (FTD) and 10-15% of all ALS patients develop FTD (ALS-FTD), resulting in poorer prognosis. The aim of this

study was to relate the degree of regional brain glucose metabolism to cognitive and behavioral impairments in ALS patients. **Methods** 75 patients diagnosed with ALS, underwent ECAS scoring and ^{18}F-FDG PET/CT. According to their ALS-specific ECAS score, patients were divided in three groups: cognitively normal ALS patients (ALS-CN), patients with cognitive or behavioral impairment (ALS-Ci/Bi) and patients with ALS-FTD. Static ^{18}F-FDG PET images were acquired 30 min after injection of approximately 150 MBq ^{18}F-FDG. PET images were analyzed using a VOI-based (Hammers atlas, PNEURO v3.6) and a voxel-based (SPM8) approach. ^{18}F-FDG uptake was normalized to the average whole-brain grey matter uptake. Correlation between regional ^{18}F-FDG uptake were assessed using linear regression analyses with ALS-specific ECAS score and the sub-scores verbal fluency and executive functioning. For all statistical analyses, the level of significance was set at $p < 0.05$ and Bonferroni correction was performed to correct for multiple testing. **Results** A voxel-wise group comparison revealed significant relative hypometabolism in the middle frontal gyrus and subcallosal area of ALS-FTD patients when compared to ALS-CN patients ($P_{FWE\text{-}corrected} < 0.001$, T=3.3, kE = 20 voxels). No differences in cerebral metabolism were found between patients with ALS-FTD and ALS-Ci/Bi. As for the VOI-based correlation analyses, a positive correlation was found between ALS-specific ECAS score and ^{18}F-FDG uptake in the prefrontal cortex (PFC) ($r = 0.50$, $p < 0.001$) and the anterior cingulate cortex (ACC) ($r = 0.56$, $p < 0.001$) with the strongest correlation observed in the subcallosal area ($r = 0.54$, $p < 0.001$). In addition to the correlation with ALS-specific ECAS score, verbal fluency correlated with ^{18}F-FDG uptake in PFC ($r = 0.40$, $p < 0.001$) and ACC ($r=0.42$, $p<0.001$) while executive functioning was only correlated to ACC activity ($r = 0.41$, $p < 0.001$). **Conclusion** ECAS performance, indicating cognitive impairment and executive disturbances in ALS, is associated with prefrontal and anterior cingulate hypometabolism. These results corroborate previous findings that ^{18}F-FDG PET could be an early marker for cognitive and behavioral decline in ALS and development of ALS-FTD.

OP431

Amyloid brain deposition in idiopathic normal pressure hydrocephalus assessed by 11C-PIB PET/CT

J. F. Jimenez-Bonilla[1], R. Quirce[1], M. De Arcocha-Torres[1], I. Martínez-Rodríguez[1], J. M. Carril[1], M. Jiménez-Alonso[1], I. Banzo[1], A. Pozueta[2], R. Martín-Laez[3], E. Rodriguez-Rodriguez[2]; [1]Servicio de Medicina Nuclear. Hospital Universitario Marques de Valdecilla. Grupo de Imagen Molecular IDIVAL. Universidad de Cantabria., SANTANDER, SPAIN, [2]Servicio de Neurología. Hospital Universitario Marques de Valdecilla. Grupo de enfermedades Neurodegenerativas IDIVAL. Universidad de Cantabria., SANTANDER, SPAIN, [3]Servicio de Neurocirugía. Hospital Universitario Marques de Valdecilla., SANTANDER, SPAIN.

Aim: *Idiopathic normal pressure hydrocephalus* (INPH) is a potentially treatable cause of cognitive impairment by surgical diversion of cerebrospinal fluid (CSF). An important comorbidity with Alzheimer's disease (AD) has been described in these patients, so an accurate selection of candidates for surgery is desirable. 11C-PIB PET/CT can detect in vivo the amyloid cerebral deposition. The aim of our work was to detect the presence and distribution of regional cerebral amyloid deposition on 11C-PIB PET/CT in patients with INPH, candidates to CSF shunting. **Materials and Methods:** Thirteen patients with clinical diagnosis of INPH (7 women and 6 men, mean age 73 ± 6 y) who had criteria for CSF shunt surgery and 7 healthy controls (4 women and 3 men; mean age 64 ± 10 y) were included in the study. Static 11C-PIB PET was acquired between 60' -90' after the intravenous administration of 555 MBq of 11C-PIB. PIB cerebral retention in INPH patients was compared with those detected in controls. Visual and semiquantitative analysis of the studies was performed. SUV regional indices were obtained by drawing manual ROIs in cerebellar, temporal, frontal, anterior cingulate, occipital, parietal and posterior cingulate cortex. Using the cerebellar cortex as reference region, SUVratios (SUVr) and global SUVratios (gSUVr) were obtained. **Results**: Visual analysis classified the studies as positive in 3, equivocal in 2 and negative in 8 patients. Semiquantitative analysis showed no overall statistically differences between the mean of gSUVr of INPH and controls (p=ns). In the group of visual positive patients, significant differences were appreciated in the mean of gSUVr compared with controls (2.297±0.188 vs 1.230 ± 0.238) ($p<0.001$). SUVr for each region was 2.152 ± 0.4879 for temporal area; 2.163 ± 0.089 for occipital area; 2.309 ± 0.169 for frontal area; 2.396 ± 0.506 for anterior cingulate; 2.319 ± 0.506 for parietal area and 2.445 ± 0.188 for posterior cingulate. All regions showed significant regional differences with control values ($p <0.001$). In the groups of equivocal and negative visual analysis, there were no statistically significant differences with controls (p = ns). **Conclusion**: Cerebral amyloid deposition was detected in 23% of INPH patients. PIB cerebral deposition was higher in frontoparietal and posterior cingulate regions. Further post-surgical studies would be desirable to elucidate if the presence of cerebral amyloid deposition may be a prognostic factor, and if this deposition is in agreement with cerebral amyloid distribution in AD patients.

Production and Automated Separation of Cyclotron Produced Cu-64 for Preclinical Purposes

V. Gupta, S. Schweitzer, S. Stricker, M. Schäfer, A. Runz, K. Kopka; German Cancer Research Center, Heidelberg, GERMANY.

Aim: Among the non-standard positron emitters, Cu-64 exhibits favorable decay characteristics ($t_{½}$ = 12.7 h, $E_{\beta+,max}$ = 0.656 MeV) for PET imaging of radiotracers with slow or delayed pharmacokinetics. The main focus of this study is on a self-constructed automated system for separation of Cu-64 produced from a 32 MeV negative-ion departmental cyclotron for preclinical research purposes. **Materials and Methods:** Cu-64 was produced via $^{64}Ni(p,n)^{64}Cu$ reaction bombarding 11.7 MeV protons at 45μAh on 100 mg of enriched Ni-64 (Chemotrade, 99.3% enrichment, thickness 350 μm) electroplated on a gold disc. The radiochemical separation of Cu-64 from the irradiated Ni-64 target, consisting of by-products for e.g. radioisotopes (Co-55, Co-57, Ni-57, Co-61), was achieved by a self-constructed automated system using the principle of anion and cation exchange chromatography (Dowex 1X8, 100-200 MESH) with diluted mixtures of hydrochloric acid in organic solvents[1]. A first prototype to automate the Cu-64 separation has been developed and successfully tested. It is based on an EtherCAT PLC System which is able to operate with any kind of actuators and sensors irrespective of manufacturers available in the market. The assembly contains two self-designed reactors and the module construction itself. It holds 4 Tevisio RD2007 activity sensors, 14 standard Bürkert valves, 3 Thomas Denver peristaltic pumps SR10/30, 2 custom made heating coils from Hotset and 2 ion exchange columns. **Results and Conclusion:** The fully automated set-up for the separation of Cu-64 from Ni-64 and by-products has been successfully implemented and tested. The complete separation process takes ca. 120 min with marginal absorbed effective. The purified Cu-64 was obtained as $[^{64}Cu]CuCl_2$ in 400 μL of 0.1M HCl, and Ni-64 was successfully recovered for further usage. The production yield of Cu-64 was 111 MBq/μAh, the radiochemical yield of $[^{64}Cu]CuCl_2$ after the separation process was about 82%. Radionuclide purity of the $[^{64}Cu]CuCl_2$ solution was > 99.9% after 12h. **Reference** *Smith SV, Waters J, Di Bartolo N.,"Separation of 64Cu from 67Ga waste products using anion exchange and low acid aqueous/organic mixtures"; Radiochimica Acta 75, 65-68 (1996)*

OP445

Cyclotron production of theranostic pair ^{43}Sc - ^{47}Sc on calcium targets

A. Bilewicz[1], R. Walczak[1], A. Majkowska[1], R. Misiak[2], J. Choinski[3], M. Sitarz[3], A. Stolarz[3], J. Jastrzębski[3]; [1]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [2]Institute of Nuclear Physics, Cracow, POLAND, [3]Heavy Ion Laboratory, University of Warsaw, Warsaw, POLAND.

Aim: The ^{43}Sc ($t_{1/2}$ = 3.89 h) is an ideal β^+- emitter in PET diagnosis. It can be used as an alternative to ^{68}Ga, because ^{43}Sc has longer half-life and forms theranostic pair with β^- emitter ^{47}Sc, that is important in planning radionuclide therapy. In comparison with ^{44}Sc -other proposed isotope of scandium - ^{43}Sc has half-life and beta plus radiation similar to ^{44}Sc, moreover gamma-ray energy emission and intensity is much lower (372 keV, 23%) than in case of ^{44}Sc (1157 keV, 99%) what is not negligible for patient and medical personnel. On the other hand ^{47}Sc- low energy β^- emitter is attractive candidate for radioimmunotherapy. In our work we propose new way for cyclotron production of ^{43}Sc in $^{42}Ca(d,n)^{43}Sc$ nuclear reaction and ^{47}Sc by proton irradiation of ^{48}Ca target in p,2n reaction. **Materials and methods**: In the present work we used enriched $^{42}CaCO_3$ and $^{48}CaCO_3$ targets (Isoflex, Russia). To manufacture the targets enriched $^{42}CaCO_3$ or $^{48}CaCO_3$ powder was pressed with graphite powder (10-25%) and mounted to a water cooled target holders and irradiated with beam of proton and deuteron at different energies. The activity of the samples were measured with high resolution γ-ray spectrometry. $CaCO_3$ targets were dissolved in 0.2 M HCl and an ion exchange resin Chelex 100 was used to separate ^{43}Sc and ^{47}Sc from calcium target materials. **Resutls:** . The obtained by deuteron irradiation of ^{42}Ca radionuclide of ^{43}Sc was radionuclidaly pure. In the product no other than ^{43}Sc radionuclides not detected. In the case of proton irradiation of ^{48}Ca obtained product contained a mixture of an radionuclides ^{47}Sc and ^{48}Sc. At optimal irradiation energy and the thickness of the target content of ^{48}Sc impurity was less than 16%. It is worth be noted that ^{48}Sc is also low energy β emitter but emits also high energy gamma quanta. **Conclusion:** The proposed methods allow to obtain high activity of ^{43}Sc and ^{47}Sc. Scandium isotopes were separated from the targets on iminodiacetic resin with efficiency of more than 90% and eluted in volume of 0.3 ml. The level of Ca^{2+} in ^{43}Sc and ^{47}Sc fraction is less than 3 μg/ml. The recovery of the calcium target is nearly quantitative making the proposed production process economically

feasible. This work was carried out as a part of the projects of the National Center for Applied Research of Poland Nr PBS3/A9/28/2015.

OP446

A Fully Automated GMP-Compatible Two-in-One Dissolution-Purification Module for Extraction of Tc-99m from Irradiated with Cyclotron Mo-100 Targets

S. V. Selivanova[1], J. A. Sader[2], A. Zyuzin[2]; [1]Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, CANADA, [2]Advanced Cyclotron Systems Inc, Vancouver, BC, CANADA.

Aim: Direct production of ^{99m}Tc with cyclotrons, utilizing ^{100}Mo as starting material, can be a viable alternative to conventional reactor-based technology. GMP-compatible manufacturing process is an essential requirement for obtaining manufacturing authorisation. Our objective was to develop a safe and reliable procedure where dissolution of solid target and processing of target solute would be combined and controlled within a single automated module. In addition, the procedure should be easily transferred to a GMP-compliant environment. **Methods:** A prototype dissolution system was designed in-house (Advanced Cyclotron Systems Inc.). The dissolution system consisted of a dissolution chamber assembly, which accommodated high-current target, and a neutralisation vial, where target solute was collected. Commercially available cassette-based automated module (MiniAIO, Trasis) was used to add reagents and solvents to the dissolution system and to process resulting target solute. To achieve controls via Trasis software, both systems were hard-wired via digital outputs of the MiniAIO unit. Layout of the MiniAIO hardware layer was redesigned to include control valves and switches of the dissolution system. Feedback was displayed through external digital inputs. The system was first optimised under simulated conditions with non-irradiated targets prepared from natural molybdenum and spiked with generator-eluted ^{99m}Tc target solute. Then, the procedure was tested using irradiated targets made of ^{100}Mo. **Results:** The prototype dissolution system was successfully interfaced with automated cassette-based purification module. This allowed uninterrupted automated target dissolution and processing. Controls of the dissolution system, including solvent addition, were entirely integrated with MiniAIO functionalities. Single program sequence included on-line conditioning of all cartridges, target dissolution, and ^{99m}Tc extraction and purification. **Conclusions:** We developed and tested an automated GMP-compatible combined dissolution-purification procedure for extraction of ^{99m}Tc from irradiated with cyclotron ^{100}Mo targets. It can permit a trained technician to perform routine productions following a standard operating procedure.

Titanium-45 as an innovative radionuclide for PET imaging: from cyclotron production to potential biomedical applications

P. Costa[1,2], L. F. Metello[1,3], F. Alves[4], S. Carmo[4], M. D. Naia[2]; [1]Nuclear Medicine Department, ESTSP.IPP, Vila Nova de Gaia, PORTUGAL, [2]CEMUC® - Physics Department, ECT-UTAD, Vila Real, PORTUGAL, [3]Nuclear Medicine Department, IsoPor SA, Porto, PORTUGAL, [4]Institute for Nuclear Sciences Applied to Health, ICNAS-University of Coimbra, Coimbra, PORTUGAL.

Introduction: In recent times, several groups are working worldwide in the extension of the number and availability of positron emitting radionuclides for PET imaging, in the way to avoid the strict dependence on ^{18}F, ^{11}C, ^{13}N and ^{68}Ga, so increasing the number of available tools for a truly practice of personalized Nuclear Medicine. From few years ago, our group is busy studying ^{45}Ti, assuming it as a potential candidate, since it presents many interesting properties: physical half-life of 3.09h, together with relevant chemical properties, that enable radiolabelling with bifunctional chelates, direct labelling of specific chemical ligands or even to be used in the radiolabeling of titanium (di)oxide nanoparticles. **Aim:** This work presents our experimental results on the determination of excitation function of ^{45}Sc(p,n)^{45}Ti nuclear reaction, that is being studied as the most interesting route to efficiently produce ^{45}Ti in low energy cyclotrons. **Material and Methods:** Cyclotron beam energy was calibrated using a copper stacked foil. The stacked foil technique was then applied using 99,5% pure Sc foils mounted on an inhouse, internally developed, aluminum target holder interspaced in some positions with 99,999% pure Cu foils. Short irradiations (~1μA during 100 seconds) in an 18 MeV cyclotron (CYCLONE 18/9, from IBA®) were implemented. Results of this activation study were evaluated using HPGe spectroscopy (always considering dead time losses ≤ 5%). **Results:** Results concerning the excitation function of the main route under study were collected, with the addition of some information regarding concurrent reactions leading to ^{44m}Sc and ^{44}Sc. Experimental results were also compared with the Monte Carlo simulation results obtained using TALYS code calculations. Our results confirm TALYS predictions and are completely comparable to other few (even incomplete) results already published. Specifically, cross-section values for the ^{45}Sc(p,n)^{45}Ti nuclear reaction presented maximum values for beam energies between 10-15 MeV, presenting an approximated plateau shape in this region. Energies higher than 16 MeV lead to co-production of ^{44}Ti, ^{44}Sc and ^{44m}Sc. **Conclusion:** Considering our results, the production of ^{45}Ti seems feasible in low energy cyclotrons, with maximum yields obtained for 10-15 MeV proton beams, allowing its production in an appropriate manner to be used in several potential biomedical applications.

OP448

Development of Pt-195m Cisplatin and Derivatives as New Imaging Agents

K. Codee-van der Schilden, O. Zwaagstra; NRG, Petten, NETHERLANDS.

Aim: Cisplatin is worldwide one of the most used anticancer agents and is applied in standard treatment procedures for several malignant tumor types. However, significant differences appear between patients and between tumors, and treatment outcome cannot be predicted. Moreover, Cisplatin can cause severe toxic side effects. We have developed Pt-195m Cisplatin as a SPECT imaging agent to enable studies of patient specific interactions with Cisplatin with the aim to improve treatment outcome and reduce toxic side effects in a personalized approach. We also developed a Pt-195m Cisplatin derivative as a new SPECT imaging probe ideally suitable for linkage to biologically active compounds to allow to study their behavior in vivo in a noninvasive manner. Materials and Methods: Platinum-195m was produced by thermal neutron irradiation of enriched Platinum-194 in the High Flux Reactor in Petten, the Netherlands for four to eight days. After sufficient cooling time, the irradiated Platinum was dissolved and analyzed by UVVIS and gamma spectroscopy. Radioactive Cisplatin and Platinum-195m ehtylenediammine dinitrate were synthesized by slight modification of known procedures[1]. An identification test was developed using UVVIS. Radiochemical purity was assessed by HPLC, radionuclide purity was determined using gamma spectroscopy and chemical purity was evaluated using nonradioactive counterparts. Results: Eight days of irradiation resulted in highest specific activity of approximately 1 mCi/mg Pt at End of Irradiation (EOI). Thorough washing of the diiodide Platinum intermediate resulted in sufficient separation of Gold and Iridium radioactive side products. UVVIS of the synthesized product showed a maximum at 301 nm and a minimum at 246 nm, which are characteristic for Cisplatin. Radiochemical purity was greater than 95 %, impurities of silver were below acceptable levels, radionuclide purity was greater than 99 %. Conclusion and future prospects: Pt-195m Cisplatin and $[Pt(NH_3)_2(NO_3)_2]$ have been successfully synthesized with good quality. In collaboration with the Dutch Cancer Institute quantification of Pt-

195m using SPECT has been shown. Automatization of Pt-195m Cisplatin has been started to enable GMP production of the product. 1: Hoeschele, J.D., Butler, T.A., Roberts, J.A., Guyer, C.E. Ac-225-PSMA-617 for PSMA targeting alpha-radiation therapy of 28 patients with mCRPC

C. Kratochwil[1], F. Bruchertseifer[2], F. L. Giesel[1], C. Apostolidis[2], U. Haberkorn[1], A. Morgenstern[2]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]European Commission - Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY.

Aim: We evaluate imaging and tumor marker response as well as clinical and hematological toxicity of targeted alpha-radiation therapy with Ac-225-PSMA-617 (TAT) in inter-individual comparison to Lu-177-PSMA-617 in dependency of prognostic factors. **Methods:** Retrospective analysis of case series about patients treated either with Ac-225-PSMA-617 (n=28) or Lu-177-PSMA-617 (n=30), after treatment stratification based on PSMA-imaging. Tumor spread, previously applied treatments and lab tests were used to analyse the prognostic profile of both cohorts. After treatment, lab tests and tumor markers were determined at least every 4 weeks. After 3 cycles (6 months) radiological restaging was performed. **Results:** The TAT group was in more advanced stage and more heavily pre-treated. Hematological toxicity was tolerable in both groups, with limitation that Lu-PSMA was restricted to oligo-multilocular bone metastases while TAT also included patients with diffuse type red marrow infiltration. Moderate xerostomia occurred occasional in the beta-radiation group but frequently and more severe during TAT. However, both imaging response and tumor markers were in favor for TAT, e.g. PSA-response was seen with 95% (Ac-225) vs 75% (Lu-177) after week-8 and 75% (Ac-225) vs 50% (Lu-177) after week-24. After TAT, 20% of patients achieved complete remission (CR) in regard to imaging and tumor markers. Some radiological CR but no biochemical CR was found after beta-radiation therapy. **Conclusions:** In regard to mCRPC alpha-emitters seem superior in comparison to beta-nuclides when tagged to the identical carrier molecule.

OP455
The Value of Ga-68-PSMA-PET/CT as a Gatekeeper for Ra-223-Dichloride Therapy

A. Bode, K. Rahbar, J. Konnert, M. Bögemann, L. Stegger; University Hospital Münster, Münster, GERMANY.

Purpose. ^{223}Ra-dichloride is a novel therapeutic option for the treatment of osseous metastases in castration-resistant prostate carcinoma. Application is currently approved for patients with symptomatic bone metastases but without visceral metastases. A successful treatment depends on an adequate uptake of ^{223}Ra in metastases, predicted by bone scintigraphy. The purpose of our study was to investigate whether ^{68}Ga-PSMA-PET/CT performed in patients intended for ^{223}Ra-dichloride therapy has incremental value over conventional staging in order to detect visceral metastases or osseous metastases without adequate uptake in bone scintigraphy. *Materials/Methods.* Additional ^{68}Ga-PSMA-PET/CT was performed in 27 patients intended for ^{223}Ra-dichloride therapy. Conventional staging included bone scintigraphy and computer tomography of the thorax, abdomen and pelvis. Visceral metastases diagnosed by ^{68}Ga-PSMA-PET/CT but not by conventional staging were recorded. In addition, the tumour extent visible with ^{68}Ga-PSMA-PET/CT was compared to the extent and intensity of tracer uptake in bone scintigraphy. Both image data sets were evaluated for mismatch patterns with absent or low uptake in the bone scan in relation to the tumour distribution. Patients with either newly diagnosed visceral metastases or significant areas of osseous tumour without adequate uptake in bone scintigraphy were re-evaluated with the option to undergo experimental ^{177}Lu-PSMA-Radioligand-Therapy instead. *Results.* In two patients previously unknown visceral metastases were detected by ^{68}Ga-PSMA-PET/CT. In four patients comparison of ^{68}Ga-PSMA-PET with bone scintigraphy revealed large volumes of tumour within the spine without adequate uptake in bone scintigraphy, most likely owing to extended bone marrow involvement with little activation of bone. In these patients the efficacy of ^{223}Ra therapy was called into question. In six other patients ^{68}Ga-PSMA-PET/CT revealed a minor mismatch with detection of smaller additional metastases mainly in the thorax and the extremities. In these patients the bulk of the tumour showed good uptake in bone scintigraphy and ^{223}Ra-dichloride therapy was performed as planned. *Conclusion.* Additional ^{68}Ga-PSMA-PET/CT in patients intended for ^{223}Ra-dichloride therapy can provide significant incremental information that may change subsequent therapeutic decisions. This scan can reveal previously unknown visceral metastases but it can also identify patients with extended areas of tumour with good PSMA expression but inadequate uptake in bone scintigraphy. The latter is of tremendous importance given the availability of the new ^{177}Lu-PSMA-Radioligand-Therapy, probably the more effective therapeutic option in these patients compared to ^{223}Ra-dichloride.

OP456

^{68}Ga-PSMA PET/CT early detection of Prostate Cancer bone metastases: the end of the osteoblastic era?

C. ARTIGAS, T. KAMOUN, C. GARCIA, Z. WIMANA, G. GHANEM, R. VAN VELTHOVEN, F. OTTE, T. GIL, P. FLAMEN; Institut Jules Bordet, Brussels, BELGIUM.

Introduction and Aim: Bone metastases (BM) are present in 90% of patients who die of Prostate Cancer (PCa). However, diagnosis of BM is usually done in advanced stages of the disease with bone scan being recommended in EAU guidelines only for PSA values >20ng/ml. Identifying those lesions in an early stage before osteoblastic activity may have a prognostic value and influence the treatment choice going from local to systemic therapies and better selecting patients candidates for oligometastatic therapeutic approach. The aim of this communication was to determine if ^{68}Ga-PSMA PET/CT is able to early detect BM, even before osteoblastic/osteolytic reaction becomes detectable. **Material and methods:** We retrospectively analyzed a cohort of 223 consecutive ^{68}Ga-PSMA PET/CT performed at our institution for PCa biochemical relapse (BCR) after local treatment with curative intent (surgery, radiotherapy or both) between November 2014 and February 2016. All patients had PSA <20ng/ml [mean 4.4ng/ml (range 0.3-15.6)]. Focal bone uptake was considered as suspected for BM if the SUVmax lesion-to-background ratio was >2. Validation criteria included the confirmation by other imaging techniques (bone scan, MRI or CT), clinical follow-up with PSA decrease after targeted therapy or increase in PSA and in number of lesions after watchful waiting period. BM were divided into (a) osteolytic, (b) osteoblastic and (c) none based on CT images. **Results:** 38/223 patients presented with at least one suspected BM at ^{68}Ga-PSMA PET/CT. Mean SUVmax lesion-to-background ratio was 15 (range 2-74). 33/38 (87%) of patients had at least one validation criteria confirming BM. 4/38 patients with suspected BM didn't have confirmation and are still on follow-up. Only one lesion was a false positive resulting in a vertebral hemangioma. A total of 235 bone lesions were detected. 32 (13%) were osteolytic, 64 (27%) osteoblastic and 163 (69%) showed no abnormality on CTscan and were considered as bone marrow lesions. Finally 26/38 (68%) patients presented with ≤3 suspected BM (oligometastatic disease). **Conclusion:** This retrospective study suggests that ^{68}Ga-PSMA PET/CT is a useful technique to early detect PCa BM in patients with BCR after local treatment with curative intent, even before those lesions become osteoblastic/osteolytic. This fact could substantially influence therapeutic strategy decision, especially for those patients with oligometastatic disease.

OP457

Validation of ^{68}Ga-PSMA-Ligand-PET/CT in Primary Staging of Prostate Cancer Patients

C. Uprimny, A. Kroiss, C. Decristoforo, L. Scarpa, D. Kendler, L. Geraldo, E. von Guggenberg, B. Nilica, S. Buxbaum, I. Virgolini; Medical University Innsbruck, Innsbruck, AUSTRIA.

Purpose: Prostate cancer (PC) cells usually show a high level expression of prostate-specific membrane antigen (PSMA) as can be assessed by ^{68}Ga-PSMA-ligand-PET/CT. The aim of this study was to assess the intensity of PSMA-expression of the primary tumour and metastases in patients with biopsy proven PC prior to therapy, and to determine if there exists an association of PSMA-expression and Gleason score (GS) or prostate specific antigen (PSA)-level. Methods and Materials: 82 patients with transrectal ultrasound (TRUS) biopsy proven PC (GS 6-10; median PSA: 10.0 ng/ml) referred for ^{68}Ga-PSMA-ligand PET/CT were retrospectively analysed (diagnostic CT: n=20). PET scans were acquired 60 minutes after injection of ^{68}Ga-PSMA-ligand (Glu-NH-CO-NH-Lys-HBED-CC) using a median activity of 145 MBq. PET images were analysed visually. In addition, maximum standardized uptake values (SUVmax) of the primary tumour and pathological lesions suspicious for lymphatic or distant metastases were calculated and compared to physiological background activity of normal prostate tissue (BGp) and the gluteal muscle (BGg). SUVmax of the primary was compared to the PSA-level and GS of the TRUS-biopsy specimen. Results: 76 patients (92.7%) demonstrated pathological tracer uptake within the prostate gland (median tumour SUVmax: 12.0). In comparison the median SUVmax of BGp and BGg was 3.85 and 1.3, respectively. PC with GS 6 and 7 showed a lower PSMA-expression (median SUVmax: 7.6) compared to patients with GS >7 (median SUVmax: 24.3). PC patients with PSA >10.0 ng/ml exhibited a higher PSMA-ligand uptake in the tumour compared to those with PSA-levels <10.0 ng/ml (median SUVmax: 17.0 versus 7.8). 23 patients (28%) showed lymph nodes (LN) with pathologic tracer accumulation consistent with metastases (n=75; median SUVmax: 11.15). In 10 patients (12.2%) pathologic skeletal lesions suspicious for bone metastases were found (n=27; median SUVmax: 8.4). Conclusion: The majority of TRUS-biopsy proven PC patients showed a pathologic ^{68}Ga-PSMA-ligand accumulation in the primary tumour on ^{68}Ga-PSMA-PET/CT. However, PC patients with GS >7 and PSA >10.0 ng/ml exhibited a higher PSMA-expression than those with low GS (6 and 7) and PSA <10.0 ng/ml. The data allow the conclusion that the higher PSMA-ligand uptake related to both PSA >10 ng/ml and GS >7 should be considered in the selection of PC patients referred to ^{68}Ga-PSMA-PET/CT for primary staging.

OP458

Comparison of ^{68}Ga-PSMA and ^{11}C-Choline using a try-modality PET/CT-MR (3.0T) system with a dedicated shuttle

O. Alonso[1,2], G. dos Santos[1,2], M. García Fontes[1], M. Rodríguez Taroco[1], H. Engler[1]; [1]Centro Uruguayo de Imagenología Molecular (CUDIM), Montevideo, URUGUAY, [2]Hospital de Clínicas, Universidad de la República, Montevideo, URUGUAY.

Multiparametric MR has shown high sensitivity and specificity for the detection of relapses in prostate cancer patients. Besides, PET/CT with ^{68}Ga-PSMA has been proposed as a promising tracer for imaging patients with biochemical recurrence (BR) at low PSA levels. The aim of this study was to prospectively compare the detection rate of ^{68}Ga-PSMA versus ^{11}C-Choline in prostate cancer patients with BR using a tri-modality PET/CT-MR system. Material and methods. Patients with BR after initial treatment were included between August 2015 and March 2016. Within 1-2 weeks PET/CT scans were performed with ^{11}C-Choline followed by ^{68}Ga-PSMA studies, with doses of approximately 400 MBq and 300 MBq, respectively. A 64-slice PET/CT scanner with TOF correction was used. Additionally, for the ^{68}Ga-PSMA scans, acquisitions with a PET/CT-MR (3.0 T) system with a dedicated shuttle, were included. An abbreviated MR protocol was planned with T1 and T2 sequences beginning at aortic bifurcation. High-resolution thin slices with T2 sequence at prostate bed and focal and panoramic diffusion (DWI) and ADC maps were obtained. MR images were performed during 30 minutes, starting 30 minutes after tracer injection. Results. A total of 36 patients were included in te study. Twenty-four (67%) underwent radical prostatectomy whereas 12 were treated with radiotherapy. The median PSA level was 3.3 ng/mL, ranging from 0.2 to 138 ng/mL. In 18 patients (50%), both scans were positive and in 8 (22%), negative. Nine patients were positive with ^{68}Ga-PSMA alone (25%) and one only with ^{11}C-Choline (3%). A total of 185 lesions were detected by at least one tracer. ^{68}Ga-PSMA had a significantly higher SUVm compared to ^{11}C-Choline: 7.0 (1.5-46) versus 4.3 (1.0-16.5), median and range for each tracer, respectively ($P < 0.0001$). Furthermore,

^{68}Ga-PSMA detected more lesions per patient compared to ^{11}C-Choline: 2.0 (0-93) versus 1.0 (0-57), respectively (P=0.023). The number of detected lesions per patient was lower for ^{11}C-Choline in patients with PSA < 3.3 ng/mL (P=0.03), but the difference was not statistically significant for ^{68}Ga-PSMA. Regarding pelvic evaluation, metastases were found in 25 patients (69%) with ^{68}Ga-PSMA PET/CT; 21 (58%) with MR (3.0 T) and 18 (50%) with ^{11}C-Choline PET/CT. MR was very useful in cases classified as indeterminate by means of PET/CT alone. Conclusion: ^{68}Ga-PSMA detected more lesions than ^{11}C-Choline in patients with prostate cancer with biochemical recurrence, regardless of PSA levels. PET/CT-MR (3.0 T) system is a feasible imaging modality that adds relevant information for patient management.

OP459

PSMA Radioligand Therapy (PRLT) of Metastatic Castration-Resistant Prostate Cancer: Safety, Efficacy and Dosimetry using the PSMA Inhibitor 617

H. R. Kulkarni, C. Schuchardt, A. Singh, K. Niepsch, R. P. Baum; THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY.

AIM: We have already had experience with the PSMA inhibitor I&T in 56 patients with progressive metastatic castration-resistant prostate cancer (mCRPC). The objective of this study was to analyze the safety and efficacy of Lu-177 labeled prostate specific membrane antigen (PSMA) ligand Lu-177 PSMA-617 in progressive mCRPC. MATERIALS AND METHODS: Thirty-nine mCRPC patients underwent a total of 78 cycles (1: n=15, 2: n=11, 3: n=11, 4: n=2) of PSMA radioligand therapy (PRLT) using Lu-177 PSMA-617. The median administered activity per treatment was 6.04 GBq (3.2 - 8.4). Ga-68 PSMA-HBED-CC (Ga-68 PSMA) PET/CT (contrast-enhanced CT) was used for patient selection and follow-up after PRLT. Response after at least 2 cycles was available at the time of analysis in 15 patients. Hematological status, renal and hepatic function and serum prostate specific antigen (PSA) levels were documented before and after therapy. Dosimetry was performed in 15 patients. RESULTS: Lu-177 PSMA-617 demonstrated intense accumulation in the metastases on post-therapy whole-body scans. The uptake was moderately intense in the kidneys and salivary glands, and mild to moderate in the intestine. The mean absorbed tumor dose was 5.1 mGy/MBq (median). Parotid glands received a higher dose (1.0 mGy/MBq) than kidneys (0.7 mGy/MBq). All patients tolerated the therapy well without any acute adverse effects. The only long-term clinical adverse effect was mild xerostomia observed in 5 patients. Grade (G) 1 hematological toxicity was noticed in 9 patients, G2 toxicity in 4 and G3-4 pancytopenia in 2 patients. Mild erythrocytopenia was the commonest sequel. Higher-grade toxicity was observed in patients (n=6) having received chemotherapy or Ra-223 treatment before. The severity of pain was significantly reduced in 4/12 (33.33 %) symptomatic patients after PRLT. Decrease in PSA was noted in 30/39 (76.9 %) patients. Molecular response evaluation (Ga-68 PSMA PET/CT) revealed complete remission (CR) in 1, partial remission (PR) in 7, stable disease (SD) in 2 and progressive disease (PD) in 5 patients. CT exhibited PR in 3, SD in 7, and PD in 5 patients. Over this period of analysis, 3 patients died (2 due to progression of disease and 1 due to myocardial infarction). The median overall and progression-free survival have not been reached yet. CONCLUSION: Lu-177 PSMA-617 appears to be safe and effective in progressive mCRPC with kinetics and dosimetry similar to Lu-177 PSMA-I&T, the first-ever PSMA inhibitor used at our center. Ga-68 PSMA PET/CT enables appropriate selection and follow-up of patients, applying the theranostics concept.

Cardiovascular System: Myocardial Perfusion - Conventional SPECT

OP460

Long-term Negative Predictive Value of Stress Myocardial Perfusion Imaging and Coronary Computed Tomography Angiography: A Meta-analysis

V. Cantoni[1], R. Green[1], W. Acampa[1], R. Assante[1], E. Zampella[1], V. Gaudieri[2], C. Nappi[1], M. Manganelli[1], M. Petretta[1], A. Cuocolo[1]; [1]University of Naples, Naples, ITALY, [2]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY.

Aim: We conducted a meta-analysis to compare the long-term negative predictive value (NPV) of stress single-photon emission computed tomography myocardial perfusion imaging (MPI) and coronary computed tomography angiography (CCTA) for the prediction of cardiovascular events in patients with suspected or known coronary artery disease (CAD). Materials and Methods: We searched PubMed, Cochrane, Web of Science and Scopus database between January 2000 and December 2015 for stress MPI and CCTA studies. We included studies that followed-up ≥100 subjects with a follow-up ≥ 5years and providing data on annualized event rate (AER). Summary risk estimates for normal perfusion at MPI or <50% coronary stenosis at CCTA were derived in random effect regression analysis, and causes of heterogeneity for demographic or clinical variables were determined in meta-regression analysis. Results: We identified 22 eligible articles (13 MPI and 9 CCTA) including 47,596 participants (34,492 in MPI and 13,104 in CCTA studies) with suspected or known CAD. The outcome of interest was the occurrence of the primary end-point considered of each study. The pooled NPV for the primary endpoint was higher in CCTA than MPI studies ($p<0.05$), ranging from 82% to 96% for MPI and from 79% to 98% for CCTA. The pooled annualized event rate (AER, per 100 person-years) was lower in CCTA than MPI studies ($p<0.05$), ranging from 0.69 to 2.28 for MPI and from 0.21 to 4.13 for CCTA. Among the studies selected, 13 MPI and 5 CCTA reported the AER for the occurrence of hard events (death and non-fatal myocardial infarction). Considering these studies, the pooled NPV for the occurrence of hard events was higher in CCTA than MPI studies ($p<0.05$) and the NPV ranged from 82% to 96% for MPI and from 87% to 99% for CCTA. Conversely, the pooled AER was lower in CCTA than MPI studies ($p<0.05$), ranging from 0.69 to 2.28 for MPI and from 0.21 to 2.63 for CCTA. A high level of heterogeneity ($P<0.0001$) was observed between studies for NPV for both MPI ($I^2=97.77\%$) and CCTA ($I^2=93.80\%$). At meta-regression analysis, a significant association between AER and hypertension ($p<0.005$) and diabetes ($p<0.01$) was found only for MPI. Conclusions: Stress MPI and CCTA have a high long-term NPV for adverse cardiac events. The lower AER in CCTA studies probably emerged for the heterogeneity of patient population included in the meta-analysis.

OP461

Prognostic value of coronary artery calcium scanning, coronary CT angiography and stress myocardial perfusion imaging in patients with suspected coronary artery disease

C. Nappi[1], S. Daniele[2], V. Gaudieri[1], W. Acampa[1], S. Segreto[1], V. Cantoni[1], R. Green[1], A. Mirabile[1], M. Imbriaco[1], M. Petretta[1], A. Cuocolo[1]; [1]University of Naples, Naples, ITALY, [2]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY.

Aim: We compared the prognostic value of coronary artery calcium (CAC) scanning, coronary computed tomography angiography (CCTA) and stress single-photon emission computed tomography myocardial perfusion imaging (MPI) in assessing cardiovascular risk in patients with suspected coronary artery disease (CAD). Material and methods: We prospectively evaluated 172 consecutive patients (age 62±11 years) at low-intermediate pre-test probability of CAD undergoing CAC scanning, CCTA and stress MPI for suspected CAD. CAC score was measured according to the Agatston method and patients were categorized into 3 groups (0, 0.01-300, and >301). Coronary artery stenoses were quantified by visual estimation as significant in the presence of ≥50% luminal narrowing. Summed stress score (SSS), summed rest score (SRS) and summed difference score (SDS) were automatically calculated. Ischemia was defined in the presence of a SDS ≥2. Major cardiac events (MACE) were considered cardiac death, nonfatal myocardial infarction and unstable angina requiring coronary revascularization. Results: Follow-up was 91% complete during a mean period of 82±34 months. In 156 subjects, 22 events occurred (4 cardiac deaths, 2 nonfatal myocardial infarctions, and 16 revascularizations for unstable angina) with cumulative event rate of 14%. Cardiac event risk increased with worsening of CAC categories. In patients with CAC of 0 (n=42) no event was observed; whilst patients with CAC 1-300 (n=98) and >300 (n=16) had 14 and 8 events, respectively (14% and 50%, respectively; P<0.001). MACE occurred in 27% of patients with ≥50% stenosis at CCTA and in 34% of patients with ischemia at stress MPI. At univariable Cox regression analysis, male gender, ln(CAC + 1), ≥50% stenosis at CCTA, SSS and SDS resulted significant predictors of MACE (all P<0.05). At multivariable analysis, only ln(CAC + 1) and SDS (both P<0.001) resulted independent predictors of events. The addition of MPI data improved the prognostic strength of the model including in hiercarical order clinical data, CAC score and CCTA findings increasing the global chi-square from 36.17 to 41.99 (P<0.05). Conversely, CCTA data did not provide significant incremental prognostic power over the model including clinical data, CAC score and stress MPI findings (global chi-square from 38.84 to 41.99 (p=0.08). Conclusions: Patients at low-intermediate pretest probability of CAD without CAC do not need further cardiac imaging investigations. Both CCS and MPI, but not CCTA, are independent predictors of MACE. Moreover, functional data by stress MPI improves risk stratification over clinical variables, CAC scanning and CCTA findings.

OP462

Future Cardiac Events in Patients with Ischemic ECG Changes during Adenosine Infusion as a Myocardial Stress Agent with Normal Cardiac Scan.

H. A. AMER, K. Niaz, H. Samiri, M. Sheikh, M. Alothman, M. Alhammad; King Abdulaziz Hospital for National Guards, Al-Ahsa 31982, SAUDI ARABIA.

Background. The development of ischemic changes during adenosine myocardial perfusion imaging (MPI) has been shown to be a predictor of CAD and consequently subsequent cardiac events and worse outcome. Some published data shown that ST-segment depression develops during adenosine administration appear to be at increased risk for future cardiac events compared with similar patients without ECG evidence of ischemia. We sought to determine the prognostic importance of adenosine-induced ischemic ECG changes in patients with normal SPECT myocardial perfusion images. **Methods:** We performed a retrospective analysis of 750 patients undergoing adenosine MPI. Patients with baseline electrocardiographic (ECG) abnormalities and or abnormal scan were excluded. The data were collected from the nuclear medicine database identifying all the reported Gated myocardial perfusion SPECT with adenosine stress tests between January 2013 and January 2015. Images were graded using the 17-segment model. Follow-up information was obtained from hospital records. All cardiac events (cardiac death, nonfatal myocardial infarction [MI], percutaneous coronary intervention, coronary artery bypass grafting, or angiography) were verified with hospital records. **Results:** Overall, 67 patients (9%) had ischemic ECG changes during adenosine infusion in the form of ST depression of >/= 1mm. Of these, 29 (43% [3.8% of all patients]) had normal MPI (positive (+) ECG group). An age- and sex-matched group of 108 patients with normal MPI without ECG changes served as control subjects (negative (-) ECG group). During a mean follow-up of 27 +/- 12 months, patients in the +ECG group had no significantly more adverse cardiac events than those in the –ECG group (nonfatal myocardial infarction and cardiac death did not differ between the 2 groups). There were no cardiac deaths in either group. One (0.9%) patient within the negative ECG group had a nonfatal MI (0.7% annual event rate after a negative MPI). Two also in this group (1.8%) patients admitted with a diagnosis of CAD where they have been ruled out by angiography. A fifth case was admitted due to heart failure that proved to be secondary to pulmonary cause and not of CAD. **Conclusions.** Patients with normal myocardial perfusion scintigraphy in whom ST-segment depression develops during adenosine stress test appear to be with no increased risk for future cardiac events compared with similar patients without ECG evidence of ischemia and consequently myocardial perfusion scan remain a main predictor for future cardiac events and worse outcome.

OP463

Cardiac stress test modalities during myocardial perfusion scintigraphy in type-2 diabetic patients: are they relevant for prognosis? A Substudy of the BARDOT Trial

F. Caobelli, J. Chronis, G. Haenny, M. Brinkert, M. E. Pfisterer, M. J. Zellweger; Universitätsspital Basel, basel, SWITZERLAND.

Objectives: to assess clinical characteristics able to predict the stress test modality and the impact of exercise level achieved on cardiovascular risk. **Background:** the Basel Asymptomatic high-Risk Diabetics' Outcome Trial (BARDOT) demonstrated that asymptomatic diabetic patients with an abnormal myocardial perfusion scintigraphy (MPS) were at increased risk of major cardiac events (MACE). It still remains unclear whether in such patients some comorbidities can predict the stress modality and whether, in patients undergoing physical stress trest, the exercise level achieved can provide further risk stratification. **Methods:** four hundred patients with type-2 diabetes and neither history nor symptoms of CAD were evaluated. They underwent clinical evaluation and MPS with either physical or pharmacologic stress test. Those able to perform an exercise stress were divided into two groups based on METs achieved (i.e <6 and ≥6, corresponding to vigorous exercise). Patients were followed up for 2 years. MACE were defined as myocardial infarction or cardiac death. **Results:** A large proportion of patients (305/400, 76.3%) could perform an adequate ergometric test, defined by reaching 85% of the predicted max heart rate. Of these, 244 (80%) could reach 6 METs. Independent predictors of a pharmacologic stress test with adenosine were smoking (OR 2.6, 95%CI 1.5-2.7, p=0.009), Body Mass Index >30 (OR 2.7, 95%CI 1.9-3.1, p=0.006), presence of peripheral neuropathy (OR 2, 95%CI 1.3-2.3, p=0.04) and peripheral arterial disease (OR 4.3, 95%CI 2.8-4.7, p<0.001). Patients undergoing pharmacological stress had a higher rate of MACE than physically stressed patients (3.2% vs 0.9%, p=0.03). Patients reaching < 6 METs during physical stress had a significantly higher MACE rate than those achieving ≥6 METs (4.9% vs 0.4%, p=0.01). Even in those patients achieving ≥6 METs, MPS showed an incremental prognostic value over pre-test information (chi-square 20.1 vs 5.4, p=0.01). **Conclusions:** In asymptomatic diabetic patients at high cardiovascular risk, specific comorbidities are highly predictive of the stress test modality used. Patients undergoing pharmacologic stress had a higher rate of MACE, similarly to those unable to reach 6 METs during physical exercise. Even in patients with preserved exercise capability, MPS provided incremental prognostic value.

OP464

Possible application of stress-only protocol in myocardial perfusion imaging

M. M. Włodarczyk[1], J. Kuśmierek[2], A. Płachcińska[1]; [1]Department of Quality Control and Radiological Protection, Medical University of Lodz, Poland, Lodz, POLAND, [2]Department of Nuclear Medicine, Medical University of Lodz, Poland, Lodz, POLAND.

Aim: The purpose of this study was to determine in which patients it is possible to use a stress-only (SO) strategy to assess myocardial perfusion. Material and methods: 154 patients (65F, 89M, mean age 61 years) without prior myocardial infarction, history of coronary artery by-pass grafting or cardiomyopathy underwent two day stress/rest Gated-SPECT/CT MPI using ^{99m}Tc-MIBI (11MBq/kg) as a radiopharmaceutical. Exercise or dipyridamole (0,7mg/kg) was used as a stressor. Studies were processed on GE Xeleris2 station without (NC) and with use of attenuation correction (AC). Two experienced nuclear medicine specialists assessed visually myocardial perfusion (a consensus) using 4-point scale (4p): 1-normal (n), 2-probably normal (pn), 3-probably abnormal (pa), 4-abnormal (a). At first stress-only images were evaluated without and with AC, then stress/rest (S/R) images without and with AC. Regional and global wall motion was also evaluated. Patients with LVEF<50% (N=14) were eliminated from further analysis. Coefficients of agreement between SO and S/R assessments were calculated in 4p scale (including Cohen's kappa) and after dichotomizing results to normal (n+pn) and abnormal (a+pa) - 2-point scale (2p). Agreement was also analyzed in subgroups (male, female, BMI<30, BMI≥30). Results: Agreement of assessments in the whole cohort (N=140) in 4p scale was equal to 58%, k=0,41 (NC) and 74%, k=0,51 (AC); in 2p scale: 80% (NC) and 89% (AC) , p=0,019. Among discordant results there were statistically significantly more abnormal results in S/R evaluation than in SO (17% vs 3%, p=0,0003 for NC and 10% vs 1%, p=0,006 for AC). Agreement in subgroups in 2p scale with AC was: for male patients with BMI<30 - 93%, with BMI≥30 - 76%, for female patients - 94% and 88%, respectively. Conclusions: Agreement of assessments of SO and S/R studies was higher after application of AC. Higher percentage of abnormal S/R study interpretations among discordant results indicates that some of myocardial perfusion defects were underestimated in SO protocol. Application of SO protocol is possible in patients with BMI<30 provided that AC is used.

OP465

The Prognostic Value of Mechanical Dyssynchrony by GSPECT vs Electrical Dyssnchrony by QRS in Patients with CAD and Ejection Fraction >35%

S. Borges-Neto, M. Fudim, P. Hess; Duke University, Durham, NC, UNITED STATES.

Background: Whether mechanical dyssynchrony measured by phase analysis of gated single-photon emission computed tomography myocardial perfusion imaging (GSPECT MPI) adds prognostic information to electrical dyssynchrony or is independently associated with death among patients with an ejection fraction >35% is incompletely understood. Methods: We identified consecutive patients with angiographically significant coronary disease who underwent GSPECT MPI. Serial Cox proportional hazards models consisting of clinical variables only, clinical variables plus mechanical dyssynchrony according to the duration of the cardiac cycle during which 95% of the ventricle is initiating contraction (phase bandwidth),clinical variables plus electrical dyssynchrony as measured by QRS duration, and a final model inclusive of all of these variables were fitted. Results: A total of 1,157 patients were identified. The median age was 64 (interquartile range (IQR) 55-72 years). Patients were predominantly white (73.8%), of male sex (67.7%), and had hypertension (76.7%). A minority had congestive heart failure (21.9%), peripheral vascular disease (10.5%), and cerebrovascular disease (12.2%). The median QRS duration was 92 (IQR 84-103) ms, while the median bandwidth was 58 (IQR 41-90)°. The median duration of follow-up was 4.3 (IQR 3.0-6.4) years. A total of 293 deaths were observed. Mechanical dyssynchrony added prognostic information independent of standard clinical variables and electrical dyssynchrony (p<001). Conclusions: Mechanical dyssynchrony measured by GSPECT MPI is independently associated with death and adds prognostic information above that provided by standard clinical covariates and electrical dyssynchrony.

OP466

The Impact of Appropriate Use Criteria 2013 on the diagnostic accuracy of SPECT-MPI

D. DATTA, K. NARVESH, S. GAMBHIR; SANJAY GANDHI POST GRADUATE INSTITUTE OF MEDICAL SCIENCES, LUCKNOW, INDIA.

ABSTRACT Background - Appropriate Use Criteria have been developed by ASNC to aid in the optimal use of SPECT- myocardial perfusion imaging (MPI), a technique that is a mainstay of risk-assessment for ischemic heart disease. In this study, we have tried to evaluate the impact of appropriate use criteria on the diagnostic value of SPECT-MPI. The sensitivity, positive predictive value and overall accuracy of SPECT-MPI is calculated under the 'appropriate' category. **Methods and Results**- A retrospective study of 100 consecutive patients undergoing outpatient, community-based SPECT-MPI and Invasive coronary angiography was conducted. The maximum time-interval between the two tests was 30 days. Subjects were categorized as normal and abnormal SPECT-MPI. The abnormal MPI test includes presence of stress-induced ischemia or non-viable myocardial tissue. The normal MPI test consists of absence of stress-induced ischemia or non-viable myocardial tissue. The coronary angiography was called positive if there was presence of more than 50% stenosis or plaquing in any coronary arteries, and was called negative in case of normal coronaries or less than 50 % stenosis in any of the coronary arteries. In the appropriate category , those with only positive coronary angiography (more than 50 % stenosis) were considered in this study, among which positive and negative Myocardial perfusion scans occupied 91% and 09% respectively. In the appropriate criteria, the Sensitivity (95 % Confidence Interval), Positive Predictive Value, and Overall Accuracy of SPECT-MPI is 90.8% (82.8 - 95.4%) , 97.8% and 89% respectively. **Conclusion-** The Appropriate Use Criteria has a definite impact on the diagnostic accuracy of SPECT-MPI. When performed for appropriate indications, SPECT-MPI continues to demonstrate high diagnostic value. Overall results indicate the appropriateness of cardiac diagnostic care in SGPGI meets international standards. **Key words**: myocardial perfusion imaging, appropriate use criteria, diagnosis, SPECT.

OP467

Assessment of Left Ventricular Remodeling by Gated SPECT Myocardial Perfusion Imaging in Diabetic Patients: a Propensity Matched Cohort Analysis

V. Gaudieri[1], C. Nappi[2], W. Acampa[2], S. Daniele[1], R. Assante[2], E. Zampella[2], M. Petretta[2], A. Genova[2], P. Buongiorno[2], A. Cuocolo[2]; [1]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [2]University Federico II, Naples, ITALY.

Aim: Left ventricular (LV) geometry is an important parameter in the pathophysiology of heart failure. Diabetes is an independent risk factor for the development of heart failure. Measures of LV remodeling automatically derived from gated single-photon emission tomography (SPECT) provide incremental and independent information over standard clinical and nuclear markers for the identification of patients with heart failure. The aim of this study was to

compare LV shape parameters and indices of diastolic function in a propensity score-matched cohort of diabetic and non-diabetic patients with normal stress myocardial perfusion imaging and preserved LV systolic function. Materials and Methods: We evaluated 1168 consecutive patients (806 non-diabetic and 362 diabetic patients) without a documented history of coronary artery disease, with normal myocardial perfusion and normal LV ejection fraction at stress gated SPECT. To account for differences in baseline characteristics between diabetics and non-diabetics patients, we created a propensity score-matched cohort considering clinical variables. An automated software program was used to calculate indices of LV diastolic and systolic function and parameters indicating shape distortion (stress end-diastolic, SIED, stress end-systolic, SIES, shape index and eccentricity index). A cut-off of 0.54 was considered to identify patients with abnormal SIES. Results: Before matching, diabetic patients were younger with a greater body mass index and higher prevalence of male gender, hypertension, dyslipidemia, smoking, family history of coronary artery disease and chest pain (all P<0.001). After matching, clinical characteristics were comparable in 332 diabetic and 332 non-diabetic patients. Diabetic patients showed significantly higher SIED and SIES values and lower eccentricity index compared to non-diabetic patients (all P<0.001). Patients with diabetes also had higher prevalence of abnormal SIES compared to those without diabetes (33% vs. 16%, P<0.001). Indices of LV diastolic function did not differ between diabetic and non-diabetics patients. Conclusions: After balancing clinical characteristics by propensity score analysis, diabetic patients with normal myocardial perfusion and preserved LV systolic function, showed a higher prevalence of abnormal LV shape parameters compared to non-diabetic subjects. Thus, shape indexes by gated-SPECT are useful for identifying early LV remodeling in patients with diabetes.

Utility of myocardial perfusion SPECT images reconstructed from early dynamic acquisition with a cadmium zinc telluride camera Comparison with conventional late acquired images

C. Kullberg[1], S. Akil[2], F. Hedeer[1], H. Engblom[2], C. Hindorf[3], J. Oddstig[3]; [1]Clinical Physiology and Nuclear Medicine, Lund, SWEDEN, [2]Lund University, Department of Clinical Sciences Lund, Clinical Physiology, Skane University Hospital, Lund, SWEDEN, [3]Radiation Physics, Lund, SWEDEN.

Introduction The cadmium zinc telluride (CZT) SPECT camera enables imaging of the entire myocardial volume simultaneously. Thus, myocardial perfusion SPECT (MPS) based on this technique could potentially enable quantification of absolute myocardial blood flow using early dynamic list-mode image acquisition. If static perfusion images, reconstructed from this early dynamic image acquisition, could replace conventional late imaging (approximately 1 hour after administration of ^{99m}Tc-tetrofosmin) the examination time would be significantly shortened. The aim of this study was to investigate whether static perfusion images reconstructed form early dynamic imaging could replace conventional late static images for diagnosing decreased perfusion in patients undergoing MPS. **Materials & Methods** The study included 39 dynamic examinations from patients with suspected or established stable ischemic heart disease (25% women, mean BMI=27). 31 examinations were performed at rest and 8 with adenosine stress. A 12-minute dynamic list-mode image acquisition, started at the time of ^{99m}Tc-tetrofosmin administration (mean activity 375MBq), as well as a conventional 8-minute static image acquisition approximately 1 hour later were performed using a CZT camera (GE NM530c). Static perfusion images were reconstructed from the early list-mode dynamic acquisition using the last 8 minutes of the 12-minute acquisition. An experienced observer visually graded both early and late perfusion images regarding image quality (poor=1 to excellent=4),

presence of extracardiac uptake (none=1 to 4=unacceptable) and diagnosis based on presence or absence of decreased perfusion (pathologic with high certainty=1, probably pathologic=2, probably non-pathologic=3, non-pathologic with high certainty=4). All image analysis were performed with the observer blinded to all patient data and timing of the acquisition. **Results** In the early reconstructed images, mean score for image quality was 2.8 (range: 2-4) and 72% of the patients had extracardiac uptake disturbing perfusion assessment. For the conventional late reconstruced images, mean score for image quality was significantly higher (3.5, range: 2-4; p<0.001) and 13% of the patients had disturbing extracardiac uptake. The diagnosis (pathological vs non-pathological) based on images reconstructed from early dynamic acquisition matched the diagnosis obtained using late conventional imaging in 87% (34/39 patients). The over all agreement of perfusion score showed a kappa value of 0.3. **Conclusion** The early static images reconstructed from the dynamic image acquisition can not be recommended for clinical routine, mainly because of significant extracardiac uptake in the majority of the patients.

OP478

Dual isotope Gated SPECT and PET CT imaging in evaluation of coronary artery disease

A. Ghilardi, G. Medolago, L. Pozzi, N. Brambati, E. Iampietro, R. Rota, L. Madaschi, C. Bianchi, A. Bruno; ASST Papa Giovannni XXIII, BERGAMO, ITALY.

Aim: we report our experience in the evaluation of extent of myocardial damage in CAD: scar, viability and ischemia using dual isotope Gated_SPECT and PET_CT imaging. **Methods**: We distinguish three different conditions: the first [A], the most common: the evaluation of extent of myocardial *scar/viability* comparing Rest[Stress] Gated_Spect MPI [Tc^{99m}_Sestamibi] to F^{18}DG PET_CT after glucose loading. The second [B]: the evaluation of direct imaging of *stress-induced myocardial ischemia* with F^{18}-DG PET_CT [no glucose loading] compared to Tc^{99m}-Sestamibi stress/rest Gated-SPECT. The third [C]: the identification of *acute ischemia* in patients referred to ED for acute chest pain with low_intermediate risk [not significant ECG changes, normal enzymes and no wall motion abnormalities] using Tc^{99m}-Sestamibi rest Gated_SPECT and F^{18}DG PET_CT [no glucose loading]. Gated_SPECT *[Tc^{99m} Sestamibi_Tc^{99m}]* was performed using Siemens Symbia S equipped with LEHR; PET images were obtained with Siemens Biograph-6. Transaxial images were reconstructed with iterative displayed as a series of short-long*[sagittal-horizontal]*-axis. **Results:** In viability evaluation [A] the typical pattern is the mismatch perfusion/metabolism with focal F^{18}DG uptake in hypoperfused segments: glucose loading is needed. If stress Gated_SPECT is perfomed also ischemia can be evaluated. In the second [B] in stress-induced ischemic myocardium F^{18}DG uptake is present *[hot spot]* in stress hypoperfused or normal reperfused segments: no glucose loading is needed. In the third [C], F^{18}DG PET_CT better than rest Gated_SPECT identifies acute ischemic segments highlighting so "called *metabolic stunning*" as a *"hot spot"* even after restoration of blood flow [no glucose loading]. In all cases it is preferable not to include diabetic patients. In A the issue is to demonstrate viability in infarcted segments that may benefit from revascularization or in presence of severe coronary stenosis. In B we prefer to study patients with multivessel coronary disease to overcome so "*called balanced ischemia*": focal ischemic uptake of F^{18}DG in normal perfused segments is a marker of anaerobic metabolism activation. Finally in C, F^{18}DG PET_CT may represent an accurate and sensitive procedure superior to Gated_SPECT in identifying acute myocardium ischemia because metabolic recovery lags behind perfusion for almost 24-30 hours. **Conclusions:** In our experience dual isotope Gated_SPECT - PET_CT imaging is an effective and accurate tool to evaluate the extent of myocardial damage in CAD in subgroups of patients in which standard usual Gated_SPECT can't fully address clinical decision making.

OP479

Radium-223 Therapy in Metastatic Castration - Is post treatment bone scan helpful to assess treatment response ?

D. Aniceto, M. Botelho Cruz, A. Nunes, V. Lewington, H. Fahim, S. Allen, C. Mills; Nuclear Medicine Service Guys and St. Thomas NHS Trust, London, UNITED KINGDOM.

Background: Prostate cancer is the 2nd commonest cause of cancer death in UK men and frequently metastasis to bone. The bone seeking radiopharmaceutical radium-223 dichloride ($^{223}RaCl_2$) has been shown to prolong survival and delay bone complications in men with castrate resistant prostate cancer (CRPC). Our aim was to assess the role of ^{99m}Tc MDP bone scintigraphy as a response marker in men undergoing $^{223}RaCl_2$ therapy and to compare this with the impact of treatment on quality of life.Methods: Data from patients with metastatic CRPC who had completed 6 cycles of $^{223}RaCl_2$ treatment at Guys and St Thomas' NHS Trust between 2015 and 2016 were reviewed retrospectively. Patients' Quality of Life (QoL) was assessed by EORTC QLQ-C30 questionnaires as part of the routine therapy procedure. All patients underwent a ^{99m}Tc MDP bone scan within two months of starting $^{223}RaCl_2$ therapy and within three months of completing the sixth cycle. Skeletal metastatic involvement was assessed semi-quantitatively using the Soloway score system. Pre and post treatment scans were compared and correlated with QoL responses for each patient. Results: 39 patients were treated, median age of 72.3 years. The interval between first evidence of metastases and first cycle of was 0.5-7.7 years. QoL scores revealed an overall sustained improvement in patients' wellbeing. Of the 77% patients who reported bone pain at the beginning of treatment, 35% recorded reduced pain score. Comparison of pre and post treatment bone scans showed skeletal metastatic progression in 44%, stable disease in 19%mixed metabolic response in 31% and improvement in 6% of patients.Discussion: Our results support published evidence that $^{223}RaCl_2$ treatment delivers improved QoL in men with metastatic CRPC. This improvement does not appear to correlate with metabolic treatment response as assessed by ^{99m}Tc MDP bone imaging, however. Conclusion: Whilst bone scintigraphy is a pre requisite for planning $^{223}RaCl_2$ molecular radiotherapy, routine post therapy imaging does not seem a useful means of assessing response and / or clinical outcome.

OP480

SPECT Myocardial Perfusion Imaging Quantification in Obese Subjects: Influence of Adipose Tissue in the Attenuation Correction with Computed Tomography Attenuation Maps

I. Melo[1], O. Stakhiv[2], M. Jessop[2], P. Begley[2], S. Dizdarevic[2], E. Sousa[1]; [1]Escola Superior de Tecnologia da Saúde de Lisboa, LISBOA, PORTUGAL, [2]Nuclear Medicine, Department of Imaging, Brighton and Sussex University Hospital NHS Trust, Brighton, UNITED KINGDOM.

Introduction: Myocardial Perfusion Imaging (MPI) is a well implemented technique for assessment of Coronary artery disease (CAD). Obese subjects have a larger amount of adipose tissue (AT) that attenuates gamma rays emitting from the heart potentially causing false positive results due to attenuation artefacts.**Aim:** To evaluate the influence of thoracic and abdominal AT, on the perfusion quantification for subjects with Body Mass Index (BMI) between 30 and 35, and above 35.**Materials and Methods:** A sample of 72 subjects, who underwent two day protocol stress-rest SPECT MPI, was divided into 4 groups by gender and BMI**.** The activity of ^{99m}Tc-tetrofosmin administered was adjusted using ranges based on the weight of the patients. All patients were referred for suspected CAD. Images were analysed with and without the incorporation of computed tomography attenuation correction (CTAC), for stress and rest studies and reconstructed by OSEM/MLEM. All image segmentation and quantification was done by myocardial wall regions for

perfusion: Anterior, Inferior, Lateral, Septal and Apical, using QGS/QPS. Each study was processed three times by one operator, and average value was used.The AT in thoracic (T7 to T8) and abdominal (T9) regions was calculated from CT acquired for attenuation correction, using ImageJ automatic threshold for segmentation, with selected Hounsfield Units from -190 to -30. Regression analyses were performed, between the thoracic and abdominal AT quantity and the difference in the perfusion values with CTAC and without CTAC. **Results:** The sample was split into 4 groups: 47 with BMI between 30 and 35 Kg/m^2 (27 male (M1) and 20 female (F1)) and 24 (13 male (M2) and 11 female (F2)) with BMI between 30 and 35 Kg/m^2 above 35 Kg/m^2.Although expecting influence of thoracic AT in women in lateral and anterior perfusion, these results showed no strong correlation. Abdominal AT influenced inferior perfusion as expected (F2:R^2=0.46). For men the results showed no strong relationship for abdominal AT, but thoracic AT showed influence on septal rest (M2: R^2=0.55), inferior rest (M2: R^2=0.56), and apical stress (M2: R^2=0.47). **Conclusion:** The influence of AT in the abdomen and thorax does not affect all groups in the same way, however the effect is more marked in the male group with large BMI.

OP481

Scintimammography in the assessment of early and final response of breast cancer to neoadjuvant chemotherapy: results of single center prospective study

S. N. Novikov, S. Kanaev, P. Krivorotko, P. Krzhivitskiy, T. Semiglazova, Z. Bryanzeva, E. Turkevich, L. Jukova; N.N. Petrov Institute Oncology, St Petersburg, RUSSIAN FEDERATION.

Purpose: to determine whether scintimammography (SMG) with 99mTc-MIBI performed after 2-3 cycles and/or at the end of neoadjuvant chemotherapy (NAC) can be used to predict complete pathologic response in breast cancer (BC). The secondary objective was to correlate accuracy of SMG with biologic subtypes of BC. **Material and methods:** 120 patients with advanced BC were included in prospective single center comparative study of taxane or taxane-doxorubicin (+/-trastuzumab) based NAC. Planar SMG with 740 MBq of 99mTc-MIBI was performed before the start, after 2-3 and at the end of NAC. Pathologic response was assessed according Miller-Payne V grade classification. Sintigraphic response was estimated as follows: progression (grade I); stabilization (II); partial effect (III); prominent efficacy (IV); complete response (V). We evaluate accuracy of grade IV-V SMG response mentioned after 2-3 cycles of NAC for predicting complete pathologic response (pCR) at the end of treatment. We determine accuracy of grade V SMG response at the end of NAC for predicting pCR. Additionally we evaluate predictive value of SMG in patients with different biologic subtypes of BC. **Results:** Grade IV-V scintigraphic response after 2-3 cycles of NAC demonstrated moderate (84%) accuracy (Ac) in predicting pCR: sensitivity (Sen) - 78%, specificity (Sp) - 84%, positive predictive value (PPV) - 56%, negative predictive value (NPV) - 94%. Grade V scintigraphic response at the end of NAC characterized by high (92%) Ac in predicting pCR: Sen - 95%, Sp -91%, PPV - 76%, NPV - 98%. We mentioned significant differences in frequency of pCR in women with luminal (pCR - 3%) and non-luminal (pCR-19%) BC but we didn't find significant differences in accuracy of SMG for predicting pCR in women with various biologic subtypes of BC. **Conclusion** 1. SMG is accurate method for predicting pCR in patients with BC. 2. Its Sen and PPV are higher at the end of NAC. 3. We didn't find correlation of BC biologic subtype and efficacy of SMG in predicting pCR.

OP482

Nuclear Medicine Departmental experience in providing efficient treatment and care for ^{223}Ra Dichloride Therapy

A. S. F. Ribeiro, S. Summers, L. Causer, T. Shepherd, I. Murray, J. Gear, G. Flux, M. Meintjes, Y. Du; Royal Marsden Hospital, Sutton, UNITED KINGDOM.

Background: Prostate cancer is unique among solid tumours, the greatest threat to patient's survival and quality of life is posed by bone metastases rather than visceral involvement. Radium dichloride therapy (223Ra) is currently used to treat advanced castration-resistant prostate cancer. Our Nuclear Medicine Department has been providing ^{223}Ra since 2004 and currently we perform an average of four treatments a week, both clinical and research patients. Our Nuclear Medicine Department provides a variety of diagnostic (both conventional nuclear medicine & PET/CT) and therapy services within a leading specialist cancer treatment hospital. Our department includes a Radioisotope Therapy Consultant (RTC), two Clinical Nurse Specialists for radioisotope therapy (CNSrt), and two Research Technologists (RT) who all work together to safely deliver ^{223}Ra. Materials and Methods: Our pathway starts with initial referral from clinical team; patients are seen by the RTC and the CNSrt/RT who advise patient on treatment and coordinate all 6 treatments, liaise directly with the clinical team (usually Urology) and patient. Our in house Radiopharmacy dispenses the solution for injection ready to be administered; the CNSrt and RT rotate in accessing the patient for suitable venous access (similar to chemotherapy access) and administering the therapy. Between cycles patients are closely monitored up either by the Urology team or the research team which normally include blood tests and scans. Our technique to administer the treatment is simple yet effective; protective personal equipment is always used: double gloves, apron, incontinence pads and always two staff members present; one member administers the treatment while the other assists and collects the radioactive waste. We also operate in a quiet environment to avoid distractions and to ensure there is no contamination. Thorough close monitoring of the room/equipment used and self-monitoring are carried out as standard of practice. Results: Our recent audit on staff exposure when administering ^{223}Ra has demonstrated average dose rate recorded of 3.67μSv/ hr (±1.4) with room contamination and self-monitoring not significant and no recorded EPD readings. Our service has been visited by other institutions to observe our practice and we have taken part in teaching sessions both across the hospital (liaising with wards and clinical teams) as well as outside training sessions. Conclusion: This study aims to disseminate our experience in providing ^{223}Ra therapy both in clinical and research settings, including our challenges and improved outcomes.

OP483

Automated production of ^{68}Ga-DOTATATE: an overview of yield and quality

T. Young-Mylvaganan, E. A. Aalbersberg, M. Geluk-Jonker, B. J. de Wit-van der Veen; The Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Introduction ^{68}Ga-DOTATATE PET/CT is an important imaging technique used for the visualization of somatostatin receptor (SSTR)-positive neuroendocrine tumours. In 2012 the NKI-AVL initially started ^{68}Ga-DOTATATE synthesis with a semi-automated module. In December 2014 a fully automated commercial system was purchased, which led to an increase in production over the past two years. Aim To present our ^{68}Ga-DOTATATE syntheses experiences and evaluate the production-rates between December 2014 and March 2016. Materials and Methods ^{68}Ga-DOTATATE is prepared on a fully automated system (Scintomics GmbH, Germany) using the ^{68}Ge/^{68}Ga-generator produced by iThemba LABS (IDB Holland bv). Quality control (QC) procedures include tests for radiochemical purity (the percentage of ^{68}Ga DOTATATE), pH, filter integrity, sterility, ^{68}Ge breakthrough and HEPES content. Before the batch is released for clinical use, all QC tests except sterility, ^{68}Ge breakthrough and HEPES need to be performed. Instant thin-layer chromatography (ITLC) and solid phase chromatography were used to determine radiochemical purity in the final product. The pH of each batch was assessed with an universal indicator strip. ^{68}Ge breakthrough was measured using gamma-ray spectrometry after complete ^{68}Ga decay (>48

hour). 2-week culture of the final product in Tryptose soya broth (TSB) indicated whether the final product was sterile. Finally, HEPES content was determined by ITLC. Results A total of 116 ^{68}Ga-DOTATATE syntheses were performed using two generators, of which 110 (95%) proved suitable for injection. 3 productions failed due to technical difficulties and 3 were rejected due to failed QC for both ^{68}Ga (III) ions and ^{68}Ga colloids. In respectively 5 and 2 cases the ^{68}Ga (III) ions and ^{68}Ga colloids were too high; these were released for patient administration by the local pharmacist. The final yield of ^{68}Ga DOTATATE was 613.00 MBq (range 285.7-1034.00 MBq) with an average radiochemical purity of 97.96% (range 87.77-99.00%). The average ^{68}Ga (III) ions were 0.79% (range 0.25-5.16%) and ^{68}Ga in colloidal form was 1.50% (range 0.56-7.49%). The average breakthrough of ^{68}Ge was 0.00032%, and was too high (>0.001%) in 2 batches of which 1 was released for clinical use. All productions were sterile and HEPES concentration exceeded the maximum limit in only 1 case. The measured pH (limit 4.0-8.0) and the filter integrity never exceeded the allowed limits. Conclusion Automated production of ^{68}Ga-DOTATATE has been implemented successfully with low failure rates (5%) and yields sufficient to prepare 2-3 syringes for patient administration per batch.

OP484

Inter operative imaging of Sentinel node procedure with use of a portable gamma camera: An technologist's perspective

L. A. van Kronenburg -Rooze, T. Young-Mylvaganan, E. C. Streefkerk, B. G. Hoving, B. J. de Wit- van der Veen; Netherlands Cancer Institute-Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.

Introduction Since 2015 technologist are performing intra-operative imaging during sentinel node (SN) procedures, primary for head/neck (HN) and penile carcinoma, using a portable gamma camera (PGC) in our institute. This specific approach assists the surgeon with accurate localization of lymph nodes. Aim Working in the operation room (OR) is a new and challenging task for nuclear technologists, so the aim of this descriptive evaluation is to provide a technologist's insight on intra-operative SN imaging. Methods /materials All OR-procedures were performed on the same (1-day protocol) or the next day (2-day protocol), depending on the OR planning. The 2-day protocol is based on the 1-day protocol, with an increased radiopharmaceutical dose due to the larger time interval. Three technologists are currently selected for the rotational intra-operative imaging team, and all underwent the 'Working in the OR'-training and are internally certified for working with the PGC. The standard SN-workflow constitutes of; Pre-operative: planar and SPECT/CT imaging by a technologist at the nuclear medicine department. SNs were appointed by a Nuclear physician and marked on the skin of the patient. Pre-operative images were also assessed by the OR-technologist. Intra-operative: the OR-technologist acquired and interpreted the PGC images in the OR. The surgeon uses the pre- and intraoperative images, a gamma probe and bleu dye to excise the allocated lymph nodes. Result In 2015, 80 penile (46x 1-day and 34x 2-day protocol) and 65 HN (35x 1-day and 12x 2-day protocol) SN-procedures were performed with use of the PGC imaging on OR. The average time a technologist was needed was 88 min. for penile and 124 min. for HN procedures. The 2-day protocol had a 79% larger time interval between imaging and OR compared to the 1-day protocol (90 MBq), and doses were adjusted (180 MBq) In penile cancer 46 and 109 were marked; 182 and 136 were removed on OR for 1-day and 2-day protocols, respectively. In HN-SN 160 and 34 were marked; 296 and 49 were removed on OR for 1-day and 2-day protocols, respectively. Conclusion Technologists have successfully assisted in 145 image guided SN-procedures at our institute. The positive feedback from technologist, surgeons and nuclear physicians on the use of intraoperative imaging by technologists suggests an increase of procedures for next year. Nonetheless, due to logistics and available material, there is now a limit of 3 sequential OR' s per day.

OP485

Time-to-peak ratio. What does it mean in myocardial perfusion imaging using IQ SPECT in patients with manifested coronary artery disease?

L. Hehenwarter, G. Schweighofer Zwink, C. Pirich; Uniklinik Salzburg, Salzburg, AUSTRIA.

Aim: To assess the added diagnostic value of time-to-peak ratio (TPR) for risk stratification in patients with manifested coronary artery disease undergoing accelerated myocardial perfusion imaging (MPI) using IQ SPECT. Material and Methods: Retrospective analysis of 183 patients with priory angiographically proven coronary artery disease (CAD) referred to our department for risk stratification with MPI performed using a two-day pharmacological stress protocol with adenosine or regadenoson and gated Tc-99m-Tetrofosmin SPECT (4 MBq/kg body weight). Data were acquired in 17 views (17 sec. each) with a Siemens Symbia T6 camera using IQ-SPECT collimators. The results were generated with Corridor 4DM software. The SSS, SRS, SDS, EF, TID, extent of ischemia in % of left ventricular area, extent of scar tissue in % of left ventricular area and TPR values of five segmented model were statistically analyzed using SPSS software. The following TPR indices were calculated: sum of defect-diagram (TPRdefect), sum of normalized diagram (TPRsumND), minimum of normalized diagram (TPRminND), maximum of normalized diagram (TPRmaxND), standard deviation of normalized diagram (TPRsdND) and range of normalized diagram (TPRranND). Results: 183 patients (130 males, 53 females) with a mean age of 67 (±11) years were analyzed of whom 90, 47 and 30 patients had 3-, 2- or 1-vessel disease, respectively. 16 patients had different disease. The following TPR indices were significantly different in patients with 3-VD compared to the remaining participants: TPRminND (44.1 ±7.3 vs. 46.9 ±6.6; $p<0.007$), TPRranND (13.8 ±7.8 vs. 11.2 ±7.8; $p<0.023$), TPRsdND (20.7 ± 11.6 vs. 17.0 ±12.0; $p<0.033$). TPR indices were significantly related to the following MPS parameters: TPRminND to SSS ($r=-0.251$; $p<0.001$), SRS ($r=-0.295$; $p<0.001$), scar ($r=-0.283$; $p<0.001$), EF post stress ($r=0.476$; $p<0.001$) and EF rest ($r=0.390$; $p<0.001$). TPRranND was significantly related to SSS ($r=0.428$; $p<0.001$), SRS ($r=0.447$; $p<0.001$), scar ($r=0.375$; $p<0.001$), EF post stress ($r=-0.629$; $p<0.001$) and EF rest ($r=-0.525$; $p<0.001$). TPRsdND was significantly related to SSS ($r=0.459$; $p<0.001$), SRS ($r=0.464$; $p<0.001$), scar ($r=0.409$; $p<0.001$), EF post stress ($r=-0.612$; $p<0.001$) and EF rest ($r=-0.519$; $p<0.001$). Conclusion: In 3-VD patients TPRminND, TPRranND and TPRsdND are different compared to the other patients, while the indices TPRdefect and TPRsumND are not.

In Vivo Study on Re-oxygenation of Tumor after Heavy Carbon-Ion Beam and Photon Beam Irradiation Using animal ^{18}F-MISO PETCT

j. cheng[1], J. Lu[2], Y. Sheng[3], Z. Jiang[4], Z. Li[4], Y. Zhang[1]; [1]Department of Nuclear Medicine, Shanghai Proton and Heavy Ion Center,Fudan University Cancer Hospital, Shanghai, CHINA, [2]Department of Radiation Oncology,Shanghai Proton and Heavy Ion Center, Shanghai, CHINA, [3]Department of Medical Physics, Shanghai Proton and Heavy Ion Center, Shanghai, CHINA, [4]Department of Nuclear Medicine, Shanghai Proton and Heavy Ion Center, Shanghai, CHINA.

Objective: Heavy carbon-ion irradiation can kill both hypoxic and non-hypoxic tumor cells. In this study, the human breast cancer ER(+) xenografts were exposed to low/medium/high dose of heavy carbon-ion and photon beam to observe the early and later re-oxygenation phenomenon with respect to different types and dose. **Methods:** The xenograft was performed ^{18}F-MISO animal PET/CT imaging, and the naturally

occurring chronic hypoxia was identified using TBR>1.4 as the threshold. Xenografts were divided into photon group and heavy carbon-ion group. Every group included three sub-groups of different dose as high dose group (single dose of 15GyE), medium (10GyE) and low (5GyE). The volume of tumor was observed and the growth curve was drawn. The animal ^{18}F-MISO PET/CT scans were performed on the high dose sub-group of photon and the low / medium / high dose sub-groups of heavy carbon-ion. The changes of oxygenation were observed on the 1st/3rd/5th/7th day for early term and on the 5th/10th/15th day for later term. **Results:** In photon group, only high dose sub-group (15GyE) inhibited tumor growth ($t=15.24$, $P < 0.001$) . While in heavy carbon-ion group, medium and high dose sub-group both inhibited tumor volume evidently ($P <0.001$ both) Early oxygenation status: in low dose heavy carbon-ion group, the TBR and HV increased slightly in the 1st and 3rd day's observations and then remained stable. In medium/high dose heavy carbon-ion groups, the phenomenon of "transient severe hypoxia" appeared in the 1st day's observation, and disappeared in the 7th, which was more remarkable in high dose heavy carbon-ion group. In high dose photon group, TBR and HV increased in the 3rd day's observation and recovered in the 7th. Later oxygenation status: in low dose heavy carbon-ion group, the TBR and HV increased obviously. In medium dose heavy carbon-ion group, the TBR and HV kept stable at first but increased at last. In high dose heavy carbon-ion group, the TBR and HV decreased continuously. In low dose photon group, the TBR and HV decreased in 5th day's observation and recovered finally**. Conclusion:**The early oxygenation status reveals that time window of "re-oxygen" of photon is the first 3-5 days after irradiation. However, no "re-oxygenation" phenomenon exists in heavy carbon-ion irradiation. The "transient severe hypoxia" will appear after heavy carbon-ion irradiation depending on the dose delivered. The inhibition / killing effect of heavy carbon-ion irradiation on tumor is not dependent on the degree of tumor oxygenation.

OP487

Novel CMKLR1-targeted peptide conjugates for molecular imaging and therapy of breast cancer

S. Erdmann, L. Niederstadt, E. L. Koziolek, N. Beindorff, J. D. C. Gomez, S. Prasad, A. Wagener, J. L. Körner, S. Hallmann, S. Exner, S. Bandholtz, V. Prasad, W. Brenner, C. Grötzinger; Charité - Universitätsmedizin Berlin, Berlin, GERMANY.

Aim Targeted imaging and therapy is a promising approach in nuclear cancer medicine. Knowledge about molecular properties as overexpression of certain receptors is thereby offering a powerful tool for tumor-selective imaging and treatment of cancer cells. We utilize novel chemerin-based peptides for receptor-ligand binding-mediated targeting of CMKLR1 overexpressing tumors in small animal models. By conjugation with radiolabeled chelator DOTA we obtain highly specific and affine tracers. The novel contrast agents enable multimodal in vivo imaging with positron emission tomography, single photon emission computed tomography and complementary biodistribution studies and provide the means for continuative targeted therapy. **Materials and Methods** We developed highly specific and affine peptide ligands for the G protein-coupled receptor CMKLR1 by substitution of wild type chemerin-9 and structure-activity relationship analysis. The combination of these peptides linked to radiolabeled (^{68}Ga/^{177}Lu) chelator DOTA and an established target-positive tumor model in immunodeficient nude mice enabled tumor-specific imaging in vivo. Therefore, we acquired small animal PET/MR and SPECT/CT images, assessed biodistribution by ex vivo measurements and investigated the tracer specificity by blocking experiments. **Results** Our novel chemerin peptide conjugates demonstrated significantly improved properties compared to the wild type peptide concerning biological activity, affinity and metabolic stability. Their target is known to be overexpressed in different pathologies, including cancer. Beside other tumor entities like pancreatic cancer, we could demonstrate CMKLR1 overexpression in breast cancer patient tissue and exemplarily in the breast cancer cell line Du4475. After establishment of the cancer model with both, a target-positive and -negative tumor, PET/MR (^{68}Ga) and SPECT/CT (^{177}Lu) imaging along with complementary biodistribution studies revealed a strong CMKLR1-specific uptake ($\leq$ 9 %ID/g) of the targeted tracers in positive tumor tissue for up to twenty-four hours. More strikingly, tumor uptake of our tracers could not only be blocked by excess of unlabeled peptide, but also significantly depended on the number of receptors expressed by the tissue. Tumor uptake, organ distribution and corresponding kinetics strongly correlated with the chemical and physical properties of the different conjugates. **Conclusion** We found the receptor CMKLR1 to be overexpressed in different tumor entities such as breast cancer. With the cell line Du4475, we had a model endogenously expressing our target to evaluate our optimized chemerin peptides as stable ligands with high affinity. Eventually, we demonstrated the applicability of our novel ^{68}Ga-and ^{177}Lu-labeled tracers by visualizing CMKLR1-positive breast cancer tumors in PET/MR and SPECT/CT imaging and thus developed promising theranostics for potential clinical Translation.

OP488

CXCR4 chemokine receptor imaging: evaluation and validation of a new configurationally restricted tetraazamacrocyclic CXCR4 antagonist, ^{64}Cu-CB-bicyclam

C. S. Miranda[1,2], B. P. Burke[3,2], R. E. Lee[3,2], S. Nigam[3,2], G. Clemente[1,2], J. A. Thompson[4,2], T. Ruest[2], T. D'huys[5], D. Schols[5], J. Greenman[1], C. Cawthorne[1,2], S. J. Archibald[3,2]; [1]School of Biological, Biomedical and Environmental Sciences, University of Hull, Hull, UNITED KINGDOM, [2]Positron Emission Tomography Research Center, Hull, UNITED KINGDOM, [3]Department of Chemistry, University of Hull, Hull, UNITED KINGDOM, [4]Hull York Medical School, Hull, UNITED KINGDOM, [5]Rega Institute for Medical Research, Leuven, BELGIUM.

Introduction: There is particular interest in imaging CXCR4 expression levels in cancer, as over-expression of CXCR4 has been linked to an aggressive phenotype and poor prognosis.[1] Attempts have been made to radiolabel small molecule CXCR4 antagonists such as AMD3100 and AMD3465 with copper-64, however, results have been unsatisfactory due to high non-specific liver uptake which may be linked to complex instability.[2,3] Incorporation of an ethylene cross bridge is known to result in a higher stability copper(II) complex along with increased receptor affinity and residence time.[4] **Aim**: The aim of this study is to validate the cross-bridged bis-cyclam derivative ^{64}Cu-CB-bicyclam as a new CXCR4 targeted imaging agent, by evaluation of tracer specificity and stability in a U87/U87-CXCR4 xenograft model. **Materials and methods**: U87 and U87-CXCR4 cells were incubated with 37 kBq of ^{64}Cu-CB-bicyclam (IC_{50} = 24 nM) to determine tracer uptake. Dynamic PET/CT imaging studies were carried out in CD-1 nude mice bearing U87/U87-CXCR4 xenografts on a Sedecal SuperArgus PET-CT scanner after injection of 9.6 ± 0.7 MBq ^{64}Cu-CB-bicyclam and uptake in various tissues quantified using tumour-to-muscle ratios. Biodistribution studies were carried out in non-tumour bearing CD-1 nude mice after injection of 740 kBq ^{64}Cu-CB-bicyclam to determine *in vivo* stability. Blocking studies were performed after pre-injection of 5 mg/kg of high affinity CXCR4 antagonist (Cu_2CB-bicyclam, IC_{50} = 4 nM). **Results:** ^{64}Cu-CB-bicyclam showed higher uptake in U87-CXCR4 than U87 cells (incubated dose 28.2±0.63% and 0.2 ±0.02% respectively). Dynamic PET/CT imaging studies showed higher tracer accumulation in U87-CXCR4 vs. U87 tumours. Tumour-to-muscle ratio at 90 min in U87-CXCR4 tumours was > 8-fold higher than for U87 (23.6 ± 2.7 vs 3.0 ± 0.5). Blocking studies with Cu_2CB-bicyclam resulted in > 92% reduction of radioactivity in U87-CXCR4 tumours (SUVmax 7.9 vs 0.5) and 89% reduction in liver (SUVmax 5.3 vs 0.6). This agrees with the biodistribution carried out in non-tumour bearing mice which showed > 90% reduction in liver uptake. **Conclusions:** To target CXCR4, a new configurationally restricted tetraazamacrocyclic CXCR4 antagonist was

developed and radiolabelled with copper-64. *In vitro* and *in vivo* data showed high specificity for the CXCR4 receptor. The significant reduction in liver uptake suggests higher *in vivo* stability.(1) J. Burger et al, Blood, 2006, 107, 5; (2) S. Nimmagadda et al., Cancer Res., 2010, 70, 3935; (3) R. A. De Silva, et al., J. Nuc. Med., 2011, 52, 986; (4) A. Khan et al., J. Am. Chem. Soc., 2009, 131, 3416.

OP489

SPECT/CT imaging of the PD-1/PD-L1 immune checkpoint pathway in syngeneic murine tumor models

S. Heskamp, J. D. M. Molkenboer-Kuenen, R. H. A. M. van de Vondervoort, O. C. Boerman; Radboud University Nijmegen Medical Centre, NIJMEGEN, NETHERLANDS.

Introduction: Programmed-death 1 (PD-1) is expressed by T-cells and is a major co-inhibitory immune checkpoint. Its ligand PD-L1 is expressed by tumor cells. By upregulating PD-L1, tumors are capable of escaping immune recognition and attack. Clinical trials with anti-PD-1/PD-L1 immune checkpoint inhibitors have shown impressive and durable antitumor activities. However, a large number of non-responding patients is unnecessarily exposed to ineffective, expensive treatment. To use these drugs more effectively, there is an urgent need for a biomarker. The aim of this study is to develop an imaging technique to non-invasively assess PD-L1 expression and PD-1+ tumor infiltrating T-lymphocytes (TILs). **Material and methods:** Anti-murine PD-1 and PD-L1 antibodies were radiolabeled with In-111. The in vitro binding characteristics were assessed using EL-4 (PD-1+) and Renca (PD-L1+) cells. Subsequently, the optimal antibody dose (1 - 1,000 μg) and time point (4, 24, 48, 72, 168 h) for imaging were assessed by ex vivo biodistribution studies and microSPECT/CT imaging in mice with s.c. syngeneic Renca, 4T1, CT26, or LLC1 tumors. Tumors and relevant organs were stained immunohistochemically for the expression of PD-L1 and TILs. **Results:** In-111-labeled antibodies specifically bound to PD-1 and PD-L1 expressing cell lines in vitro. The optimal antibody dose to target PD-L1-expressing Renca tumors was 30 μg and highest tumor-normal tissue contrast was obtained 24 to 72 h post injection. Tumor uptake in Renca, 4T1, CT26, and LLC1 was 15 ± 5 %ID/g, 16 ± 6 %ID/g, 11 ± 6 %ID/g, and 6 ± 3 %ID/g, respectively, and correlated with PD-L1 expression as determined immunohistochemically. Enhanced uptake was also observed in spleen (17 ± 2 %ID/g), brown fat (19 ± 2 %ID/g), and duodenum (10 ± 2 %ID/g). Immunohistochemistry confirmed PD-L1 expression in these organs. The optimal antibody dose to target PD-1 was 3 μg. MicroSPECT/CT showed heterogeneous uptake of the radiolabeled anti-PD-1 antibody in 4T1 tumors. Ex vivo biodistribution studies showed a tumor uptake of 14 ± 4 %ID/g. Other organs which showed uptake of the anti-PD-1 antibody were thymus (10 ± 2 %ID/g), spleen (10 ± 3 %ID/g), and lymph nodes (14 ± 5 %ID/g). **Conclusion:** These studies demonstrate that PD-L1 and PD-1 can be imaged with microSPECT/CT. These techniques can potentially be used to non-invasively select tumors that are most likely to respond to immune checkpoint inhibitor therapy and to monitor PD-1/PD-L1 during conventional anti-cancer treatment and disease progression.

OP490

Characterising ^{111}In-anti-γH2AX-TAT in Targeting the DNA Damage Signal Associated with Wnt Activated Colorectal Cancer

M. Konstantinou[1], J. Knight[2], T. Hay[1], P. Shaw[1], M. Smalley[1], B. Cornelissen[2], A. R. Clarke[1]; [1]Cardiff University, Cardiff, UNITED KINGDOM, [2]University of Oxford, Oxford, UNITED KINGDOM.

Objectives: Colorectal cancer (CRC) is the second most commonly diagnosed cancer has a poor 60% 5-year survival rate. The Wnt signalling pathway is fundamental for homeostasis of the intestinal epithelium. Its deregulation drives development of CRC and induces DNA damage. Histone-2AX (H2AX) is a component of the nucleosome whose phosphorylated form, γH2AX, is a marker of DNA damage. The VillinCreERApcfl/fl mouse model is an inducible genetically engineered mouse model of CRC, where tamoxifen-induced deletion of the APC gene induces Wnt signalling and precipitates a crypt-progenitor-like phenotype. Here, we assess whether the DNA damage generated in this CRC mouse model with Wnt signalling deregulation can be targeted using 111In-anti-γH2AX-TAT, a γH2AX-imaging agent we developed previously. Methods: 111In-anti-γH2AX-TAT, based on anti-γH2AX antibodies conjugated to the cell-penetrating peptide TAT to allow cellular internalisation and nuclear localisation, was produced as previously described. The VillinCreERApcfl/fl model was induced by tamoxifen three times in a day by either intraperitoneal (IP) injection (80 mg/kg) or gavage (60 mg/kg). γH2AX immunohistochemical analysis was performed three days post induction to assess γH2AX levels. Three days post induction, another group of mice was injected intravenously with 111In-anti-γH2AX-TAT or isotype control RIC (5 μg/mouse; 1 MBq/μg). At 24h post-injection SPECT/CT imaging and biodistribution studies were performed. Results: Immunohistochemical analysis showed that on day three post-induction using either IP injection or gavage, overall intestinal γH2AX levels were significantly elevated compared to controls. However, the intensity of γH2AX staining was higher by IP injection compared to gavage. In vivo experiments highlighted that 111In-anti-γH2AX-TAT uptake is more prominent in the induced intestine (2.46±0.57% ID/g) compared to controls (1.41±0.29% ID/g, $p<0.05$). Conclusion: Irrespectively of the technique used for inducing VillinCreERApcfl/fl model, DNA damage levels were elevated as a result of Wnt signalling activation. Nonetheless, the extent of the DNA damage is different when comparing gavage with IP injection, highlighting IP injection as the technique that generates higher grade of DNA damage. The in vivo 111In-anti-γH2AX-TAT accumulation is significantly higher after Wnt signalling activation. Taken together, these promising results suggest that γH2AX imaging could be exploited for early detection of CRC.

OP491

Targeted in vivo PET/CT imaging of integrin α2β1 in a orthotopically-implanted non-small cell lung cancer model

C. Huang[1], S. Hsu[1], Y. Chung[1], W. Chang[1], Y. Lin[1], T. Yen[1,2], F. Huang[3]; [1]Center for Advanced Molecular Imaging and Translation, Chang Gung Memorial Hospital, Taoyuan, TAIWAN, [2]Department of Nuclear Medicine, Chang Gung Memorial Hospital, Taoyuan, TAIWAN, [3]Department of Biochemical Science and Technology , National Taiwan University, Taipei, TAIWAN.

Introduction: The mounting evidences clearly demonstrate the pro-oncogenic role of integrin α2β1 and its aberrant expression might contributes to non-small lung cancer (NSCLC) induced invasion and metastasis. Therefore, the development of integrin α2β1 targeted agent may significantly increase the detection specificity towards various lung cancer types increased with their malignancy level. **Methods:** The orthotopic A549 human NSCLC model was established by tail vein injection with $2x10^6$ cells. The mice (n = 5) were imaged in the prone position in the microPET/CT scanner. The tumor-bearing mice were injected with 6.6 −7.4 MBq of ^{68}Ga-A2B1 tracer and the 15 min acquisition of static scans was obtained at 15 min after injection. The average radioactivities of regions-of interest (ROIs) were determined by multiple regions of interest volumes manually using 50% of maximum minus minimum %ID/g value within a tumor or an organ. At the end of each scan, the animals were sacrificed. The tumor and major tissues and organs were dissected, and *ex vivo* autoradiography and immunohistochemistry images were acquire to confirm the tracer distribution results. **Results:** The PET/CT images of the orthotropic NSCLC mouse model unambiguously demonstrated the accumulation of integrin tracers in the tumor lesions. The average tumor

uptake was measured as 1.05± 0.12 SUVmax (n=5), the ratios of tumor/normal (T/N) was 2.29 making the tumor is clear visible. The autoradiography is further performed to compensate the resolution limitation of microPET results, which showed that integrin tracers penetrated the lung capillaries and located in the tumor nodules as early as 15min post-injection. The integrin targeting tracer showed the high T/N ratio in the excised lung tumor autoradiography and the value was calculated as 4.59, which was much higher than that of the PET imaging-derived data. The biodistribution data expressed as a percentage of injected dose/gram of tissue (%ID/g) were calculated. The tracers mainly located in the liver (2.53±0.47) and kidney (8.25±2.61), respectively. The combined PET/CT imaging data were analyzed to provide unique diagnostic parameter such as aggressive potential, which were correlated with histological changes during the tumor growth. **Conclusion:** The development of an accurate noninvasive imaging technique to detect primary, recurrent and metastatic non-small cell lung cancer is critical for the effective management of this group of patients. The integrin $\alpha 2\beta 1$ tracer ^{68}Ga-A2B1 can more subjectively adequate evaluate the integrin profiling, which potentially leading to better evaluate the disease course and therapeutic efficacy at the earliest stages of treatment.

OP492

Comparison of PSMA protein expression and radiopeptide internalization of prostate cancer models with and without castration resistance

B. Meller, F. Bremmer, C. O. Sahlmann, C. Bouter, L. Trojan, J. Meller, P. Thelen; Georg-August-University Göttingen, Göttingen, GERMANY.

Aim: Investigation if prostate specific membrane antigen (PSMA) protein expression and tracer internalization is influenced by castration resistance and androgen deprivation. Methods: Human prostate cancer cells were grown permanently with testosterone (T, revCRPC) or without T (CRPC) with and without abiraterone acetate (AA). RevCRPC-cultures represent therefore the androgen sensitive cell type, CRPC the castration resistant and CRPCAA the androgen deprivation tolerant cell type. In these cell lines PSMA protein expression was determined by western blot analysis and visualized by immunohistochemical staining. In parallel cultures androgen deprivation was increased by testosterone withdrawal and AA supplementation. Beside determination of the PSMA mRNA by qPCR over 4 w, the cell surface bound and internalized fraction of ^{68}Ga-PSMA-HBED-CC was investigated. Results: In contrast to castration resistant cells androgen sensitive cells exhibited significant lower PSMA proteins (<10%). The highest expression was determined in the AA insensitive cell type. These results could by verified by immunhistochemical staining. In internalization experiments these results could be confirmed whereby the ratio between membrane bound and internalized fraction remained nearly constant (25-35%). Androgen deprivation treatment over 4 w resulted in significantly increasing PSMA mRNA expression in revCRPC (>900 %) as well as in CRPC (>500 %). Short-time (48 h) androgen deprivation of androgen sensitive revCRPC cells by testosterone withdrawal and abiraterone acetate treatment resulted in inhibition of proliferation as well as in increasing uptake of ^{68}Ga-PSMA-HBED-CC on a higher level than in abiraterone acetate insensitive CRPCAA cells. Conclusions: The PSMA protein expression was directly correlated with castration resistance and/or tolerance against AA in the investigated systems. PSMA expression could be stimulated by increasing androgen deprivation in androgen sensitive and castration resistant cells. This should be considered in repeated PSMA-PET/CT investigations and might be useful to increase therapy efficiency of PSMA-directed therapies.

Does digital PET fit EARL accreditation specifications for tumour imaging?

D. Koopman[1], M. L. Groot Koerkamp[2], H. Arkies[1], P. L. Jager[1], S. Knollema[1], C. H. Slump[2], P. G. Sanches[3], J. A. van Dalen[4]; [1]Isala, Department of Nuclear Medicine, Zwolle, NETHERLANDS, [2]MIRA Institute for Biomedical Technology and Technical Medicine, Enschede, NETHERLANDS, [3]Philips Healthcare, Eindhoven, NETHERLANDS, [4]Isala, Department of Medical Physics, Zwolle, NETHERLANDS.

Background: Recently, a prototype digital PET system (Philips Healthcare) with digital photon counting technology using silicon photomultipliers was introduced. In clinical practice, EARL FDG-PET/CT accreditation specifications for tumour imaging are widely used for standardization and multi-centre trials. However, EARL specifications are based on analog PET systems.The aims of this study were (1) to evaluate whether a prototype digital PET system can fit EARL accreditation specifications for tumour imaging and (2) to determine the minimal scan duration for digital PET, compared to a state-of-the-art analog PET system, that results in image noise levels fulfilling EARL requirements. **Method:** As a part of system acceptance tests, we performed a phantom study using the NEMA image quality phantom filled with FDG-activity, with sphere-to-background ratio 10:1. The background was filled with 2.0 kBq/mL. We acquired PET/CT scans with 10 minutes scan duration on both prototype digital PET and analog state-of-the art PET (Ingenuity TF, Philips Healthcare). PET data were reconstructed using default settings with 4x4x4 mm^3 voxels. For digital PET data, we performed additional reconstructions using a Gaussian post-smoothing filter with varying kernel widths of 1-8 mm. We determined mean and maximum contrast recovery coefficients (CRC) for all spheres. Results were compared with EARL accreditation specifications. Additionally, we performed reconstructions using multiple shorter scan times per bed position, using list mode clipping, for both digital and analog PET. In each reconstructed image, we measured the covariance in the background, which was defined as standard deviation divided by the mean value. For both systems we determined the acquisition time at which the covariance was 15%, which is the minimum EARL requirement. **Results:** For digital PET using default reconstruction settings, the maximum CRC for the smallest phantom sphere was above the EARL upper limit. Applying a Gaussian post-smoothing filter of 3 mm resulted in CRCs that best fitted within EARL specifications. Using PET reconstructions consistent with EARL, covariance levels of 15% were found at an acquisition time of 54 seconds in analog PET and at 38 seconds in digital PET, given a fixed FDG-activity. **Conclusion:** Digital PET fits EARL specifications when using default PET reconstructions with 4x4x4 mm^3 voxels and a 3 mm Gaussian post-smoothing filter. To reach similar image noise levels, this study indicates that the administered FDG-activity or scan time per bed position can be reduced by typically 30% with digital PET, compared to a state-of-the-art analog PET system from the same vendor.

First clinical experience of dose and acquisition duration reductions in PET ^{18}F-FDG imaging with a BGO PETCT system .The added value of Bayesian Penalized Likelihood reconstruction algorithm: Prospective study on 116 patients

c. frederic, D. Vallot, L. chaltiel, A. Fernandez, S. Zerdoud, L. Dierickx, M. Bauriaud, S. Brillouet, O. Caselles; institut universitaire du cancer de Toulouse Oncopole, toulouse, FRANCE.

Introduction Traditional PET image reconstruction algorithms, such as Ordered Subsets Expectation Maximization (OSEM), cannot be run to full convergence because image noise increases with each iteration. Therefore,

the convergence is stopped after a predetermined number of iterations, typically two or four. However, under-converged images may introduce bias that can directly impact lesion quantitation. New technology now enables PET images to be reconstructed to full convergence using a Bayesian Penalized Likelihood (PL) reconstruction algorithm that aims to improve the signal-to-noise ratio (SNR) and standard uptake value (SUV) accuracy. Full BGO PET CT is reported to have a NEMA sensitivity of 22 cps/kBq and a larger axial field of view (26 cm) that could allow to reduce both the injected activity and the acquisition time per bed position. However, no clinical evaluation of the PL reconstruction algorithm on this new PET system has not been reported so far *Methods* We performed a prospective study on 116 patients, injected with a median of 2.19 MBq/kg of ^{18}F-FDG. Images were reconstructed using two different algorithms: OSEM and PL regularization algorithm. The SNR was calculated in the liver and SUV_{peak} was also determined in lesions or focal physiological uptake. Differences between the two algorithms were analyzed using the Wilcoxon test for paired samples. P-values below 0.05 were considered statistically significant n algorithm that aims to improve the signal-to noise ratio (SNR) and standard uptake value (SUV) accuracy. *Results* 116 patients (48 males and 68 females) weighing between 45-125 kg were analyzed. The median injected activity of ^{18}F-FDG was 2.19 MBq/kg, with a range of 1.67-4.01 MBq/kg depending on the patient's body mass index (BMI). The total amount of injected activity per patient ranged from 75.10 to 401.45 MBq. The entire duration of the PET acquisition was 10 minutes. The use of the full convergence PL reconstruction improved the SNR (median of 12%, increasing with patient's BMI), increased the lesion's SUV_{peak} (p below 0.0001) and lowered the volume of injected activity. *Discussion-Conclusion* PL reconstruction demonstrated the capability to reduce both injected activity and acquisition duration by 50% compared to the guidelines without visually impairing the image quality, SNR and lesion's SUV_{peak}. The clinical benefit of increased SUV value due to PL reconstruction on lesion detectability remains to be established.

OP495

A new Zeolite PET phantom to test accuracy of PET image quantative analysis

F. Zito[1], C. Soffientini[2], E. De Bernardi[3], R. Casati[1], R. Benti[1], G. Baselli[2]; [1]FONDAZIONE IRCCS CA' GRANDA Ospedale Maggiore Policlinico, Milan, ITALY, [2]DEIB, Department of Electronics, Information, and Bioengineering, Politecnico di Milano, Milan, ITALY, [3]Department of Medicine and Surgery, Tecnomed Foundation, University of Milano Bicocca, Milan, ITALY.

Purpose: The use of ^{18}F-FDG PET images for diagnosis or treatment planning requires accurate quantification of lesion volume and uptake. Automatic segmentation algorithms (AS) can allow correct definition of lesion borders by overcoming operator dependance of manual delineations. The assessment of PET-AS algorithms requires both realistic data sets and ground truth contours. Physical phantoms satisfy the second requirement, but regular shapes, homogeneous activity, and cold object walls commonly limit the realism of the uptake pattern.This work presents the design of a phantom in which radioactive zeolites, immersed in a warm heterogeneous background, simulate realistic-wall-less lesions with irregular shape and known activity. **Methods:** Zeolites**,** aluminosilicate minerals, having adsorbing properties, were characterized and used to simulate lesions. Selected samples were heated to eliminate the adsorbed humidity, soaked in an ^{18}F-FDG radioactive solution, extracted and wrapped in Parafilm before being inserted in a proper phantom. Three different types of zeolites (PRODAC and ZEOVIT clinoptilolites, St Cloud cabazite) were evaluated in terms of homogeneity and radioactive uptake, and also of CT contrast useful for contouring ground truth in PET/CT scans. After zeolite family selection, ^{18}F-FDG soaking solutions for lesion simulations were planned. Heterogeneous lesions were simulated by the perfect matching of two parts of broken zeolites, loaded in two different radioactive solutions. Heterogeneous background was obtained by immersing tissue paper balls with about 2mm diameter and polypropylene sponge pieces of about 2cm x 2cm x 2cm (560 g/m^3) into a warm solution. Background mean activity and variability was a posteriori assessed by drawing ROIs on phantom PET images. The phantom was assembled using the PH-24 Myocardial Phantom (Capintec, Inc); the two lung cavities were filled with radioactive pieces of sponge; the mediastinum was filled with a ^{18}F-FDG water solution and a little plastic box containing radioactive paper balls was positioned in its centre. **Results:** Natural PRODAC clinoptilolite resulted the most suitable zeolite for PET lesion simulation. The heterogeneous background showed an uptake variability from 269% to 443% times higher than that obtained with a uniform radioactive solution. The assembled phantom included 7 lesions with volumes ranging from 1.86ml to 7.24ml and background contrasts in the range of 4.8:1 to 21.7:1. **Conclusions:** A novel phantom for the evaluation of PET-AS algorithms and for assessing PET quantitative accuracy was developed providing a data set with both reference contours and activity ground truth, in a wide range of volumes and lesion to background contrasts.

OP496

Quantification of tumor uptake with molecular breast imaging (MBI)

S. Bache, B. Lopez, G. Rauch, B. Adrada, A. Jessop, **S. C. Kappadath**; UT MD Anderson Cancer Center, Houston, TX, UNITED STATES.

Aim: Molecular Breast Imaging (MBI) uses small dual-headed semiconductor-based gamma camera in a mammographic configuration to obtain functional images of 99mTc-sestamibi uptake in breast. Currently, MBI images are purely qualitative. We have developed a novel attenuation correction algorithm to quantify uptake with MBI; the accuracy and robustness of this methodology is presented together with clinical applications. **Materials and Methods**: A 7cm thick phantom containing 99mTc-water simulating breast tissue and fillable spheres simulating tumors were imaged with a GE 750b MBI system. Six spheres ranging in diameter from 9mm to 27mm were imaged with sphere-to-background ratios (SBRs) of 3.5, 2.6, 1.7 and located at depths of 2cm, 4cm, 6cm within the water-bath (total of 54 unique scenarios). Sphere images were acquired in-air for ground truth. Decay-corrected projection images were scatter-corrected using a custom dual-energy-window technique (Bache et al, J Nucl Med 56(3):45, 2015). To estimate true counts, T, from each sphere, the geometric mean (GM) of the counts within square ROIs circumscribing the sphere on the two projections was calculated as $T=[C_1C_2\exp(-ux)F]^{1/2}$, where C is counts, μ is linear attenuation coefficient of water, and x is detector separation. We introduce 4 unique definitions of F to account for background activity: standard GM (GMstd), background-subtracted GM (GMbc), MIRD Primer 16 factor (GMmird16), and a novel "volumetric" factor (GMvol). Error in T was estimated with respect to in-air conditions. The quantitative accuracy of T using different GM definitions was calculated as a function of SBR, depth, and sphere size. Tumors in serial MBI scans of patients undergoing neo-adjuvant chemotherapy were delineated by radiologists. GMvol was used to compute 99mTc-sestamibi SUV. **Results**: Mean errors (95%CI range) for all 54 unique scenarios were 167%(-127%, 460%), -16%(-38%, 5%), 19%(-17%, 55%), 3.8%(-24%, 17%) for the GMstd, GMbc, GMmird16, and GMvol. GMmird16 varied the most under differing SBR with COV of 209%, while GMbc and GMvol were least sensitive to SBR with COVs of 25% and 19%. GMvol was the least sensitive to variations in sphere diameter with COV of 28%, compared to 37% and 110% for GMbc and GMmird16. All 3 non-standard GM formalisms were insensitive to depth with COV of ~5%. Tumor SUV changes correlated well with pathological response. **Conclusion**: Using our novel geometric mean formalism, GMvol, we obtained accurate estimates of tumor uptake in MBI images (error <5%; 95%CI ~20%) under a variety of SBRs, tumor sizes, and depths. Research support: GE Healthcare.

The impact of prompt gamma compensation on myocardial blood flow measurements in dynamic rubidium-82 PET

I. S. Armstrong, M. J. Memmott, C. M. Tonge, P. Arumugam; Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

Introduction: There is increasing evidence demonstrating a clinical role for myocardial blood flow (MBF) and myocardial flow reserve (MFR) - the ratio of MBF at stress to rest. There are however technical factors that might have an impact on these measurements. The desire for a standardised technique necessitates an understanding of these factors. Unique to rubidium-82 is the Prompt Gamma Compensation (PGC) to compensate for the 776 keV gamma-ray emissions that can cause erroneous coincidence events. PGC has been shown to improve image quality but its impact on MBF or MFR has not been evaluated. **Methods:** 50 sets of routine dynamic rubidium-82 stress and rest images from 29 male (median [inter-quartile range] BMI: 28.4 [25.2-30.5]) and 21 female (median [inter-quartile range] BMI: 33.8 [26.7-38.7]) were acquired on Siemens Biograph mCT. 1110 MBq of rubidium-82 was used for stress and rest; 18-frame dynamic images were reconstructed with and without Siemens PGC using 3D-OSEM (2i24s, 6.5mm post-filter). The area under the curve (AUC) for the blood input function (BIF) was calculated. Stress MBF, rest MBF and resulting MFR were calculated using Siemens syngoMBF. Relative differences of values with and without PGC were calculated along with Wilcoxon rank test and Mann-Whitney U test for statistical analysis. **Results:** With PGC applied, the BIF AUC was significantly greater by +14.0% stress and +14.6% at rest ($p<0.001$) with no significant differences between the relative BIF AUC increases during stress or rest. Over all patients, no significant differences were observed for stress MBF, rest MBF or MFR. However, significant differences in stress and rest MBF were seen in obese (BMI > 30) patients ($n=23$) but not in non-obese patients. With PGC applied, the median [inter-quartile range] relative change of MBF was -7.0% [-13.3% to +1.8%] for stress ($p<0.01$) and -5.8% [-16.1% to +3.0%] for rest ($p=0.02$) in the obese patients. No significant difference was observed in MFR for either obese patients or non-obese patients. **Conclusion:** The use of PGC in rubidium-82 dynamic image reconstruction can result in a small but significant reduction of measured absolute MBF in obese patients. Stress and rest values are reduced by similar relative amounts and, as such, MFR is preserved. The use of PGC does not appear to result in any significant differences in MBF or MFR for non-obese patients.

Radiomics texture features variability and Reproducibility in advance image reconstruction setting of oncological PET/CT

I. Shiri[1], A. Rahmim[2,3], H. Abdollahi[1], P. Ghafarian[4,5], A. Bitarafan[1,6], M. AY[7,8], M. BakhshaieshKaram[4,5]; [1]Department of Medical Physics, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Radiology, Johns Hopkins University, Baltimore, MD, UNITED STATES, [3]Department of Electrical and Computer Engineering, Johns Hopkins University, Baltimore, MD, UNITED STATES, [4]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Cardiovascular Intervention Research Center, Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [7]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences,, Tehran, IRAN, ISLAMIC REPUBLIC OF, [8]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim Radiomics features derived from oncological PET images are now recognized as valuable tool for future prognostic and predictive models, knowledge about their variability and Reproducibility is essential. The purpose of current study was to investigate the variability and reproducibility of radiomics texture feature in oncological PET/CT due to different advance image reconstruction parameters. **Material and method** PET images of the NEMA-IQ phantom containing 6 hot spheres (diameter10 to 37mm) were acquired on GE Discovery 690 PET/CT scanner. The 3D iterative reconstruction was done using OSEM + PSF and OSEM+ PSF + TOF with two and three iteration and eight post-reconstruction filters width 1 to 6.4 mm. The five largest spheres were analyzed. PET-based VOIs were drawn automatically by applying a threshold of 50% of SUVmax. All analysis was performed in Matlab R2013b. For each VOI, 80 radiomic features were based on intensity histograms (IH), gray level co-occurrence (GLCM), gray level run-length (GLRLM), neighborhood-difference matrices (NDM), gray level size-zone texture matrices (GLSZM) and SUV statistics. All radiomics features were categorized into 4 groups based on coefficient of variation (COV): a very small (COV≤5%), small (5%<COV≤10%), intermediate (10%<COV≤20%) and large (COV>20%) range of variation with respect to the mean. **Result** Approximately 71% of the radiomics features (57/80) had a significantly smaller variance. TLG, SUVmean, 10 SUV statistics and 27 texture feature had the best performance with a COV less than 5%. 18 features had COV between 5 and 10%,12 features had COV between 10 and 20%, Whereas 11 features such as LZE and HGLZE from GLSZM were the least robust. SUVSkewness, Coarseness, RLV are in the large variation group for all reconstruction algorithms. **Conclusion** The sensitivity of PET Radiomics textural features to advance reconstruction parameters is feature-dependent. Therefore, texture Features with high COV are more prone to errors if employed to quantitative oncological PET image. Radiomics texture Features with low COV over different reconstruction are better candidates for reproducible tumor quantification. Robustness of (57/80) texture feature between different advance images reconstructions may be high enough to allow the extraction of texture feature values for oncological PET image.

Evaluation of primary prostate pathologies by large-scale analysis of non-invasive PET-MRI features with Machine-Learning approaches

L. Papp[1], S. Hartenbach[2], A. Duhovic[1], P. Baltzer[3], I. Rausch[4], T. Beyer[4], M. Susani[5], L. Kenner[5], C. Seitz[6], S. Shariat[6], M. Hacker[1], M. Hartenbach[1]; [1]Medical University of Vienna, Division of Nuclear Medicine, Vienna, AUSTRIA, [2]German Armed Forces Hospital Ulm, Institute of Pathology, Ulm, GERMANY, [3]Medical University of Vienna, Division of General and Paediatric Radiology, Vienna, AUSTRIA, [4]Medical University of Vienna, Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA, [5]Medical University of Vienna, Clinical Institute of Pathology, Vienna, AUSTRIA, [6]Medical University of Vienna, Department of Urology, Vienna, AUSTRIA.

Introduction Prostatic tissue offers a wide range of pathologies from benign alterations and non-significant cancers up to aggressive tumor patterns. So far imaging has played a minor role in tissue characterization. Our goal was to provide a PET-MRI based classification model built on

large-scale analysis of multi-modal and parametric features incorporating supervised Machine-Learning (ML) approaches. **Materials and Methods** To date, 30 of 60 collected prostate patients were processed having a dual-tracer multiparametric PET/MRI (^{18}F-FMC, ^{18}F-FMC+^{68}Ga-PSMA$^{HBED-CC}$ (dual-tracer) PET, and ADC-map) together with the respective histopathological analysis to serve as a reference. Manual retrospective delineation of lgPIN, hgPIN, BPH, Prostatitis, Gleason 3 and Gleason >3 regions over PET/MRI images was performed on the Hybrid-3D software (Hermes Nuclear Diagnostics, Stockholm, Sweden) when at least one PET/MRI parameter matched the pathology in a lesion >5mm axial size. Tumour-to-background ratio (TBR) of PET region voxel values were calculated (background: gluteal muscle). Overall 56 general and textural (neighbourhood grey-tone difference matrix (NGTDM), grey-level co-occurrence matrix (GLCM)) based parameters were calculated over PET TBR, T2 and ADC delineated regions of each case. An automated feature selection and feature weight estimation ML algorithm was implemented to minimize the classification error of a multivariate weighted-Gaussian classifier function over predefined grading clusters. The ML algorithm was first executed as a binary classifier to separate Benign (Prostatitis, lgPIN, hgPIN, BPH) and Tumour (all Gleason) groups, then as a unary classifier to separate BPH, Gleason 3 and Gleason 4 groups. Both classifiers were validated by comparing their results to histology-derived grading values serving as reference to calculate sensitivity and specificity over a multivariate confusion matrix. **Results** The binary classification resulted 98% sensitivity and 94% specificity where the ML-selected features were: dual-tracer TBR (homogeneity-GLCM, complexity-NGTDM), ^{18}F-FMC TBR (homogeneity-GLCM, uniformity-GLCM, busyness-NGTDM), T2 (homogeneity-GLCM, contrast-GLCM, complexity-NGTDM), ADC (volume, dissimilarity-GLCM, busyness-NGTDM). In case of the unary classification the sensitivity and specificity values were: BPH: (98%, 96%), Gleason 3: (78%, 94%) and Gleason 4: (94%, 89%) respectively with ML-selected features of: dual-tracer TBR (mean, homogeneity-GLCM, dissimilarity-GLCM, contrast-NGTDM), ^{18}F-FMC TBR (mean, variance, homogeneity-GLCM, contrast-GLCM, contrast-NGTDM), T2 (homogeneity-GLCM, coarseness-NGTDM, contrast-NGTDM, complexity-NGTDM), ADC (mean, volume, dissimilarity-GLCM, contrast-NGTDM). **Conclusions** Both the binary and the unary classification validations have shown high sensitivity and specificity indicating that there is a high potential in characterizing prostate lesions based on PET/MRI-derived textural parameters. As a next step, our method will be validated in an approved prospective clinical trial setting in our working group (Clinicaltrials.gov: NCT02659527).

OP501

Comparison of integrated ^{18}F-FDG PET/MRI and MRI alone for the evaluation of patients with lymphoma

J. Grueneisen[1], L. M. Sawicki[2], B. M. Schaarschmidt[2], V. Ruhlmann[1], M. Forsting[1], L. Umutlu[1]; [1]University Hospital Essen, Essen, GERMANY, [2]University Hospital Dusseldorf, Dusseldorf, GERMANY.

Aim: To compare the diagnostic performance of integrated ^{18}F-FDG PET/MRI and MRI alone for whole-body staging of patients with lymphoma. **Material and Methods:** A total of 48 consecutive patients underwent 52 whole-body ^{18}F-FDG PET/MRI (Biograph mMR, Siemens) examinations for pretreatment staging as well as for therapy monitoring and surveillance of lymphoma disease. Two physicians analyzed the MRI datasets, followed by a second reading of ^{18}F-FDG PET/MRI datasets. Both readers were instructed to identify the total number of tumor lesions. Apparent diffusion coefficients (ADC) and standardized uptake values (SUV) were determined and served as an orientation for a differentiation between malignant and benign lesions. Sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy for the identification of patients with lymphoma disease as well as the detection of malignant lesions were calculated for ^{18}F-FDG PET/MRI and MRI alone. **Results:** Malignant lesions were present in 28 of the 52 examinations. ^{18}F-FDG PET/MRI enabled correct identification of disease presence with a sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy of 100%, 92%, 93%, 100% and 96%. The respective values for MRI alone were 89%, 83%, 86%, 87% and 87%. Differences between the two imaging modalities were not statistically significant ($p > 0.05$). Furthermore, a total 96 nodal regions were analyzed of which 62 (65%) were affected with active lymphoma disease. ^{18}F-FDG PET/MRI revealed significantly higher values for the detection of lymphoma lesions (97%, 91%, 95%, 94% and 95%) when compared to MRI alone (84%, 74%, 85%, 71% and 80%). Calculated statistical values for the identification of extranodal sites did not show a significant difference between ^{18}F-FDG PET/MRI and MRI alone ($p > 0.05$). **Conclusion:** The present study underlines the usefulness of ^{18}F-FDG PET data as a valuable additive to MR imaging for a more accurate evaluation of patients with lymphomas. Combining high-quality MR and simultaneous PET-imaging, integrated 18F-FDG PET/MRI enables an accurate staging of lymphoma patients and may serve as a valuable alternative/adjunct for the clinical work-up.

OP502

Evaluation of PET and MR datasets in an integrated 18F-FDG PET/MRI setting: comparison of different MR sequences for whole-body staging of patients with a suspected tumor recurrence of breast cancer

J. Grueneisen[1], J. Kirchner[2], A. Wetter[1], V. Ruhlmann[1], M. Forsting[1], L. Umutlu[1]; [1]University Hospital Essen, Essen, GERMANY, [2]University Hospital Dusseldorf, Dusseldorf, GERMANY.

Aim: To assess the diagnostic value of different MR sequences and ^{18}F-FDG PET data, acquired with an integrated PET/MR scanner, for whole-body restaging of breast cancer patients. **Material and Methods:** A total of 35 consecutive patients with a suspected tumor recurrence of breast cancer were prospectively enrolled for a whole-body ^{18}F-FDG PET/MRI (Biograph mMR, Siemens) examination. The whole-body MR protocol comprised: 1) T2w HASTE ax., 2) DWI ax. and 3) post-contrast T1w VIBE ax. Two readers evaluated the following datasets, while in each reading session a different constellation of available MR sequences was utilized: 1. MRI alone, 2. PET/MR-HASTE/DWI, 3. PET/MR-HASTE/VIBE, 4.PET/MR-HASTE/DWI/VIBE. they were instructed to identify the total number of tumor lesions in each reading session. The diagnostic confidence for each detected lesion (3 point ordinal scale) and the lesion conspicuity (4 point ordinal scale) for the three different MR sequences were additionally rated. **Results:** Tumor recurrence was present in 24/35 (69%) patients and a total of 155 lesions (malignant, n = 112; benign, n = 43) were described. On a lesion based analysis, MRI revealed a sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy of 81%, 86%, 94%, 64% and 83%, respectively and a confidence level (CL) of 2.23 ± 0.70 for the identification of tumor recurrence. In all three PET/MR readings higher values than for MRI alone were obtained (PET/MR-HASTE/DWI: 92%, 91%, 96%, 81% and 92%, CL: 2.44 ± 0.67; PET/MR-HASTE/VIBE: 94%, 91%, 96%, 85% and 93%; CL: 2.65 ± 0.53; PET/MR-HASTE/DWI/VIBE: 95%, 93%, 97%, 87% and 94%, CL: 2.72 ± 0.49). Furthermore, mean values for lesion conspicuity were 3.31 ± 0.80 (VIBE), 3.01 ± 0.84 (HASTE) and 2.84 ± 1.14 (DWI), respectively and differed significantly from each other. **Conclusion:** Our results demonstrate the usefulness of 18F-FDG PET data as a valuable additive to MR imaging for more accurate restaging of breast cancer patients. Furthermore, the presented data underline the benefit of contrast-enhanced MR sequences and questions the use of DWI. Since well-considered MR protocols are required for an accurate and effective oncological work-up of breast cancer patients using integrated PET/MRI, the omission of DWI may enable a distinctive reduction in scan-duration accompanied by improved patient comfort.

OP503

Real-time PET/Hyperpolarized MRS/Ultrasound Molecular Imaging Fusion for Focal Prostate Cancer Detection and Guided Biopsy

K. S. Valluru, J. Park, S. V. Bachawal, C. Liu, V. Taviani, P. K. Gulaka, Y. Saenz, S. A. Felt, J. G. Vilches-Moure, B. Daniel, Z. Cheng, D. M. Spielman, **J. K. Willmann**; Stanford University, Stanford, CA, UNITED STATES.

Background: Blinded transrectal ultrasound (TRUS) biopsy can fail to identify prostate cancer (PCa) in 10-25% of patients. Also, many men without PCa undergo unnecessary biopsies, with attendant morbidity. Accurate prostate imaging could help eliminate unnecessary biopsies or improve their yield. Hyperpolarized ^{13}C Magnetic Resonance Spectroscopy (HMRS) provides metabolic MR imaging of cancer with substantially enhanced signal-to-noise ratios, with ^{13}C-pyruvate reported as safe and effective in PCa patients. Furthermore, ultrasound molecular imaging (USMI) with vascular endothelial growth factor receptor type-2 (VEGFR-2)-targeted microbubbles (MB_{VEGFR2}), and PET imaging with gastrin-releasing peptide receptor-targeted tracer reported promising results. In this study, we investigated the clinical translational feasibility of real-time PET/HMRS/USMI fusion and TRUS biopsy using an *in vivo* canine PCa model. **Materials and Methods:** $60x10^6$ Ace-1 cells were orthotopically-transplanted in the prostate of immunosuppressed sexually mature (18-30 months, 10-12Kg) dogs (n=3). Two weeks later, simultaneous prostatic PET/HMRS/USMI was performed with ^{68}Ga-NODAGA-RM1 (~1mCi) dynamic PET scan in all the dogs and an additional ^{18}F-FDG (~2mCi) scan in dogs 2 and 3. ^{1}H-MRI and ^{13}C HMRS (250mM pyruvate, 0.8mL/Kg) images were acquired using ^{13}C/1H dual-tuned endorectal receive and ^{13}C clamshell transmit coils. Subsequently, USMI (BR55, 0.05mL/Kg) and real-time fusion with TRUS (dog 1: HMRS/MRI, dog 2: PET/HMRS/MRI, dog 3: PET/HMRS/MRI+ Biopsy) was implemented followed by histological analysis (H&E) of the resected prostate and biopsy samples. **Results:** In all dogs, Ace-1 tumors were seen on TRUS and T_2-weighted MRI, while USMI revealed peripheral binding in tumors, associated with rapid clearance (~3 minutes), possibly due to low affinity of BR55 for canine VEGFR-2. In dog 1, ^{68}Ga PET showed no specific uptake but HMRS showed increased ^{13}C-lactate production in tumor (lactate/pyruvate=0.5). H&E confirmed PCa with ~1 mm heterogenic nests surrounded by inflammatory cells. In dog 2, FDG-PET and HMRS showed elevated metabolic activity with lactate/pyruvate=0.64 in tumor, with no ^{68}Ga-tracer uptake. On H&E, extracapsular growth of PCa was confirmed. In dog 3, ^{18}F-FDG and ^{68}Ga showed uptake in tumor with little signal observed on HMRS. Overall, in each dog the tumors were confirmed to be viable at least by one physiological imaging modality showing the benefit of multimodality imaging in improving the diagnosis of PCa. **Conclusion:** Real-time fusion of PET/HMRS/MR images with TRUS is feasible and allows guided PCa biopsy. Our study lays the groundwork for potential clinical translation of this approach for improved guided biopsy results in patients.

OP504

Imaging patients with breast and prostate cancers using combined 18F-NaF/18F-FDG and TOF simultaneous PET/MRI

I. Sonni, R. Minamimoto, V. Taviani, A. Loening, S. S. Gambhir, S. Vasanawala, A. Iagaru; Stanford University, Stanford, CA, UNITED STATES.

Introduction: We previously reported the pilot evaluation of a simultaneous PET/MRI scanner with TOF capability, as well as the use of combined ^{18}F NaF/^{18}F FDG PET/CT in cancer patients. Here we prospectively compared the combined ^{18}F NaF/^{18}F FDG PET/ MRI against ^{99m}Tc-MDP in patients with breast and prostate cancers for the detection of metastatic disease. **Methods:** Thirty-seven patients referred for ^{99m}Tc-MDP bone scans were prospectively enrolled from Oct 14 to April 2016. The cohort included 26 men with prostate cancer and 11 women with breast cancer, 41 - 85 year-old (average 63.4±12). ^{18}F NaF (0.7-2.2 mCi, mean: 1.1 mCi) and ^{18}F FDG (3.6-5.5 mCi, mean: 4.1 mCi) were subsequently injected from separate syringes. The PET/MRI was done 6-30 days (average 9.3 ± 3.2) after bone scan. The whole body MRI protocol consisted of T2-weighted, DWI, and contrast-enhanced T1-weighted imaging. Lesions detected with each test were tabulated and the results were compared. **Results:** All patients tolerated the PET/MRI exam, and PET image quality was diagnostic despite the marked reduction in the administered dosage of radiopharmaceuticals (80% less for ^{18}F NaF and 67% less for ^{18}F FDG compared to standard protocols). Sixteen patients had no bone metastases identified on either scans. Bone scintigraphy and PET/MRI showed osseous metastases in 20 patients, but more numerous bone findings were noted on PET/MRI than on bone scintigraphy in 9 patients. One patient had negative bone scan, but bone metastases were seen on PET/MRI. Lesions outside the skeleton were identified by PET/MRI in 7 patients. **Conclusion:** The combined ^{18}F NaF/^{18}F FDG PET/MRI is superior to ^{99m}Tc-MDP scintigraphy for evaluation of skeletal disease extent. Further, it detected extra-skeletal disease that may change the management of these patients, while allowing a significant reduction in radiation exposure from lower dosages of PET radiopharmaceuticals administered. A combination of ^{18}F NaF/^{18}F FDG PET/MRI may provide the most accurate staging of patients with breast and prostate cancers prior to the start of treatment.

OP505

Comparison of 18F-FDG PET/MRI and MRI for whole-body staging of patients with primary cervical cancer

J. Grueneisen[1], L. M. Sawicki[2], B. M. Schaarschmidt[2], A. Wetter[1], V. Ruhlmann[1], L. Umutlu[1]; [1]University Hospital Essen, Essen, GERMANY, [2]University Hospital Dusseldorf, Dusseldorf, GERMANY.

Aim: The aim of this study was to compare the diagnostic potential of integrated 18F-FDG PET/MRI and MRI alone for the assessment of the primary tumors as well as whole-body staging of patients with cancers of the uterine cervix. **Material and Methods:** The study was approved by the local institutional ethics committee. A total of 42 consecutive patients with histopathologically proven primary cancers of the uterine cervix were prospectively enrolled in this trial. All patients underwent an integrated whole-body 18F-FDG PET/MRI examination, which comprised a contrast-enhanced whole-body MR protocol including dedicated imaging of the female pelvis. Two physicians separately evaluated the MRI data, followed by readings of the 18F-FDG PET/MRI datasets. They were asked to determine the local tumor spread of primary tumors as well as the occurrence of nodal and distant metastases. **Results:** Both, MRI and 18F-FDG PET/MRI allowed for the correct identification of 41 of the 42 primary cervical tumors. In one patient with FIGO stage Ia, the tumor could not be identified based on either imaging technique. Furthermore, MRI and 18F-FDG PET/MRI showed an equivalent diagnostic performance and enabled correct determination of the T-stage in 37 (85.7%) out of the 42 patients. In 19 of the 42 patients lymph node metastases were present. 18F-FDG PET/MRI revealed higher values for sensitivity (84% vs. 68%), specificity (92% vs. 87%) and diagnostic accuracy (88% vs. 79%) in comparison to MRI alone for the identification of nodal positive patients. A total of 3 patients had distant metastases which could be correctly detected with both imaging modalities. **Conclusion:** The present results demonstrate the usefulness of 18F-FDG PET data as a valuable additive to MR imaging for more accurate nodal staging of patients with primary cervical cancer. For the determination of the local tumor spread 18F-FDG PET/MRI and MRI performed equally. Combining high-quality MR and simultaneous PET-imaging, integrated 18F-FDG PET/MRI enables an accurate primary staging of tumors of the uterine cervix and may serve as a valuable alternative/adjunct for the clinical work-up in a pretreatment setting.

Left and right ventricular peak emptying and filling rates measured by gated tomographic radionuclide angiography using a cadmium-zinc-telluride SPECT gamma camera in chemotherapy-naïve cancer patients

N. L. Hansen, B. Zerahn; Herlev Hospital, Herlev, Copenhagen, DENMARK.

Aim: To establish normative data of left and right ventricular peak emptying and filling rates assessed with 99mTc-Human Serum Albumin equilibrium radionuclide angiography using a cadmium-zinc-telluride (CZT) SPECT gamma camera. **Materials and Methods:** The study included 718 newly diagnosed cancer patients (393 females) without diabetes mellitus or known cardiovascular diseases referred for routine baseline assessment of left ventricular function prior to potential cardiotoxic chemotherapy. Each acquisition was analysed twice and mean values of left ventricular emptying (LPER), left ventricular filling (LPFR), right ventricular emptying (RPER), and right ventricular emptying (RPFR) peak rates were obtained. **Results:** LPER and RPER did not differ between gender; LPFR and RPFR were higher in women (Students t test, $p < 0.03$). Mean and SD were: LPER (women -3.41 ± 0.9 ml/s, men -3.53 ± 0.8 ml/s), RPER (women -2.26 ± 0.6 ml/s , men -2.28 ± 0.56) LPFR (women 3.03 ± 0.86 ml/s, men 2.7 ± 0.83 ml/s), RPFR (women 1.82 ± 0.62 ml/s, men 1.73 ± 0.7). An index defined as peak filling rate/peak emptying rate (PFR/PER) for left and right ventricle was introduced, as this was less dependent of heart rate. Left ventricle PFR/PER was -0.91 ± 0.23 (women), and -0.78 ± 0.23 (men). Right ventricle PER/PFR was -0.82 ± 0.24 (women), and -0.77 ± 0.27 (men). LPER increased numerically with age in women ($p < 0.0001$, $R^2 = 0.044$), RPER increased numerically with age in both genders ($p = 0.0,1$ $R^2 = 0.013$). LPFR decreased with age in both genders ($p < 0.004$, $R^2 = 0.017$ in women, $R^2 = 0.076$ in men), RPFR decreased with age in women ($p = 0.005$, $R^2 = 0.016$). Left and right PFR/PER decreased numerically with age for both genders ($p < 0.004$, R^2 varied between 0.02 and 0.13). In patients where rates for early filling and atrial filling could be obtained separately (n=516, 416 women), we calculated right and left E/A ratio (early/atrial filling rate), which decreased with age in both genders ($p < 0.00001$, R^2 varied between 0.06 and 0.25). **Conclusion:** Reference values for ventricular peak filling and emptying rates in chemotherapy-naïve cancer patients without cardiopulmonary disease are presented. Filling rates tended to be higher in women and decrease with age, the latter in accordance with age-related increasing fibrosis. Emptying rates generally increased numerically with age, which could be related to age-related changes in heart rate and size.

OP507

Impact of spatial resolution on the assessment of left and right ventricular function by gated bloodpool SPECT: a simulation study using the 4D-MCAT phantom

A. Fernando[1], N. Delcroix[2], P. Segars[3], D. Mariano-Goulart[4], F. Ben Bouallègue[4], A. Manrique[1]; [1]EA4650 Université de Caen Normandie, Caen, FRANCE, [2]CNRS UMS 3408 GIP Cyceron, Caen, FRANCE, [3]Duke University, Carl E. Ravin Advanced Imaging Laboratories, Durham, NC, UNITED STATES, [4]CHRU de Montpellier - Inserm U1046 - CNRS UMR 9214, Montpellier, FRANCE.

Introduction: The new CZT based cameras improve spatial resolution in cardiac perfusion SPECT. However, the impact of the increased resolution on gated bloodpool SPECT (GBPS) measurements is poorly documented. **Materials and methods:** 15 different dynamic three-dimensional mathematical cardiac torso (MCAT) phantoms with increasing ventricular size were generated. We simulated a 360° SPECT acquisition using a Matlab program (72 projections every 5°) with two different Poisson noise levels. The spatial resolution was successively set to 6 mm and 12 mm to mimic both CZT and conventional Anger camera resolutions. All sinograms were then reconstructed using filtered backprojection (Hamming filter). Finally, the 60 reconstructed datasets were converted into a DICOM format and processed using software based on a watershed immersion algorithm (Tompool®, Montpellier University, France) to assess the left ventricular (LV) and right ventricular (RV) ejection fractions (EF) and volumes (end-diastolic volume: EDV or end-systolic volume: ESV). **Results:** Simulated LVEDV ranged from 26 to 277 ml. GBPS post-processing using Tompool was successful in 52/60 cases, but failed in 8 cases with smallest hearts size examined at low (12 mm) resolution. Compared to true values, GBPS overestimated left and right ventricular volumes (LVEDV: 156±77ml vs. 125±80 ml, LVESV: 58±26 ml vs. 38±25 ml, RVEDV 200±108 ml vs. 170±109 ml, RVESV: 106 ±60 ml vs. 86±55 ml, all p values <0.0001 vs. true volumes) and underestimated left and right EF (LVEF: 62±7% vs. 69±1%, p <0.0001; RVEF: 47±5 vs. 49±1%, p <0.01). A linear model analysis demonstrated that spatial resolution, but not the noise level, significantly impacted the assessment of LV and RV volumes and ejection fractions, the increase in spatial resolution leading to a reduced measurement bias (all p values < 0.001). The correlation between measured and true volumes was high for RVEDV and LVEDV (r^2 values range: 0.92-0.98) whatever the resolution. For LVESV, the correlation was higher using 6-mm (r^2= 0.95) compared to 12-mm resolution (r^2= 0.80). Due to larger systolic volumes, this difference was not observed for RVESV (6mm: r^2= 0.99; 12mm: r^2= 0.98). **Conclusion:** This phantom study demonstrated that spatial resolution has a significant impact on left and right ventricular function assessment using GBPS, suggesting an increased accuracy when using a CZT-like spatial resolution.

OP508

Gamma-cameras are likely to be less vulnerable to small heart motions when equipped with CZT detectors

L. IMBERT[1,2,3], J. SALVADORI[3], Y. PETEGNIEF[4], R. SABBAH[4], H. BOULAHDOUR[4], G. KARCHER[1,2,5], P. MARIE[1,2,6]; [1]CHU NANCY HOPITAL BRABOIS ADULTES, VANDOEUVRE LES NANCY, FRANCE, [2]Plateforme d'Imagerie Expérimentale, Nancy, FRANCE, [3]Institut de Cancérologie de Lorraine, Vandoeuvre-lès-Nancy, FRANCE, [4]CHRU DE BESANCON, BESANCON, FRANCE, [5]Université de Lorraine, Faculté de Médecine, Nancy, FRANCE, [6]INSERM, U1116, Nancy, FRANCE.

Introduction. Solid-state CZT cameras provide high-quality images, with better contrast and signal-to-noise ratio than conventional Anger cameras, but it is not known whether they are vulnerable to small cardiac motions, which are frequently documented during patients' SPECT recordings. This study was aimed to assess the motion-related increase in the heterogeneity of the myocardial activity recorded on a left ventricular phantom with 2 CZT cameras, the Discovery NM-530c (GE) and the D.SPECT (Spectrum Dynamics) in comparison with an Anger camera (Symbia T2, Siemens) equipped with an astigmatic (IQ.SPECT) or parallel-hole (Conv.SPECT) collimator. **Methods.** The left ventricular insert, which walls were filled-in with a solution containing ^{99m}Tc, was placed at the center of the field of view and for the second half of the SPECT recordings, this insert was

translated with various amplitudes in 6 different directions (-X/+X, -Y/+Y et -Z/+Z). SPECT images were reconstructed with the parameters recommended for clinical routine for each of the 4 cameras. Mean activity was determined for 17 left ventricular segments with the QPS software, and the motion-related increase in heterogeneity between segments' activities was assessed with: 1) the coefficient of variation of the segments' activities (ratio of the standard deviation to the mean) and 2) the number of segments becoming definitely abnormal with a mean activity < 60% of maximal voxel activity. **Results.** The coefficient of variation of the segments' activities was markedly lower in static conditions for the two CZT cameras (D.SPECT: 5.2% Discovery: 5.4%) than for the Anger ones (IQ.SPECT: 9.5%, Conv.SPECT: 8.0%) and these coefficients exhibited further deteriorations according to motion amplitude. For motions of 10-mm, these coefficients were on average: 6.0% for D.SPECT, 7.0% for Discovery, 11.5% for IQ.SPECT and 8.3% for Conv.SPECT. Up to motions of a 10-mm amplitude, the mean number of segments becoming definitely abnormal was low for the CZT cameras (none for D.SPECT and 1 for Discovery) and higher for the Anger ones (3 for both IQ.SPECT and Conv.SPECT). **Conclusions.** When compared with Anger cameras on phantom recordings, CZT cameras exhibit a lower vulnerability to small heart motions, with a lower number of artefactual segmental defects. This may be explained by the higher homogeneity of the activity recorded with CZT detectors and by the limited deteriorations associated to small motions.

OP509

Myocardial Perfusion Imaging with CZT SPECT: Dual Cardiac and Respiratory Gating and Motion-Free SPECT Diastolic Images

D. Daou[1,2], R. Sabbah[3], C. Coaguila[4], H. Boulahdour[3]; [1]Cochin Hospital, APHP, Paris, FRANCE, [2]EA 7334 REMES, Université Paris-Diderot, Sorbonne Paris-Cité, Paris, FRANCE, [3]CHU Jean Minjoz, Besançon, FRANCE, [4]Centre Hospitalier de Bigorre, Tarbes, FRANCE.

Aim: We recently developed a data-driven respiratory-motion (RM) correction program (REGAT) to process myocardial perfusion (MPI) with CZT SPECT and reported its clinical feasibility and interesting impact on image characteristics. In this MPI CZT SPECT pilot study, we evaluate the feasibility of dual cardiac-respiratory gating with REGAT, its capacity to generate motion-free diastolic SPECT images and its impact on image characteristics. Materials and Methods: Were included 7 patients addressed for a stress/rest 99mTc-Tetrofosmin MPI. All patients had prone stress (2 MBq/Kg, 5 min) than rest MPI 3-hours later (6 MBq/Kg, 10 min) on Discovery NM 530c. Only rest list mode acquisitions were processed to generate dynamic SPECT studies using a sampling duration equal to mean ECG RR/16 msec. Each dynamic SPECT study was processed to calculate a data-driven RM curve and generate a mean RM GSPECT study (16 bins). The ECG trigger contained in the list mode was used to generate a mean ECG GSPECT study (16 bins) which was used to generate a corresponding diastolic SPECT study -does not account for RM- by summing bins 1 and 12 to 16 (D-SPECTs) (38% of RR ~4 min acquisitions). The RM curve and the list mode ECG trigger were also used to generate a mean dual cardiac-respiratory gated study (256 bins). The above RM GSPECT was reconstructed and summed either without (SPECTs) or after rigid realignment of cardiac RM. The calculated cardiac RM shifts in the patient's 3-axis were used to process and realign the mean dual cardiac-respiratory gated SPECT projections generating a mean RM-free ECG gated SPECT study. This served to generate a RM-free study by summing all bins (SPECTs-RMfree) and a diastolic RM-free study by summing bins 1 and 12 to 16 (D-SPECTs-RMfree).Were noted for each study the maximal RM in the cranio-caudal (CC), minimum left ventricular cavity counts (LV-Min), maximum LV myocardial counts (LV-Max), FWHM of anterior (FWHM-ant) and inferior (FWHM-inf) LV myocardial wall. Contrast = (LV-Max - LV-Min)*100/(LV-Max + LV-Min). Results: CC was 12±5 mm and > 10 mm in 4/7 pts. D-SPECTs and D-SPECTs-RMfree were very good quality. For SPECTs, D-SPECTs, SPECTs-RMfree, and D-SPECTs-RMfree:

FWHM-ant were	5.9±0.7	5.5±0.6	5.5±0.7	and 5±0.4 mm
FWHM-inf were	6.7±0.6	6.5±0.8	6.2±0.3	and 6.1±0.7 mm
Contrast	83±6	91±5	86±7	and 93±6 %.

Conclusion: Dual cardiac and respiratory gating of MPI CZT SPECT is feasible with REGAT. It provides very good quality cardiac and RM-free diastolic SPECT images with the best image characteristics.

OP510

CZT SPECT Cardiac Radionuclide Angiography: Feasibility of Data-Driven Respiratory-Motion Gating with REGAT Software

D. Daou[1,2], R. Sabbah[3], C. Coaguila[4], H. Boulahdour[3]; [1]Cochin Hospital, APHP, Paris, FRANCE, [2]EA 7334 REMES, Université Paris-Diderot, Sorbonne Paris-Cité, Paris, FRANCE, [3]CHU Jean Minjoz, Besançon, FRANCE, [4]Centre Hospitalier de Bigorre, Tarbes, FRANCE.

Aim: We recently reported the clinical feasibility of a data-driven respiratory-motion (RM) correction program (REGAT) to process 99mTc-Tetrofosmin myocardial perfusion (MPI) with CZT SPECT. In this preliminary study, we evaluate the feasibility of dual cardiac-respiratory gating with REGAT to process CZT SPECT cardiac radionuclide angiography (RNA). Materials and Methods: Were included 18 patients having a rest cardiac 99mTc-Angiocis RNA on Discovery NM 530c (500 MBq, 5 min acquisition). List mode acquisitions were processed to generate dynamic SPECT studies using a sampling duration equal to mean ECG RR/16 msec. Each dynamic SPECT study was processed to calculate a data-driven RM curve and generate a mean RM GSPECT study (16 RM bins). The ECG trigger contained in the list mode was used to generate a mean ECG GSPECT study (16 ECG bins). The RM curve and the list mode ECG trigger were also used to generate a mean dual cardiac-respiratory GSPECT study (256 bins). RM GSPECT was reconstructed and rigidly realigned focusing on left and right ventricles. The calculated cardiac RM shifts in the patient's 3-axis were used to process and realign for RM the mean dual cardiac-respiratory GSPECT projections generating a mean RM-free ECG GSPECT study by summing all respiratory bins (ECG-GSPECTs-RMfree, 16 ECG bins, it maintains all acquired counts) or by summing only end-expiratory bins corresponding arbitrarily to 30% of respiratory time (ECG-GSPECTs-EE, 16 ECG bins). Were noted: quality of RM curves and image quality of GSPECT, and the maximal respiratory motion in the 3 axis: cranio-caudal (CC), left-right arm (LR) and ventral-dorsal (VD) axis. Results: REGAT generated good quality RM curves. Cardiac motion was the largest in CC (7.2±5.8 mm). CC was ≥ 10 mm (2-FWHM) in 5/18 pts and ≥ 15 mm (3-FWHM) in 2/18 pts. LR and VD cardiac motion were 1.72±1.31 mm and 0.59 ±0.47 mm. LR and VD were < 5mm in all 18 patients. ECG-GSPECTs-RMfree were good quality. But ECG-GSPECTs-EE were of insufficient quality. Conclusion: Dual cardiac and respiratory gating of RNA CZT SPECT appears feasible with REGAT. It provides cardiac RM magnitude in the 3-axis globally concordant with those in the literature. ECG-GSPECTs-RM-free was of good quality but may suffer limitations inherent to rigid alignment. ECG-GSPECTs-EE does not need alignment but provides inadequate image quality

due to restricted respiratory bin sampling. To overcome this, it needs to be evaluated on longer acquired studies. Their impact on quantification of cardiac function needs to be evaluated.

OP511

Differences in attenuation pattern in myocardial perfusion SPECT between CZT and conventional gamma cameras

J. Oddstig[1], E. Martinsson[2], F. Hedeer[3], H. Engblom[3], C. Hindorf[1]; [1]Radiation Physics, Skane University Hospital, Lund University, Lund, SWEDEN, [2]Radiation Physics, Lund University, Lund, SWEDEN, [3]Department of Clinical Physiology and Nuclear Medicine, Skane University Hospital, Lund, SWEDEN.

Background A new generation of gamma cameras with cadmium zinc telluride (CZT) detectors and pinhole collimators has been introduced. The use of pinhole collimators and static gantry result in different image appearance compared to conventional gamma cameras with parallel-hole collimators and rotating gantry. To what extent the attenuation pattern differs between the two cameras is not known. Therefore, the aim of the present study was to compare the position, extent and depth of attenuation defects in myocardial perfusion SPECT (MPS) for a CZT and a conventional gamma camera. **Material and Methods** Phantom measurements were performed on both a CZT camera (GE NM 530c) and a conventional gamma camera (GE Ventri) using a cardiac phantom including lung insert (Data Spectrum Corporation). Twenty patients underwent a 2-day stress-rest protocol (4MBq/kg, stress and rest) and were examined on both cameras approximately 1 hour after administration of ^{99m}Tc-tetrofosmin. All images were corrected for attenuation by an externally acquired CT. Reconstruction parameters recommended by the manufacturer were used. The localization, extent and depth of the attenuation defect was quantified using the software Segment (version 1.9) by comparing the attenuation-corrected and non-attenuation-corrected images for both phantoms and patients. The extent of attenuation for each camera was defined by visual delineation of the ratio between the attenuation-corrected and non-attenuation-corrected phantom images. **Results** The localization of an attenuation defect was shifted counter-clockwise from the inferolateral wall to the lateral wall for the CZT camera compared to conventional camera in both the patient and the phantom measurements. Based on the manual delineation of the attenuation in the phantom ratio images the attenuation threshold was 0.90 and 0.85 for the CZT and conventional camera, respectively. When applying these thresholds in patients the attenuation defect was 23% and 14% ($p<0.05$) of the total myocardium (mean) for the CZT and conventional camera, respectively. In the phantom experiments the percent of maximum counts within the attenuation defect was 73% and 67% for the CZT and conventional gamma camera, respectively. For the attenuation defect in the patient images was the percent of maximum counts 72% for the CZT and 68% ($p<0.05$) for the conventional camera. **Conclusions** Attenuation defects have different location, extent and depth when comparing a CZT camera to a conventional gamma camera which needs to be taking into consideration when evaluating perfusion images.

OP512

Interstudy repeatability of left and right ventricular peak emptying and filling rates using a cadmium-zinc-telluride SPECT gamma camera for radionuclide angiography

N. L. Hansen, B. Zerahn; Herlev Hospital, Herlev, DENMARK.

Aim: To assess interstudy repeatability of left and right ventricular peak emptying and filling rates assessed with 99mTc-Human Serum Albumin equilibrium radionuclide angiography using a cadmium-zinc-telluride (CZT) SPECT gamma camera. **Materials and Methods:** The study included 46 newly diagnosed cancer patients (35 females) without diabetes mellitus or known cardiovascular diseases referred for routine baseline assessment of left ventricular function prior to potential cardiotoxic chemotherapy. A dose of 550-600 MBq 99mTc-labeled human serum albumin (HSA) was administered intravenously to each patient. Two acquisitions were performed on a CZT cardiac SPECT gamma camera, GE Discovery 530c (GE Healthcare, Milwaukee, WI, USA), between which the patient was repositioned. Each acquisition was analysed twice by two experienced technologists using a Xeleris 3 Imaging workstation reorientation software (version no. 3.0562) and Cedars-Sinai QBS processing software (revision 2009.0), and mean values of left ventricular emptying (LPER), left ventricular filling (LPFR), right ventricular emptying (RPER), and right ventricular filling (RPFR) peak rates were obtained. Interstudy repeatability was assessed by calculating the intraclass correlation coefficient (ICC) with 95% confidence intervals for the two acquisitions. Furthermore, Bland-Altman analysis was carried out in order to assess proportional bias. **Results:** One patient had an extremely high influence on the simple linear regression analysis carried out for identification of proportional bias (Cook's distance > 1). A review of the raw data revealed a high intra-observer variation for both acquisitions. Subsequently, this patient was excluded from the analysis. ICC and 95% confidence intervals for LPER, RPER, LPFR, and RPFR were 0.99 (0.99-1.00), 0.94 (0.89-0.97), 0.99 (0.98-0.99), and 0.84 (0.72-0.91) respectively. There was no significant proportional bias for any of the variables. **Conclusion:** The CZT camera provides reproducible estimates of left and right ventricular peak emptying and filling rates. Peak filling and emptying rates might be useful for monitoring cardiac function in cancer patients receiving potential cardiotoxic chemotherapy. However, in cases where a high intra-observer variation is found, outcome should be interpreted with caution.

Targeted radionuclide therapy of non-Hodgkin B-cell lymphoma using ^{177}Lu-lilotomab or ^{177}Lu-rituximab: a radiobiological approach

A. Pichard[1], S. Marcatili[2], A. Courteau[2], R. Ladjohounlou[1], G. Cartron[3], I. Navarro-Teulon[1], A. Repetto-Llamazares[4], H. Heyerdahl[4], M. Bardiès[2], J. Dahle[4], J. Pouget[1]; [1]IRCM/INSERMU896, Montpellier, FRANCE, [2]UMR 1037 INSERM/UPS, Centre de Recherche en Cancérologie de Toulouse, Toulouse, FRANCE, [3]Centre Hospitalier Universitaire de Montpellier, Montpellier, FRANCE, [4]Nordic Nanovector ASA, Oslo, NORWAY.

Aims. We investigated *in vitro* and *in vivo* in mice the therapeutic efficacy of ^{177}Lu-lilotomab, a monoclonal antibody targeting CD37 receptor expressed by B lymphoma cells. **Materials and methods.** *In vitro*, Ramos (Burkitt) and DOHH2 (follicular) lymphoma cell lines were exposed for 18 hours to increasing activities (0—6 MBq/mL) of ^{177}Lu-rituximab, ^{177}Lu-lilotomab, of the non-specific ^{177}Lu-cetuximab or to unlabelled mAbs (0-40μg/mL). A radiobiological model considering the cytotoxic effects of radiation alone, of cold antibody alone or of the ARC was established using a mathematical model. This model was next used for predicting the *in vivo* therapeutic efficacy of the three latter ARC in mice bearing Ramos or DOHH2 tumour xenografts. The approach relied on *in vitro* and *in vivo* absorbed dose assessment using MIRD formalism. **Results.** We showed in Ramos and DOHH2 cells the highest cytotoxicity of ^{177}Lu-rituximab, followed by ^{177}Lu-lilotomab and the lowest for ^{177}Lu-cetuximab. The highest sensitivity to ARC was observed in DOHH2 presumably because of their p53 wild type status. Unlabelled rituximab was more efficient in killing cells than lilotomab mainly through apoptosis induction. We determined that in the radiation sensitive DOHH2 cell line, radiation produced by ^{177}Lu could counterbalance the lower efficacy of lilotomab compared with rituximab, such that

^{177}Lu-lilotomab or ^{177}Lu-rituximab showed the same cytotoxicity. The contribution of radiation to cell killing was much lower in the radiation resistant Ramos cells and ^{177}Lu-rituximab was then more efficient than ^{177}Lu-Lilotomab in that cell line. *In vivo* we showed that ^{177}Lu-rituximab was more toxic than ^{177}Lu-lilotomab and led to a lower maximum tolerated activity. In addition, we showed that one injection of naked rituximab or lilotomab in Ramos tumour xenograft was accompanied by similar increase in median survival. This suggests that under these conditions, naked antibodies have similar (and rather weak) efficacy *in vivo*. Therefore, only final tumour absorbed dose explained the differences in therapeutic efficacies of ^{177}Lu-rituximab and ^{177}Lu-lilotomab. In this respect, we confirmed that the median survival of mice treated with ^{177}Lu-rituximab, ^{177}Lu-cetuximab or ^{177}Lu-lilotomab was proportional to the tumour absorbed dose and was greater for the latter antibody. Similar analysis is ongoing in DOHH2 tumour xenograft treated with ARC. **Conclusion.** We established *in vitro* a radiobiological model to predict *in vivo* the therapeutic efficacy of ^{177}Lu-rituximab, ^{177}Lu-lilotomab or ^{177}Lu-cetuximab. This model was validated by *in vivo* data showing that in mice with Ramos tumour xenograft, ^{177}Lu-lilotomab was more efficient than the two other ARCs.

OP514

Simultaneous PET-MR First Pass Perfusion Imaging using a Novel Cardiac Perfusion Phantom

J. O Doherty[1], E. Sammut[1], P. Schleyer[2], J. Stirling[1], P. Marsden[1], A. Chiribiri[1]; [1]King's College London, London, UNITED KINGDOM, [2]Siemens Healthcare UK, London, UNITED KINGDOM.

Background: PET-MRI scanners are increasingly being employed for quantitative myocardial perfusion imaging. We describe a feasibility study of simultaneous first-pass PET-MRI of gadolinium-based contrast agent (GBCA) and PET radiotracer in a dedicated hardware cardiac perfusion phantom, showing repeatability in the quantified perfusion measurements of the resulting simultaneous dynamically acquired traces. Methods: [18F]-NaF and GBCA were injected simultaneously into the phantom using a range of ground-truth myocardial perfusion rates (F_T) of 1 ml/g/min to 5 ml/g/min. MRI and PET data analysis was performed to compare signal time traces in the aorta and the myocardial sections of the phantom, which simulate an image-derived arterial input function (AIF) and myocardial uptake respectively. PET quantification of perfusion flow resulting in values of K_1 (ml/g/min) was performed using a single tissue compartmental model, while MR relative perfusion measurements of the tissue impulse response function ($h(t)$) were calculated using a diluted prebolus of contrast ($h(t)_{PB}$) as the input function using a signal deconvolution technique. Results: Image analysis show simultaneous dynamic PET and MR signal traces at the aorta input and through the myocardial compartments. Calculation of perfusion parameters showed both K_1 and $h(t)_{PB}$ to be linearly related with F_T, and also linearly related to each other (R^2=0.99). The highest difference in perfusion values between K_1 and F_T was at 1 ml/g/min of 16% but the mean difference for other flow rates was <3%. Conclusion: This study shows that the novel perfusion phantom allows reliable, reproducible simulation of the myocardial kinetics for simultaneous PET-MR imaging, and will find use in protocol design, comparison of PET quantification software and development of MR-based quantification techniques.

OP515

Effect of Data-Driven Respiratory Gating on Lu-177 SPECT/CT Scans

J. C. Sanders[1,2], T. Kuwert[2], A. H. Vija[3], A. K. Maier[1], P. Ritt[2]; [1]Pattern Recognition Lab, University of Erlangen-Nuremberg, Erlangen, GERMANY, [2]Clinic of Nuclear Medicine, University Hospital Erlangen, Erlangen, GERMANY, [3]Siemens Healthcare GmbH, Molecular Imaging, Hoffman Estates, IL, UNITED STATES.

Aims: Due to long projection times, traditional SPECT imaging suffers from blurring caused by patient breathing motion. This may adversely affect personalized dosimetry for targeted Lu-177 therapies that relies on precise volume of interest (VOI) delineation and quantitation. A data-driven respiratory gating method was recently proposed for Tc-99m liver acquisitions to mitigate this effect, but due to the lower resolution and different activity distributions in Lu-177 imaging, it is yet to be established whether or not this method is applicable for the latter isotope. This study aimed to apply the data-driven respiratory gating method to Lu-177 scans and investigate its effectiveness in these cases. **Methods:** 7 patients undergoing targeted radionuclide therapy were injected with 6.1±1.0 GBq of either Lu-117-PSMA (2 patients) or -DOTATATE (5 patients) prior to SPECT/CT acquisitions at 4, 24, 48, and 72 h.p.i., yielding a total of 28 datasets. Data was acquired with a Symbia T2 SPECT/CT (Siemens Healthcare) for 60 15sec views, and a data-driven respiratory gating method was used to subdivide list-mode data into 5 gates, which were reconstructed separately using prototype xSPECT Quant software (20iterations/1subset, attenuation and scatter correction, 10mm post-smoothing).VOIs were defined at spinal and ilial bone lesions (*BL*, n=20), bladders (*B*, n=16), left/right kidneys (*KL*/*KR*, n=20), and liver lesions (*LL*, n=31) using a 50% iso-contour in the SPECT image. VOIs were excluded where spillover into neighboring tissue with high activity concentration (e.g. pancreas) precluded clear delineation. The center of mass in each VOI was calculated for each reconstructed gate. Using the beginning inspiration gate as reference, maximum translation along the head/foot axis during the respiratory cycle was then recorded. **Results:**Translations of *BL* and *B* VOIs were -0.1 ±1.8 and -0.5±2.3mm, respectively, and insignificant (p=0.89 and 0.43). Motions in *KL*, *KR*, and *LL* VOIs were -7.2±3.8, -5.8±4.1, and -8.1±3.9mm, respectively. All motions in the latter group were significantly greater than zero with p<0.001. There was no significant difference between the magnitude of left and right kidney motion (p=0.31). **Conclusion:** In this preliminary study, translations after respiratory gating were found to be insignificant in tissues assumed to be unaffected by respiratory motion (spinal and ilial bone lesions, bladder), whereas those in regions known to be affected by respiration (liver, kidneys) were significant. These results indicate that the respiratory gating method is indeed able to capture breathing motion for Lu-177 imaging. More patients must be analyzed to characterize its performance and assess clinical utility.

OP516

A software for characterizing intra-tumor heterogeneity in multimodality imaging and establishing reference charts

C. NIOCHE[1], F. ORLHAC[1], M. SOUSSAN[2], S. BOUGHDAD[3], J. ALBERINI[3], I. BUVAT[1]; [1]IMIV, CEA, Inserm, CNRS, Univ. Paris-Sud, Université Paris Saclay, CEA-SHFJ, 91400, Orsay, FRANCE, [2]HU-Paris Seine Saint Denis site Avicenne ap-hp, 93000 Bobigny, FRANCE, [3]Institut Curie-Hôpital René Huguenin, 92210 Saint-Cloud, FRANCE.

Objectives: Textural analysis is gaining considerable interest in medical imaging, in particular to characterize tumor heterogeneity. Yet, values corresponding to heterogeneous tumors are unknown. We developed an easy-to-use freeware enabling calculation of a broad range of conventional, textural and shape indices from PET, MR and CT images to speed up the creation of reference charts. **Methods**: The LIFEx freeware does not rely on any commercial libraries. LIFEx is dedicated to researchers, radiologists, nuclear medicine physicians and oncologists and includes a user interface displaying conventional indices (eg SUV, metabolic volume and total lesion glycolysis in FDG PET) and a large variety of histogram, textural and shape indices. Calculation options (eg, resampling method and number of grey

levels for textural analysis) can be changed by the user. LIFEx reads DICOM images locally or over a network using a DICOM browser, is compatible with Osirix and includes a powerful 3D reconstruction-based slice viewer. Volumes of interest can be imported, drawn and manipulated using LIFEx. Results are exported in Excel format files. LIFEx runs on Windows, MacOs and Linux platforms. It is distributed with examples and includes a tutorial. Users can contribute to the gathering of index values in different tissue types and different images. A public database of reference values is being built and integrated in the software for assisting result interpretation. **Results**: LIFEx has been distributed to research labs, nuclear medicine and radiology departments for investigating different tumor types (gliomas, cervix, lung, breast, and colorectal tumors). The intuitive interface made it fast to master for staff, and allowed us to start building databases of normal textural values in brain (white and grey matter), breast, liver, lung, fat, and muscles for various imaging equipments and protocols in PET and CT, while MR data are currently being collected and processed. The collected data resulted in a large set of reference charts characterizing the values and variability of the textural indices in PET and CT as a function of the organ, scanner and imaging protocol when using identical calculation formula. **Conclusions**: The availability of a free software to calculate indices characterizing tumor heterogeneity facilitates the collection of data by independent centers. The on-going creation of reference charts for various indices, organs, imaging modalities and protocols should contribute to a better understanding of the potential and limitation of textural analysis in PET, CT and MR.

OP517

Dynamic scanning, kinetic modelling and parametric images reveal lung inflammation

I. Velikyan[1], J. Sörensen[1], J. Retamal[2], F. Suarez-Sipmann[2], S. Jalkanen[3], G. Antoni[4], G. Hedenstierna[2], A. Roivainen[5], A. Larsson[6], M. Lubberink[1]; [1]Section of Nuclear Medicine and PET, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN, [2]Hedenstierna laboratory, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN, [3]MediCity Research Laboratory and Department of Medical Microbiology and Immunology, University of Turku, Turku, FINLAND, [4]Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, [5]Turku PET Centre, University of Turku, Turku, FINLAND, [6]Hedenstierna laboratory, Department of Surgical Sciences, Uppsala, SWEDEN.

Aim: Development of radiopharmaceuticals for fast, noninvasive, specific and quantitative imaging of acute lung inflammation is a challenging task. The apparent uptake in positron emission tomography (PET) images is a manifestation of a number of physiological processes. Dynamic scanning, kinetic modelling, and parametric net influx rate (K_i) images were employed in order to elucidate target specific binding of [^{68}Ga]Ga-Siglec-9/PET-CT in porcine model of acute respiratory distress syndrome (ARDS). **Material and Methods:** Pigs with induced ARDS were first intravenously administered with [^{15}O]water (421±4 MBq) for dynamic scanning during 10 min. Then ^{68}Ga-labeled 1,4,7,10-tetraaza cyclododecane-1,4,7-tris-acetic acid-10-ethylene glycol-conjugated Siglec-9 motif peptide ([^{68}Ga]Ga-Siglec-9; 120±36 MBq) was intravenously administered for dynamic scanning during 90 min followed by whole-body examination. Arterial blood samples (1 mL) were collected at 0.5, 1, 2, 5, 7, 10, 15, 20, 30, 45, 60, 75, 80 and 90 min post injection. Lung tissue perfusion was quantified from dynamic [^{15}O]water/PET. The dynamic [^{68}Ga]Ga-Siglec-9/PET data from the lung was fitted to a reversible two-tissue compartment model. Net uptake rate ($k_i=K_1*k_3/(k_2+k_3)$) was calculated as the slope of the linear portion of the time-activity-curve TAC, starting at 15 min post injection. Parametric K_i images were generated using a basic function method. **Results:** Injured lungs demonstrated 10-fold lower tissue perfusion and 2-fold lower standardized uptake value (SUV) as compared to that of the healthy ones. The right and left ventricular TACs of [^{15}O]water/PET fit best as input function respectively in the healthy and injured lungs. The kinetics of [^{68}Ga]Ga-Siglec-9 distribution was described by the reversible two-tissue compartment model well. K_i value was 2.2 times higher for the healthy lungs, however when normalized to the tissue perfusion the value was found 4 times higher for the injured lungs. The retention of the tracer was also statistically higher for the injured lungs. **Conclusions:** The correction for the tissue perfusion, that strongly influences the accessibility of [^{68}Ga]Ga-Siglec-9 to the target, revealed higher net influx rate for the injured lungs thus allowing the detection of pulmonary inflammation. This finding would not be possible on the bases of SUV readings only. Furthermore the parametric K_i images improved the quantification accuracy and image contrast.

OP518

BRAF V600E Mutation In Papillary Thyroid Cancer: Its Influence On Radioiodine Postsurgical Therapy - Preliminary Results

M. Domínguez-Ayala[1], P. Mínguez-Gabiña[2], A. Expósito Rodríguez[1], E. Rodeño Ortiz de Zarate[2], T. Gutiérrez Rodríguez[1], B. Barrios Treviño[1], M. Paja Fano[1], A. Gómez Palacios[1]; [1]H.U. Basurto, Bilbao, SPAIN, [2]H.U. Cruces, Barakaldo, SPAIN.

OBJECTIVE: The BRAF V600E mutation in papillary thyroid cancer (PTC) has been related to resistance to iodine in recurrent disease. However, this influence is not known in the early stages of disease. Our aim was to evaluate the effect of the BRAF V600E mutation in PTC after the postsurgical ablation of thyroid remnants with ^{131}I. MATERIALS AND METHODS: A prospective cohort study was designed, from September 2015 to February 2016, which included patients with PTC receiving ablative ^{131}I therapy after surgical treatment. All of them were operated by the same surgical centre and by the same surgical team. Two different groups were established: patients who had BRAF V600E mutation (BRAF +) and those without it (BRAF-). Variables were described of age, gender, tumor stage, thyroglobulin values after 6 months of the radioiodine therapy, and the therapeutic administered activity. To determine the influence of the mutation in the radioiodine uptake in the remnants, SPECT/CT based dosimetry of thyroid remnants was performed. RESULTS: 17 patients giving in total 32 thyroid remnants with an average of 1.8 per patient were included. 76% of patients were women and 59% of patients were BRAF +. In both BRAF + and BRAF - patients, age was similar. BRAF + patients had more advanced tumor stages (II and III) (50% vs 29%). Thyroglobulin values at 6 months were significantly higher for the BRAF + group (mean 0.91 vs 0.18; p = 0.47) and also was the administered activity (mean 3638 MBq vs 2590 MBq; p = 0.053). The BRAF + patients had a lower absorbed dose to thyroid remnants per administered activity (5.5 Gy/GBq vs 12.4 Gy/GBq; p = 0.18) and a lower remaining activity in remnants per the unit mass and per administered activity at 7 days (0.006 %/g vs 0.022 %/g p = 0.28). The effective half-life of the radioiodine in the remnants was higher for BRAF- patients (69 h vs 47 h p = 0.26). CONCLUSIONS According to the initial results, more than half of patients with PTC showed BRAF V600E mutation. After postsurgical ablation with ^{131}I, the mutation involved a lower absorbed dose per administered activity, lower relative activity per unit mass after 7 days and faster washout of the radioiodine. We need more long-term studies with a larger population to confirm these results and know their clinical consequences.

OP519

Induction and Maintenance Regimen with Peptide Receptor Radionuclide Therapy Lu-177-DOTA-TATE (PRRT) Improves Progression Free Survival (PFS) in Patients with Advanced Neuroendocrine Tumours (NETs)

A. J. B. McEwan[1], M. Wieler[1], M. B. Sawyer[1], D. W. Morrish[1], B. A. Schaitel[2], L. D. Schrader[2], D. Murray[1], W. Makis[1], T. McMullen[1]; [1]University of Alberta, Cross Cancer Institute, Edmonton, AB, CANADA, [2]Alberta Health Services, Cross Cancer Institute, Edmonton, AB, CANADA.

Introduction: A PRRT protocol of induction (4 cycles) and maintenance (up to 8 cycles) treatments is a novel and effective therapeutic option for patients with advanced gastrointestinal and pancreatic NETs (GEPNETs). Aims: We hypothesize long-term and ongoing therapy with Lu-177 improves outcomes, and is effective and safe for these patients. We evaluated PFS in a cohort with GEPNETs following an induction regimen of Lu-177 (4 cycles of up to 6.11 GBq/cycle every 10 - 14 weeks) and maintenance (up to 8 cycles of up to 4.07 GBq/cycle every 5.5 - 10 months). Materials and methods: A subset of 139 participants enrolled in this Lu-177 study have PNETs (n=44), GNETs (n= 85), or presumptive GNETs (n=10)). Of these 139 participants, 30 had 1-2 cycles, 26 had 3-4 cycles, 34 had 5-6 cycles, 28 had 7-8 cycles, 13 had 9-10 and 8 had 11-12 cycles of Lu-177 therapy. Cumulative mean administered dose was 5.76 ± 2.39 GBq (1-2 cycles); 17.90 ± 3.35 GBq (3-4 cycles); 23.67 ± 3.87 (5-6 cycles); 32.98 ± 4.34 GBq (7-8 cycles); 40.25 ± 2.88 GBq (9-10 cycles) and 48.88 ± 6.02 GBq (11-12 cycles). Doses were modified by defined algorithm for age, metastatic burden and renal function. Results: 111 patients remain on treatment and 28 have stopped treatment: 1 is surgically confirmed disease free (after 4 cycles); 13 discontinued due to biochemical, anatomic or symptomatic progression between cycles (after 1-2 cycles, n=2; after 3-4, n=3; after 5-6, n=1; after 7-8, n=4; after 9-10, n=2; after 11-12, n=1); 14 died (after 1-2 cycles, n=4; after 3-4, n=1; after 5-6, n=5; after 7-8, n=3; after 9-10, n=1). Mean time from first treatment was: 12.4 weeks, 1-2 cycles; 36.8 weeks 3-4 cycles; 17.7 months 5-6 cycles; 34.2 months 7-8 cycles; 46.9 months 9-10 cycles and 58.1 months 11-12 cycles. A Kaplan-Meier survival curve shows median PFS has not yet been reached at 59.3 months. Transient Grade 3 renal and haematological toxicity were seen; no Grade 4 toxicity was observed. Conclusion: These data support our hypothesis that a long term regimen of induction and maintenance therapy with Lu-177 improves PFS in patients with GEPNETs, and supports the hypothesis of low dose hypersensitivity as the mechanism of action for PRRT in GEPNETs. This regimen is more effective than literature reported treatment regimens; in this cohort, median PFS has not been reached at 59.3 months.

OP520

Secondary glioblastoma multiforme - local alpha emiters targeted therapy with ^{213}Bi-DOTA-substance P

L. Królicki[1], A. Morgenstern[2], J. Kunikowska[1], H. Koziara[3], B. Królicki[3], M. Jakuciński[4], D. Pawlak[5], C. Apostolidis[6], F. Bruchertseifer[6]; [1]Nuclear Medicine Department, Medical University of Warsaw, Warszawa, POLAND, [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY, [3]Department of Neurosurgery, Institute of Psychiatry and Neurology, Warszawa, POLAND, [4]Department of Nuclear Medicine, Brodnowski Hospital, Warszawa, POLAND, [5]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock-Swierk, POLAND, [6]European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY.

Glioblastoma multiforme (GBM) is the most common and malignant brain tumor. GBM may be primary or secondary. Primary GBM develop rapidly in elderly patients without histologic evidence of a less malignant precursor lesions. Secondary GBM origin from low-grade diffuse astrocytoma or anaplastic astrocytoma, with manifestation in younger patients. Histologically, primary and secondary GBM are largely indistinguishable, but they differ in their genetic and epigenetic profiles. Secondary GBM accounted for about 9% of all GBM. The median overall survival time in patients with secondary GBM without treatment is 7.8 months, and in patients after surgery and radiotherapy - 27.1 months. Advancements in the past decades have not significantly increased the overall survival of patients with this disease. GBM has been demonstrated NK-1 receptor system and substance P can be used as a ligand for targeted therapy. Alpha emitter, like ^{213}Bi offers the new potential for selective irradiation of tumors, with minimizing damage to adjacent tissue. **Material and methods:** In general, 50 patients with different glia tumors were treated in the study. Secondary glia tumor IV was diagnosed in 7/50 patients. In all cases standard therapy were performed. Following intracavitary or intratumoral insertion of 1-2 catheter systems, patients were treated with 2-8 doses of 2 GBq ^{213}Bi-DOTA-Substance P (^{213}Bi-SP) in intervals of 2 months. ^{68}Ga-DOTA-Substance P (^{68}Ga-SP) was co-injected with the therapeutic doses to assess biodistribution using PET/CT. Therapeutic response was monitored with MRI. Study was approved by the ethical committee of the Medical University of Warsaw. **Results:** Clinically, treatment with activity up to 13 GBq ^{213}Bi-SP was well tolerated and PET/CT imaging showed high retention of the radiolabeled peptide at the tumor site. No any serious adverse reactions was shown. Median progression free survival was 13.6 months. Median overall survival from the diagnosis time was 46.8 months. Follow up of therapeutic responses and toxicity is continued and patient recruitment is ongoing. **Conclusions:** Treatment of secondary GBM with ^{213}Bi-SP is safe and well tolerated. Targeted alpha therapy with ^{213}Bi-SP may evolve as a promising novel option for treatment of secondary GBM.

OP521

Assessing Yttrium-90 Microsphere Delivery Systems Following Radioembolization: A Feasibility Study Using Digital Photon Counting PET/CT Technology

C. L. Wright[1], K. Binzel[1], J. Zhang[1], M. Jedlicka[1], R. L. Anderson[1], P. Maniawski[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Philips Healthcare, Cleveland, OH, UNITED STATES.

Aim: It has been demonstrated that ^{90}Y generates a small fraction of discrete annihilation photons which can be detected and imaged using conventional photomultiplier tube-based PET systems. A recent technological innovation has led to the replacement of these photomultiplier tubes in the PET gantry with new, solid-state, digital photon counting PET detectors (dPET). The objective of this study is to assess the technical capability of a dPET/CT system for imaging very low doses of residual ^{90}Y activity within microsphere delivery systems. **Materials and Methods:** Imaging was performed using a pre-commercial release dPET/CT system (Vereos, Philips). In this feasibility study, six ^{90}Y delivery systems were imaged following radioembolization procedures. Residual ^{90}Y activities in the delivery systems ranged from 9 - 288 MBq. One source vial of unused ^{90}Y microspheres was also imaged. Two dPET acquisitions were obtained in list-mode using total imaging times of 7 min and 60 min. These datasets were reconstructed with ToF and using a standard definition voxel size of 4x4x4 mm^3. In addition, list-mode clipping of the dPET data was used to generate subsampled reconstructions in order to simulate virtual faster image acquisition times ranging from 50 min down to 7 min. Matched comparision of image quality for the actual and simulated dPET datasets was performed using the

Intellispace Portal workstation by a blinded reader panel. **Results:** Digital PET imaging of low levels of residual 90Y activity within the delivery system is feasible and produces evaluable images. There was consistent 90Y activity detected in the source vial and, in some cases, activity in the catheter tubing. Although the 60 min acquisitions yielded more 90Y counts, there was no qualitative difference in 90Y detectability or image quality when compared with 7 min acquisitions. Likewise, subsampled listmode dPET datasets produced simulated 7 min acquisitions which were visually identical to the actual acquisitions.**Conclusion:** Our study demonstrates that dPET/CT detection of residual ^{90}Y activity within microsphere delivery systems is feasible. In particular, this new digital photon counting PET detector technology allows for fast image acquisition and promises even faster acquisition with no significant impact on the qualitative assessment of this residual ^{90}Y activity. Continued refinement of ^{90}Y dPET image acquisition and image reconstruction methodologies will enable both fast and accurate evaluation of ^{90}Y microsphere delivery systems in the case of ^{90}Y misadministration events.

OP522

Radiation exposure of the kidneys affects haematological response during ^{177}Lu-DOTATATE treatment

J. Svensson[1], R. Hermann[2], K. Holgersson[1], B. Wängberg[3], A. Sundlöv[4], J. Tennvall[4], K. Sjögreen Gleisner[5], P. Bernhardt[2]; [1]Department of Oncology, The Sahlgrenska Academy, Gothenburg University, Göteborg, SWEDEN, [2]Department of Radiation Physics, The Sahlgrenska Academy, Gothenburg University, Göteborg, SWEDEN, [3]Department of Surgery, The Sahlgrenska Academy, Gothenburg University, Göteborg, SWEDEN, [4]Department of Clinical Sciences, Lund University, Lund, SWEDEN, [5]Department of Medical Radiation Physics, Lund University, Lund, SWEDEN.

Aim Radionuclide therapy with ^{177}Lu-DOTATATE is a valuable treatment option in the management of patients with neuroendocrine tumours overexpressing somatostatin receptors. The amount of treatment is usually restricted by a fixed absorbed dose limit to the kidneys, or by persistent haematological toxicity. To better understand which patients will tolerate the treatment, and who should be considered for other treatment; clinical background information is important, including renal and bone marrow function, tumour burden and previous treatment. In this study, the impact of absorbed renal dose on the haematological response was investigated. *Materials and methods* This study analyses the results from 34 of the 80 patients included in the prospective ILUMINET study (EUDRACT 2011-000240-16), treated with 7.4 GBq of ^{177}Lu-DOTATATE on one to eight occasions. Patients included in the study had a progressive disease according to RECIST criteria, tumours judged to overexpress somatostatin receptors by SSTR imaging and a GFR of &gt 50 ml/min. Treatment was given as a 30 min infusion together with kidney protecting amino acids, at 8 to 12 week intervals until a BED of 27 Gy (Stage 1 of the study) or 40 Gy (Stage 2) to the kidneys was reached. Some patients ended treatment earlier because of persisting haematological toxicity or disease progression. For dosimetry planar whole-body images were acquired at 1.5, 24, 48 and 168 h p.i. and a SPECT/CT at 24 h p.i. Dosimetry was based on a hybrid technique utilising both planar and SPECT activity data. Patient bone marrow function was monitored by blood sampling for haemoglobin, white blood cell and platelet counts weekly. *Results* The development of haematological toxicity was correlated to the total absorbed renal dose according to the decline in haemoglobin ($r=-0.40$, $p=0.04$) and platelet counts ($r=-0.43$, $p=0.02$)), but not to the activity amount given. Baseline GFR also affected the haematological toxicity according to haemoglobin values ($r=0.49$, $p=0.01$). *Conclusion* The correlation between radiation exposure of the kidneys and the decline in haemoglobin and platelet values during ^{177}Lu-DOTATATE treatment can not be explained by the total amount of activity given. Instead renal function at baseline seems to be a risk factor, and possibly also the magnitude of the radiation of the kidneys, which may affect the ability to produce erythropoietin in response to the decline in haemoglobin.

The diagnostic value of I-124 PET/ CT in the follow-up of patients with differentiated thyroid carcinoma

E. I. Klaver, H. Arkies, S. Mijnhout, A. Franken, P. L. Jager; Isala Klinieken, Zwolle, NETHERLANDS.

Purpose: The aim of this retrospective study is to evaluate the diagnostic role of I-124 PET/ CT in the evaluation 6 month or 1 year after ablation-therapy of patients with well differentiated thyroid cancer (DTC). **Methods:** The results of 29 eligible I-124 PET/ CT-scans performed in XX48 DTC patients between February 2013 and February 2016 are evaluated. PET was done using 74 MBq I-124, imaging at 24 and 96 hours with recombinant thyroid hormone (rTSH) stimulation. Thyroglobulin (Tg) and antibodies (Ab) were measured. Findings on the 124-I PET/ CT were compared with subsequent I-131 post-treatment scan in 6 cases and in the remaining with combination of laboratory, radiological, pathological or surgical outcome data over max. 2,5 year follow up. Recurrence was based on laboratory findings (Tg), positive imaging as interpreted by experts. **Results:** 23 I-124 scans showed no uptake and in all there were no signs of recurrence. In 11 scans (8 patients) the I-124 scan showed uptake: in 2 rest thyroid tissue, 1 lymph node metastases in the neck and 2 both (in these 2 metastases were unexpected and led to upstaging from N1a tot N1b). All of these 5 patients received a therapeutic dose of I-131, and the PET findings were concordant on the post-treatment scan. In the remaining 6 cases 2 scans of the same patient were considered false-positive because of a histologically proven ductus thyreoglossis cyst, and one given I-131 therapy was retrospectively unjustified. In the other 4 scans the I-124 showed aspecific uptake, and I-131 therapy was not given. In 1 patient the I-124 scan did not detected miliairy lungmetastases, although positive on the I-131 post-treatment scan, but CT was normal. This leads to a sensitivity for the detection of Iodine avid remnants or metastases of 80%, specificity 96%, positive predictive value 80% and negative predictive value 96%. **Conclusion:** in this retrospective study the I-124 PET/ CT proved to be a reliable diagnostic tool for the evaluation of I-131 ablation in patients with DTC.

OP535

Differentiated Thyroid Cancer lymph-node relapse. Relevance of adjuvant RAI after lymphadenectomy. A multicentric study

G. Bottoni[1], F. Bertagna[2], M. Puntoni[1], A. PICCARDO[1], G. Treglia[3], M. Bertoli[4], L. Foppiani[1], U. Catrambone[1], A. Arlandini[1], B. Dib[1], M. Massollo[1], I. Bossert[1], M. Cabria[1], L. Giovanella[5]; [1]AZIENDA OSPEDALIERA GALLIERA, GENOVA, ITALY, [2]Department of Nuclear Medicine, University of Brescia and Spedali Civili di Brescia, Brescia, ITALY, [3]Department of Nuclear Medicine and PET/CT Centre, Oncology Institute of Southern Switzerland, Switzerland., Bellinzona, SWITZERLAND, [4]2)Department of Nuclear Medicine, University of Brescia and Spedali Civili di Brescia,, Brescia, ITALY, [5]Department of Nuclear Medicine and PET/CT Centre, Oncology Institute of Southern Switzerland, Bellinzona, SWITZERLAND.

Aim: Lymphadenectomy is the therapy of choice when differentiated thyroid cancer (DTC) lymph-node relapse is detected on neck ultrasonography and cytologically confirmed. Radioiodine therapy (RAI) is the adjuvant treatment after thyroidectomy for intermediate/high risk DTC patients. However, its adjuvant role after lymph-node dissection for DTC relapse, is not established. Our aim is to evaluate the impact of adjuvant RAI on progression free survival (PFS) and on overall survival (OS) in patients affected by DTC lymph-node relapse and previously treated with lymph-adenectomy. We also assessed the association between PFS and OS and the main prognostic factors able to influence DTC outcome. **Materials and methods:** we retrospectively evaluated DTC patients treated with lateral lymph-node dissection for disease relapse. All patients were previously treated with total thyroidectomy and radioactive remnant ablation for intermediate/high risk DTC. Clinical and histological data obtained during follow-up were used to assess the response and outcome. The association between adjuvant RAI, thyroglobulin levels on suppressive levothyroxine treatment after lymphadenctomy (Tg-on) and other risk-factors and either PFS and OS was evaluated through univariate and multivariate analyses, respectively. **Results** We evaluated 113 patients of which 64 were treated with adjuvant RAI (median activity 4440 MBq). During a median 5.7-year follow-up, 27 patients showed recurrence and 13 died. Kaplan-Meier PFS and OS curves showed that age on diagnosis, histology, tumor dimension, nodal status on diagnosis, percentage of positive nodes on relapse, tumor histology, DTC virulence, and Tg-on were all associated with prognosis. On the other hand, adjuvant RAI itself was not associated with PFS and OS. However, the adjuvant RAI effect was significantly different between patients with Tg-on ≥1 ng/ml and those with Tg-on <1 ng/ml (interaction p value=0.002 for PFS and 0.03 for OS). Indeed, patients with Tg-on ≥1 ng/ml treated with adjuvant RAI showed a better PFS (p=0.0005) and OS (p=0.005) than untreated ones. When we adjusted risk using a multivariate Cox model, Tg-on (HR 16,1, p=0.0001) and adjuvant RAI (HR: 0.37, p=0.03) remained the most important factors associated with PFS but only Tg-on remained associated with OS (HR: 8.6, p=0.01). Nonetheless, a trend towards a lower risk of mortality (HR: 0.34, p=0.09) emerged for patients treated with adjuvant RAI. **Conclusions:** Adjuvant RAI after lymphadenectomy for DTC relapse is significantly associated with a better PFS. However, its use should be reserved only for DTC patients with Tg-on ≥1 ng/ml.

OP536

The sensitivity and positive predictive value (PPV) of ^{131}I-post-therapy whole body scan is higher than serum Tg values in detecting metastases in early stage of differentiated thyroid cancer patients

A. Campenni'[1], S. Pignata[1], M. Mure'[1], F. Di Mauro[1], M. Stipo[1], M. Siracusa[1], R. Ruggeri[2], S. Baldari[1]; [1]Unit of Nuclear Medicine of Messina, Messina, ITALY, [2]Unit of Endocrinology of Messina, Messina, ITALY.

AIM: Differentiated thyroid cancer (DTC) is a rare tumor but is the most common malignancy of the endocrine system. The work-up of DTC

patients includes (near)total-thyroidectomy [(n)TT], thyroid remnant ablation (TRA) with 131-radioiodine and long life follow-up. ^{131}I-post therapy whole body scan (pT-WBS) and serum thyroglobulin (Tg) are used in identifying metastatic patients. Some authors evaluated the possibility to use post-surgical Tg values in deciding for or against TRA. The aim of our study was to verify the sensitivity and PPV of ^{131}I-pT-WBS compared to serum Tg levels in detecting metastases in early stage of DTC patients. **MATERIAL AND METHOD:** We retrospectively reviewed the records of 1102 consecutive patients affected by DTC and referred to our Nuclear Medicine Unit in the last five years. For the study, we selected 570 out of 1102 (52%) patients affected by pT1-pT3 DTC (F= 450, M= 120, mean age 48.5±13.2, ranges 17-82 years; F/M ratio= 3.7:1). Exclusion criteria were: 1) presence of loco-regional or distant metastases at the time of recruitment; 2) age ≤16 years; 3) positive thyroglobulin-antibody (Tg-Ab); 4) pT4 stage, 5) poorly-differentiated thyroid cancer. The majority of patients (560/570, 98.2%) were affected by papillary carcinoma while the remaining (1.8%) had follicular carcinoma. Before TRA, all patients underwent neck-ultrasonography, laboratory test and, if treated in hypothyroid state, radioiodine thyroid uptake. Patients underwent TRA in hypothyroid state (321/570, 56%) or after recombinant-human-TSH stimulation (249/570, 44%). Serum Tg values evaluated both before TRA (on L-T4 therapy) and at TRA were matched with ^{131}I pT-WBS results. **RESULTS**: ^{131}I pT-WBS discovered metastases in 82 out of 570 (14.4%) patients. Seventy-three out of these patients (90.2%) showed serum Tg levels ≤1 ng/ml in post-surgical period. At the time of TRA, forty of them (54%) maintained serum Tg levels ≤1 ng/ml. Comparing pT-staging, 33, 2 and 5 patients had pT1, pT2 and pT3 lesions, respectively. The majority of these patients (38/40, 95%) showed regional lymph-node metastases at ^{131}I-pT-WBS while three had lung metastases (one of them also showed lymph-node metastasis). The metastases were confirmed by targeted morphological studies. **CONCLUSION:** Serum Tg levels obtained in post-surgical period cannot be used to decide for or against TRA and to predict the outcome of patients. In early stage of DTC, ^{131}I-pT-WBS is an accurate method in detecting metastases also in patients with stimulate serum Tg values ≤1 ng/ml, showing sensitivity and PPV significantly higher than serum Tg (100% vs 29.3% for both).

OP537

Clinical outcome of postoperative radioiodine therapy with high dose and low dose in intermediate risk differentiated thyroid cancer patients

J. Jeong[1], E. Kong[2], S. Jeong[1], S. Lee[1], J. Lee[1], K. Chun[2], B. Ahn[1]; [1]Kyungpook National University Hospital, Daegu, KOREA, REPUBLIC OF, [2]Yeungnam University Hospital, Daegu, KOREA, REPUBLIC OF.

Purpose: We evaluated the response to radioiodine (RAI) therapy with high dose (HD) or low dose (LD) using two criteria (with or without whole body scan (WBS)) and re-classification system in Korean differentiated thyroid cancer (DTC) patients with intermediate risk (IR). Additionally we evaluated long-term clinical outcomes. Methods: A total of 204 DTC patients with IR who underwent postoperative RAI therapy at two hospitals from 2003 to 2004 were enrolled retrospectively. 124 patients were treated with 3.7 to 7.4GBq (HD) in one center and 80 patients were treated with 1.1GBq (LD) in the other center. Patients were categorized as having excellent (ER), indeterminate (IDR), biochemical incomplete (BIR), or structural incomplete response (SIR) according to re-classification system at during the first 2 years of follow-up using thyroglobulin, ultrasonography, and WBS. Data were also assessed the success rate of RAI therapy with or without WBS results. Recurrence was defined as newly detected pathologically proven lesion. Results: There was no significant difference in the success rate between HD and LD groups regardless of whether WBS was included in the criteria or not (54.84% vs. 46.25% with WBS results, p=0.23; 60.48% vs. 62.5% without WBS results, p=0.77). On the basis of re-classification system, ER was observed in 54.84% of patients treated with HD and in 45.0% of those treated with LD, IDR was found in 34.68% of patients treated with HD and in 30.0% of patients treated with LD, BIR was found in 4.03% of HD group and in 13.75% of LD group, SIR was found in 6.45% of HD group and in 11.25% of LD group (p=0.04). BIR or SIR rate was lower in patients treated with HD compared to patients treated with LD (HD, 10.48%; LD, 25.0%, p=0.01). At last follow-up (HD, median 11years; LD, median 10years), patients with ER maintained no evidence of disease state. After initial RAI therapy, additional RAI therapies were given to 8 patients of HD group and 18 patients of LD group who got the IDR or BIR. However 7 patients (5 patients with IDR, 2 patients with BIR) in HD group and 7 patients (5 patients with IDR, 2 patients with BIR) in LD group had a recurrence. Conclusion: This study suggested that LD therapy seems to be insufficient to DTC patients with IR. In LD group, there were more BIR or SIR to initial therapy and more additional RAI therapies were needed.

OP538

Effectiveness of pre-therapy red marrow and blood dosimetry in ^{131}I treatment of metastatic thyroid cancer

E. Richetta, G. Lo Moro, M. Pasquino, C. Cutaia, S. Valzano, L. Radici, R. Pellerito, M. Stasi; AO Ordine Mauriziano, Turin, ITALY.

AIM Despite the therapy of the metastatic thyroid cancer with ^{131}I is well consolidated some patients still are refractory because of the treatment's sequence. A single high activity treatment seems to improve the outcome compared to several lower activity ones, but it can be inhibit by excessive irradiation at organ at risk such as red marrow or blood as surrogate. A personalized dosimetry could help the physician in determining the optimal activity. To this aim pre-therapy residence time and doses were compared to in-therapy results in order to investigate repeatability and effectiveness of different dosimetric methods. **MATERIALS AND METHODS** We analyzed 88 advanced metastatic thyroid patients (32M, 56 F); after the administration of a ^{131}I tracer activity (15,7 MBq) 114 pre-therapy dosimetries to red marrow (AIFM and Traino Methods) and to blood (EANM Method) were performed and then repeated after therapy (7600±750 MBq). Blood samples (2, 24, 48 and 96 h p.a.) converted into activity-curves allowed the estimation of the blood residence time (τ_{bl}). Whole-body AP-PA measurements were performed at same time of blood sampling during pre-therapy and AP every 2 h during hospitalization with detectors placed on patient's bed, to evaluate residence times (τ_{WB}). Pre-therapy (PT) and in-therapy (IT) residence times and doses to red marrow and blood per activity unit were compared with Wilcoxon paired-samples test. Percentage dose differences were also evaluated. **RESULTS** Blood mean residence times τ_{bl} were 0.000656 h/ml and 0.000668 h/ml for PT and IT respectively with a mean percentage difference equal to 1.6±25.4 %; p-value (0.991) did not show a statistical significant difference. Whole-body mean τ_{WB} were 23.86 h and 25.056 h for PT and IT, respectively (percent difference 0.5±32%); p-value (0.043) showed a statistical difference probably due to the different measurements scheduling-time. The statistical analysis confirmed a significant differences for whole-body component of doses (AIFM 0.0146, Traino 0.0196 and EANM 0.016). The different dosimetric method showed similar percentage differences between PT and IT dosimetry (AIFM and Traino -2.02±22.5 %, EANM -1.4±23.1%) and 69.5 % of patients showed a difference within 20 %. **CONCLUSION** Pre-therapy red marrow ^{131}I dosimetry predicts accurately the in-therapy results and can be safely implemented to help the physician in the determination of a personalized therapeutic activity.

OP539

Early and Late Adverse Effects of Radioiodine Therapy for Pediatric Differentiated Thyroid Cancer

D. Albano, Sr., F. Bertagna, G. Magri, M. Panarotto, R. Giubbini; Spedali Civili Brescia, Brescia, ITALY.

Aim: radioiodine therapy (I131) for differentiated thyroid cancer is generally a safe and efficient treatment, but has some potential side effects consequent to radioiodine. These potential adverse effects are well described in adults and little analyzed in pediatrics. Our aim was to analyze early and late adverse events of radioactive iodine-131 in pediatric patients. **Materials and methods**: all consecutive patients <18 years treated for pediatric differentiated thyroid cancer in our department in the period 1980-2015 were evaluated for early and late side effects of radioiodine therapy. Early side effects, which occur during or shortly after therapy, include gastrointestinal symptoms (nausea and emesis), radiation thyroiditis, sialadenitis/xerostomia, dry mouth and transient bone marrow suppression. Late complications include permanent salivary gland dysfunction, permanent bone marrow suppression, pulmonary fibrosis, secondary cancers and fertility problems. Statistical analysis was carried out with the Student's t test. P-Value of ≤0.05 was considered as statistically significant. **Results**: 105 patients (77 female, 28 male; median age 15 years, range 4-17 years) were treated with 131I for differentiated thyroid cancer in our department. Totally, they underwent 302 radioiodine treatments (overall 46092 mCi): 50 children underwent only one radiometabolic treatment for ablation of thyroid remnant. Median follow-up time was 150 months (range 8-348 months). Thirty-six patients (34%) had almost one early adverse event; 31 had nausea and/or emesis; 24 sialoadenitis/xerostomia, 20 thyroiditis, 15 dry mouth and 5 transient bone marrow suppression. All early side effects were correlated with the amount of radio-activities administrated in any single treatment ($p<0.001$). Fourteen children (13%) developed ≥1 late complication: 2 permanent salivary gland dysfunction, 4 permanent bone marrow suppression, 5 pulmonary fibrosis, 4 secondary malignancies (2 breast cancer and 2 leukemia) and 5 fertility alterations. All late adverse events, except fertility alterations, were correlated with number of radiometabolic therapies and cumulative activities of 131I. Early and late adverse events were not correlated with sex, age and histotype. **Conclusions**: radioiodine therapy in pediatric is a safe and efficient treatment. The risk of developing some early and late side effects is not different than of adults. Early side effects are associated with the amount of administrated activities of any treatment, while the late effects are correlated with number of treatments and cumulative activities of radioiodine, except for fertility problems.

OP540

The influence of single dose recombinant human thyroid stimulating hormone on the efficacy of radioiodine therapy in patients with subclinical hyperthyroidism with low RAIU

S. Abdelrazek, M. Mojsak, P. Szumowski, J. Mysliwiec, A. Polak, M. Janica, K. Lomperta; Department of Nuclear Medicine, Medical University of Bialystok, BIALYSTOK, POLAND.

The aim of our study was to evaluate the influence of recombinant human thyroid-stimulating hormone (rhTSH) on the efficacy of radioiodine therapy in patients with subclinical hyperthyroidism (SHT) with low RAIU. Materials and methods: The study was performed on 40 patients with subclinical hyperthyroidism all with multinodular goitre (MNG) referred for radioiodine therapy (32 females and 8 males, aged 32-75 years). Qualification of these patients were based on: normal levels of serum fT3 and fT4, low levels of serum TSH (<0.1mU/L), and RAIU < 15%. Thyroid volume ranged between 70-145ml. Malignant changes were excluded in all nodules by fine needle aspiration biopsy. All the patients had serum TSH levels <0.1 mU/l and low RAIU (7-14%), 24 h after a diagnostic dose of I-131 (4 MBq). All the patients received a single intramuscular dose of 0.05 mg rhTSH (thyrogen). 24 h later diagnostic dose of ^{131}I was administered and thyroid scan with RAIU after 24 and 48 h was estimated. Therapeutic dose of I-131 was given on the third day of rhTSH administration. Serum levels of TSH, fT4 and fT3 were determined, 24 and 72 h after rhTSH administration and on the 3rd day after radioiodine therapy. The therapeutic activity of I-131 calculated by Marinelli's formula and ranged between 280 and 600 MBq. The absorbed dose ranged between 150 and 220 Gy. Follow up control was done every 6 weeks. Thyroid ultrasound, and thyroid scan were done again after 6 and 12 months of radioiodine therapy. Results: A significant increase (3-11 fold) in 24 h RAIU was observed after rhTSH administration. The distribution of radioiodine was more homogeneous 48 h after rhTSH administration. After 12 months 91% of patient were in euthyroid state and 9% develop hypothyroidism. After 6 months the mean reduction in goitre volume was 30% and 45-55% after 12 months. The medium therapeutic activity of I-131 was 400 MBq. Conclusions: Pre-treatment with rhTSH reduce the therapeutic dose of I-131 by 50-58% without compromising the result of thyroid volume reduction. rhTSH makes radioiodine therapy more effective in the patients with subclinical hyperthyroidism with low RAIU.

OP541

Feasibility of thyroid uptake measurements with the CoTI device

E. J. Kranenborg, R. van der Boor, A. E. Gelderblom, K. A. J. van Gils, J. B. A. Habraken; St. Antonius Hospital, Nieuwegein, NETHERLANDS.

Introduction The CoTI (**Co**llar **T**herapy **I**ndicator) is a portable device for thyroid uptake measurements. It consists of two gamma detectors which are placed in a collar worn by the patient. This makes it a convenient device for thyroid measurements. However, it may be susceptible to errors due to patient movement or poor positioning. **Aim** The aim of this study is to assess the feasibility of performing thyroid uptake measurements using the CoTI, particularly regarding detector positioning. **Methods and materials** *Preliminary tests* To assess the influence of collar movement, we performed preliminary tests with 18 volunteers to determine the maximum shift in collar position due to movement or intra-operator variability in positioning the collar. We also determined the maximum shift from the anatomical position necessary to achieve the highest count rate in 23 patients scheduled for thyroid measurements. *Patient tests* Based on these maximum shifts, we measured the effect on the count rate in 25 patients scheduled for I-123 uptake measurements. We placed the collar at the anatomical position (baseline) and shifted it 2.0 cm right, 2.0 cm left, 2.0 cm caudal and 1.0 cm cranial. We compared the measured counts of the combined detectors to the baseline position. *Phantom tests* To determine the accuracy of the position of each detector in the collar we used an anthropomorphic thyroid phantom. We measured the count rate for each detector at 49 different positions and compared them to the baseline (midline of the collar at the centre of the phantom). **Results** Results are presented as a percentage of the baseline count rate. The patient tests show a decrease in average count rate in relation to the baseline at right lateral shift (90.6%), left lateral shift (91.8%) and cranial shift (77.0%). Caudal shift leads to an increase (122.1%). The phantom tests show an increase in count rate in relation to the baseline for each detector at medial shift, with a maximum score of 245%. Shifting the detector in lateral, caudal or cranial direction shows a decrease, with a minimum score of 21%. **Conclusion** The placement of the collar on the patient can easily vary and the detectors are generally not in the optimal position in the collar. Both aspects can lead to a difference in count rate, which linearly affects the calculated uptake. Therefore a more sophisticated collar or stringent procedures are necessary to accurately measure thyroid uptake using the CoTI.

Therapeutic Potential of 47Sc in Comparison to 177Lu and 90Y: Preclinical Investigations

K. Siwowska; Paul Scherrer Institute, Villigen, SWITZERLAND.

Aim: The concept of theragnostic application (PET/β^--therapy) with the matched pair of Sc-nuclides (^{44}Sc/^{47}Sc) was recently proposed and exemplified in our group. The aim of the present study was to evaluate ^{47}Sc ($T_{1/2}$ = 3.35 d, Eβ^- = 162 keV) for therapeutic purposes using a DOTA-folate conjugate and compare it to the effects obtained with the same compound labeled with ^{177}Lu and ^{90}Y. Materials and methods: Labeling of a DOTA-folate with ^{47}Sc, ^{177}Lu and ^{90}Y was performed at a specific activity of 10 MBq/nmol. ^{47}Sc-folate was compared with the ^{177}Lu- and ^{90}Y-labeled compounds in vitro using FR-positive IGROV-1 tumor cells. In vivo studies were performed with tumor-bearing mice for comparison of the anti-tumor effects obtained with each of the radiofolates applied at 10 MBq ^{47}Sc-folate, 10 MBq ^{177}Lu-folate and 5 MBq ^{90}Y-folate, respectively. The mean absorbed tumor and kidney doses were calculated based on biodistribution results, under the assumption that the tissue distribution would be equal for all radiofolates. Results: Radiolabeling of the folate conjugates was achieved with >96% radiochemical purity. In vitro cell uptake was FR-specific, proven by a reduced uptake (<1%) when cells were co-incubated with excess folic acid. The calculated tumor doses were determined as 17 Gy, 21 Gy and 21.5 Gy for mice treated with ^{47}Sc-folate, ^{177}Lu-folate and ^{90}Y-folate, respectively. In vivo experiments confirmed the dose-dependent effect, as the relative time which passed until the tumors reached a ten-fold increased size was determined to be 1.5 for ^{47}Sc-folate-treated mice, 1.8 for ^{177}Lu-folate-treated mice and 2.0 for ^{90}Y-folate-treated mice, compared to 1.0 for untreated controls. The average survival time of ^{47}Sc-folate-treated mice was significantly increased (33 days) as compared to the survival time of untreated controls (21 days). The average survival time for ^{177}Lu-folate and ^{90}Y-folate-treated mice was 43 and 41 days, respectively. Significant accumulation of all folates in the kidneys resulted in kidney doses of 18 Gy, 23 Gy and 22Gy for ^{47}Sc-folate, ^{177}Lu-folate and ^{90}Y-folate, respectively, all below the critical limit of ~25 Gy. Conclusion: In vitro and in vivo studies confirmed a dose-dependent and FR-specific therapeutic efficacy of ^{47}Sc-folate. The low β^--energy of ^{47}Sc is clearly preferred to the high-energy β^--particles of ^{90}Y, which comprise a higher risk of undesired effects to normal tissue. The excellent decay characteristics of ^{47}Sc, together with the fact that a diagnostic match for PET exists, make ^{47}Sc highly attractive for clinical translation.

OP544

Role of ADAMTS2 and ADAMTS5 Genes in Radioiodine Induced Damage to the Salivary Glands of Rats: Genetic, Immunohistochemical and Histopathological Evaluations

M. SADIC[1], K. DEMIREL[1], S. O. HALACLI[2], E. KARAKOK[3], G. KOCA[1], O. EKINCI[3], K. DEMIRCAN[4]; [1]Ministry of Health Ankara Training and Research Hospital, ANKARA, TURKEY, [2]Hacettepe University, School of Medicine, ANKARA, TURKEY, [3]Gazi University, Faculty of Medicine, ANKARA, TURKEY, [4]Turgut Ozal University, Faculty of Medicine, ANKARA, TURKEY.

Background: Aim of this study which is the first in this area was to determine the role of the ADAMTS2 and ADAMTS5 genes on parotid gland (PG) and submandibular gland (SMG) damage occured after high dose RAI administration. **Methods:** Sixty four male Wistar albino rats (mean weight 285±55 gr, 6-8 months) were included and sacrified as follows; Control (n=20): Group 1: 4th hour (n=6), : 24th hour (n=20), Group 3: 48th hour (n=6), Group 4: 7th day (n=6), Group 5: 30th day (n=6) after RAI administration. 3 mCi I-131 was administered to all rats except control group. According to the sacrification, PG and SMG were removed surgically. Biodistribution and histopathologic studies were performed on the removed SGs. Real time PCR and immunohistochemical analysis were applied to show mRNAs and protein expression levels of ADAMTS genes. Differences between groups were statistically evaluated. **Results:** In biodistribution studies, the highest values were observed in 4 hours in PG. In RAI treated groups, ADAMTS2 and ADAMTS5 gene expression was observed to increase while there is no any mRNA or protein expression in the control group. ADAMTS2 expression in Groups 2 and 3, ADAMTS5 expression in Groups 2 and 5 for SMG, ADAMTS2 expression in Groups3 and 5, ADAMTS5 expression in Groups2 and 4 for PG were statistically significant (Table). By means of immunohistochemistry analysis, the staining pattern in the extracellular source was also observed to in the overexpressed ADAMTS2 and ADAMTS5 groups. Nuclear coarsening and partial focal subnuclei vacuolization were determined in all RAI administered group by histopathologic examinations. **Conclusion:** An increase mRNA expression levels of ADAMTS2 and ADAMTS5 genes were detected in RAI administered groups. These results suggested that ADAMTS2 and ADAMTS5 genes might play role on radioiodine induced SGs changes. Further studies are needed to understand better the subpathways related to ADAMTS genes.

OP545

Localized irradiation of cell membrane by Auger electrons is cytotoxic through non-targeted effects involving p38 and JNK signaling pathways

S. Paillas[1,2], R. Ladjohounlou[1], C. Lozza[1], A. Pichard[1], V. Boudousq[1], M. Jarlier[3], E. Deshayes[1], J. Sosabowski[2], T. Chardès[1], I. Navarro-Teulon[1], R. Mairs[4], **J. POUGET**[1]; [1]IRCM/INSERMU896, Montpellier, FRANCE, [2]Barts Cancer Institute, Queen Mary University of London, London, UNITED KINGDOM, [3]ICM, Montpellier, FRANCE, [4]Institute of Cancer Sciences, University of Glasgow, Glasgow, UNITED KINGDOM.

Aims: We have investigated *in vitro* and *in vivo* the contribution of bystander effects to the efficacy of Auger electron emitter (^{125}I) labeled monoclonal antibodies (^{125}I-mAbs) targeting the cell membrane. **Materials and methods:** *In vitro*, colorectal HCT116 cells were exposed to increasing activities (0-4MBq/mL) of either non-internalizing anti-CEA, internalizing anti-HER1 or of the non-targeting PX ^{125}I-mAbs. Cells were also exposed up to 20 kBq/ml of 5-[(125)I]iodo-2'-deoxyuridine (^{125}IUdR). Direct and bystander cytotoxic effects were measured using clonogenic assays and standard medium transfer protocol. DNA damage, lipid raft formation and activated signaling pathways were also measured. Activated signaling pathways were further investigated using protein arrays together with pharmacological inhibitors. The role of oxidative stress was investigated using N-Acetyl-L-Cystein (NAC) or dimethyl sulfoxide (DMSO), two radical scavengers. ^{125}I-radioimmunotherapy was carried out *in vivo* using mice bearing intraperitoneal tumors and the relationship between energy deposition in tumors using digital autoradiography and spatial distribution of 53BP1 foci was determined by immunofluorescence. **Results:** No cytotoxicity was observed either both donor or recipient cells after donor cells were treated with the ^{125}I-PX antibody. Bystander effects measured in recipient cells were associated with lipid raft formation in donor cells treated with anti-CEA or anti-HER1 ^{125}I-mAbs and their disruption with filipin or methyl-β-cyclodextrin (MBCD) significantly reduced the bystander response. Incubation of donor cells with either NAC or DMSO, increased the survival of donor and recipient cells indicating the involvement of oxidative stress in the observed bystander effects. We have identified that p38 and c-Jun N-terminal kinase (JNK) were the predominant proteins involved in lipid-raft activated signaling cascades and participated in subsequent cytotoxic effects of targeting ^{125}I-mAb in both donor and recipient cells. In addition, we have also shown that the bystander response induced by ^{125}I-mAbs against cell surface receptors was comparable to that obtained with ^{125}IUdR targeting the cell nucleus. *In vivo*, our results indicate DNA damage in mouse tumor xenograft sections beyond the expected Auger electron range suggesting the involvement of bystander effects also *in vivo*. Moreover, we found that the

statistical significance of tumor growth delay induced by ^{125}I-mAb was removed after inhibition of lipid raft formation. **Conclusion:** Our *in vitro* and *in vivo* results provide evidence that the cell membrane plays an essential role in the mediation of the bystander response induced by anti-CEA or anti-HER1 ^{125}I-mAb. p38 and JNK appear to be the main proteins responsible for cytotoxic effects measured in donor and recipient cells.

OP546

Modulation of glutathione synthesis for radio-sensitization of Breast Cancer Stem cells: a novel therapy concept

A. Morgenroth[1], T. Miran[1], N. Drude[1], A. T. Vogg[1], F. M. Mottaghy[1,2]; [1]University of Aachen, RWTH Aachen, Aachen, GERMANY, [2]Maastricht University Medical Center, Department of Nuclear Medicine, Maastricht, NETHERLANDS.

The estrogene receptor, progesterone receptor and HER2neu negative breast cancer phenotype exhibits enhanced treatment unresponsiveness. These cells represent a cancer stem cell (CSC) population whose unique therapy resistance is attributed to reactive oxygen species (ROS) defense through up-regulation of glutathione (GSH) synthesis. Since efficiency of cancer therapies rely on generation of ROS and induction of oxidative stress, targeting of antioxidant system may impair ROS defense ability of CSC and thereby sensitize them to endogenous nanoirradiation. We evaluated therapeutic potential of I-125-ITdU for targeting of breast CSC after inhibition of ROS scavenging enzyme GSH synthase with Buthionine Sulfoximine (BSO). For CSCs isolation, MDA MB-231 cells were incubated with CD24 and CD44 MicroBeads. The CD Marker expression was investigated by FACS. Cells were incubated with 1.0 mM BSO for 2d under hypoxia and normoxia. The GSH and ROS were evaluated using Thiol Green dye and H_2DCFDA by FACS, respectively. Apoptotic cells were identified using PI by FACS and γ-H2AX staining by microscopy. For therapy study, BSO treated (5mmol/kg) and untreated SCID breast CSC xenografted mice received 3 injections of 5-7 MBq I-125-ITdU (6 h p.i. BSO, cycle per week). Therapy efficiency was monitored by FDG-μPET. The purity of isolated CSC was more than 98%. BSO treatment of CSC yielded a decreased GSH and an increased ROS level. The modulation of GSH level affected the therapeutic efficiency of I-125-ITdU. In the therapy study, BSO pre-treated animals showed a significant reduction in tumor size and an improved survival as compared to the BSO-untreated control group. No radiotoxicity was detected in liver, spleen and small intestine. This is the first report to demonstrate that modulation of GSH increases radiosensitivity in highly resistant stem cells of breast cancer.

OP547

NeoBOMB1, a novel GRP analog, for theranostic use in oncology

S. U. Dalm[1], I. L. Bakker[1], E. de Blois[1], G. N. Doeswijk[1], F. Orlandi[2], D. Barbato[2], M. Tedesco[2], T. Maina[3], B. A. Nock[3], M. W. Konijnenberg[1], M. de Jong[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]Advanced Accelerator Applications, Colleretto Giacosa, ITALY, [3]INSRATES NCSR Demokritos, Athens, GREECE.

Background: Overexpression of the gastrin releasing peptide receptor (GRPR) has been reported on several major cancers, including prostate and breast cancers. Targeting this receptor with radiolabeled peptide analogs for imaging and therapy could have a significant impact on the staging and treatment of GRPR-expressing tumors. NeoBOMB1 is a novel DOTA-coupled peptide with high GRPR affinity and excellent in vivo stability. The aim of our preclinical study was to explore the theranostic use of ^{68}Ga-NeoBOMB1 and ^{177}Lu-NeoBOMB1 at two different specific activities, in order to find the peptide amount with the most optimal tumor to background ratios. Materials and methods: Biodistribution and imaging studies were performed in Balb c nu/nu mice xenografted with the GRPR-expressing PC-3 cells. For the biodistribution studies animals were injected with either 13 MBq ^{68}Ga-NeoBOMB1 (in total 250 pmol peptide) or 1 MBq ^{177}Lu-NeoBOMB1 (in total either 200 pmol or 10 pmol peptide). At different time points post injection (p.i.) animals were euthanized, organs and tumors were excised and radioactivity uptake (%ID/g) was determined. Biodistribution data was used to determine pharmacokinetics, mouse dosimetry and predict patient dosimetry. In addition, PET/CT and SPECT/MRI was performed with ^{68}Ga-NeoBOMB1 and ^{177}Lu-NeoBOMB1, respectively. Results: Biodistribution studies with ^{68}Ga-NeoBOMB1 resulted in a tumor and pancreas uptake of 12.4±3.3 and 22.7±3.3 %ID/g at 2 h p.i., respectively, with clearance half-lives of 6.9±2.8 h and 12.9±4.0 h. With the ^{177}Lu-NeoBOMB1 the tumor uptake at 4 h p.i. was 17.9±3.3 and 11.6±1.3 %ID/g, leading to an absorbed tumoral dose of 570 and 435 mGy/MBq, for the 200 pmol and 10 pmol peptide dose, respectively, with clearance half-lives of 36±3 h and 29±3 h. Uptake in the GRPR-expressing pancreas was 19.8±6.9 and 105±13 %ID/g at 4 h p.i. for the 200 pmol and 10 pmol peptide dose of ^{177}Lu-NeoBOMB1, respectively, but with faster clearance half-lives than those from tumors. In mice the absorbed dose tumor/pancreas ratio increased with increasing peptide amount (from 0.2 to 2.2, with 10 pmol and 200 pmol, respectively). The uptake kinetics of ^{68}Ga-NeoBOMB1 provided good indications of doses achieved with ^{177}Lu-NeoBOMB1. Using the data to predict patient dosimetry we found a kidney, pancreas and liver exposure of 0.10, 0.65 and 0.06 mGy/MBq, respectively. Furthermore, imaging studies resulted in good tumor visualization. Conclusion: Our findings indicate that the GRPR-antagonist ^{68}Ga/^{177}Lu-NeoBOMB1 is a very promising theranostic pair with favorable biodistribution characteristics for nuclear imaging and therapy, especially with the higher peptide amount applied.Table:

OP548

Chimeric Version of the Anti-CD37 Antibody Radionuclide Conjugate Betalutin® (NNV009) elicits an Anti-Tumour Response in Non-Hodgkin Lymphoma and Chronic Lymphocytic Leukemia Models

H. Heyerdahl[1], A. O'Shea[1], K. B. Melhus[1], B. Eiriksdottir[2], A. H. V. Repetto-Llamazares[1], J. Dahle[1]; [1]Nordic Nanovector ASA, Oslo, NORWAY, [2]ArcticLAS ehf, Reykjavik, ICELAND.

Aim: The novel antibody-radionuclide-conjugate (ARC) ^{177}Lu-DOTA-lilotomab (^{177}Lu-DOTA-HH1; Betalutin®) is based on the murine anti-CD37 antibody lilotomab and is currently in a clinical phase 2 trial for treatment of non-Hodgkin Lymphoma (NHL). A chimeric version of the lilotomab antibody (NNV003) is currently under development and may have potential advantages over the murine antibody by reduced immunogenicity and immunotherapeutic effects of the naked antibody through ADCC induction. The objective of the current study was to investigate the immunological ADCC and CDC potency as well as the therapeutic potential and adverse effects of the naked and radiolabeled antibody in NHL and Chronic Lymphocytic Leukemia (CLL) models. **Materials and Methods:** ADCC and CDC assays were performed in four different NHL and CLL cell lines; DOHH-2 (transformed follicular lymphoma), REC-1 (mantle cell lymphoma), Ramos (Burkitt's lymphoma) and MEC-2 (CLL), using FcRγ3a immortalized NK92 cells as effector cells. For *in vivo* studies, the NNV003 antibody was conjugated with p-SCN-Bn-DOTA prior to labelling with ^{177}Lu to make the ARC NNV009. Biodistribution was measured in mice with NHL (DOHH-2) and CLL (MEC-2) xenografts. Therapeutic and adverse effects of the naked antibody and ARC were investigated in mouse models bearing disseminated NHL and CLL human xenografts. Toxicity was additionally tested in immunocompetent Balb/c mice. **Results:** The NNV003 antibody elicited ADCC lysis in all four cell lines tested. Minimal CDC activation was observed. Biodistribution was relevant in both mouse models with specific tumour uptake. Survival was significantly extended in DOHH-2 xenograft-bearing RAG2 mice treated with NNV003 naked antibody (2-30 mg/kg) and ARC NNV009 (200-400

MBq/kg) compared to groups given NaCl and isotype control naked and ^{177}Lu-labeled antibody ($p<0.0002$). Survival was extended in MEC-2 xenograft-bearing SCID mice treated with NNV009 (100 MBq/kg) compared to mice treated with NaCl, NNV003 (0.5 mg/kg) and isotype control (100 MBq/kg) ($p<0.05$). Transient hematological effects were observed in the highest radioactivity groups in all studies, with reduction of white blood cell and platelet counts 1.5-3 weeks after injection, recovering after 5 weeks. Naked antibody NNV003 at doses ≤40 mg/kg was well tolerated with no observed adverse effects. **Conclusion:** *In vitro* and *in vivo* studies have shown that the chimeric naked antibody NNV003 elicits ADCC in NHL and CLL cell lines. Both NNV003 and ^{177}Lu-labeled antibody NNV009 showed statistically significant survival increases in mouse models with disseminated NHL and CLL xenografts. The results provide a good rationale for clinical testing in patients suffering from CD37-expressing B-cell malignancies.

Australian multicentre evaluation of clinical management intent utilising Ga68-PSMA PET scans in patients with prostate cancer

P. Roach[1,2], R. Francis[3,2,4], L. Emmett[5], E. Hsiao[1], A. Kneebone[1], G. Hruby[1], T. Eade[1], Q. Nguyen[6,7], B. Thompson[7,6], M. McCarthy[8], C. Tang[4], P. Brenner[9], P. Stricker[9,6], A. Scott[10,2]; [1]Royal North Shore Hospital, St Leonards, AUSTRALIA, [2]Australasian Radiopharmaceutical Trials Network, Sydney, AUSTRALIA, [3]University of Western Australia, Perth, AUSTRALIA, [4]Sir Charles Gairdner Hospital, Perth, AUSTRALIA, [5]St Vincent's Hospital, Sydney, AUSTRALIA, [6]The Garvan Institute of Medical Research, Sydney, AUSTRALIA, [7]Australian Prostate Cancer Research Centre – New South Wales (APCRC-NSW), Sydney, AUSTRALIA, [8]Fiona Stanley Hospital, Perth, AUSTRALIA, [9]St Vincent's Prostate Cancer Centre, Sydney, AUSTRALIA, [10]Olivia Newton-John Cancer Research Institute, Melbourne, AUSTRALIA.

Aim: Conventional imaging has limitations in the accurate evaluation of Prostate cancer (PCa). Ga68-Prostate Specific Membrane Antigen (PSMA) PET scanning is a new imaging technique that has been shown to be more accurate than conventional imaging techniques in many patients. This Australian multicentre study sought to determine whether the findings of PSMA PET imaging impacts on planned clinical management. Materials: Four centres throughout Australia participated in this prospective study. Local institutional ethics approval was obtained at each site. Prior to undertaking Ga68-PSMA PET imaging, referring medical specialists were required to complete a survey detailing relevant demographic and clinical data as well as the proposed management plan. Once the referring specialist was provided with the Ga68-PSMA PET scan results, they were asked to complete a follow up survey, primarily seeking to determine whether their management plan would change based on the PSMA PET scan finding. Results: For the period between August 2015 and March 2016, 285 patients with PCa had pre- and post-Ga68 PSMA management plans completed by their referring specialists. Scans were performed for primary staging in 22% patients and for a rising PSA following surgery and/or radiotherapy in 78% of patients. On the pre-PSMA management plan, the most common treatment intent was for targeted or localised treatment (66%), followed by systemic therapy (18%) and surveillance (16%). On the post PSMA survey the clinicians indicated that the PSMA scan lead to a change in planned management in 55% of patients. The PSMA scan revealed disease that was not previously suspected in the prostate bed (30% of patients), locoregional lymph nodes (36% of patients) and distant disease (16% of patients). In those in whom there was no management change, the survey indicated this was most often due to no additional information being provided from the PSMA scan. Conclusions: These preliminary results indicate that PSMA PET scans detect previously unsuspected disease and change planned clinical management in a high proportion of patients with prostate cancer. This demonstrates the potential clinical value of PSMA PET in treatment planning in this patient group.

Staging primary prostate cancer with ^{68}Ga-PSMA$^{HBED-CC}$/[^{18}F]Fluorocholine-PET/MRI

M. Hartenbach[1], P. Baltzer[1], S. Hartenbach[2], M. Susani[3], C. Seitz[4], L. Kenner[3], G. Kramer[4], A. R. Haug[1], W. Wadsak[1], M. Mitterhauser[1], A. Ponholzer[5], M. Lamche[5], S. Shariat[4], M. Hacker[1]; [1]Medical University of Vienna, Dep. of biomed. imaging and image guided therapy, Vienna, AUSTRIA, [2]German Armed Forces Hospital, Institute of Pathology, Ulm, GERMANY, [3]Medical University of Vienna, Institute of Pathology, Vienna, AUSTRIA, [4]Medical University of Vienna, Dep. of Urology, Vienna, AUSTRIA, [5]Hospital St. John of God, Urology, Vienna, AUSTRIA.

Introduction/Objectives Staging primary prostate cancer lacks of accuracy and reliability although invasive methods are used for clinical staging nomograms. The aim of this study was to determine the clinical impact and staging performance of non-invasive hybrid multiparametric ^{68}Ga-PSMA$^{HBED-CC}$/[^{18}F]Fluorocholine-PET/MRI (dtPET/MRI) in patients with biopsy proven prostate cancer, scheduled for radical prostatectomy. Methods 80 patients, scheduled for radical prostatectomy, underwent dtPET/MRI for primary staging. cTNM-staging was performed prospectively according to UICC 2009. dtPET/MRI impact on guideline-conform treatment decision was corrected, when conventional, guideline-conform imaging modalities delivered equal information (CT/bone scan). Clinical pre-therapeutic TN-prediction was performed using the MSKCC-prediction nomogram. dtPET/MRI and prediction nomogram were correlated with post-surgery results. dtPET/MRI M1b-staging was verified by histology or follow-up exams. '2x2' tables were evaluated. Two-tailed Fisher Exact was used for level of significance. Results In 56 of 80 patients (70%), radical prostatectomy was still chosen as primary treatment, but 5 had additional radiotherapy (RT)/antihormonal therapy (aHT). 5 had primary RT due to T4-status, 2 RT + aHT due to N1-status, 9 chose active surveillance (minimal tumor burden), 4 palliative TUR-P+aHT/chemotherapy (cT3b/T4, N+/M+) and 6 primary aHT/chemotherapy. Initial mean PSA was 11.88ng/ml (n=80). Treatment changed in 28/80 patients (35%) due to imaging, and in 24/80 patients (30%) due to dtPET/MRI. dtPET/MRI T2 vs. T3a/b staging had a sens./spec/acc./npv/ppv/rel.risk of: 84%/72%/77%/67%/88%/5.3 *(P<0.001)*. MSKCC nomogram: 67%/44%/54%/48%/63%/1.3 *(P=0.54)*. N-staging dtPET/MRI sens./spec/acc./npv/ppv/rel.risk: 67%/97%/91%/86%/92%/10.3 *(P<0.001)* MSKCC nomogram: 25%/100%/83%/100%/82%/5.7 *(P=0.044)*. dtPET/MRI M1b-status sens./spec/acc./npv/ppv were 100% respectively *(P<0.001; n=32)*. Conclusions Hybrid multiparametric dtPET/MRI prior primary treatment of prostate cancer patients led to a remarkable change in the therapeutic management in this dual center evaluation. Furthermore, non-invasive dtPET/MRI was more reliable than common used invasive staging nomograms and provided additional highly accurate information on patient's M-status.

OP552

The clinical impact of additional late PET/CT-imaging with ^{68}Ga-PSMA-11 (HBED-CC) in the diagnosis of recurrent prostate cancer

A. Afshar-Oromieh[1], L. Sattler[1], C. Kratochwil[1], F. Giesel[1], K. Kopka[2], U. Haberkorn[1]; [1]University Hospital of Heidelberg, Heidelberg, GERMANY, [2]Div. of Radiopharmaceutical Chemistry, German Cancer Research Center, Heidelberg, Germany, Heidelberg, GERMANY.

Aim: PET/CT with the small molecule inhibitor of the prostate-specific membrane antigen ^{68}Ga-PSMA-11 is regarded as a significant step forward in the diagnosis of prostate cancer (PCa). While ^{68}Ga-PSMA-11 PET/CT is routinely performed at 1h p.i., it is known that later images show most tumor lesions with higher tracer uptake and contrast. The aim of this retrospective evaluation was to investigate the clinical impact of late PET-imaging with ^{68}Ga-PSMA-11. **Methods:** 117 patients with recurrent PCa (median PSA 2.6 ng/ml) who were referred to ^{68}Ga-PSMA-11 PET/CT were included in this evaluation. All of them were scanned 1h p.i. and a 3h p.i. in order to increase the probability of tumor detection or to clarify unclear findings. Both scans were analyzed with regard to tumor detection. Quantitative assessment of tracer uptake (SUVmax) of 222 tumor lesions in 83 patients was performed in both scans. **Results:** In 84 of 117 patients (71.8%), at least one tumor suspicious lesion was detected in, both, early and late scans. 7 of 117 patients (6%) showed each one suspicious finding in early scans which, however, could not be confirmed as PCa lesions in late scans[AA1] . 5 patients who showed no suspicious findings in early scans presented with one PCa lesion in late scans. Overall, 18 of 222 lesions (8.1%) in 14 of 83 (16.9%) different patients were visible in late scans only. Amongst them, local relapse lesions demonstrated the highest rate: 5 of overall 15 local relapses (33.3%) were visible in late images only. 73.9% of all tumor lesions presented with significantly higher uptake in late images whereas 15.3% of them presented with significantly lower uptake in late images. **Conclusion:** ^{68}Ga-PSMA-11 PET/CT at 3h p.i. is a powerful method to clarify unclear findings in early images and to find additional lesions in patients with PCa.

OP553

68Ga-PSMA PET/CT in Staging and Restaging of prostate Cancer Patients: Comparative Study with 18F-Choline PET/CT

W. Langsteger[1], L. Imamovic[1], H. Geinitz[2], C. Schiller[1], F. Moinfar[3], A. Rezaee[1], L. Pallwein-Prettner[4], W. Loidl[5], M. Beheshti[1]; [1]PET-CT Center Linz, St. Vincent's Hospital, Linz, AUSTRIA, [2]Department of Radiation Oncology, St. Vincent's Hospital, Linz, AUSTRIA, [3]Department of Clinical Pathology, St. Vincent's Hospital, Linz, AUSTRIA, [4]Department of Radiology, St. Vincent's Hospital, Linz, AUSTRIA, [5]Prostate Cancer Center Linz, Department of Urology, St. Vincent's Hospital, Linz, AUSTRIA.

Aim 11C- and 18F-choline PET/CT have been established in the assessment of prostate cancer (PCa) patients. However, it suffers to differentiate malignant vs benign prostate hyperplasia and detect small lesions. Recently, 68Ga-PSMA (PSMA) PET/CT was introduced as promising imaging in assessment of PCa. This study was designed for comparison of detection rate between PSMA and 18F-fluoromethylcholine (FCH) PET/CT scan in staging and recurrent Pca patients. **Material & Methods** In this prospective study 22 consecutive PCa patients (mean age 68±7) underwent both PSMA and FCH PET/CT with a maximum interval of 4 weeks without any treatment in between. Patients with systemic therapy and known second cancer were excluded. Pathologic findings in each imaging modalities have to be clarified histopathologically or by conventional imaging modalities and/or clinical follow-up. **Results** ***Staging:*** *10* histopathologically verified high-risk PCa patients were examined. The mean of PSA was 32.2 ±26.4 ng/ml (range: 1.29 - 61.33). Both imaging modalities were able to detect the index lesion in the prostate gland. Overall, a total number of 25 and 20 positive lymph nodes (LN) were detected on PSMA PET/CT and FCH PET/CT, respectively. Malignant LN showed significantly higher uptake on PSMA-comparing FCH PET/CT [mean SUVmax: PSMA PET/CT: 12.8 (range: 2.8-34); FCH PET/CT: 6.6 (range: 2.3-12.3)]. Bone metastases (BM) were detected in 3 patients by FCH PET/CT but PSMA PET/CT was negative in one patient with BM in the pelvic skeleton. ***Restaging:*** 12 patients with biochemical recurrence were included in this study. The mean of PSA was 7.3 ng/ml (range: 0.07 - 42.02). Local recurrences (LR) with pathologically increased tracer uptake were detected in 2 patients on both imaging modalities; However, LR show markedly higher uptake on PSMA PET/CT (SUVmax: PSMA: 12.4; FCH: 4.9). In addition, PSMA PET/CT was able to detect higher number of metastatic LN compared with FCH PET/CT (7 vs 6) with significantly better tumor to background ratio (SUVmax 8.7 on PSMA vs 4.45 on FCH). Both imaging modalities were able to detect 5 BM. One false positive bone lesion was detected on PSMA PET/CT. **Conclusion** PSMA PET/CT reveals a more promising role in staging and re-staging of prostate cancer patients even with low PSA level. Markedly higher tumor to background contrast is seen on PSMA PET/CT which allows higher detection rate especially in the small lesions. However, the value of this modality in the assessment of bone metastases should be further evaluated in future studies.

OP554

Probability of positive ^{68}Ga-PSMA PET/CT as a function of serum PSA: an optimal PSA cut-off in patients with biochemical recurrence after radical prostatectomy?

L. Tosco[1,2], O. Gheysens[3,1], W. Everaerts[2,4], M. Albersen[2,4], L. Cromphout[2], C. M. Deroose[3,1], K. Van Laere[3,1], S. Joniau[2,4], **K. E. Goffin**[3,1]; [1]Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM, [2]Urology, UZ Leuven, Leuven, BELGIUM, [3]Nuclear Medicine, UZ Leuven, Leuven, BELGIUM, [4]Department of Development and Regeneration, KU Leuven, Leuven, BELGIUM.

Introduction: After radical prostatectomy (RP), 20-30% of patients experience biochemical recurrence (serum PSA increase). ^{68}Ga-PSMA PET/CT is useful to detect locoregional and distant recurrences of prostate cancer, with an increasing detection rate depending on the PSA level. In this study, we investigated the relationship between ^{68}Ga-PSMA PET/CT positivity and PSA level in depth to determine an optimal PSA cut-off value to guide the indication for ^{68}Ga-PSMA PET/CT imaging after RP. **Materials and methods:** We retrospectively evaluated all consecutive ^{68}Ga-PSMA PET/CT scans (n=129) in patients with biochemical recurrence after RP between January 2015 and April 2016. A ^{68}Ga-PSMA PET/CT scan was considered positive when there was focal uptake above background not corresponding to physiologic uptake. To evaluate the effect of PSA on the positivity of the ^{68}Ga-PSMA PET/CT, we performed a logistic regression analysis. A ROC curve analysis was applied to determine an optimal PSA cut-off value. **Results:** The median PSA value was 1.16 ng/ml (range 0.02-56.2). The probability of a positive ^{68}Ga-PSMA PET/CT scan in function of PSA values followed a sigmoidal curve on a logarithmic PSA scale, and varied from 41% at a PSA value of 0.02 ng/ml, 50% at 0.58 ng/ml, 75% at 2.45 ng/ml to up to 100% at PSA values above 10 ng/ml. The odds ratio for PSMA PET/CT positivity per logarithmic unitary increase in PSA level was 1.82 (95% confidence interval (CI): 1.29-2.60). The area under the ROC curve for PSA was 0.78 (95% CI 0.70-0.85). A PSA value of 0.38 ng/ml was identified as the optimal cut-off for maximal combined sensitivity/specificity to have PSMA PET/CT positivity and therefore a clinically helpful scan (sensitivity 85%, specificity 60%). **Conclusion:** The probability of a positive ^{68}Ga-PSMA PET/CT scan in patients with biochemical recurrence after RP increases with PSA value in a log-sigmoidal fashion. Our study showed that a PSA value of 0.38 ng/ml can be regarded an optimal threshold for ^{68}Ga-PSMA PET/CT positivity. However, even at the lowest PSA values, the calculated probability of a positive scan was still above 40%.

OP555

68Ga-PSMA PET/CT in Preoperative Staging of Intermediate and High Risk Prostate Cancer Patients

C. Schiller[1], **M. Beheshti**[1], H. Geinitz[2], B. Aschacher[2], F. Moinfar[3], G. Broinger[3], L. Pallwein-Prettner[4], W. Loidl[5], W. Langsteger[1]; [1]PET-CT Center Linz, St. Vincent's Hospital, Linz, AUSTRIA, [2]Department of Radiation Oncology, St. Vincent's Hospital, Linz, AUSTRIA, [3]Department of Clinical Pathology, St. Vincent's Hospital, Linz, AUSTRIA, [4]Department of Radiology, St. Vincent's Hospital, Linz, AUSTRIA, [5]Prostate Cancer Center Linz, Department of Urology, St. Vincent's Hospital, Linz, AUSTRIA.

Aim 68Ga-PSMA (PSMA) PET/CT is introduced as new promising imaging in assessment of prostate cancer (PCa). This study assesses the impact of PSMA PET/CT in preoperative staging of intermediate and high risk Pca patients. **Material & Methods** Sixty-one histopathologically proven consecutive intermediate risk (5) and high risk (56) PCa patients (mean age 69 ± 8) who underwent PSMA PET/CT for preoperative staging, were included in this study. Patients with previous hormone and/or radiotherapy and known second cancer were excluded. PET/CT imaging was performed 60 min. after intravenous injection of 140 MBq Glu-NH-CO-NH-Lys-(Ahx)-[68Ga(HBED-CC)] (68Ga-PSMA) with 3min/bed position acquisition time. Pathologic findings in each imaging modalities have to be clarified histopathologically or by other imaging modalities and/or clinical follow-up. **Results** Patients had a mean PSA level of 27.2 ± 38.4 ng/ml (range: 0.78 - 224.7 ng/ml) and median Gleason score of 8. At least one malignant lesion was detected in the prostate gland in all patients. PSMA PET/CT detected lymph node metastases in 18 patients, bone metastases in 12 patients and both bone and lymph node metastases in 6 patients. All extraglandular metastases were detected in high risk patients while none of intermediate risk patients showed lymph nodes or bone metastases. No significant difference in mean PSA value was found in patients with lymph nodes (44.9 ± 55.8) and bone metastases (52.6 ± 69.3). PSMA PET/CT changed patients' management in 20 % (12/61) of high risk PCa patients. **Conclusion** PSMA PET/CT showed a promising role in staging of high risk prostate cancer patients. It was well able to detect lymph nodes as well as bone metastases and changed the patients' management in 20 % of the cases.

OP556

Intra-individual comparison of the PSMA-ligand ^{99m}Tc-MIP-1427 with ^{99m}Tc-MDP bone scan in patients with osseous metastasized prostate cancer

H. Rathke[1], F. L. Giesel[1], A. Afshar-Oromieh[1], S. Haufe[1], W. Mier[1], J. W. Babich[2], U. Haberkorn[1], C. Kratochwil[1]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, NY, UNITED STATES.

Purpose: To evaluate the diagnostic potential of the PSMA-targeting tracer ^{99m}Tc-MIP1427 in comparison to conventional bone scan with ^{99m}Tc-MDP in patients with known osseous metastasized prostate cancer using identical imaging equipment/protocol. **Methods:** In this ongoing evaluation patients with known metastatic disease were staged with both, conventional bone scan and PSMA-scintigraphy, within a time-frame of <10days. Until know, n=20 patients were evaluated with a blind-read by two experts in nuclear medicine. Imaging included planar whole-body scans and two bed positions SPECT or SPECT/CT 3h after injection of either 500-750 MBq ^{99m}Tc-MIP1427 or 600-750 MBq ^{99m}Tc-MDP. Lesions were scored: typical tumor / equivocal / benign lesion / normal, within a standard reporting schema divided into defined anatomical regions. **Results:** One patient had a PSMA-negativ tumor phenotyp. In one patient the PSMA-ligand demonstrated only faint tumor uptake but, nevertheless, was diagnosed identical to the high uptake bone scan. 5 patients demonstrated equal findings in both examinations. 5 patients presented with additional visceral metastases in PSMA-imaging, which were predictably not diagnosed with conventional bone scan. However, SPECT/CT was required to distinguish between soft tissue uptake and overlapping bone. 4 patients had superscan character in bone scan, in contrast extend of red marrow involvement was evaluable more detailed by PSMA-imaging. In two patients PSMA-scan found tumor-typical lesions in more regions than MDP. In the rest of the patients identical pathological findings were reported with both tracers, however with bone scan more of the lesions were scored equivocal or presumably benign while PSMA more often resulted in tumor typical appearance. **Conclusion:** In the intra-individual analysis between the ^{99m}Tc-labeld PSMA-ligand and conventional bone scan the directly tumor targeting PSMA-tracer demonstrated clearly superior in comparison to bone scan which is based on secondary reactions of the tumor stroma environment. However, SPECT or SPECT/CT is often pivotal to differentiate between bone metastases and extra-osseous tumor lesions. Rare cases of PSMA-negative tumor phenotypes remain limitations.

OP557

Safety Evaluation and Cardiovascular Responses of the ^{68}Ga-PSMA Ligand used for PET/CT Imaging in Patients with Prostate Cancer in a Prospective, Multicenter Trial

J. B. Nielsen, Jr.[1,2], H. D. Zacho[1,2], U. Haberkorn[3], L. J. Petersen[1,2]; [1]Dept. of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, [2]Dept. of Clinical Medicine, Aalborg University, Aalborg, DENMARK, [3]Dept. of Nuclear Medicine, University Hospital of Heidelberg, Heidelberg, GERMANY.

Aim: Safety reviews of non-marketed drugs are mandatory for obtaining regulatory approval for clinical or experimental use in many countries. Often safety reporting is scarcely reported in imaging trials, largely due to retrospective data collection. The aim of this study was to evaluate the safety profile and cardiovascular response of the ^{68}Ga-PSMA ligand used for PET/CT imaging in prospective clinical trials. **Materials and Methods**: A total of 77 patients with newly-diagnosed or recurrent prostate cancer participated in two prospective trials. Safety reporting was identical in the two trials. Patients were actively asked to report any AE during the ^{68}Ga-PSMA administration and until the end of the day of the PET/CT scan. Any AE was classified as mild, moderate or severe by the patients and categorized by Common Terminology Criteria for Adverse Events (CTCEA) v4.0 by the physician. Blood pressure (BP) and heart rate (HR) were measured prior to injection (baseline), immediately after the tracer injection, and at 1, 10 and 60 min post-injection (p.i.). A final assessment was made after the PET/CT scan. The definitions of hemodynamic adverse events were as defined: Brachycardia (HR < 50 beats per minute), tachycardia (HR > 100 beats per minute), hypertension (systolic BP > 180 mmHg) or hypotension (systolic BP < 100 mmHg). **Results**: There was no reported AE. Mean systolic BP was 149 mmHg at baseline, and 145, 145, 139, 147 and 150 mmHg at injection, 1, 10, 60 minutes p.i. and after the PET/CT scan, respectively. There was no significant change in BP (p=0.74, ANOVA). Additionally, mean HR was 67 beats per minute at baseline, and 65, 62, 64, 62 and 62 beats per minute at injection, 1, 10, 60 minutes p.i. and after the PET/CT scan, respectively. There was no significant changes in mean heart rate (p=0.78). No patients developed de novo hypertension, hypotension, bradycardia, or tachycardia. Five patients presented with hypertension at baseline, but did not increase their systolic BP during/after the scan. Six patients showed brachycardia at baseline, none of these patients showed further decrease in HR p.i. **Conclusion**: ^{68}Ga-PSMA PET/CT is very well tolerated. None of the patients experienced any AE and there were no changes in blood pressure or heart rate. We conclude that ^{68}Ga-PSMA is safe for human application.

First Validation of Myocardial Flow Reserve (MFR) by Dynamic SPECT Acquisitions using CZT camera in Comparison with O^{15}-water PET in patients with Stable Angina. Preliminary Results of Waterday Study

D. Agostini[1], V. Roule[1], C. Nganoa[1], J. Wain-Hobson[1], D. Peyronnet[1], M. Maguet[1], R. Baavour[2], N. Roth[2], F. Beygui[1], **A. Manrique**[1]; [1]CHU Caen, Caen, FRANCE, [2]Spectrum Dynamics Medical, Caesara, ISRAEL.

Introduction. Quantification of myocardial blood flow has previously demonstrated diagnostic incremental value in patients with CAD using PET imaging. The advent of novel CZT camera has opened new perspectives for perfusion quantification using dynamic SPECT acquisitions. We appraised the feasibility of myocardial flow reserve (MFR) estimation using CZT camera in patients with stable angina and its correlation to MFR as measured using O^{15}-water PET data. **Materials and methods**. 16 patients (12 M, 4 F; 66± 7 yo) with stable CAD (intermediate risk factors with angina 9/16 pts) and positive ischemia test (10/16 pts) were prospectively included during the angiographic procedure (clinicaltrials.gov: NTC 02278497). 6-min dynamic SPECT acquisitions using an injector to deliver a bolus injection of $^{(99m)}$Tc-sestamibi [(3 MBq/kg at rest and 9 MBq/kg after regadenoson (400 μg,IV)] were performed using a CZT camera (D-SPECT, Spectrum Dynamics, Israel). The whole procedure lasted for 60 min for a patient in a supine position. The same procedure was done for O^{15}-water PET within 2 weeks. For SPECT, reconstructed frames were automatically segmented to extract the vascular input function and the myocardial uptake curve. One-compartment kinetic modeling was used to estimate global uptake values, and then MBF was derived using Leppo correction. MBF at rest and stress were assessed and then MFR as a ratio of stress MBF/rest MBF. For PET, parametric MBF images were generated and analyzed quantitatively using Corridor 4DM, INVIA (Ann Arbor,USA). An ischemia by PET and SPECT was considered present if MFR was lower than 2. **Results**. Rest vs stress injected activity was 310 ±67 vs 817 ±166 MBq, respectively; P<0.05. The total injected dose was 1127±228 MBq. Global stress and rest MBF by SPECT correlated well with those measured by PET [DSPECT(MBF) = 0.078+ 0.74 x PET(MBF); r^2=0.84; P= 10^{-4}]. Stress MBF with SPECT was significantly lower (1.99± 0.66) than that with PET (2.51± 0.87 ml/min/g; P= 0.0011). Rest MBF with SPECT was significantly lower (0.706± 0.27) than that with PET (0.926± 0.22 ml/min/g; P= 0.002). However, MFR with SPECT was slightly higher (3.10± 0.74) than that with PET (2.91± 0.88; P= 0.05). **Conclusion**. SPECT estimations of MBF and MFR using dynamic CZT camera acquisitions appear to correlate well with O^{15}-water PET measurements in patients with stable CAD.

OP559

Assessment of Myocardial Flow Reserve (MFR) by Dynamic SPECT using CZT camera and Comparison with invasive Fractional Flow Reserve (FFR) Measurements in Patients with Stable Angina. Preliminary Results of Waterday Study

D. Agostini[1], V. Roule[1], C. Nganoa[1], J. Vigne[1], T. Salomon[1], J. Wain-Hobson[1], M. Maguet[1], R. Baavour[2], N. Roth[2], F. Beygui[1], A. Manrique[1]; [1]CHU Caen, Caen, FRANCE, [2]Spectrum Dynamics Medical, Caesara, ISRAEL.

Introduction. Quantification of myocardial blood flow has previously demonstrated diagnostic incremental value in patients with CAD using PET imaging. The advent of novel CZT camera has opened new perspectives for perfusion quantification using dynamic SPECT acquisitions. We appraised the feasibility of MFR estimation using a CZT camera in patients with stable angina and its pertinence with respect to angiographic and FFR data. **Materials and methods**. 19 patients (15 M, 4 F; 66± 8 yo) with stable CAD (intermediate risk factors and angina 9/19 pts) and positive ischemia test (13/19 pts) were prospectively included during the angiographic procedure (clinicaltrials.gov: NTC 02278497). 6-min dynamic SPECT acquisition using a contrast injector to deliver a bolus injection of ^{99m}Tc-sestamibi (3 MBq/kg at rest and 9 MBq/kg after regadenoson 400 μg, IV) were performed using a CZT camera (D-SPECT, Spectrum Dynamics, Israel). The whole procedure lasted for 60 min for a patient in supine position. Reconstructed frames were automatically segmented to extract the vascular input function and the myocardial uptake curve. One-compartment kinetic modeling was used to estimate global uptake values, and then MBF was derived using the Leppo correction. Global stress and rest MBF were assessed and then MFR as the ratio of stress MBF/rest MBF was done. All patients underwent 3 FFR measurements (LAD+CX+RCA) during the angiography. A stenosis was considered obstructive if greater than 50% and an FFR abnormal if ≤ 0.8. An ischemia by SPECT was considered present if MFR was lower than 2. **Results**. Rest vs stress injected activity was 310 ±67 vs 817 ±166 MBq, respectively; P<0.05. The total injected dose was 1127±228 MBq. Global stress MBF (1.99± 0.66 ml/min/g) was significantly higher than rest MBF (0.706± 0.27, P= 0.002). Pts with FFR≤ 0.8 showed a trend of decreasing stress MBF (1.64± 0.78 ml/min/g) vs pts with FFR> 0.8 (stress MBF= 1.99± 0.76 ml/min/g; P= 0.05). In pts with FFR ≤ 0.8: MFR tended to drop to 2.22± 1.31 when compared with pts FFR> 0.8: MFR was 3.10± 0.74; P= 0.05. With the cutoff of 2, the sensitivity, specificity and accuracy of MFR were, respectively, 71%, 93% and 89.5% for the detection of abnormal FFR. The total (rest+stress) effective dose was 8.92±1.81 mSv. **Conclusion**. Dynamic SPECT estimations of global stress MBF and MFR using CZT camera appear feasible, reliable and correlate well with invasive angiographic findings as FFR measurements in patients with stable CAD.

OP560

High diagnostic performances of 82Rubidium PET as compared to 99mTechnetium MIBI with CZT gamma cameras for detection of coronary artery disease in women and overweight people

F. Hyafil[1], R. Chequer[1], E. Sorbets[2], C. Estellat[3], F. Rouzet[1], H. Regaieg[1], S. Leygnac[1], M. Milliner[1], R. Ben Azzouna[1], L. Imbert[4], P. Marie[4], D. Le Guludec[1]; [1]Department of Nuclear Medicine, Bichat Hospital, AP-HP, PARIS, FRANCE, [2]Department of Cardiology, Avicennes Hospital, AP-HP, Bobigny, FRANCE, [3]Unité de Recherche Clinique, Bichat Hospital, AP-HP, PARIS, FRANCE, [4]Department of Nuclear Medicine, Brabois Hospital,, Vandoeuvre-les-Nancy, FRANCE.

Background. In obese patients and women, most non-invasive tests offer poor diagnostic performance for the detection of coronary artery disease (CAD). CZT gamma cameras owing to their cardiac-centred design and ^{82}Rubidium(Rb)-PET thanks to accurate attenuation correction might prove particularly interesting in this population. **Purpose.** The objectives of this study were to compare the diagnostic performance and associated radiation exposure of ^{82}Rb-PET-MPS and ^{99m}Tc-MIBI-MPS with CZT gamma cameras for the detection of CAD in women and overweight people. **Methods.** Men with BMI ≥ 25 and women referred for MPS with a pre-test intermediate prevalence of CAD were considered for inclusion. All patients underwent a gated MPS with ^{99m}Tc-MIBI using CZT cameras in association to the best stress test feasible (exercise and combined tests were prioritized) and a gated MPS with ^{82}Rb-PET and pharmacological stress using dipyridamole. Patients with at least one MPS considered as positive were referred for coronary angiography (CA). Patients were classified as positive for myocardial ischemia in case of significant stenosis

on CA or, in absence of CA, occurrence of cardiovascular event during the following year. After exclusion of 17 patients with missing information, diagnostic performance of each MPS were compared in the remaining 294 patients using the Mc Nemar test. Effective doses related to the injection of each radiotracer and CT acquisitions were calculated using the recommendations of ICRP. **Results.** A total of 311 patients (143 women) with mean BMI of 31.8 ± 6.5 were included in the study. Three patients had a MPS with ^{82}Rb-PET-CT not interpretable and were excluded from the analysis. Sixty CA were performed and 35 showed significant stenosis. CA could not be performed in 12 patients with at least one positive MPS and 2 patients were lost to follow-up. In the remaining 294 patients, sensitivity for the detection of CAD was significantly higher with ^{82}Rb-PET-MPS than with ^{99m}Tc-MIBI-MPS (83.3 [95% CI: 71.1; 95.5] vs. 55.5 [39.3; 71.7], respectively; p = 0.02), whereas the specificity was equally high for both tests (93.4 [90.4; 96.4] vs. 95.7 [93.2; 98.2], respectively; p = 0.22). Mean total effective dose per patient for MPS was significantly lower with ^{82}Rubidium-PET-CT as compared to ^{99m}Tc-MIBI-scintigraphy with CZT cameras (4.1 ± 1.4 vs. 10.0 ± 3.3 mSv; p < 0.05). **Conclusions.** In women and overweight patients, ^{82}Rb-PET-MPS offers higher diagnostic performances and lower radiation exposure for the detection of CAD as compared with ^{99m}Tc-MIBI-MPS using CZT cameras.

OP561

Comparison of myocardial perfusion scintigraphy (MPS) between CZT detector cardiac gamma camera and conventional dual head gamma camera

S. S. SINGH; Narayana Hrudalaya, BANGALORE, INDIA.

INTRODUCTION: SPECT MPI is a widely used non-invasive method for the detection of suspected obstructive coronary artery disease (CAD). Conventional SPECT uses Thallium doped Sodium Iodide i.e. NaI(Tl) crystals for myocardial perfusion imaging in which there is indirect conversion of the gamma rays to an image after passing through number of intermediate steps. The new cardiac camera with Cadmium Zinc Telluride (CZT) semiconductor crystals, converts radiation to electronic signals directly without intermediate conversion steps, resulting in improved sensitivity and spatial resolution. **AIM OF THE STUDY:** Comparison of Myocardial perfusion scintigraphy between new CZT detector cardiac camera and conventional dual head gamma camera. **MATERIALS AND METHODS:** This prospective study involved 52 patients with significant coronary artery disease (mean age group of 60 ±15 years, 50males and 2females). Clinical history and investigation details comprising of symptoms, ECG, coronary angiogram details were collected. Patients had undergone ^{99m}Tc-sestamibi 1 day stress rest protocol/ rest stress protocol and stress and rest image acquisition was performed on CZT dedicated cardiac gamma camera and conventional dual head NaI(Tl) within 10 minutes of each other as per ASNC guidelines. Image processing and reconstruction was done on Xeleris-3 workstation using ECTool box (version 3.2) to generate corresponding slices and polar plots. Interpretation of stress and rest images was done by two experienced Nuclear Medicine Physicians and summed stress score (SSS), summed rest score (SRS) and summed difference score (SDS) was derived. Correlation between above parameters and was done using Spearman correlation coefficient and cronbach alpha. **RESULTS:** Correlation coefficient between two observers for CZT detector camera was determined as 0.92 (p<0.001) for SSS, 0.94 (p<0.001) for SRS, 0.82 (p<0.001) for SDS and for conventional gamma camera was determined as 0.95(p<0.001) for SSS, 0.96 (p<0.001) for SRS, 0.91 (p<0.001) for SDS. Internal consistency between two cameras for LAD territory was determined as 0.99 for SRS and 0.79 for SDS, for LCX territory was determined as 0.94 for SRS and 0.94 for SDS and for RCA territory was 0.96 for SRS and 0.54 for SDS. **CONCLUSIONS:** In the present study, there is overall good to excellent correlation between perfusion images obtained from both the cameras. Territory wise, there is poor agreement between the data obtained from two cameras in the RCA territory, good agreement in LAD territory and excellent agreement in LCX territory. **KEYWORDS:** ASNC: American Society of Nuclear Cardiology, LAD: left anterior descending, LCX: left circumflex, RCA: right coronary artery.

OP562

Myocardial scintigraphy with D-SPECT: How much can we reduce patient radiation dose without decreasing image quality and diagnostic confidence?

E. Olsson[1], A. Davidsson[1], J. Engvall[1], B. Holmberg[1], M. Ochoa-Figueroa[1], V. Sanchez-Rodriguez[1], G. Varelogianni[1], P. Norberg[2]; [1]Department of Clinical Physiology, Department of Medical and Health Sciences/Cardiovascular Medicine, Linköping University, Linköping, SWEDEN, [2]Department of Medical Physics and Department of Medical and Health Sciences, Linköping University, Linköping, SWEDEN.

Aim Image quality has become increasingly important in SPECT myocardial perfusion imaging (MPI) in terms of accurate reporting of ischemia with reliable quantitative measurements of myocardium at risk. Dedicated cardiac gamma camera CZT-systems with increased sensitivity produce improved image quality and may allow injected dose and radiation exposure to be lowered. The choice of count level and its impact on image quality and diagnosis is still debated. Our aim was to identify the lowest count level that still maintained diagnostic confidence.**Materials and Methods** A thorax-heart phantom was used to simulate two patient studies, one with two ischemic and another with two infarct defects. Imaging was performed with a D-SPECT camera (Spectrum Dynamics) with four count levels; 1, 0.75, 0.5 and 0.25Mcounts. 34 patients examined with clinically indicated MPI (tetrofosmin, 6MBq/kg) were retrospectively included, aiming at 10 with normal, 10 with intermediary and 14 with pathological (ischemia/infarct) MPI results. The images with the three lower count levels were digitally generated from the clinical 1Mcount image. The 136 patient and 8 phantom cases were visually assessed in random order by 6 physicians, using a four grade scale, assessing 3 questions on image quality and 5 regarding diagnosis. Statistical analysis was performed using Visual Grading Regression with p<0.05 considered significant. Quantification of defects (percentage of LV myocardium) was performed for both the phantom and the patient studies for all four count levels looking for a 5% change. **Results** Image quality decreased gradually for all count levels (p<0.05). For the diagnostic questions the result was non-significant between the 1 and 0.75Mcount level for identifying normality (p=0.07), ischemia (p=0.13) and infarct (p=0.42). For false positive findings the result was non-significant for the intermediary (p=0.11) and the ischemia/infarct (p=0.27) groups, but in the group with normal MPI result diagnostic confidence was gradually lower for each reduction in counts (p<0.01). Quantitative evaluation of the patient study is in process. The results in the phantom study showed similar diagnostic confidence in all questions (p>0.05) and similar defect size (p>0.05) for the four count levels. **Conclusion** Visual assessment indicated significant differences in image quality between the four count levels. Diagnostic questions suggest that the count level could be reduced to 0.75Mcounts, at a cost of increasing false positive findings in the group with normal MPI. The phantom study indicated that further dose reduction was possible, which was not corroborated when using real patient data.

OP563

Routine evaluation of left ventricular function with CZT-SPECT, low injected activities and limited recording times

L. IMBERT[1], M. CLAUDIN[1], W. DJABALLAH[1], V. NICOLAS[1], S. POUSSIER[2], V. ROCH[1], M. PERRIN[1], A. VERGER[1], H. BOUTLEY[2], G. KARCHER[1], P. MARIE[1]; [1]CHU NANCY HOPITAL BRABOIS ADULTES, VANDOEUVRE LES NANCY, FRANCE, [2]GIE NANCYCLOTEP, NANCY, FRANCE.

Purpose. Gamma-cameras, equipped with Cadmium-Zinc-Telluride (CZT) detectors, allow to perform myocardial perfusion imaging (MPI) with protocols involving low injected activities and limited recorded counts and recording times. This study aimed at determining whether the routine assessment of left ventricular (LV) function with such limited counts protocols and a 16-interval gated-SPECT compares well with reference values from cardiac MRI. **Methods.** The study included patients having undergone cardiac MRI and a MPI routinely planned on a CZT camera with a low-dose protocol (120MBq of Tc-99m Sestamibi for stress and 360 MBq at rest for 75kg body weight) and while targeting the recording of only 500 myocardial kcounts in order to limit the recording times (<10 min for stress, <4 min for rest). SPECT-images were reconstructed with a specific method maintaining sufficiently high spatial (8 mm) and temporal (16 frames/cycle) resolutions. **Results.** Seventy-six patients were included among whom 44 had evidence of myocardial infarction at MRI. Mean ejection fraction was 45±13% at MRI and mean effective dose was 3.5±1.7 mSv for the total MPI protocol. Correlations between CZT-SPECT and MRI were good to excellent for ejection fraction (r^2=0.77), end-diastolic (r^2=0.88) and end-systolic (r^2=0.93) volumes, with global underestimations for end-diastolic (-46±25 mL) and end-systolic (-20±19 mL) volumes. The analysis of segmental contractility correlated well between the two techniques (kappa score=0.72±0.02). **Conclusion.** LV function, routinely assessed by 16-interval gated-SPECT on a CZT camera with low injected activities, limited recording times and an adapted method of image-reconstruction, correlates well with the reference assessment from cardiac MRI.

OP564

The effect of dose reduction on left ventricular volumes and ejection fraction assessed by cadmium-zinc-telluride SPECT gamma camera gated tomographic radionuclide angiography

T. Q. Nguyen, J. Rydberg, B. Zerahn, B. Kristensen; Herlev Hospital, Herlev, DENMARK.

Aim: To examine the effect of reducing dose when measuring left ventricular ejection fraction (LVEF) and left ventricular volumes by cadmium-zinc-telluride (CZT) SPECT gamma camera gated tomographic radionuclide angiography (MUGA). **Materials and methods:** From September 2015 to March 2016, two consecutive MUGAs were performed on 46 patients who were injected first with a quarter of a full dose and subsequently adding up to a full dose of 550 MBq 99m Tc-HSA. All acquisitions were performed on a dedicated cardiac CZT SPECT gamma camera, GE Discovery 530c, using 16 bins and requesting 600 accepted beats in a 20% energy window centered on 140 keV. Each acquisition was then analyzed twice by two experienced technologists using a Xeleris 3 Imaging workstation reorientation software (version no. 3.0562) and then a Cedars-Sinai QBS processing software (revision 2009.0). Data on heart rate (HR), left ventricular end diastolic volume (LVEDV), left ventricular end systolic volume (LVESV), LVEF, and count rate were registered. Intraobserver variation was assessed in terms of interclass correlation coefficient (ICC) for each dose level and comparisons were done with paired Student's t-test. **Results**: The quarter dose series of acquisitions had a median count rate of 1.30 kcounts/sec (range: 0.58 - 2.78) while the median count rate for full dose was 4.40 kcounts/sec (range: 2.02 - 8.39). Dose reduction gave rise to significantly lower LVEDV (mean: 91.4 mL vs. 96.0 mL; p = 0.001) and LVESV (mean: 34.2 mL vs. 38.4 mL; p < 0.001). Subsequently this gave rise to a significantly higher LVEF (mean: 63.4 % vs. 60.5 %; p < 0.001). There was significantly higher HR during quarter dose acquisition compared to full dose (70.9 vs. 69.6; p = 0.004). Reducing dose did not significantly change the intraobserver variation as the ICC between the two observers remained above 0.99 for all test variables with overlapping 95% confidence intervals. **Conclusion:** Reduction of dose in CZT detector based MUGA causes a decrease in ventricular volumes and a higher LVEF which can be explained by a partial volume effect. The significantly higher HR may also contribute to this effect and was most likely caused by nervousness from the patient at the start of the examination. However, reproducibility in terms of intraobserver variation is not compromised by dose reduction. Subsequently, it is possible to adjust CZT-detector based MUGA outcome to a reference method without compromising reproducibility within the dose range mentioned above.

OP565

Agreement between conventional and CZT cameras for the assessment of myocardial viability

B. Vagne, R. DE PAOLA CHEQUER, N. MIKAIL, H. REGAIEG, A. HALKOVICH, F. HYAFIL, D. LE GULUDEC, F. ROUZET; Hopital Bichat, Paris, FRANCE.

Introduction: ^{201}Thallium (Tl-201) myocardial SPECT is well established to assess myocardial viability. New generation of *solid-state detectors gamma-camera* (CZT) offers technical advantages over conventional cameras (CC). So far, both systems have been compared exclusively in the detection of myocardial ischemia. The objective of the present study was to evaluate the agreement between quantitative analysis obtained on CC and on CZT for the assessment of myocardial viability. Methods: Patients referred for viability assessment during a 16-month period were prospectively included. Four hours after injection of 1 MBq/Kg Tl-201, they underwent sequentially and in a random order an acquisition on both a CC (INFINIA, GEMS) and on a CZT (D-SPECT, Spectrum Dynamics). The necrosis extent was quoted on the 17-segments model. The tracer uptake value in the necrosis area was quantified both automatically (QPS software, Cedars-Sinai) per vascular territory (% of pixel maximal value) and manually using the ratio between a manually drawn regions of interest (ROI) on the necrosis area (≥1 per patient) and remote healthy myocardium (using pre-set threshold values: non viable<0.50≤indeterminate <0.65≤viable). Quantitative continuous values obtained on both cameras were compared by use of Bland-Altman plots, and the agreement between cameras for viability ratings was assessed by weighted kappa coefficient. Results: The study population consisted of 57 patients (mean age: 67±13 years; 12% women; LVEF: 38±14 %; ≥2-vessel disease: 72%). The mean difference between CC and CZT in necrosis extent was 0.05 segment [-1.60; 1.71] and the mean difference in uptake value per vascular territory was 2.0% [11.0; 15.1], with a bias proportional to the uptake value. Out of 65 necrosis areas analyzed, 49 were concordant (75%) and the agreement was considered substantial (kappa: 0.7). In most cases of discordance, the difference in uptake ratio was <5% but on either side of a threshold value. The most frequent discordance related to areas considered as indeterminate on the CC and non viable on the CZT. Conclusion: the present study suggests substantial agreement between CC and CZT cameras in the quantification of myocardial Tl-201 uptaked, thus supporting the use of new generation systems for viability assessment and subsequent dose reduction. Follow-up studies are required to determine the need to refine threshold values.

In-vivo PET Imaging of αvβ3 / α5β1 Integrin Expression Using Ga-68-Avebetrin and Ga-68-Aquibeprin in Mouse Models of Rheumatoid Arthritis

P. Sommer[1], **J. Notni**[2], K. Steiger[3], G. Topping[4], S. Ziegler[4], W. Weichert[3], M. Schwaiger[4], H. Kessler[5], R. Meier[1], H. Wester[2]; [1]Department of Diagnostic and Interventional Radiology, TU Munich, Munich, GERMANY, [2]Pharmaceutical Radiochemistry, Garching, GERMANY, [3]Institute for Pathology, TU Munich, Munich, GERMANY, [4]Department of Nuclear Medicine, TU Munich, Munich, GERMANY, [5]Center for Integrated Protein Science, TU Munich, Garching, GERMANY.

Rheumatoid Arthritis (RI) is the most common chronic inflammatory joint disease. Symptoms are painful, swollen joints and joint degradation, caused by an autoimmune reaction induced by a combination of genetic and environmental factors. Currently, diagnosis is mainly based on clinical symptoms, while detection of RI onset prior to physiological manifestation could enable early treatment and improve long-term outcome for risk patients. We investigated the suitability of αvβ3/α5β1 integrin targeted PET imaging with Ga-68-Avebetrin and Ga-68-Aquibeprin, respectively, for early detection of RI. *Methods:* Collagen-induced arthritis (CIA) mouse models were generated according to Nat. Protocols 2007;2:1269 by intradermal injection of an emulsion of type II collagen (CII) ion in complete Freund's adjuvant (CFA) (induction), followed after 14d by another injection of CII in incomplete Freund's adjuvant (IFA) (boostering), into the tail base of arthritis-susceptible DBA/1 mice. Starting 21 days after boostering, 5 cohorts of 6 mice each were investigated (one cohort per week). Animals were subjected to paw scoring, MR imaging (7T small animal scanner), and static PET imaging (Ga-68-Avebetrin and 6h later with Ga-68-Aquibeprin, each 20 MBq, 0.5 nmol, 1.5 h p.i.), and subsequently sacrificed. Paws, ankle and knee joints were removed, decalcified and slices analyzed by histology and immunohistochemistry (MOVAT staining / β3- and α5-IHC). *Results:* Uptake of both Ga-68-Avebetrin and Ga-68-Aquibeprin was observed not only in arthritic paws and ankles/knees but also in some hidden joints not accessible for physical examination (shoulder/pelvis), and in some physically inconspicuous limb joints. Accumulation in arthritic joints was comparable for both tracers (2.6±0.3 %IDg), while normal joints showed background uptakes <0.5 %ID/g. Joint uptakes could be reduced to 10-20 % by means of coinjection of 100 μg of the respective precursor, proving integrin-specificity. Negative cross-blockade studies with 100 μg of the respective other precursor proved selectivity of both tracers for their respective integrin targets. Presence of β3 and α5 integrin in PET-positive joints was confirmed by IHC. *Conclusions:* Ga-68-Avebetrin and Ga-68-Aquibeprin PET enabled selective imaging of elevated αvβ3/α5β1 integrin expression in arthritic joints of mice, suggesting that these integrins can act as biomarkers for RI. Moreover, our results indicate that αvβ3/α5β1 integrin PET can detect RI already in pre-symptomatic stages, which is potentially useful for improved management of RI in risk patients.

OP567

Feasibility of Ultra High Definition Dynamic PET/MR for Evaluation of ACL Graft Viability

K. Binzel[1], R. Moore[1], X. Liu[1], M. U. Knopp[2], R. Magnussen[1], C. Kaeding[1], D. Flanigan[1], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Pepperdine University, Malibu, CA, UNITED STATES.

Injury to the anterior cruciate ligament (ACL) is common. Cases of a complete tear usually require surgical placement of a graft to restore stability and function to the knee. We have previously demonstrated the utility of a combined ultra-low dose PET/CT/MR approach for a molecular imaging assessment of graft healing. Here we demonstrate the feasibility of further refinement by use of ultra-high definition (UHD) reconstruction. 10 patients with recent ACL surgery underwent MRI and dynamic PET on a next-generation pre-commercial release digital PET/CT system (Vereos Philips). Using an ultra-low dose (<111 MBq) ^{18}F-FDG protocol, images were acquired continuously for 75 minutes. The PET listmode data were then reconstructed using standard definition (SD) 64 mm^3 voxel volume with frame times of 5 and 15 minutes. Ultra-high definition (UHD) images with 1 mm^3 voxel volume were reconstructed for the same frame durations. PET images were manually co-registered with MRI. Regions of interest (ROIs) were placed over the distal, middle, and proximal portions of the graft, the femoral and tibial tunnels, the posterior cruciate ligament (PCL) and quadriceps muscle for reference. Matched ROIs were placed over the contralateral knee. The kinetic characteristics of FDG uptake was assessed over the 75 minute acquisition. Dynamic PET reconstruction with UHD settings could be completed for all patients. As expected, the noise level in the fourfold increased reconstruction matrix or 1/64th voxel volume increased which was mitigated by modified iterative reconstruction with lower number of subsets. The anatomic detail and ability to more precisely delineate the graft and anatomical structures was markedly improved by the considerable reduction in partial volume. Consistent with prior studies, the uptake kinetics of FDG in the graft and bone tunnels was elevated shortly after surgery with a lower level in the less than 6 month group. With time, the uptake intensity decreased, eventually becoming equivalent to that in the healthy knee. Ultra-High definition reconstruction is feasible even in ultra-low dose dynamic acquisition of the knee to assess graft viability using next generation digital PET. The larger reconstruction matrix reduces partial volume and thus enables the more precise assessment especially of small structures, such as those in the knee. The FDG PET/MR approach to evaluate graft viability continues to mature into a clinically feasible molecular imaging tool.

OP568

Idiopathic inflammatory myopathy: Quantification of ^{99m}Tc-pyrophosphate uptake by SPECT/CT

K. F. Thøgersen[1,2], S. Hvidsten[2], L. P. Diederichsen[3], S. Jacobsen[4], P. F. Høilund-Carlsen[2,5], J. A. Simonsen[2]; [1]Aalborg University Hospital, Aalborg, DENMARK, [2]Odense University Hospital, Dept. of Nuclear Medicine, Odense, DENMARK, [3]Odense University Hospital, Dep. of Rheumatology, Odense, DENMARK, [4]Rigshospitalet, Dept. of Rheumatology, Copenhagen University Hospital, Copenhagen, DENMARK, [5]University of Southern Denmark, Dept. of Clinical Research,, Odense, DENMARK.

Aim Diagnosing idiopathic inflammatory myopathy (IIM) can be challenging and is currently based on clinical examinations, blood analyses and muscle biopsies. Imaging is not routine. Due to the patchy distribution of pathological muscle changes in IIM, biopsies may be falsely negative, which calls for non-invasive, accurate tests to detect inflammation. We present a way to distinguish between IIM patients and healthy controls using technetium-99m-pyrophosphate (^{99m}Tc-PYP) SPECT/CT, where increased uptake indicates inflammation. **Materials and methods** We compared ^{99m}Tc-PYP SPECT/CT scans of 77 patients, 56 women and 21 men, aged 23-78 years, diagnosed with polymyositis (PM), dermatomyositis (DM) or cancer associated myositis (CAM) with scans of 48 healthy controls. We performed semi-quantitative assessment by

calculating mean standard uptake values (SUVmean) in volumes of interest (VOIs) in selected muscles and a qualitative assessment scoring the amount of tracer uptake by scores of 1 to 4 with 4 indicating highest uptake, by visual assessment to determine the uptake pattern (patchy versus not patchy). **Results** Patients had significantly higher SUVmean in all muscles of interest compared with controls (right m. triceps brachii 46.0 g·mL^{-1} vs. 30.1 g·mL^{-1}, p<0.0004, left 45.3 g·mL^{-1} vs. 30.1 g·mL^{-1}, right m. biceps brachii 48.6 g·mL^{-1} vs. 37.7 g·mL^{-1}, left 50.0 g·mL^{-1} vs 36.1 g·mL^{-1}, right m. quadriceps proximally 39.0 g·mL^{-1} vs. 28.7 g·mL^{-1}, left 39.9 g·mL^{-1} vs. 28.6 g·mL^{-1}, right m. quadriceps mid-thigh 39.8 g·mL^{-1} vs. 29.1 g·mL^{-1}, left 38.4 g·mL^{-1} vs. 28.1 g·mL^{-1}, right m. quadriceps distally 33.2 g·mL^{-1} vs. 24.1 g·mL^{-1}, left 31.5 g·mL^{-1} vs. 23.0 g·mL^{-1}, p for all <0.00001). Qualitative scores were distributed significantly different between groups with a larger fraction of patients being scored as "patchy" compared to controls (24% vs. 6% for the upper limbs, 21% vs. 6% for the lower limbs, p for both <0.02). Compared with controls, patients had a higher median visual score (2 vs. 1, p<0.0001) for their upper limbs but the same median visual score of 2 for their lower limbs. As an added bonus, qualitative assessment allowed also for localization of hot spots relevant to biopsy. **Conclusions** Quantitative assessments by ^{99m}Tc-PYP SPECT/CT consistently showed 30%-50% higher muscular uptake in IIM patients than in controls. Qualitative assessment showed higher visual uptake in the upper limbs and the patchy pattern typical of IIM was seen more often in patients than in controls. These findings put ^{99m}Tc-PYP SPECT/CT forward as having a potential role in the diagnosis and monitoring of IIM.

OP569

Innovative positioning and immobilisation techniques to refine SPECT-CT imaging of the foot and ankle

N. Soneji, D. Dalili, Y. Berkowitz, M. Vartzokas, J. Hubber, S. Yusuf, K. Wallitt, N. Davey, S. Khan, D. Amiras, H. Tam; Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Purpose: The investigation of foot and ankle pain can be challenging due to the complexity of the osseous anatomy and numerous articulations. Each imaging modality offers different benefits and limitations. SPECT-CT with 99m-Tc MDP or HDP has a high sensitivity for identifying osseous/articular pain generators (OAPG) and provides precise anatomical localisation. Failure to accurately co-register the SPECT and CT dataset through movement artefact has significant potential to lead to erroneous treatment. Various deformation-based software co-registration regimes can partially overcome this issue but may introduce other misregistration artefacts that can be more difficult to detect than the simpler image overlay method. The image overlay method, however, can only perform simple corrections for linear movements but is inadequate when there is movement at the joints. Manual correction for co-registration is also time consuming. Limb immobilisation is a simple solution that keeps the limb in an anatomical position during image acquisition and reduces movement artefact, thereby minimising the need to correct co-registration. We investigated the added value of utilising a standard Aircast® boot to immobilise the affected limb(s) and maintain anatomical alignment of the foot during SPECT-CT acquisition, comparing the diagnostic quality of these studies with those performed with the traditional use of immobilisation with tape. Methods and Materials: Retrospective review was performed of 10 consecutive patients referred for foot and ankle SPECT-CT immobilised with an Aircast® boot during image acquisition compared with 10 consecutive patients immobilised using the traditional tape method. The SPECT-CT images were then evaluated independently using a qualitative score by 2 nuclear medicine radiologists and a musculoskeletal radiologist with respect to the following categories: 1) the quality of the images 2) spatial localisation and 3) diagnostic certainty. Inter-rater agreement was compared using Fleiss kappa statistics. Performance categories of Aircast-immobilised and tape-immobilised studies were compared with Fisher's exact test. Results: Inter-rater agreement was "substantial-perfect" (0.80-0.94) for assessment of the 3 parameters. Aircast-immobilised studies showed superior image quality (p=0.014) and spatial localisation (p<0.0001) over tape-immobilised studies. This led to an improvement in diagnostic certainty where 70% of tape-immobilised scans provided optimal diagnostic certainty compared to 100% in Aircast-immobilised scans which was however non-significant (p=0.211). Conclusion: The use of an Aircast® boot during acquisition of both SPECT and CT greatly improves the quality and spatial localisation of potential OAPG.

OP570

Bone scintigraphy of feet: Considerations when moving from planar imaging to SPECT/CT alone

P. C. Holdgaard, H. C. Larsen; Department of Nuclear Medicine, Vejle, DENMARK.

AIM: Our standard imaging of feet was previously planar in 2-5 projections. We have experienced an increased use of supplementary SPECT/CT. Static images of feet require a long acquisition time and an additional SPECT/CT increases the time. We wanted to examine if the same information and conclusions could be obtained by a SPECT/CT alone, eliminating the need for planars. METHODS AND MATERIALS: Thirteen consecutive patients were scanned with both planar of feet in 5 projections and SPECT/CT with and without X-SPECT® reconstruction. Eleven of the thirteen also had a whole-body acquisition. All data were blinded and planar and SPECT/CT were first evaluated separately. All lesions were marked on an anatomical bone image and scored (1-5) for localisation certainty, intensity, intensity certainty and pathological degree. Also a conclusion was given and overall score (1-5) for the reporters diagnostic certainty, difficulty to interpret and time usage. Finally the exams were unblinded and the results were compared side by side for each patient. X-SPECT® reconstruction was qualitatively compared with the SPECT/CT RESULTS: SPECT/CT scored better for localisation (p<0,01), a tendency to score lesions more intense (p=0,07), a little higher pathological degree on lesion basis (p=0,01), same intensity certainty (p=0,97) and same number of lesions (p=0,23). Overall conclusion on patient basis: the planar scored higher on diagnostic certainty (p=0,02), felt easier to interpret (p=0,01) and were faster to interpret (p<0,01). Overall X-SPECT® reconstructions showed the same lesions as SPECT/CT but with reduced intensity, consistent with planar findings. General learning points were: Characterisation of lesions on CT (5 of 13 patients) can help the aid diagnosis. Appropriate thresholding of SPECT images is difficult in minor lesions. Absolute quantification would be helpful. CT volume rendering was useful for localisation in the small bones where cross-sectional imaging is difficult. In future acquired planar images could be substituted with reprojections from the SPECT. CONCLUSION: The SPECT/CT alone images in all the patients gave the same information as planars and as expected, improved localisation and reduced the total acquisition time when done without planars. Awareness of interpretation should be given to small weak lesions that look more pathologic on SPECT/CT compared with reporting practice for planars.

OP571

Hybrid SPECT/CT images in the evaluation of patient with rheumatoid arthritis of the hand: Correlation with clinical features and MRI

M. Yoo[1], S. Ha[1], J. Paeng[1], D. Lee[1], J. Chung[1], K. Kang[1], S. Hong[2], Y. Song[3], G. Cheon[1]; [1]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Department of Radiology and Institute of Radiation Medicine, Seoul National University College of

Medicine, Seoul, KOREA, REPUBLIC OF, [3]Division of Rheumatology, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.
Purpose: The assessment of rheumatoid arthritis (RA) involvement in hand has been limited to multipinhole single photon emission computed tomography (SPECT) in nuclear medicine due to the small size of the hand joints. We investigated the diagnostic value of SPECT-CT hybrid images in small joint arthritis of hand in patients with rheumatoid arthritis. Methods: Hybrid SPECT-CT scan with Technetium-99m methylene diphosphonate and 3-tesla magnetic resonance imaging (MRI) were prospectively performed in 15 patients with rheumatoid arthritis, and 3 healthy control subjects. Total 338 joints consist of 170 metacarpophalangeal (MCP) joints and 168 proximal interphalangeal (PIP) joints were investigated. SPECT-CT hybrid images were analyzed using semi-quantitative assessment by region-of-interest (ROI) analysis. For MR images analysis, synovitis and bone inflammation were scored following the subscores of the Rheumatoid Arthritis MRI Score (RAMRIS). The clinical symptoms about tenderness and swelling of the finger joints were also investigated. Result: The SPECT-CT uptake ratio of total joints demonstrated significant correlation to the RAMRIS score ($r=0.671$, $p<0.0001$). The mean uptake ratio of hand joints in healthy control subject and patient with rheumatoid arthritis were 1.48 ±0.27 and 2.66±1.89, respectively. The SPECT-CT uptake ratio of total joints showed significant difference according to the presence of swelling and tenderness (2.13±1.40 vs 3.70±2.28, $p<0.01$ and 2.13±0.9 vs 3.11 ±2.34 $p<0.01$, respectively). In PIP joints group, SPECT uptake ratio showed significant difference between the subgroups which stratified by the score of RAMRIS ($p<0.01$). But in MCP joints group, the SPECT-CT uptake ratio only showed significant difference between normal and severe synovitis subgroups ($p<0.01$). Conclusion: Hybrid SPECT/CT images of the small finger joints in patients with RA can reflect the severity of bone inflammation affected by severity of the synovitis. Hybrid SPECT/CT images can be useful to localize and measure the severity of active arthritis in hand with RA.

OP572

Can the associated use of SPECT/CT in vertebral bone scintygraphy help to identify different lesions in patients with previous spinal fusion?

A. L. Santos Carreño, O. Ajuria Ilarramendi, A. Ortega Manrique, M. E. Rioja Martin, P. Paredes Rodriguez, J. M. Castro Beiras; Hospital Universitario Ramon y Cajal, Madrid, SPAIN.

Purpose: The aim of this study is to compare the findings of ^{99m}Tc HDP bone selective planar scintygraphy with SPECT/CT in patients with previous spinal fusion. Materials and methods: We analyzed 118 patients with spinal fusion, since July/2011 until April 15/2016, who were referred for a bone scintigraphy study. A two-phases vertebral bone scan was performed with ^{99m}Tc HDP including pool imaging followed by a delayed selective image. A SPECT/CT imaging centred over the localization of spinal fusion was subsequently performed. The median age was 60,5 years. 66 were female and 35 male. The median time from surgery for the study was 23,5 months with a range of 5 to 278 months. Results: We review 118 patients. 7 patients were excluded because they didn't have spinal fusion at the time of the study; we didn't found planar image in 4 and SPECT/CT in 6. Finally 101 patients have been analyzed. The planar study and SPECT/CT were normal in 3 patients. 37 patients had normal planar study, but in the SPECT/CT were found different kinds of lesions; 22/37 patients had screw lossening in the SPECT/CT, and 15/37 had degenerative changes or uptake (abnormal/normal) in the bone injert of posterior fusion. 61 patients had abnormal uptake in the planar study and the SPECT/CT. 33/61 patients had screw loosening in the SPECT/CT, 24 of these patients had only non-specific changes (degenerative) in the planar study, 2 were classified by compression fracture in planar, and 7 were classified as pathological by viewing the bone injert of posterior fusion. 12 patients had compression fracture in the SPECT/CT, 3 also viewed in planar, and one of them with screw loosening associated. The compression fracture was only viewed in SPECT/CT in 9 patients. The remaining patients had minor injuries like degenerative changes or uptake (abnormal/normal) in the bone injert of posterior fusion. Conclusion: In patients who have previous spinal fusion, the associated use of SPECT/CT in vertebral bone scintygraphy, allows to increase the sensitivity for identifying lesions and also contributes to help detect other different types of injuries.

OP573

Stress injury detection with three phase dynamic Tc-99m MDP bone scan in adult athletes with calf pain;Contribution of SPECT/CT, preliminary findings

A. Ayan[1], B. Gunalp[1], E. Balkan[1], S. İnce[1], K. Okuyucu[1], A. Orscelik[2], N. Arslan[1]; [1]Gulhane Military Medical Academy,Department of Nuclear Medicine, ETLIK/ANKARA, TURKEY, [2]Gulhane Military Medical Academy,Department of Sports Medicine, ETLIK/ANKARA, TURKEY.

Aim :Stress fractures in the lower extremity are common injuries among individuals who participate in endurance , high load bearing activities as running, military training.Therefore require proper diagnosis which is necessary for appropriate management . Our aim in this study was to evaluate stress injury type with three phase bone scan, contribution of SPECT/CT and relation of symptom duration in adult athletes with calf pain. Patients and Methods :128 patients (10 female,118 male) with a mean age of 23,63 ±5,96 with tibial pain who had undergone a three phase dynamic Tc-99m MDP bone scan between January 2014 and March 2016 were included to the study. Their medical histories, radiologic examinations, bone scan findings and SPECT/CT findings were reviewed retrospectively . Stress injury types were determined up to their uptake features and intensity in three phase dynamic images. In case of subtle, inappropriate or other sites of uptake in whole body images then a SPECT /CT was performed. Among 128 patients 36 had also undergone a SPECT /CT scan. Duration of symptoms were statistically analyzed.Results :63/128 bone scan revealed one or more foci compatible with stress injury. 36/128 patients had also a SPECT / CT scan . 17 /63 patients who have stress injury in bone scans had positive findings bilaterally. SPECT /CT images revealed stress fractures of metatarsal region in nine patients and also demonstrated five other causes of Tc-99m MDP uptake which were a fibroxantoma , a giant cell bone tumour, a polyosthotic bone disease , an osteoid osteoma and a unilateral sacroileitis.Duration of tibial pain symptoms was 21,17±19,95 weeks Our statistical analysis demonstrated that in 5/31 patients with stress injury symptoms lasting more than 36 weeks only five had a positive bone scan or a stress injury compatible lesion in SPECT/CT findings whereas the positive bone scan and SPECT/CT findings were 39/58 patients with symptoms lasting less than 36 weeks. ($p<0,0001$). Conclusion:Dynamic -three phase bone scan is a conventional method in assessing stress injuries. Perfusion and blood pool images are essential parts of bone scan in definition of stress injuries. SPECT/CT imaging has a leading role for better anatomic and morphologic characterization of injury and for also other musculoskeletal disorders that may offer a different opportunity for treatment and follow ups. Duration of symptoms may also be an important factor in defining probable stress injury patients.

OP581

Mono-layer cell culture kinetics and dosimetry for intracellular uptake of ^{177}Lu-DOTA-octreotate in the Golgi apparatus

M. W. Konijnenberg[1], D. C. van Gent[2], M. de Jong[1], J. Nonnekens[2]; [1]Radiology & Nuclear Medicine, Erasmus MC, ROTTERDAM, NETHERLANDS, [2]Molecular Genetics, Erasmus MC, ROTTERDAM, NETHERLANDS.

Background: The dose-response relation is not well known for tumour cell survival after Peptide Receptor Radionuclide Therapy (PRRT) with ^{177}Lu-DOTA-octreotate. Dosimetry models for spherically shaped cells are available, e.g. MIRDcell dosimetry. Monolayer cultured cells and especially their cytoplasms are far from spherical, but more spread-out. Possible source compartments within the cell are cell membrane, cytoplasm, Golgi apparatus and cell nucleus. Exact dosimetry is needed for somatostatin-receptor subtype 2 (SSTR2)-positive cells after escalating amounts of ^{177}Lu-DOTA-octreotate to evaluate the radiobiology of low dose rate PRRT in comparison to external beam exposure. **Materials and Methods:** 10^5 Human osteosarcoma cells stably expressing SSTR2 were plated in 12-well plates (1.12 cm^2). The next day the cells were incubated for 4h with 5×10^{-8}M/2.5MBq or 5×10^{-9}M/0.25MBq ^{177}Lu-DOTA-octreotate (specific activity 53MBq/nmol) and the medium was refreshed. Both uptake and clearance kinetics of ^{177}Lu-DOTA-octreotate in medium, cell surface and intracellular fraction were determined at 15 minutes intervals during the 4h incubation phase and then at 24h intervals over a 6 day irradiation phase. The morphology of the cells was determined using fluorescent confocal microscopy. A stylized fluid drop model of 5x5 cells was developed in the Monte Carlo code MCNP6. The cell membrane, cytoplasm and Golgi apparatus were modelled as source volumes within the central cell. The emission spectra from ^{177}Lu were used to calculate absorbed doses to all cell compartments, both in the source cell as in neighbouring cells. **Results:** Cellular uptake of ^{177}Lu-DOTA-octreotate from the medium proceeded with a half-life of 31.1±0.2 minutes and reached 13.1±0.3 %AD (Added Dose) after 4h. The internalized activity of 0.0135±0.0002 %AD/cell showed a bi-phasic clearance: 97% with 14.7±0.6h half-life and 3% with $T_{1/2}$>160 h. Staining showed that the intracellular uptake was >90% confined to the Golgi apparatus. The resulting absorbed dose S-values were within 15% of the MIRDcell S-values, but the S-value for activity in the Golgi was 45% lower than a homogeneous activity distribution in the cytoplasm. The absorbed dose to the cells was 1.5Gy for 0.25MBq and 2.4Gy for 2.5MBq. Homogeneous cytoplasmic uptake of the internalized activity would have led to absorbed doses of 2.4 and 3.7Gy, respectively. **Conclusion:** ^{177}Lu-DOTA-octreotate targets to the Golgi apparatus after internalisation. A mono-layer dosimetry model for the in-vitro cell plating experiments has been developped and led to significant changes in the cell dosimetry for source activity in the Golgi apparatus. More reliable dose-effect curves are now possible in cell survival after PRRT.

OP582

CD 44 Glioblastoma stem cells and resistance to alpha ionizing radiation: new insights into therapy

E. Rosiak[1], R. Matyskiel[1], H. Koziara[2], B. Królicki[2], L. Królicki[1]; [1]Department of Nuclear Medicine, Medical University of Warsaw, Warsaw, POLAND, [2]Department of Neurosurgery, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, POLAND.

AIM: Alpha-particles have a particular advantage in targeted therapy because of their high potency and specificity. Targeted alpha therapy with ^{213}Bi-labeled DOTA-Substance P (^{213}Bi-SP) is a promising novel option for local therapy in patients with recurrent glioblastoma multiforme (GBM). Glioblastoma multiforme (GBM) resistance to ionizing radiation has been hypothesized to be mediated by a tumor subpopulation, called cancer stem cells (CSCs). The aim was to investigate whether CD44 (+) CSCs contribute to the radioresistance of GBM to alpha therapy.**MATERIALS**: CD 44 (+) CSCs and CD44(-) GBMs cells *in vitro* were obtained from surgical tumor samples from 58 patients with histologically confirmed of GBM . The glioblastoma cells were treated with single dose of 1,2MBq ^{213} Bi-SP/1ml medium and cultured for 10 days under normoxia. **METHODS**: Following flow cytometry, CD44(+) CSCs and CD44(-) GBM cells were isolated using magnetic cell separation. The level of apoptosis and necrosis we performed by flow cytometry. Expression of *VEGF* (Vascular Endothelial Growth Factor) mRNA and stem cell marker CD44 mRNA were analyzed by semiquantitative RT-PCR. Experimental data was obtained at 1 h, 3 h, 6 h, 12 h, 24 h, 48 h, 72 hours and 10 days after application of isotopes for cell cultures. **RESULTS:** 72 hours after the treatment with ^{213} Bi-SP apoptosis level was significantly higher in CD44 (-) GBM cells than in CD44 (+) CSCs (74± 3.46 % v 49± 2.00 p=0.001). 10 days after treatment 32,00 ± 7.06 % of the CD44(+) CSCs survived and 100% ± 0.00% of CD44 (-) GBM cells died (p = 0.001). 10 days after irradiation CD44 (+) CSCs and CD44 () GBM cells had significantly higher the expressions of VEGF than before irradiation (3.8-fold and 3-

fold respectively). We found fourfold increased gene expression of CD44 in CD44 (-) GBM cells. **CONCLUSION:** CD44(+) stem cells play an important role in radioresistance of GBM. These cells possess a greater potential to survive alpha radiation and may contribute to the recurrence of GB. Therefore therapeutic strategies that selectively target CD44(+) CSCs , combined together with alpha ionizing radiation and anti-angiogenic agents need further evaluations .

OP583

Evaluation of S Values for Beta Particles with Monte Carlo Code Gate V6.2 for Unit Density Spheres of Various Sizes

A. BORA; Yeditepe University, ISTANBUL, TURKEY.

Objective: In this study, it was aimed to test the efficiency of Monte Carlo Code GATE V6.2 in dosimetric applications for small structures by evaluation of S-values for unit density spheres in various radii. **Method:** Spheres with various radii (0.133650 cm to 6.203505 cm) and masses (0.01 g to 1000 g) are simulated. All the spheres are filled with water. Different sources (^{131}I, ^{90}Y, ^{18}F) with 10MBq activity are used. Source related decay data are acquired from MIRD RADTABS program. GATE V 6.2 includes DoseActor tool for internal dosimetry applications was preferred to use . Calculation of absorbed dose is made as follows; (1) dose due to a particle is calculated (Gy/Particle), (2) the result is multiplied by the abundance of the related radionuclide, (3) unit conversion is made from Gy/Bq-s to mGy/MBq-s. Data that are acquired from the simulation is compared with the reference data from Radiation Dose Assessment Resource (RADAR). **Results:** For ^{131}I, spheres with mases 0.01g. to 0.5 g have relative errors between 8.16-10.41 %, while spheres with masses 1g - 1000 g have relative errors between 4.13% to 6.73%. For ^{90}Y, spheres with masses 0.01g. to 40 g have relative errors between 14.71-6.94 %, while spheres with masses 100g to 1000 g have relative errors between 6.01 % to 1.44 %. For ^{18}F,spheres with masses 0.01g. to 0.5 g have relative errors between 6.69-6.12 %,while spheres with masses 1g to 1000 g have relative errors between 2.72 % to 3.68 %. **Conclusion:** Unit Density Sphere model (UDSM) S-value results are accurate when compared to the reference values especially for bigger sphere masses. As the structure of sphere (tumor or cancer cell clusters) gets smaller, radionuclide properties becomes significant for dose calculations. The administered dose depends on tumor structure and radionuclide properties. Monte Carlo Code GATE V6.2 is an efficient code for assessment of internal dosimetry applications. Simulation results are highly correlated with reference values.

Development of an early brain metastasis geometric model for Geant4-DNA simulation

N. Falzone[1], X. Liu[1], M. Bernal[2], A. Corroyer-Dulmont[1], M. Sarmiento Soto[1], N. R. Sibson[1], K. A. Vallis[1]; [1]University of Oxford, Oxford, UNITED KINGDOM, [2]UNICAMP, Campinas, BRAZIL.

AIM: Brain metastases develops frequently in patients with lung and breast cancers, however treatment is mainly palliative and commonly comprises whole-brain irradiation. The pressing therapeutic challenge presented by brain metastases is the need to treat the whole brain in a molecularly targeted manner at an early stage when relatively few metastatic tumour cells have invaded the brain parenchyma. The aim of this preliminary study is to develop a geometric model of early brain metastasis to evaluate the theoretical efficacy of α- and β-emitting radionuclides for molecular radiotherapy (MRT). **MATERIALS AND METHODS:** Histological sections of mouse brain parenchyma were used to inform vessel diameter and cell geometry. The Geant4-DNA general purpose Monte Carlo (MC) simulation toolkit was used to simulate the coupled transport of charged particles and photons of ^{212}Pb (an α emitter) and ^{177}Lu (a short range β^- emitter) and tallied the energy losses produced when the complete decay spectra interacted with liquid water. Energy deposition was evaluated at various positions as a radial function from the point source at the centre of the vessel. The energy deposition phase space at some discrete radius value were superimposed on a atomic resolution DNA geometrical model to estimate single- and double-strand break yields. In particular, double-strand break yield can serve as an indicator of the biological effectiveness of the radiation qualities in question. **RESULTS:** Energy deposition decreased as a function of radial distance from the linear source represented by the vessel, and the range of the particulate radiation. ^{212}Pb may be more suitable for short range targeting of early invasive cancer cells than ^{177}Lu. Double-strand break yield tends to increase with the capacity of radiation to form energy deposition clusters. **CONCLUSION:** MC simulation of an early brain metastatic model could provide invaluable insight into the potential efficacy of α- and β-emitting radionuclides for MRT. Furthermore, the model can be extended as a predictive indicator of DNA double-strand break production by specific radionuclides.

OP585

The mTOR inhibitor temsirolimus acts as a radiosensitizer in neuroendocrine tumor cells

S. Exner, S. Erdmann, V. Prasad, C. Grötzinger; Charité - Universitätsmedizin Berlin, Berlin, GERMANY.

Neuroendocrine tumors (NETs) express somatostatin receptors that are currently utilized for diagnostic and therapeutic approaches. For peptide receptor radionuclide therapy (PRRT), somatostatin analogs are coupled to radionuclides like 90Y or 177Lu, which after injection are bound and taken up specifically by NETs. PRRT can deliver radiation doses of up to 250 Gy to the tumors. Nevertheless, complete remission is extremely rare, compared to similar radiotherapies for thyroid cancer and non-Hodgkin lymphoma. The additional use of radiosensitizing agents could be a promising approach. In that way, mTOR inhibitors like temsirolimus may contribute to an improved therapeutic outcome of PRRT. To investigate this, NET cell lines of different origin were incubated with or without temsirolimus and exposed to different radiation doses from an external 137Cs source between 0 and 10 Gy. Cells were harvested at distinct timepoints, stained with propidium iodide and the cell cycle distribution was assessed by FACS analysis. In addition, proliferation and viability were assessed by alamar blue assay, cell counting and clonogenic assay. Initially, the response of five neuroendocrine tumour cell lines (BON, H727, QGP-1, LCC18, UMC11) to temsirolimus was investigated. The treatment with different concentrations resulted in a biphasic inhibition of cell proliferation with two IC50 values in the nanomolar and micromolar range, respectively. Further on, temsirolimus induced a G1 arrest in the tumor cells after 24 hours as measured by cell cycle analysis. In radiation experiments all tested NET cell lines showed a radiation-induced decline in G1 cells as well as a G2/M arrest and a reduced clonogenic survival after radiation. In contrast, additional pretreatment with temsirolimus revealed an increase of cells in G1 and a decrease of the radiation-induced G2/M arrest. The combined therapy also showed a reduced viability and clonogenic survival of the tumor cells compared to radiation or temsirolimus treatment alone. In this particular case, the G1 arrest seems to sensitize NET cells to radiation therapy. Further experiments using 177Lu-Octreotate instead of an external radiation source are planned to simulate PRRT in vitro. Additional studies, especially in vivo, are needed to better understand the influence of radiosensitizing agents like temsirolimus on neuroendocrine tumor cells to pave the way for a significant increase in the overall therapeutic efficacy of PRRT.

OP586

Synergistic Treatment of KLK10 and Iodine-131 in PC3 Cell Line

J. Hu[1], Q. Qu[1], Y. Miao[1], Y. Wu[2], B. Li[1]; [1]Department of Nuclear Medicine, Rui Jin Hospital, Shanghai Jiaotong University, School of Medicine, Shanghai, CHINA, [2]Department of Pathophysiology, Key Laboratory of Cell Differentiation and Apoptosis of Chinese Ministry of Education, Shanghai Jiaotong University, School of Medicine, Shanghai, CHINA.

Aim: The tumour suppressor role of KLK10 gene in PC3 cell line has been proven in our previous study, by repressing proliferation, enhancing apoptosis and decreasing glucose metabolism. Radiotherapy is also an important treatment method for prostate cancer. Based on this, our study is to investigate the effect of synergistic therapy of KLK10 gene and radioactive iodine 131 in PC3 cell line. **Materials and methods:** To transfer KLK10 and sodium/iodide symporter (hNIS) gene into PC-3 with the recombinant lentiviral vector (pLVX-KLK10-IRES-hNIS-puro) to up-regulate the KLK10 and hNIS expressions. The high-purity, high KLK10 and hNIS stable expressing cell line, named as PC-3-KLK10-hNIS, was obtained by puromycin selection, and confirmed by western blot. Via the same method, PC-3-0-hNIS cell line was obtained as radiation therapy control, PC-3-KLK10-0 cell line as single gene therapy control, PC-3-CON cell line as negative control. Iodine 125 uptake, efflux, as well as uptake-inhibition by NaClO4 assays were undergone in these four cell lines to detect the function of hNIS protein. After iodine 131 treatment, experiments of CCK-8 cell proliferation, cell clone formation and cell cycle were done with these radiation and non-radiation cell lines to evaluate the treatment effect. **Results:** The stable NES1 expression in PC-3-KLK10-0 and PC-3-KLK10-hNIS cell lines was validated by western blot. Interestingly, the hNIS expression could be detected in PC-3-KLK10-0 and PC-3-CON cell lines, although it was much lower than that in PC-3-0-hNIS and PC-3-KLK10-hNIS cell lines. However, the function of hNIS protein in PC-3-KLK10-0 and PC-3-CON cell lines was almost invalid respectively, because the uptake level of iodine 125 was extremely low. The hNIS over-expressed cell lines had the obvious iodine 125 uptake ability. The peak value and peak time in PC-3-0-hNIS was 6.2 times than that in PC-3-CON and at 60 min, as well as those in PC-3-KLK10-hNIS was 4.6 times and at 120 min. And NaClO4 could inhibit the uptake abilities of these two cell lines. Iodine 125 efflux from cell cytoplasm to extracellular could be detected constantly lasting for 2 hours. After 16 h radiation of iodine 131(3.7 MBq per $4*10^5$ cells), the growth rate of PC-3-KLK10-hNIS was lowest in all cell lines, consistent with the result of cell clone formation assay. Cell cycle assay showed a cell arrest in G1 phase of PC-3-KLK10-hNIS cell line. **Conclusion:** The effect of synergistic therapy of KLK10 gene and radioactive iodine 131 in PC3 cell line was better than single method treatment.

A new bifunctional chelator for ^{89}Zr-immuno-PET: DFO*-pPhe-NCS and the comparison with the current clinical standard DFO-pPhe-NCS

D. J. Vugts[1], C. Klaver[1], C. Sewing[1], A. J. Poot[1], K. Adamzek[1], S. Huegli[2], C. Mari[2], I. E. Valverde[3], G. Gasser[2], T. L. Mindt[4,5], G. A. M. S. van Dongen[1]; [1]VU University Medical Center, Amsterdam, NETHERLANDS, [2]University of Zurich, Zurich, SWITZERLAND, [3]University of Basel Hospital, Basel, SWITZERLAND, [4]ETH, Zurich, SWITZERLAND, [5]General Hospital of Vienna, Vienna, AUSTRIA.

Objectives: Desferrioxamine (DFO) is currently the chelator used in clinical ^{89}Zr-immuno-PET studies. This chelator, however, does not provide full coordination of Zr^{4+} and leaves two coordination sites available for coordination of e.g. water molecules, which are relatively labile ligands. The incomplete coordination of ^{89}Zr by DFO has been suggested to result in instability of the complex and as a consequence, in unwanted bone uptake of the radionuclide *in vivo*. Recently, DFO*, the octadentate version of DFO has been developed, which provides full coordination of ^{89}Zr. This new chelator showed excellent *in vitro* stability in DFO challenging experiments.[1] Following this promising result, now DFO*-*p*Phe-NCS has been synthesized and used to prepare ^{89}Zr-DFO*-mAb conjugates which are *in vitro* and *in vivo* compared with the current standard ^{89}Zr-DFO-mAb. **Methods:** DFO* was reacted with *p*-phenylenediisothiocyanate resulting in bifunctional DFO*-*p*Phe-NCS. Next, DFO*-*p*Phe-NCS and DFO-*p*Phe-NCS (i.e. DFO-Bz-NCS, Macrocyclics) were reacted with trastuzumab, cetuximab and rituximab and radiolabeled with ^{89}Zr according to literature procedures.[2] For *in vitro* and *in vivo* comparison, trastuzumab was used as model protein. *In vitro* stability experiments were performed in 0.9% NaCl, histidine/sucrose and serum. *In vivo* the two complexes were compared in a N87 tumor xenograft model. **Results:** All antibody conjugates could be radiolabeled with >80 % efficiency at 0.5 mg/mL resulting in radioimmunoconjugates with a good radiochemical purity (>97.5%) and optimal immunoreactive fraction (>90%). *In vitro* stability of ^{89}Zr-DFO*-trastuzumab was superior over ^{89}Zr-DFO-trastuzumab in 0.9% NaCl showing after 3 days at 4°C for ^{89}Zr-DFO-trastuzumab 57.6% intact tracer and for ^{89}Zr-DFO*-trastuzumab 94.5% intact tracer. In histidine/sucrose both products were stable and there was no difference in stability. In human serum ^{89}Zr-DFO*-trastuzumab was also more stable than ^{89}Zr-DFO-trastuzumab: after 72 h at 37°C 97.5% and 77.7% intact tracer was left, respectively. The *in vivo* tumor uptake of both conjugates was comparable: 32.6 ± 12.0 and 29.1 ± 8.7 % ID/g for DFO* and DFO-conjugates at 144 hr post injection, respectively. Bone uptake was gradually increasing for ^{89}Zr-DFO-trastuzumab, while gradually decreasing for ^{89}Zr-DFO*-trastuzumab resulting in a >3.6 fold higher uptake in bone containing organs for DFO. **Conclusion:** The octadentate chelator DFO* holds great promise as new chelator for ^{89}Zr-immuno-PET studies given its improved *in vitro* stability and *in vivo* performance. **References:** 1. M. Patra et al., Chem. Commun. 2014, 50, 11523-11525. 2. M.J.W.D. Vosjan et al, Nature Protocols 2010, 5, 739-743.

OP588

MA-NOTA: a new chelator for efficient ^{64}Cu antibody radiolabeling

M. Moreau[1], S. Poty[1], J. Vrigneaud[2], P. Walker[3], M. Guillemin[2], O. Raguin[4], A. Oudot[2], C. Bernhard[1], C. Goze[1], F. Boschetti[5], B. Collin[1,2], F. Brunotte[2,3], F. Denat[1]; [1]ICMUB - UMR CNRS 6302, Dijon, FRANCE, [2]Centre G.-F. Leclerc, Dijon, FRANCE, [3]Le2i - UMR CNRS 6306, Dijon, FRANCE, [4]Oncodesign, Dijon, FRANCE, [5]CheMatech, Dijon, FRANCE.

Introduction: ^{64}Cu has an ideal half-life for studies of labeled fragments of antibodies and such radiotracers have attracted considerable interest in the field of targeted radionuclide therapy and diagnosis. Unfortunately, the chelation of copper is not as easy as that of other metals and the release of copper is a limiting issue for its use. We hypothesized that MA-NOTA might be a highly efficient chelator for ^{64}Cu labeling and the aim of the present study was to compare the biodistribution of the radioactivity after intravenous injection of Fab-fragments of antibodies conjugated to various bifunctional chelators (BFC), DOTA, DOTA-GA, NODA-GA and MA-NOTA in mice bearing subcutaneous tumors. **Method**: These four chelators, bearing a *p*-benzyl-isothiocyanate functionalization group, were conjugated to Fab-trastuzumab - which targets the HER2/neu receptor - and were radiolabeled with ^{64}Cu. Stability of the formed complexes was evaluated by competition with 2,000 fold EDTA at 37°C. *In vitro* binding assays were performed on HCC1954 cells to determine affinity and immunoreactivity of the four radioimmunoconjugates. Finally, PET/MR imaging and biodistribution studies were performed in mice-bearing breast cancer BT-474 xenografts overexpressing HER2 in order to compare the four radiolabeled Fab-trastuzumab. **Results**: The degree of

conjugation ranged from 2.4 to 4.3 macrocycles per Fab. Radiolabeling of the immunoconjugates with ^{64}Cu was performed in high yields after 45 min at 37 °C, and the purity of each ^{64}Cu-BFC-Fab-trastuzumab reached 97 % after purification. The complexes showed relatively good stability during competition with 2,000 molar excess of EDTA at 37°C (88 % to 95 % at 48 h). The affinity of each ^{64}Cu-BFC-Fab-trastuzumab ranged from 10.1 ± 2.5 nM to 49.3 ± 5.9 nM as evaluated by *in vitro* binding assays using HCC1954 breast cancer cell, and immunoreactity was > 30 %. BT-474 tumors were clearly visualized on PET images at 4 and 24 h post-injection. The tumor uptakes of ^{64}Cu-BFC-Fab-trastuzumab reached 8.9 to 14.2 %ID/g 24 h post-injection and significant differences in liver uptake were observed depending on the attached BFC, with the lowest uptake for MA-NOTA-conjugated fragments. **Conclusion**: As the liver uptake of the ^{64}Cu has been shown to increase with the instability of the chelation, the present results suggest that *p*-NCS-MA-NOTA stands out from the other chelators, including the commonly used DOTA and NODA-GA, as the most promising BFC for radiolabeling antibodies with ^{64}Cu.

OP589

Development and application of first ^{44}Sc-labeled Affibody molecule

H. Honarvar[1], C. Müller[2], N. van der Meulen[2], S. Cohrs[2], K. Westerlund[3], A. Eriksson Karlström[3], R. Schibli[2], V. Tolmachev[1]; [1]Rudbeck Laboratoriet, Uppsala, SWEDEN, [2]Paul Scherrer, Villigen-PSI, Zurich, SWITZERLAND, [3]School of Biotechnology, KTH Royal Institute of Technology, Stockholm, SWEDEN.

Aim: Treatment with the anti-HER2 antibody trastuzumab improves survival of breast cancer patients with tumours having high HER2-expression (3+ according to immunohistochemistry using HercepTest). Affibody molecules are small (7 kDa) scaffold proteins, which can be used as molecular imaging probes. A clinical study has demonstrated that PET-imaging using ^{68}Ga-labeled Affibody molecules enables discrimination between breast cancer metastases with high (3+) and low (2+ or less) HER2-expression. The best discrimination was obtained at 4 h p.i.; however the half-life of ^{68}Ga resulted in low activity in tumours. Scandium-44(94.27% β^+ branching) is a positron-emitting radionuclide with 3.5-fold longer half-life than ^{68}Ga, which is favourable for imaging over several hours. The aim of this study was to develop and evaluate ^{44}Sc-labelled HER2-binding Affibody molecules for PET imaging. **Material and Methods:** The synthetic second generation anti-HER2 DOTA-$Z_{HER2:2891}$ Affibody molecule was labelled with ^{44}Sc and, for comparison, with ^{68}Ga. In vitro binding specificity and cellular processing of radioconjugates was studied using HER2-expressing SKOV3.ip cells. An in vitro competitive binding assay was performed using ^{111}In-DOTA-$Z_{HER2:2891}$ and conjugates loaded with non-radioactive gallium and scandium. The biodistribution of ^{44}Sc-DOTA-$Z_{HER2:2891}$ and ^{68}Ga-DOTA-$Z_{HER2:2891}$ was compared in nude mice bearing SKOV3.ip xenografts. To verify in vitro specificity, mice with HER2-negative Ramos xenografts were used. Imaging studies were performed with a G8 benchtop PET/CT scanner. **Results:** The difference between IC_{50} for ^{nat}Ga-DOTA-$Z_{HER2:2891}$ (5±2nM) and ^{nat}Sc-DOTA-$Z_{HER2:2891}$ (6±2nM) was not significant. The binding of the ^{44}Sc-DOTA-$Z_{HER2:2891}$ to SKOV3.ip was HER2-specific in vitro and in vivo. Biodistribution patterns of ^{44}Sc- and ^{68}Ga-DOTA-$Z_{HER2:2891}$ were similar. There was no significant difference between tumour uptake of ^{44}Sc-DOTA-$Z_{HER2:2891}$ (12.8±1.6 %ID/g) and ^{68}Ga-DOTA-$Z_{HER2:2891}$(14.4±2.1 %ID/g), at 3h p.i., however the tumour-to-blood ratio for ^{68}Ga-DOTA-$Z_{HER2:2891}$ (46±9) was higher than for ^{44}Sc-DOTA-$Z_{HER2:2891}$(15±2). The radioactivity concentration in blood and normal organs decreased significantly for ^{44}Sc-DOTA-$Z_{HER2:2891}$ at 6h p.i., resulting in tumour-to-blood ratio of 51±8. The tumour uptake was 8.2 ±2.1%ID/g at this time point. PET/CT imaging confirmed the results of biodistribution experiments showing distinct uptake of the ^{68}Ga- and ^{44}Sc-labeled Affibody molecules in SKOV3.ip tumours while accumulation in Ramos tumours was almost absent **Conclusion:** For the first time ^{44}Sc was successfully used for labelling of an Affibody molecule. In this pilot preclinical study ^{44}Sc-DOTA-$Z_{HER2:2891}$ proved to be useful for imaging of HER2-expressing tumours at several hours after injection. Our results hold promise for future application of ^{44}Sc-labeled Affibody molecules in the clinics.

OP590

Anti HER2 Nanobody Labeled with ^{225}Ac as a Potential Radiopharmaceutical for TRT

M. Pruszyński[1], E. Cędrowska[1], V. Radchenko[2], K. D. John[2], F. Bruchertseifer[3], A. Morgenstern[3], M. D'Huyvetter[4], T. Lahoutte[4]; [1]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [2]Los Alamos National Laboratory, Los Alamos, NM, UNITED STATES, [3]Joint Research Centre – Institute for Transuranium Elements, Karlsruhe, GERMANY, [4]Vrije Universiteit Brussel, Brussels, BELGIUM.

Aim: Human epidermal growth factor receptor type 2 (HER2) is overexpressed in breast, ovarian, non-small cell lung, gastric and colon cancers, and portends poor prognosis. Intact mAbs are not always ideal vectors for radioimmunotherapy due to their slow pharmacokinetic and normal-tissue clearance. Nanobodies (Nbs) are single domain antibodies derived from *Camelidae*. Their small size (~15kDa), nM-range affinity, low immunogenicity, rapid clearance from blood and normal tissues and ease of tumor penetration make them a very attractive platform for targeted radionuclide therapy (TRT). The goal of this study was to develop and characterize a potential molecular-targeted drug based on the anti-HER2-Nb labeled with ^{225}Ac. Materials and methods: The anti-HER2 2Rs15d-Nb was conjugated with *p*-SCN-Bn-DOTA, purified and DOTA-2Rs15d-Nb analyzed by mass spectrometry. DOTA-2Rs15d-Nb was labeled with ^{225}Ac and with the more conventional radioisotope ^{177}Lu for comparison, and finally obtained radiobioconjugates were evaluated by TCA precipitation, ITLC, and gel electrophoresis. Stability was determined in PBS, human serum and cell culture medium for 10 days at RT and 37^{o}C. Binding specificity and affinity assays were evaluated using SKOV-3 (HER2+) and MDA-MB-231 (HER2-) cells; immunoreactive fraction (IF) by the Lindmo method. Cell viability was assessed using the MTS colorimetric assay. Results: DOTA-2Rs15d-Nb conjugate was labeled with ^{177}Lu and ^{225}Ac with an efficiency of 81.1 ± 15.4% (n = 3) and 87.2 ± 8.8% (n = 8), respectively. TCA precipitation, ITLC, and SDS-PAGE indicated that >95% of radioactivity was protein-associated. Stability in biological solutions, according to ^{225}Ac radionuclide, was above 90% over 10d. Radiobioconjugates bound specifically to HER2 on SKOV-3 cells with 69-83% IF and a Kd of 4.06 ± 0.45 nM. Blocking of HER2 with 100>excess of cold 2Rs15d-Nb reduced binding almost 30-fold, whereas cold Trastuzumab did not compete with radiobioconjugates to binding sites. Low level of binding (0,3%) was observed for MDA-MB-231 (HER2-) cell line. Internalization assay indicated about 40% of initially bound radioactivity was trapped intracellularly for ^{177}Lu-DOTA-2Rs15d-Nb over 24h. Cytotoxicity studies demonstrated that ^{225}Ac-DOTA-2Rs15d-Nb significantly reduced SKOV-3 cell viability in a dose dependent manner. The estimated median lethal dose values (LD_{50}), after 24-h incubation, were equal to *ca.* 1.5 kBq/mL and 350 kBq/mL for ^{225}Ac-DOTA-2Rs15d-Nb and ^{225}Ac-DOTA, respectively. Conclusions: ^{225}Ac-DOTA-2Rs15d-Nb showed strong *in vitro* therapeutic potential. Therefore, this radiobioconjugate is a promising agent that warrants future *in vivo* evaluation and TRT in SKOV-3 xenografted mice. This work was supported by the Polish National Science Center under grant 2013/09/D/ST4/03791.

OP591

Improving of molecular design of a novel Affibody-fused HER2-recognising anticancer toxin using radionuclide-based techniques

M. Altai[1], H. Liu[2], A. Orlova[3], V. Tolmachev[1], T. Gräslund[4]; [1]Imuunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]DIVISION OF PROTEIN TECHNOLOGY, KTH, Stockholm, SWEDEN, [3]Department of Medicinal Chemistry, Division of Molecular Imaging, Uppsala, SWEDEN, [4]DIVISION OF PROTEIN TECHNOLOGY, KTH, Uppsala, SWEDEN.

Aim. Targeted delivery of drugs and toxins is a promising approach for treatment of disseminated cancers. Several antibodies-based toxin conjugates and fusion proteins are under development. However, the large size of antibodies results in poor tumor penetration. Small size toxin-fused antibody domains have short plasma half-life and low bioavailability. We have constructed a series of novel Affibody-fused toxins (affitoxins). The affitoxins include the deimmunized PE38X8-toxin fused to the HER2-binding Affibody molecule $Z_{HER2:2891}$. A role of fusion with albumin binding domain ABD_{035} for the half-life extension and the use of $(HE)_3$ tags for reduction of hepatic uptake was evaluated using nuclide-based techniques. We expected that radionuclide-based techniques would permit for more sensitive tracking and more accurate quantification of cellular processing and tissue distribution compared to alternative approaches. **Methods.** The H_6-Z_{HER2}-PE38, $(HE)_3$-Z_{HER2}-PE38X8, and $(HE)_3$-Z_{HER2}-ABD-PE38X8 HER2-specific constructs and control $(HE)_3$-Z_{Taq}-ABD-PE38X8 were conjugated with a CHX-A"-DTPA chelator and labelled with ^{111}In. The binding specificity to and cellular processing by HER2-expressing cells was studied using SKOV-3 cell line. Affinity of labelled constructs to HER2-expressing cells was measured using LigandTracer Yellow. The influence of the composition of the histidine-containing tags tag on hepatic uptake of the affitoxin and the feasibility of extending its plasma half-life using ABD_{035} was evaluated in NMRI mice. Mice bearing SKOV-3 xenografts were injected with ^{111}In-$(HE)_3$-Z_{HER2}-ABD-P38X8 and sacrificed at 1, 4 and 24 p.i. To confirm HER2 mediated uptake of the affitoxin, an additional group of mice was injected with the non-HER2-specific affitoxin, ^{111}In-$(HE)_3$-Ztaq-ABD-PE38X8. **Results.** All affitoxins were efficiently labelled with ^{111}In (yield=84-95%) with preserved specificity of binding to HER2-expressing cells and a picomolar affinity. ^{111}In-$(HE)_3$-Z_{HER2}-ABD-P38X8 demonstrated more rapid internalization by SKOV-3 cells in vitro compared to the control H6-tag containing variant. In vivo, the incorporation of more hydrophilic (HE)3-tag reduced the liver uptake by 20% compared to H_6-tag containing variants. The residence time of the ABD_{035}-fused affitoxin, ^{111}In-$(HE)_3$-Z_{HER2}-ABD-PE38X8, in the blood was on average 28-fold higher than that of 111In-(HE)3-ZHER2-PE38X8 and the kidney uptake was on average 6-fold lower. ^{111}In-$(HE)_3$-Z_{HER2}-ABD-PE38X8 targeted HER2-expressing xenografts in mice specifically. The tumour uptake of the HER2-affitoxin peaked at 24 h p.i. (5.5±1 %ID/g). **Conclusion.** Novel affitoxin construct $(HE)_3$-ZHER2-ABD-PE38X8 demonstrated reduced hepatic uptake, longer residence in circulation and specific targeting of HER2-expressing xenografts. A particular advantage of radiolabelling is that it enabled to study quantitatively the biodistribution of several alternative constructs. Thus it represents a powerful tool in drug development.

OP592

Dual-targeting of tissue factor and CD105 for PET imaging of pancreatic cancer

W. Cai, H. Luo, C. G. England, S. Shi, S. A. Graves, R. J. Nickles; University of Wisconsin-Madison, MADISON, WI, UNITED STATES.

Objective: Pancreatic adenocarcinoma is a highly aggressive cancer, currently treated with limited success and dismal outcomes. Early detection and treatment offer the potential to reduce cancer morbidity and mortality, yet over 80% of patients are diagnosed with advanced disease. Developing highly-specific non-invasive imaging probes for pancreatic cancer is essential to improving diagnostic accuracy and monitoring therapeutic intervention, which was the goal of this study. **Methods:** A bispecific heterodimer was synthesized by conjugating an anti-tissue factor (TF) Fab (i.e. ALT-836-Fab) with an anti-CD105 Fab (i.e. TRC105-Fab), via the bioorthogonal "click" reaction between tetrazine (Tz) and *trans*-cyclooctene (TCO). The heterodimer was labeled with ^{64}Cu for positron emission tomography (PET) imaging of nude mice bearing BXPC-3 xenograft and orthotopic pancreatic tumors. **Results:** A competitive binding assay was performed to determine and compare the binding affinities of heterodimer, ALT-836-Fab, and TRC105-Fab to BXPC-3 cells. The results of the binding isotherm showed a concentration-dependent displacement of bound ^{64}Cu-NOTA-heterodimer with IC_{50} values of 11.35±1.04, 288.9±18, and 583.9±36 nM for heterodimer, ALT-836-Fab, and TRC105-Fab, respectively. Only a partial displacement of the bound radioligand at high concentrations (μM) of the competing antibody fragments demonstrated the bivalent nature of heterodimer binding. PET imaging of BXPC-3 xenograft tumors (which express high levels of both TF and CD105) with ^{64}Cu-labeled heterodimer displayed significantly enhanced tumor uptake (28.8±3.2 %ID/g; n = 4) at 30 h p.i., as compared to each of their mono-specific Fab tracers (12.5±1.4 and 7.1±2.6 %ID/g; n = 3). In addition, the activity-concentration ratio allowed for effective tumor visualization (tumor/muscle ratio of 75.2 ±9.4 at 30 h p.i.; n = 4). Blocking experiments were performed to confirm tracer specificity in vivo. Tracer uptake in all major organs was similar between ^{64}Cu-NOTA-heterodimer and ^{64}Cu-NOTA-heterodimer with TF or CD105 blockade, except the BXPC-3 tumor (significantly higher in the former), further confirming the TF and CD105 dual-specificity of ^{64}Cu-NOTA-heterodimer. Furthermore, ^{64}Cu-NOTA-heterodimer enabled sensitive detection of orthotopic pancreatic tumor lesions in mice with an uptake of 17.1±4.9 %ID/g at 30 h p.i. and tumor/muscle ratio of 72.3 ± 46.7 (n=3). **Conclusion:** This study demonstrates that dual-targeting of TF and CD105 provided synergistic improvements in both affinity and specificity of the heterodimer. Dual-targeted imaging agents of pancreatic and other cancers may allow for earlier pancreatic cancer detection, as well as reliable monitoring of therapeutic response.

OP593

The value of Zirconium-89 Positron Emission Tomography (^{89}Zr-PET) during the phase 1 study of a new antibody construct: ^{89}Zr-labeled cergutuzumab amunaleukin as an example

B. J. de Wit - van der Veen[1], M. Huisman[2], O. S. Hoekstra[2], M. P. M. Stokkel[1], E. van Brummelen[1], E. Mulder[2], G. A. M. S. van Dongen[2], D. J. Vugts[2], H. Verheul[2], T. K. Nayak[3], J. Saro[4], S. Evers[4], J. H. M. Schellens[1], C. W. Menke-van der Houven van Oordt[2]; [1]The Netherlands Cancer Institute, Amsterdam, NETHERLANDS, [2]VU University Medical Centre, Amsterdam, NETHERLANDS, [3]Roche Pharma Research and Early Development, Basel, SWITZERLAND, [4]Roche Pharma Research and Early Development, Zurich, SWITZERLAND.

Aim: Zirconium-89 Positron Emission Tomography (^{89}Zr-PET) can be used in Phase 1 trials as a tool to elucidate potentially uncertain distribution patterns of an antibody in tissues and tumour lesions. A step-wise ^{89}Zr-PET approach evaluates; I. biodistribution at low antibody dose, II. tumour accumulation at maximal dose, and III. biodistribution alterations throughout therapy cycles. This methodology was implemented in the Phase 1 trial with cergutuzumab amunaleukin, an engineered Interleukin-2 variant (i.e., abolished CD25 binding) antibody targeting Carcinoembryonic Antigen (CEA-IL2v). Methods: Patients (pts) with solid CEA-positive or -negative (CEA+/-) tumours were divided in three groups; I. CEA+/- dosed at 6 mg, II. CEA+/- dosed at 30 mg, and III. CEA+ dosed at 20-30 mg. Administrations during cycle 1 contained radiolabelled CEA-IL2v (± 50 MBq/2 mg ^{89}Zr-CEA-IL2v), pts in sub-group III received ^{89}Zr-CEA-IL2v in cycle 4 if tumour uptake was visible in cycle 1. ^{89}Zr-PETs were acquired

at day 2 and 5. Visible tumour uptake higher than surrounding tissue was regarded as 'positive' by a Nuclear Physician. Results: *Tumour accumulation* In group I (4 pts CEA+, 3pts CEA-), tumour accumulation was observed at 6 mg in 1/4 CEA+ pts. No uptake was seen in CEA- pts. At the maximum tolerated dose of 30 mg (group II, 4 pts CEA+, 4 pts CEA-) tumour accumulation was observed in 4/4 CEA+ pts, compared to 0/4 CEA- pts, indicating that tumour uptake is related to CEA-status. In group III (20 mg dose followed by 30 mg maintenance, 8 pts CEA+), the second ^{89}Zr-CEA-IL2v administration in cycle 4 showed reduced uptake in tumour lesions. These results indicate that levels of cold antibody at start and during treatment are an important factor to consider for tumour accumulation. *Biodistribution* In all groups accumulation was observed in the liver, spleen and lymph nodes independent of CEA-status, suggesting IL-2 receptor mediated accumulation in lymphoid tissues. Marked differences were observed in cycle 4 compared to cycle 1 with reduced accumulation in the spleen and increased accumulation in the liver. Also, ^{89}Zr-CEA-IL2v blood plasma levels showed a faster decline in cycle 4. These results indicate an altered pharmacokinetic-profile. Conclusion: ^{89}Zr-PET visualized biodistribution and tumour accumulation during this Phase 1 study with cergutuzumab amunaleukin, thereby shedding light on the complex relation between pharmacokinetics and -dynamics related to the targets CEA and IL2v. The proposed methodology is generic, and can be considered to visualize in vivo behaviour of novel ^{89}Zr-labeled multi-target drugs.

OP594

Anti-HER2 Single Domain Antibody 2Rs15d Labeled with ^{18}F Using a Residualizing Label: Preliminary Evaluation

G. V. Vaidyanathan[1], Z. Zhou[1], D. McDougald[1], T. Lahoutte[2], M. R. Zalutsky[1]; [1]Duke University Medical Center, Durham, NC, UNITED STATES, [2]Free University of Brussels, Brussels, BELGIUM.

Aim: We have evaluated the utility of an anti-HER2 single domain antibody (sdA) 5F7, labeled with ^{18}F using the residualizing label [^{18}F]RL-I, as a potential tracer for determining HER2 status in preclinical breast cancer (bc) models (*Org. Biomol. Chem*. 2016;14:1261-1271; *J. Nucl. Med*. 2016; PMID: 26912425). Unlike 5F7, sdA 2Rs15d does not compete with trastuzumab for HER2 binding, and should be more suitable for the determinination of reponse to trastuzumab therapy. A phase I study of this sdA labeled with ^{68}Ga was recently performed and delineation of both primary and metastatic cancer was possible (*J. Nucl. Med*. 2016; 57:27-33). In the current work, 2Rs15d was labeled with the versatile PET radionuclide ^{18}F using [^{18}F]RL-I and evaluated in vitro and by microPET imaging. Methods: 2Rs15d was labeled using [^{18}F]RL-I in borate buffer, pH 8.5. Radiochemical purity (RCP) of [^{18}F]RL-I-2Rs15d was determined by TCA precipitation, ITLC, SEC and SDS-PAGE. Binding affinity and immunoreactive fraction (IRF) of [^{18}F]RL-I-2Rs15d to HER2 was determined using HER2-expressing BT474M1 cells. Internalization in BT474 M1 cells in vitro was performed in a paired-label format along with 2Rs15d labeled using [^{125}I]SGMIB (*Nat. Protocols* 2007;2:282-286). MicroPET/CT imaging was done in a BT474M1 xenograft-bearing SCID mouse after administering [^{18}F]RL-I-2Rs15d. Results: 2Rs15d was coupled to [^{18}F]RL-I in 47.8 ±2.6% yield and with a RCP of >95%. [^{18}F]RL-I-2Rs15d had a Kd of 7.1 ±0.4 nM and an IRF of 78.8±7.6%. The percentage of initially-bound radioactivity that was internalized in BT474 M1 cells at 1, 2 h and 4 h was similar for ^{18}F (43.7±3.6, 36.5±2.6 and 21.8±1.3) and ^{125}I 49.2±2.2, 39.6±1.1 and 23.6±0.1) ($P < 0.05$ at 1 h). MicroPET/CT imaging clearly delineated the tumor, which exhibited uptake and retention of radioactivity — 13.3±5.7, 13.7±5.4, and 13.2±5.3 %ID/g (SUV: 2.3±0.9, 2.4±0.9, 2.3±0.9) at 1, 2 and 3 h, respectively. The tumor uptake is 58% and 70% of that obtained by microPET imaging for [^{18}F]RL-I-5F7 at 1 h and 2 h, respectively. However, uptake of [^{18}F]RL-I-2Rs15d observed in this study is considerably higher than that reported for ^{68}Ga-labeled 2Rs15d, albeit in the SK-OV-3 mouse model (*J. Nucl. Med.* 2013; 54:776-784). Kidneys and bladder were the only other organs that were visible. Conclusion: Given that high contrast PET image was obtained with [^{18}F]RL-I-2Rs15d as early as 1 h, it warrants further evluation as an agent for determination of HER2 status, and especially for determining response to therapy with trastuzumab in bc patients.

Validation of high-risk CT & PET features for prediction of local recurrence after SBRT

K. Wagner[1], S. Adebahr[1,2], E. Gkika[1], T. Brunner[1,2], J. Ruf[3], H. Rischke[1,3], A. Grosu[1,2], W. Vach[4], U. Nestle[1,2]; [1]Department of Radiation Oncology, Freiburg University Medical Center, Freiburg, GERMANY, [2]German Cancer Consortium (DKTK), Heidelberg, Partner Site Freiburg, Freiburg, GERMANY, [3]Department of Nuclear Medicine, Freiburg University Medical Center, Freiburg, GERMANY, [4]Center of Medical Biometry and Medical Informatics, Freiburg University Medical Center, Freiburg, GERMANY.

Background and purpose: Detection of local recurrence (LR) after stereotactic body radiotherapy (SBRT) for lung lesions using RECIST-Criteria can be difficult because of radiation-induced CT lung changes. The role of PET/CT in this aspect has not yet been determined. High-risk CT-features (HR-CTF) for prediction of LR have been proposed in a case control study that included a blinded read by two teached radiation oncologists after appropriate teaching (Huang et al., Radiother Oncol. 2012 and 2013). In consensus formation (CF), the presence of ≥ 3 HR-CTF was highly sensitive and specific for LR (both ≥ 90%). The aim of the current study was to validate these CT-criteria in combination with PET-imaging features without teaching and CF in a prospective SBRT trial cohort. **Materials and methods**: In Interviews, CT image datasets of a prospective patient group treated with SBRT (57 patients with 65 pulmonary lesions), who had as well FU-PET/CTs were scored by 4 experienced blinded observers (two radiation oncologists + one nuclear medicine physician = observer 1-3; and one radiologist) using a structured questionnaire. RECIST results and all single HR-CTF were assessed. In a prospective time-point ordered sequence of follow up -CT datasets of each patient, observers determined their suspicion of LR. When this was the case, available PET/CT images of this time point were shown and analyzed qualitatively, then quantitatively. Review sequence was stopped as soon as the observer diagnosed LR in both CT and FDG-PET. For observer 1-3 inter-observer variability (IOV) was determined using Cohen's kappa. Regarding LR-detection, accordance of observers' results with the reference standard (defined by clinical long term courses including information on imaging and biopsy if available) was analyzed, sensitivity and specificity were calculated. ***Results:*** IOV between the Observers 1-3 were "slight" to "fair" for CT-Criteria (k=0.120 to k=0.357), with additional PET information it was "almost perfect", qualitative and quantitative (both k=0.862). For observers 1-4 sensitivity and specificity for RECIST were 46% and 95% and for single HR-CTF it were 17-58% and 56-96%, respectively; If ≥ 3 HR-CTF pertained, sensitivity and specificity were 50% and 81% respectively. PET/CT analysis was highly sensitive (100%) but varyingly specific (44-91%). ***Conclusion:*** While neither RECIST nor the previously defined HR-CTF could be validated as reliable predictors of LR, PET/CT seems to offer more accurate and diagnostic information about local recurrence after SBRT leading to a higher inter observer agreement in independent review.

OP597

Role of Dynamic FDG PET/CT Acquisition in Evaluation of Response to Chemotherapy in Advanced NSCLC

A. Sharma, A. Mohan, A. S. Bhalla, P. K. Julka, C. S. Bal, M. C. Sharma, C. Patel, A. K. Pandey, C. Das, S. Thulkar, V. Sreenivas, G. Kumar, A. Sharma, R. Kumar; All India Institute of Medical Sciences, Delhi, INDIA.

Introduction: The role of Dynamic PET/CT acquisition in Oncological patients is currently limited and primarily used for research purposes. However, when used as a routine procedure in patients evaluated following chemotherapy, dynamic PET/CT may carry additional value in predicting response in these patients. **Aim:** The current study aims to evaluate the possible role of dynamic PET/CT in patients with advanced stage NSCLC at baseline as well as following 4 cycles of chemotherapy. **Material and Methodology:** Seventeen patients (10 males and 7 females) with mean age 59.5 years with histopathologically diagnosed NSCLC (10 Squamous Cell Carcinoma and 7 Adenocarcinoma) were enrolled into this prospective study. Each patient underwent a prechemotherapy and post 4 cycle of chemotherapy dynamic acquisition with the primary tumor in the FOV for 60 minutes immediately followed by a routine whole-body static acquisition. Kinetic parameters from dynamic study (namely Ki and MRglu) were estimated at 30 and 60 minute as per Patlak graphical analysis. Routinely employed whole body quantification parameters (SUVmax, SUVavg, MTV, TLG) were also evaluated and included for analysis. The response evaluation was performed as per RECIST 1.1 and EORTC criteria. Appropriate statistical methods were applied and results were obtained with P value of less than 0.05 considered statistically significant. **Results:** Of the 17 patients, 3 had TNM stage 3 disease while 14 were at stage 4 on baseline evaluation. When we compared prechemotherapy and postchemotherapy PET/CT scan as per predefined response criteria, 11 patients were classified as responders (all Partial Response) and 6 as non - responders (2 Stable Disease, 4 Progressive Disease). With paired samples t-test, excepting MTV and TLG, the difference in means of pre-therapy and post-therapy SUVmax, SUVavg, TBR, Ki30, Ki60, MRglu30 and MRglu60 were all statistically significant (P lt 0.05). To assess the discriminatory ability for non-responders, ROC curve analysis was performed between the Delta values (representing percent change) of kinetic parameters (Ki60, Ki30, MRglu60, MRglu30) and static semiquantitative parameters (SUVavg, SUVmax, TBR). ROC curve analysis showed more robust AUC values for DeltaKi60 (0.864), DeltaKi30 (0.900), DeltaMRglu60 (0.918) and DeltaMRglu30 (0.936) as against for DeltaSUVmax (0.845), DeltaSUVavg (0.845) and DeltaTBR (0.755); the Delta values for kinetic parameters obtained at 30 minutes of dynamic study had maximum AUC values. **Conclusion:** Our study suggests that dynamic PET/CT kinetic parameters, particularly the percent changes in the MRglu values, carry a higher discriminatory ability for non-responders in patients undergoing chemotherapy for advanced NSCLC.

OP598

Role of 18F-FDG PET/CT scan in predicting a pathological non-invasive status in solid-type Stage-I pulmonary adenocarcinomas

A. Filice[1], F. Lococo[2], C. Rapiceta[2], D. Formisano[3], A. Tartaglione[1], S. Bellafiore[4], M. Roncali[1], S. Taddei[5], F. Fioroni[6], M. Paci[2], A. Versari[1]; [1]Nuclear Medicine Unit IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [2]Unit of Thoracic Surgery IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [3]Department of Infrastructure Research and Statistics IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [4]Unit of Pathology IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [5]Unit of Pulmonology IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [6]Medical Physics Unit IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY.

Objective: ^{18}F-FDG-PET/CT is currently utilized for the characterization of solitary pulmonary nodules but there are various factors that can lead to false-negative results in PET/CT. On the other hand, low ^{18}F-FDG uptake can predict a non invasive status in this context. We aim to clarify possible factors causing false-negative PET results in solid-type pulmonary adenocarcinomas (PA), and to evaluate the relationship between ^{18}F-FDG uptake and histologic subtypes of PA because low ^{18}F-FDG uptake can identify possible candidates for sublobar resection. **Methods:** we retrospectively reviewed PET/CT-records, clinical information, preoperative thin-section CT-images, and pathological features (classified by the IASLC/ATS/ERS subtyping criteria) of 94 consecutive patients, 58 males and 36 females (mean age= 68.7 yrs, range 42-85), with solid-type Stage-I NSCLCs. Patients underwent surgical resection at Our Institution from 01/2007 to 12/2014. Univariate and multivariate logistic analysis were used to identify and weigh the independent predictors of PET-findings: body weight, blood glucose level, tumor-size, and histological classification. **Results**: seventeen lesions (18.1%) were judged as PET-negative and 77 lesions (81.9%) as PET-positive. Overall, mean SUVmax was 8.0 (range 0-35) with higher SUVmax-values ($p<0.001$) in PA>2cm (mean SUVmax=10.6) than PA<2cm (mean SUVmax=4.8). PET false-negative (FN) results were also differently distributed (27.9% in PA <2cm vs 9.8% in PA>2 cm, $p=0.023$). Most lesions with positive PET/CT findings were located in the upper zones of the lung. When we divided the PA in 2 histological groups (Group 1 ["colloid/mucinous/lepidic"] vs Group 2 ["micropapillary/solid/acinar/papillary"]), the radiometabolic patterns were significantly different [mean SUVmax 3.8 in Class-A vs 9.9 in Class-B, $p<0.001$]. Similarly, a different distribution of PET FN-cases was observed (38.7% FN in Class-A vs 7.9% FN in Class-B, $p=0.001$). Both the tumor-size (cut-off=2cm) and IASLC/ATS/ERS aggregated clusters were clinically relevant factors for determining whether PET results were negative or positive, but only histology was statistically significant (OR:6.1, 95%CI: 1.85-20.15, $p=0.003$). **Conclusions**: tumor-size and histopathological findings were significantly associated with ^{18}F-FDG-uptake in solid-type PA. Although lesions ≤2cm and "colloid/mucinous/lepidic" adenocarcinomas have a tendency for a very low ^{18}F-FDG uptake we know that this pattern can be a favorable predictive factor to identify a non invasive status of the neoplasms and patients could be candidates for sublobar resection. However, in presence of a solitary pulmonary nodules newly diagnosed, in order to avoid diagnostic errors it is very important to discuss the cases in a multidisciplinary setting.

OP599

Multiparametric evaluation of [^{18}F]FLT uptake and perfusion in EGFR-mutated NSCLC patients undergoing treatment with a EGFR Tyrosine Kinase Inhibitor

R. Iqbal, G. M. Kramer, V. Frings, E. F. Smit, O. S. Hoekstra, R. Boellaard; VU University Medical Center, Amsterdam, NETHERLANDS.

Background: 3′-deoxy-3′-[^{18}F]fluorothymidine ([^{18}F]FLT) was proposed as an imaging biomarker for the assessment of *in vivo* cellular proliferation with positron emission tomography (PET). The aim of the current study was to gain insight in the parametric relationship between [^{18}F]FLT uptake and perfusion in non-small cell lung cancer (NSCLC) patients undergoing treatment with a tyrosine kinase inhibitor (TKI). **Methods:** Six patients with metastatic NSCLC, having an activating epidermal growth factor receptor (EGFR) mutation were included in this study. Patients underwent [^{15}O]H_2O and [^{18}F]FLT PET/CT scans at three different time points: 7 d before treatment, and 7 and 28 d after start of treatment with a TKI (gefitinib or erlotinib). Parametric analyses were performed to generate quantitative 3D images of both perfusion and [^{18}F]FLT volume of distribution (V_T) . Next, multiparametric

classification was performed by classifying voxels as low and high perfusion and/or low and high V_T using an absolute threshold based on the average tumor values of all lesions (for all time points). By combining these initial classifications, voxels were allocated to 4 categories (low perfusion-low V_T, low perfusion-high V_T, high perfusion-low V_T and high perfusion-high V_T). **Results:** A total of 17 perfusion and 20 [^{18}F]FLT PET/CT scans were evaluated. The average tumor values across all lesions were 0.53±0.26 mL/mL/min and 4.25±1.71 for perfusion and [^{18}F]FLT V_T, respectively. Multiparametric analysis suggested a shift in voxel distribution, particularly regarding V_T: from at least 47% voxels of each lesion classified in the "low- and high perfusion-high V_T category" to at least 77% voxels classified in the "low- and high perfusion-low V_T category". The shift was most prominent 7 d after treatment and remained relatively similar afterwards. Changes in perfusion and its distribution were minimal. **Conclusion:** The present data indicate that parametric changes in [^{18}F]FLT uptake do not seem to be the result of parametric changes in perfusion, suggesting that [^{18}F]FLT uptake distribution and its change is independent of perfusion. **Keywords:** positron emission tomography (PET), non-small cell lung cancer (NSCLC), [^{18}F]FLT, perfusion, tyrosine kinase inhibitors (TKIs)

OP600

FDG PET-CT SUVmax and IASLC/ATS/ERS histologic classification: a new profile of lung adenocarcinoma with prognostic value

M. Suárez-Piñera[1], L. Pijuan[2], A. Rodriguez-Fuster[3], A. Mestre-Fusco[1], M. Cufi[4], A. Taus[5], A. Sánchez-Font[6], N. Rodriguez de Dios[7], F. Zuccarino[4], V. Curull[6], F. Fernández-Alarza[4], J. Belda-Sanchis[3]; [1]Nuclear Medicine Department, Hospital del Mar Parc de Salut Mar, Barcelona, SPAIN, [2]Pathology Department, Hospital del Mar Parc de Salut Mar, Barcelona, SPAIN, [3]Thoracic Surgery Department, Hospital del Mar Parc de Salut Mar, Barcelona, SPAIN, [4]Radiology Department, Hospital del Mar Parc de Salut Mar, Barcelona, SPAIN, [5]Oncology Department, Hospital del Mar Parc de Salut Mar, Barcelona, SPAIN, [6]Pneumology Department, Hospital del Mar Parc de Salut Mar, Barcelona, SPAIN, [7]Radiotherapy Department, Hospital de la Esperanza Parc de Salut Mar, Barcelona, SPAIN.

Aims: Tumor stage is the strongest prognostic factor in lung adenocarcinoma (LA) and the best guide for treatment decisions. Histopathological and metabolic criteria may be useful to overcome the heterogeneity problem in LA. The aims of this study were to determine whether the F18-FDG PET/CT standard uptake value (SUVmax) can provide information about IASLC/ATS/ERS histological subtypes of LA and to evaluate whether the combination of both parameters can prognostically stratify these patients. Methods: 103 cases of surgically resected LA with presurgical FDG-PET/CT were retrospectivelly reviewed. FDG uptake was quantified using SUVmax. All resected specimens were histologically classified according to IASLC/ATS/ERS classification of LA adenocarcinoma in situ -AIS-, minimally invasive adenocarcinoma -MIA- and invasive adenocarcinoma (divided into lepidic, papillary, acinar, solid, micropapillary and mucinous based on the predominant pattern). These lesions were grouped in 3 categories using prognostic criteria: Group 1; low grade (AIS, MIA), group 2; intermediate grade (lepidic, acinar, papillary) and group 3; high grade (micropapillary, solid and mucinous). One way analysis of variance and Bonferroni´s test were performed to evaluate statistical differences between groups. Overall and disease-free survival rates were calculated by the Kaplan-Meier method. Results: The distribution of histological subtypes were: AIS (n=4), MIA (n=4), lepidic predominant (n=13), acinar predominant (n=51), papillary predominant (n=12), micropapillary predominant (n=2), solid predominant (n=12) and invasive mucinous adenocarcinoma (n=5). SUVmax values (mean±SD) were: 2.4±2.7 in group 1, SUVmax 7.7±6.6 in group 2 and SUVmax 8.3 ±5.6 group 3. Mucinous adenocarcinomas (group 3) showed a low mean SUVmax (2.6±1.4) despite its high histological grade, probably related to the mucus content. Acinar adenocarcinoma (group 2) showed a high variability SUVmax 8.6±6, no statistical differences were found with solid tumors (group 3) SUVmax 10.1±4.9. A reason for these results in the acinar tumor could be the variability of the second cellular component. We obtained a significantly highest SUVmax value in acinar tumors accompanied by a second histological subytpe intermediate or high grade than pure acinar or accompanied by the low grade subtype Increased SUVmax were associated with poor prognostic tumors. We found significant differences in SUVmax among 3 subgroups corresponding to recurrence risk (p<0,0001) Conclusions: SUVmax can be an orientative parameter of histological LA subtypes according the proposed IASLC/ATS/ERS classification, specifically for high-intermediate grade. The hetereogeneity observed in LA seems to be related to different histologyc subtypes and metabolic behaviour (SUVmax), reflecting different malignant grade and different prognosis.

OP601

The role of FDG-PET/ceCT in peritoneal mesothelioma

A. Skanjeti[1], J. Dubreuil[1], P. Rousset[2], D. Rubello[3], N. Bakrin[4], G. Passot[4], S. Isaac[5], O. Glehen[4], F. Giammarile[1]; [1]Hospices Civils de Lyon - Nuclear Medicine, Lyon, FRANCE, [2]Hospices Civils de Lyon - Radiology, Lyon, FRANCE, [3]Santa Maria della Misericordia Hospital - Nuclear Medicine, Rovigo, ITALY, [4]Hospices Civils de Lyon - General and oncologic surgery, Lyon, FRANCE, [5]Hospices Civils de Lyon - Pathology, Lyon, FRANCE.

Purpose. To assess glucose metabolism of Multicystic Peritoneal Mesothelioma (MPM) and Epithelioid Peritoneal Mesothelioma (EPM), by FDG-PET/CT and to assess the prognostic impact of FDG uptake. *Material and Methods*. Twenty-three patients (9 males, age 54±16 years) scheduled for peritoneal mesothelioma treatment by cytoreductive surgery and intraperitoneal chemotherapy, underwent FDG-PET/CT between September 2009 and March 2014. No previous treatment was performed. FDG-PET/CT was interpreted by two nuclear physicians as positives or negatives for the presence of EPM or MPM, respectively. SUVmax of each lesion was measured retrospectively based on lesions described on post-surgery data. At laparotomy, disease extension was estimated with the Peritoneal Cancer Index (PCI). Median follow-up was 27 months (95%CI 12.9-37.8), time to recurrence were recorded. *Results*. Nine patients had MPM and 14 EPM. PET showed a mild focal uptake in one case of MPM, while in 8 patients no abnormal uptake was observed at the site of the primary disease. PET was positive in 12/14 patients with EPM. Sensitivity, specificity and accuracy were respectively 86%, 89%, and 87%. Nine patients with EPM had recurrent disease, 3 died during follow-up, while no patients with MPM had recurrent disease. MPM histology was associated with a lower $SUVmax_{lesion}$, $SUVmax_{lesion/liver}$, PCI, younger age, and it was observed only in women. $SUVmax_{lesion}$ and age were associated with Progression Free Survival (PFS) in patients with EPM. *Conclusion*. FDG-PET/CT showed significant differences between MPM and EPM while $SUVmax_{lesion}$ was associated with PFS in EPM. Then, FDG-PET/CT is a promising tool in patients with EPM.

OP602

Effect of segmentation method on texture parameters' reproducibility and predictive / prognostic ability when derived from 18F-FDG PET scans in patients with non-small cell lung cancer

U. Bashir, G. Azad, M. Siddique, N. Patel, S. Dhillon, D. Landau, V. Goh, G. J. Cook; St. Thomas' Hospital, London, UNITED KINGDOM.

Background: 18F-FDG PET derived measures of tumour heterogeneity are increasingly being reported as potential biomarkers of cancer classification, prognostication, and response prediction. A number of

segmentation methods have been used but their effects on repeatability and predictive / prognostic power have not been evaluated. Purpose: The purpose of our study was to compare three segmentation techniques, i.e. freehand, threshold-based, and fuzzy locally adapative bayesian (FLAB), on 18F-FDG PET scans from patients with NSCLC i) to measure inter-observer reproducibility and ii) to determine the effects of different segmentation methods on the predictive ability of multiple texture features in terms of overall survival and response to chemoradiotherapy. Materials & Methods: 18F-FDG PET scans acquired before chemoradiotherapy on 53 patients (mean age: 65.8 years; 31 males, 22 females) with non-small cell lung cancer were examined retrospectively. Three readers (clinical oncologist, radiologist and nuclear medicine physician) drew freehand regions of interest around the tumours and the freehand ROIs were then processed by software (implemented in MATLAB 2013b) to generate segmentation ROI maps based on intensity threshold (40% of maximum) and FLAB. For each segmentation technique, the agreement between the three observers was assessed using the intra-class correlation (ICC) coefficient. Univariate cox regression was used to examine the association between each of the PET texture parameters and patient survival time, taking 0.01 as p-value cut-off to determine statistical significance. This conservative cut-off was chosen to correct for the large number of texture parameters. The differences between mean texture-values of responders and nonresponders were assessed using Mann-Whitney U test. Results: Compared with FLAB, threshold-based segmentation showed significantly higher ICC in 24 of 85 parameters, whereas freehand ROIs showed lower ICC in 36 parameters and higher ICC in 1 On survival anlaysis, threshold-based segmentation yielded the greatest number of significant associations between survival and texture values (8 vs. 2 for FLAB and 1 for freehand). Responders and nonresponders showed statistically different mean texture values for 6 features when tumour were segmented using FLAB, compared with 5 and 2 features using freehand and 40% threshold respectively. Conclusion:The tumour segmentation techniques - FLAB, freehand, and threshold-based - overlap in their ability to predict survival and response to treatment and seem generally comparable. However, 40% threshold-based ROI segmentation shows significantly less inter-observer variability that the other two, a property that makes it a favourable choice for tumour segmentation from 18F-FDG PET images.

OP603

FDG-PET early identifies lesions at risk of recurrence under treatment by tyrosine kinase inhibitors in patients with metastatic (EGFR)-mutated lung adenocarcinoma

A. ADENS, G. PETYT, A. CORTOT, H. LAHOUSSE, G. COLLET, C. HOSSEIN-FOUCHER, D. BELLEVRE; CHRU Lille, Lille CEDEX, FRANCE.

Background : ^{18}F-FDG PET/CT is used to evaluate the response to treatment and to detect earlier the recurrence in patients with lung cancer. The aim of the study was to determine the predictive value of metabolic parameters measured by PET/CT to identify lesion with higher risk of progression, in patient treated by tyrosine kinase inhibitor (TKI) in first line for metastatic lung adenocarcinoma harboring activating epidermal growth factor receptor (EGFR) mutation. Methods: Thirteen patients were retrospectively analyzed. Eighty-nine lesions among patients with multiple lesions were analyzed. SUVmax, SUVmean, Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis(TLG) were measured on ^{18}F-FDG PET/CT for each lesion at baseline and at first treatment evaluation. At baseline, lesions were separated into tertile, depending on their metabolic activity. At first evaluation, lesions were divided in two groups as follow: incomplete response (metabolic lesion was still measurable) and complete response (no visually detected lesion). In the patient-based analysis, progression free survival (PFS) was compared regarding complete or incomplete response status at first treatment evaluation PET/CT. Results: At baseline, a lesion with high metabolic parameters (SUVmax, MTV, TLG) was significantly associated to earlier progression (p=0.0028, p=0.0028 p=0.0032 respectively). At time of first evaluation, lesions considered in incomplete response were significantly associated with high risk of progression (OR= 9.6, p=0.0004). On patient based analysis, complete response on first PET/CT evaluation, was predictive of a significantly better PFS (354 days vs. 184 days, p=0.03). Conclusion: Lesions with incomplete early metabolic response were significantly associated with a high risk of progression, in patients with lung adenocarcinoma treated by TKI. Identification of these lesions could affect therapeutic management such as close follow-up or local therapy.

Does fractional flow reserve truly identify coronary artery stenosis causing myocardial ischemia?

R. Assante[1], E. Zampella[1], C. Nappi[1], V. Gaudieri[2], T. Mannarino[1], G. Rossi[1], W. Acampa[1], M. Petretta[1], G. Arena[3], P. Golino[3], A. Cuocolo[1]; [1]University Federico II, Naples, ITALY, [2]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [3]Cardio-thoracic and respiratory sciences, Second University of Naples, Naples, ITALY.

Aim: Despite the clinical importance of coronary physiological assessment, the relationship between coronary flow reserve (CFR) and fractional flow reserve (FFR) remains poorly defined. We aimed at studying the relationship between absolute CFR and FFR in patients with stable coronary artery disease. Material and Methods: A total of 54 patients with stable coronary artery disease underwent Rb-82 positron emission tomography (PET)/computed tomography (CT) cardiac imaging at rest and after pharmacological stress test (dipyridamole 0.142 mg/kg/min for 4 min). Thereafter, all patients also underwent invasive coronary angiography with FFR assessment. At PET/CT cardiac imaging, resting and hyperemic myocardial blood flow (MBF) and CFR were automatically quantified. CFR was calculated as the ratio of hyperemic to baseline MBF and was considered reduced when <1.74. At coronary angiography, FFR was measured during intracoronary administration of adenosine (200 μg) and was considered abnormal when ≤0.8. A total of 60 coronary artery stenoses were studied. Results: A significant, albeit modest, correlation between CFR and FFR (r=0.38, P=0.003) was found. In particular, of the 34 coronary artery stenoses with an abnormal FFR value ≤0.8, 18 (53%) showed a reduced CFR, while the other 16 (47%) coronary artery stenoses had a normal CFR. In contrast, of the 26 coronary artery stenoses with a FFR value above 0.8, only 5 (19%) showed a reduced CFR, while the other 21 (81%) had a normal CFR. Conclusions: In this preliminary series, FFR values >0.8, indicating a non-significant coronary artery stenosis, show an excellent correlation with absolute CFR, while pathological FFR values (<0.8) poorly correlate with a reduced CFR. This discordance should be probably taken into account when facing the choice of recommending revascularization solely on the basis of FFR values.

OP605

Role of microvascular dysfunction in the weak association found between stress myocardial blood flow measured with 82Rubidium PET and FFR values measured during coronary angiography?

R. Chequer[1], E. Sorbets[2], A. Touati[1], S. Leygnac[1], M. Milliner[1], N. Mikail[3], H. Regaieg[1], R. Ben Azzouna[1], G. Ducrocq[4], F. Rouzet[1], D. Le Guludec[1], **F. Hyafil**[1]; [1]Department of Nuclear Medicine, Bichat Hospital, AP-HP, PARIS, FRANCE, [2]Department of Cardiology, Avicennes Hospital, AP-HP, Bobigny, FRANCE, [3]Department of Nuclear Medicine, Beaujon Hospital, AP-HP, Clichy, FRANCE, [4]Department of Cardiology, Bichat Hospital, AP-HP, PARIS, FRANCE.

Background. Fractional flow reserve (FFR) allows for invasive hemodynamic evaluation of the impact of coronary stenosis on blood flow. ^{82}Rubidium(Rb)-positron emission tomography (PET) provides noninvasive quantification of absolute myocardial blood flow (MBF) during pharmacological stress. **Purpose.** The aim of this study was to test whether stress MBF quantified noninvasively with Rb-PET predicted the FFR measured invasively in corresponding coronary arteries. **Methods.** A total of 20 patients who underwent MPS with Rb-PET and coronary angiography (CA) with measurement of FFR were included in this study. PET was acquired in a dynamic mode during the injection of 10 MBq/kg of ^{82}Rubidium and intravenous dipyridamole-induced hyperemia. Stress MBF values were calculated for the left ventricle (global LV MBF) and for each of the 17 segments of the AHA classification using the FlowQuant software. FFR was measured in 29 different coronary arteries with stenosis > 50 % after intra-coronary injection of adenosine. The lowest value of stress MBF quantified with Rb-PET in a coronary territory was compared to the minimal FFR value measured along the corresponding coronary artery. **Results.** Among the 29 coronary arteries evaluated with FFR, 14 had a FFR ≤ 0.80 and 15, a FFR > 0.80. Only a weak correlation was found between minimal stress MBF quantified with Rb-PET and minimal FFR in corresponding coronary artery ($r = 0.28$; $p = 0.13$). Using a threshold for minimal stress MBF < 1.8 ml/mn/g in each coronary arterial territory, sensitivity and specificity for the detection of FFR ≤ 0.80 was 100 % and 50 %, respectively. In coronary arteries with a FFR ≤ 0.80 during CA, all corresponding arterial territories had a minimal stress MBF ≤ 1.8 ml/mn/g quantified with Rb-PET (mean MBF = 1.2. ± 0.3 ml/mn/g). In the remaining 15 coronary arteries with FFR > 0.80, 8 arterial territorial presented a minimal stress MBF < 1.8 ml/mn/g. In all these patients, global LV MBF was < 2 ml/mn/g in absence of 3-vessel disease suggesting diffuse microvascular dysfunction, whereas in the remaining 7 coronary arteries the global LV MBF was > 2 ml/mn/g (mean global LV MBF = 1.4 ± 0.3 vs. 3.0 ± 0.7 ml/mn/g, respectively; $p = 0.001$). **Conclusions.** In this study, only weak correlation was found between stress MBF quantified with Rb-PET and FFR measured invasively during CA, mostly because of the addition of microvascular dysfunction to the impact of epicardial coronary stenosis in stress MBF measurements.

OP606

Rubidium-82 PET myocardial blood flow compared to fractional flow reserve in patients with coronary artery disease

J. J. Boer, J. M. H. de Klerk, E. A. de Vrey, B. J. G. L. de Smet; Meander medical centre, Amersfoort, NETHERLANDS.

Purpose Measurement of the fractional flow reserve (FFR) is the current gold standard in assessing the significance of coronary stenosis. Rubidium-82 (Rb-82) allows non-invasive measurement of myocardial bloodflow (MBF) during stress and rest down to the microvascular level allowing the detection of microvessel disease. In this retrospective study we compared the Rb-82 derived MBF measurements introduced in our hospital in 2014 to FFR measurements and other coronary angiography (CAG) findings. Method and materials In 2014 RB-82 myocardial perfusion PET was performed in 482, 182 of these patients underwent coronary angiography. In these patients we correlated the findings of FFR and degree of visual stenosis in each major coronary vessel to the Rb-82 derived flow measurements. We documented the result in treatment with regard to revascularization or conservative drug therapy. Results A total of 182 CAG and 42 FFR findings in 482 patients were found. FFR measurements were rarely performed in patients with perfusion deficits corresponding with a visual significant epicardial stenosis, due to immediate intervention. In 46% of the vessels with visual stenosis > 50% both the FFR and MBF were normal. In 48% of the cases there was discrepancy between the FFR and Rb-82 derived MBF. In 20% of all patients there was a decreased FFR and normal MBF. There was no significant correlation between the MBF and visual degree of stenosis. All patients with a FFR below 0,8 received revascularization. In the subgroup of patients (n=9) with decreased coronary stressflow and FFR above 0,8 none underwent revascularization. Conclusion There is a significant number of patients with discrepancy between MBF and FFR measurements. Possible explanations include the difference between focal versus more diffuse epicardial coronary artery disease and the presence of microvessel disease. Further investigation is required to determine whether rubidium-82 derived MBF can be of additional value in identifying culprit lesions and to select patients for revacularisation.

OP607

Combined Assessment of Myocardial Perfusion and Coronary Flow Reserve by Hybrid Rb-82 PET/CT Imaging Improves the Identification of Obstructive Coronary Artery Disease

E. Zampella[1], R. Assante[1], W. Acampa[1], C. Nappi[1], V. Gaudieri[2], M. Panico[2], T. Mannarino[1], V. Vultaggio[1], P. Buongiorno[1], M. Petretta[1], A. Cuocolo[1]; [1]University Federico II, Naples, ITALY, [2]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY.

Aim: Positron emission tomography (PET)/computed tomography (CT) myocardial perfusion imaging (MPI) allows the incorporation of coronary flow reserve (CFR) into clinical protocol. We sought to determine whether the combined analysis of MPI and CFR improves the diagnostic accuracy of PET/CT to predict obstructive coronary artery disease (CAD). Materials and Methods: We evaluated 130 consecutive patients (age 60±11 years) with suspected or known CAD referred to stress Rb-82 PET/CT imaging and invasive coronary angiography. Myocardial perfusion was quantified automatically for left anterior descending (LAD), left circumflex (LCX) and right (RCA) coronary artery territories as ischemic total perfusion defect (ITPD) for 390 vessels. Resting and hyperemic myocardial blood flow (MBF) and CFR were automatically quantified. CFR was calculated as the ratio of hyperemic to baseline MBF and was considered reduced when <1.74. Obstructive CAD was defined as ≥75% stenosis at coronary angiography. Logistic regression analyses were used to determine the variables associated with obstructive CAD. Net reclassification improvement (NRI) was calculated to assess whether CFR can reclassify patients with obstructive CAD. Results: MPI was normal in 65 (50%) patients. Mild-moderate (ITPD 1-9%) and severe (ITPD ≥10%) reversible perfusion defects were observed in 44 (34%) and 21 (16%) patients, respectively. In the overall population, obstructive CAD was present in 40 (31%) patients. Patients with obstructive CAD had a higher prevalence of reduced CFR (<1.74) (47% vs. 22%, P<0.05) and a higher ITPD value (8.6±7 vs. 2.9±3, P<0.001) compared to those without. At univariable analysis, age (P<0.05), reduced CFR (P<0.05) and ITPD (P<0.001) were significant predictors of obstructive CAD. At multivariable analysis, only reduced CFR (P<0.05) and ITPD (P <0.001) were independently associated with presence of obstructive CAD. The addition of CFR to clinical data and ITPD increased the global chi-square value of the model in predicting obstructive CAD (chi-square from 46 to 52, P< 0.05). At per-vessels analysis, 55 (14%) vessels showed obstructive stenosis and 335 (86%) did not. The mean CFR was significantly lower in coronary vessels with obstructive stenosis as compared to other vessels (1.7±0.7 vs. 2.3±0.8, P<0.01). NRI obtained by adding CFR to a model including clinical data and ITPD was 0.6. Conclusions: CFR provides incremental information about the presence of obstructive CAD over established cardiac risk factors and MPI parameters. A combined use of MPI and CFR can help to predict more accurately the presence of obstructive CAD.

OP608

Myocardial Blood Flow Quantification in PET: Can We Agree on Values?

S. V. Nesterov[1,2], J. M. Knuuti[1]; [1]Turku PET Centre, Turku, FINLAND, [2]Institute of Evolutionary Physiology and Biochemistry RAS, St. Petersburg, RUSSIAN FEDERATION.

PET myocardial blood flow (MBF) quantification needs dedicated software (SW). The number of existing SW tools and tracer-kinetic models they implement is substantial and grows; they all are separately validated and then used in research or clinic; however, the global standard for PET MBF quantification is yet missing. To standardize, we must assess the agreement between the existing SW tools. AIM. To assess the agreement between the SW tools for PET MBF quantification using Rb-82, O-15 water and N-13 PET. MATERIALS AND METHODS. We finalized cross-comparing Rb-82 (N=48 and 10 SW) and O-15 water (N=91; 5 SW) PET data from CAD-suspected patients, and are in the process of comparing N-13 PET (11 SW). SW tools included CardiacVUer, Carimas, Corridor4DM, FlowQuant, HOQUTO, ImagenQ, MunichHeart, QPET, PMOD, Syngo.MBF, and UW-QPP. Experts have used one of the SW tools each to analyze global, regional (LAD, LCx and RCA) and segmental MBF and MFR using dynamic PET scans—rest and pharmacologically induced stress. We applied a custom linear mixed model for the repeated measures to produce the two agreement metrics—intraclass correlation coefficient (ICC) and difference between the values from the models—calculated pairwise. Differences below 20% of median values with corresponding ICCs above 0.75 witnessed to good reproducibility. RESULTS. Rb-82: differences between global and regional MBF values as measured with different SW tools could be as large as 130%; nonetheless, the tools that implemented the 1-TCM (Lortie et al. 2007) could be used interchangeably on global and regional levels. On the segmental level, however, only four tools—Carimas, PMOD, QPET, and syngo MBF—fulfilled the criteria for agreement.O-15 water: the studied SW tools demonstrated good intraobserver reproducibility, yet the agreement between the tools did not fulfill the predetermined criteria even on the global and regional levels. CONCLUSION. Values received from PET MBF quantification depend on the implemented kinetic model and, to a certain extent, depend on the software tool used. The extent, in our studies, depended on the PET tracer.

OP609

Validation of Carimas2.9 vs Carimas1 on ^{15}O-water cardiac perfusion ischemic cutoff value

C. Han, J. Knuuti; Turku PET Centre and Turku University Hospital, TURKU, FINLAND.

Purpose: Carimas is a widely used analysis tool for ^{15}O-labeled water cardiac perfusion study, developed in Turku PET Centre of Finland (http://www.turkupetcentre.fi/carimas). Cutoff value for ischemia in absolute terms has been validated in Carimas1 as 2.4 ml/g/min for stress study (Circ Cardiovasc Imaging 2011). However, it is unknown that if this value is still validated in new generation of Carimas (Carimas2). This study was designated to investigate the validation of this absolute cutoff value in Carimas2 based on clinical cardiac perfusion study data. **Materials and Methods:** 96 patients with moderate (30%-70%) pretest likehood of coronary artery disease underwent ^{15}O-labeled radio water PET studies during adenosine stress were enrolled. Patient images were analyzed using Carimas1 and Carimas v2.9 independently. Absolute myocardial blood flow was calculated. The patients and the vessel regions (LAD, RCA and LCX) then were classified as normal or abnormal based on a cutoff value of 2.4ml/g/min. Cohen's Kappa analysis was employed for validation. **Results:** Total number of vessel regions is 288 (96*3) in 96 patients. Application of cutoff value of 2.4ml/g/min to Carimas2 results in: true positive 79, false positive 10, false negative 19, and true negative 180, respectively. Cohen's Kappa is 0.773 and agreement 0.899. In patient-based analysis: true positive 31, false positive 3, false negative 2, and true negative 60, respectively. Cohen's Kappa is 0.885 and agreement 0.947. **Conclusions:** Using the same absolute cutoff of 2.4 ml/g/min for evaluating ischemia on ^{15}O-labeled radio water cardiac perfusion study, new generation of Carimas (Carimas v2.9) gives a substantial agreement of accuracy compared with Carimas 1.Therefore, new generation of Carimas can be used for analyzing cardiac PET perfusion studies.

OP610

Absolute Stress Myocardial Blood Flow Determines Ventricular Function and Synchrony Better than Myocardial Perfusion Reserve: a 13N-ammonia PET Study

L. Juárez-Orozco[1], E. Alexanderson[2], R. A. Dierckx[1], H. H. Boersma[1], C. J. Zeebregts[1], N. Prakken[1], R. A. Tio[1], R. H. J. A. Slart[3]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Instituto Nacional de Cardiología "Ignacio Chávez", Mexico City, MEXICO, [3]University of Twente, Enschede, NETHERLANDS.

Introduction. Cardiac PET represents the reference technique for the absolute quantification of myocardial blood flow(MBF) and perfusion reserve(MPR). EKG-Gated PET datasets additionally assess ventricular function in three complementary spheres: systolic, diastolic and ventricular synchrony. Stress MBF and MPR have proved superior diagnostic performance to relative measurement of myocardial tracer retention and recent studies suggest that stress-MBF may outperform MPR in the detection of significant coronary artery disease(CAD). Our aim was to evaluate whether stress MBF or MPR better relates with integral ventricular function in patients with known or suspected CAD. **Methods.** We studied 248 patients who underwent a rest - adenosine-stress PET perfusion scan with ^{13}N-ammonia for the evaluation of myocardial ischemia. Quantitative perfusion was assessed by stress MBF and MPR. Ventricular systolic function was evaluated through the left ventricular ejection fraction(LVEF), diastolic function through the mean filling rate in the first third of diastole(MFR/3) and ventricular synchrony through entropy(E). Clinically relevant variables considered were: gender, age, body mass index(BMI), hypertension(HTN), dyslipidemia, type-2 diabetes mellitus(DM2), smoking habit, prior MI, scar extent and semi-quantitative ischemic burden(SDS). We performed a multivariate analysis of variance (GLM) inputting LVEF, MFR/3 and E as the dependent variables (integral ventricular function). We included both stress-MBF and MPR into the model along with the relevant covariates. The independent significance of the included predictors was tested using Pillai's trace criterion F-statistic. **Results.** Our sample included 166 men and 82 women with a mean age of 63±11 and 67±11 years. There were 60% of patients with HTN, 55% with dyslipidemia, 21% with DM2, 45% of smokers and 34.7% with a previous MI. Quantitative perfusion documented a mean stress-MBF of 1.99±0.74mL/g/min and a mean MPR of 2.54±0.92. Ventricular function measurements showed a mean LVEF=61.6±15%, mean MFR/3=1.12±0.38EDV/s and mean E=45.6±11.2% . The multivariate analysis demonstrated that stress-MBF is a significant predictor ($F[3,174]=7.25, p<0.001$) for integral ventricular function (LVEF, MFR/3 and E) while MPR only showed a trend towards significance ($F[3,174]=2.47, p=0.063$). Gender, age, DM2 and extent of previous MI were also significantly related to the dependent variables. **Conclusions.** Stress MBF is better related to integral ventricular function than MPR, as evaluated by PET, when accounting for relevant covariates. Our results suggest that the reported better performance of stress MBF for diagnosing significant CAD could be, at least partially, linked to its stronger relationship to ventricular function measurements. Further research into the preferential application of stress MBF in cardiac PET imaging is warranted.

OP611

Diffuse subendocardial hypoperfusion leads to transient left ventricular cavity dilation by ^{13}N-ammonia perfusion PET imaging in hypertrophic cardiomyopathy patients

H. Yalcin[1], I. Valenta[2], F. Yalçin[1], A. Tahari[2], N. Kucukler[1], N. Vasquez[1], I. Pozios[1], Y. Zhou[2], M. Pomper[2], T. Abraham[1], T. Schindler[2], M. R. Abraham[1]; [1]JOHNS HOPKINS UNIVERSITY, Hypertrophic Cardiomyopathy Center of Excellence, Department of Medicine, BALTIMORE, MD, UNITED STATES, [2]JOHNS HOPKINS UNIVERSITY, Division of Nuclear Medicine, Department of Radiology, BALTIMORE, MD, UNITED STATES.

Objectives: To investigate the mechanisms underlying vasodilator-induced transient left ventricular cavity dilation (LVCD) in HCM. **Background:** Vasodilator-induced transient LVCD has been linked to reduction in global myocardial blood flow, but direct proof for subendocardial hypo-perfusion during LVCD by positron emission tomography (PET) is lacking in HCM patients. **Methods**: Rest and stress ejection fraction (LVEF) and MBF were quantified in the subepicardial and subendocardial regions of the LV and globally, in 104 HCM patients, using $^{13}NH_3$-PET. HCM patients were divided into two groups, based on the presence or absence of LVCD ($LVvolume_{stress}/LVvolume_{rest}$>1.13). LV wall thickness, LV outflow tract gradients (LVOTG), diastolic function (E/E') were assessed by Echocardiography. Analysis of baseline and stress EKGs was performed digitally using Cardio Calipers software. **Results**: Transient LVCD was seen in 55 patients (52%). Maximum LV wall thickness (2.19±0.6 vs 1.94±0.4cm; p=0.02), stress LVOTG (65±51 vs 44±34 mmHg; p=0.016), mitral E/E' (20±9 vs 15.1±5.14, p=0.001) and ischemic ST-T changes following vasodilator infusion (p=0.008) were significantly higher in HCM patients with LVCD, when compared to patients without LVCD. Rest LVEF was preserved and similar in the 2 groups. Patients with LVCD had lower stress-LVEF (43±11 vs 53±10; p<0.001), lower stress-MBF in the subendocardial region (1.69±0.77 vs 2.33±1.03 ml/min/g; p<0.001) and greater regional myocardial perfusion abnormalities (SDS score: 7.0±6.1 vs 3.9±4.3; p=0.004) by PET, than patients without LVCD. The transmural perfusion gradient (subendocardial MBF /subepicardial MBF ratio), an indicator of subendocardial perfusion was similar in HCM patients with/without LVCD at baseline. Notably, HCM patients with LVCD had greater reduction in the transmural perfusion gradient (~62%) following vasodilator, when compared to HCM patients without LVCD (~25%), resulting in lower stress-transmural perfusion gradients in LVCD patients (0.85±0.22, $LVCD^+$ vs. 1.09±0.39, $LVCD^-$; p<0.001). Global myocardial flow reserve (MFR), stress-LVEF and stress-transmural perfusion gradient were associated with LVCD. **Conclusion**: Diffuse subendocardial hypoperfusion and myocardial ischemia resulting from microvascular dysfunction, contribute to development of transient PET-LVCD in HCM.

JDTic-based radiotracers for Kappa Opioid Receptor PET Imaging: Design, Synthesis, Pharmacology, Molecular Modeling Studies, Radiolabelling, in vivo Characterization and Metabolic Investigation

C. Perrio[1], S. Schmitt[1], J. Delamare[1], O. Tirel[1], M. Dhilly[1], F. Fillesoye[1], N. Colloc'h[2]; [1]UMR 6301 ISTCT, LDM-TEP, CNRS, CEA, Université Caen Normandie, CAEN, FRANCE, [2]UMR 6301 ISTCT, CERVOxy, CNRS, Université Caen Normandie, CAEN, FRANCE.

Aim. JDTic belongs to a unique class of compounds exhibiting pure opioid antagonist activity that may prove useful in the treatment of obesity, psychosis and depression, as well as opioid and cocaine abuse and other central nervous system disorders.[1] We anticipated that ^{11}C- and ^{18}F-radiolabelled derivatives of JDTic would represent attractive radiopharmaceuticals to investigate drug addiction and associated psychiatric disorders (schizophrenia, depression) by PET imaging. Methods. We designed and synthesized a series of *N*, *O*-methyl and fluoroalkyl derivatives of JDTic. We compared their opioid receptor properties in both in vitro assays and modeling approach. The *N*-methyl and *N*-fluoropropyl JDTic derivatives were concluded to possess favorable properties to be considered as a valuable candidates as imaging agent. We performed their radiolabelling with carbon-11 and fluorine-18 by ^{11}C-methylation and ^{18}F-fluoropropylation respectively. We determined their biodistribution and specific binding after pre-treatment with U50,488 in mouse and rats by microTEP and microdissection. Additional radiometabolization and metabolization studies were undertaken in vivo and in vitro in mouse or human liver microsomes by UPLC-MS. Results. We found that all new fluorinated compounds bound selectively KOR but in less extent than JDTic and its *N*-methylated derivative. *N*-Fluoroalkylation was preferable to *O*-alkylation to keep a selective KOR binding. Modeling studies based on the crystal structure of the JDTic/KOR complex revealed that fluorine atom in the N-fluoropropyl JDTic derivative was involved in the selective KOR binding. Radiochemistry was performed efficiently to lead to the two target radioligands. The N-[^{11}C]-methyl JDTic derivative (10% total radiochemical yield, 60 min total synthesis time, RAS = 1.5-4.5 GBq/μmol) was found to display a high specific binding in vivo whereas the N-[^{18}F]-fluoropropyl JDTic (5% total radiochemical yield, 2.5 h total synthesis time, RAS = 41-89 GBq/μmol) was quickly metabolized. In vitro metabolization investigation revealed identity of a piperidine as the major metabolic fragment of *N*-fluoropropyl JDTic. Under similar conditions, JDTic itself was found to be stable. Conclusion. Our finding demonstrates that N-[^{11}C]-methyl JDTic derivative represents a promising KOR radioligand but N-fluoroalkylation is detrimental for in vivo stability. However, JDTic remains a lead KOR antagonist for the development of new metabolically stable drugs. (1) Thomas et al, J. Med. Chem. 2003, 46, 3127.

OP613

The neuroinflammatory and behavioral response to recurrent psychosocial stress: An [^{11}C]PBR28 PET imaging study in stress-sensitized aged rats

P. Kopschina Feltes[1,2], E. F. J. de Vries[1], L. E. Juárez-Orozco[1], D. Vállez García[1], C. M. Moriguchi-Jeckel[2], R. A. J. O. Dierckx[1], J. Doorduin[1]; [1]University of Groningen, Groningen, NETHERLANDS, [2]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, BRAZIL

.

Introduction: Neuroinflammation plays an important role in the relationship between psychosocial stress and depressive-like behavior. However, it is still unknown if prior exposure to psychosocial stress has long-term influences in the response to a recurrence of the stressful stimulus later in life. The present study aimed to evaluate the behavioral and neuroinflammatory profile after repeated social defeat (RSD) in stress-sensitized and stress-naïve aged rats. Methods: Fourteen months old stress-sensitized Wistar rats (n=10), exposed during adolescence to 5-days of RSD, underwent the same RSD protocol after one year. Stress-naïve age-matched rats (n=8) were subjected to RSD without previous adolescent RSD exposure. The RSD protocol was performed by introducing the experimental rat (intruder) inside the home cage of a dominant Long Evans (resident) rat for a total of 60 min each day (experimental days 0-4). The protocol was considered successful when the intruder indicated defeat by adopting a submissive posture for at least 3 sec. Anhedonic behavior was assessed through the sucrose preference test on day -2 and 5. On day -1 and 11, neuroinflammation was measured by a 30-min static PET scan, performed 45 min after injection of ^{11}C-PBR28. Results: Decreased sucrose preference (-25%, p=0.003) was observed in stress-sensitized rats only on day 5, while no difference was found in stress-naïve rats after RSD. On day 11, within-group comparison demonstrated that stress-naïve rats showed an *increased* ^{11}C-PBR28 uptake in the frontal cortex association (+16%, p=0.035), cingulated cortex (+21%, p=0.008), orbitofrontal cortex (+20%, p<0.001), and medial/prefrontal cortex (+27%, p<0.001), while stress-sensitized rats had a *decreased* ^{11}C-PBR28 uptake in the cerebellum (-9%, p=0.004), frontal cortex association (-12%, p<0.001), medial/prefrontal cortex (-12%, p=0.002), and orbitofrontal cortex (-13%, p<0.001). Notably, the between-group comparison on day -1 showed a significant increased ^{11}C-PBR28 uptake in stress-sensitized rats for the cingulate cortex (25%, p=0.022), frontal cortex association (33%, p=0.001), orbitofrontal cortex (45%, p<0.001) and medial/prefrontal cortex (47%, p<0.001). No differences between groups were observed on day 11. Conclusion: Rats that were stress-sensitized at adolescence showed higher

neuroinflammatory levels in areas associated with depression at old age than stress-naïve rats. RSD exposure at old age provoked anhedonic-like behavior and decreased microglia activation in stress-sensitized rats. In contrast, stress-naïve rats demonstrated an increased neuroinflammatory profile in the same areas after RSD exposure at old age, but without anhedonic symptoms. This distinctive neuroinflammatory and behavioral response to psychosocial stress warrants further research into the long-term effects of early-life stress exposure.

OP614

^{18}F FDG-PET and fMRI-based Connectivity Analysis of the Posterior Cingulate Cortex/Precuneus in Social Anxiety Disorder

A. Doruyter[1], L. Taljaard[1], D. Stein[2], P. Dupont[3], C. Lochner[1], J. Warwick[1]; [1]Stellenbosch University, Cape Town, SOUTH AFRICA, [2]University of Cape Town, Cape Town, SOUTH AFRICA, [3]KU Leuven, Leuven, BELGIUM.

Aim: Resting-state functional connectivity (RFC) in SAD has been investigated almost solely using temporal correlations of blood oxygen level dependent (BOLD) signal on functional magnetic resonance imaging (rs-fMRI). Nuclear methods possess several advantages to rs-fMRI in neuroimaging research and remain underutilized. In light of evidence that the default mode network (DMN) may play a role in social cognition we investigated RFC of the posterior cingulate cortex/precuneus (PCC/Precun) seed, a core node of this network, in SAD using both rs-fMRI and F-18 FDG-PET. **Materials and methods:** SAD participants and healthy controls (HCs) completed the Liebowitz Social Anxiety Scale (LSAS) and underwent resting-state FDG PET and MRI (rs-fMRI and T1-weighted structural). The State Trait Anxiety Inventory (STAI-S) was completed at both imaging visits. Preprocessing was performed in SPM-12. Seed-to-voxel, whole-brain RFC analysis was performed on a PCC/Precun seed described by Greicius using the functional connectivity toolbox and customized scripts in SPM-12. Conjunction analysis was performed to identify shared correlations in the FDG-PET analysis. In the SAD group, a correlation between connectivity and disease severity (LSAS score) was investigated. Statistical threshold was set at p<0.001 uncorrected (voxel level) combined with p<0.05 FDR-corrected at the cluster level. **Results:** Ten SAD participants and 10 age and gender-matched HCs were included. STAI-S scores were similar at imaging visits. On rs-fMRI the SAD group demonstrated reduced connectivity between the PCC/Precun seed and a cluster overlapping left striatum and thalamus. On FDG-PET the SAD group demonstrated reduced connectivity between the PCC/Precun seed and clusters overlapping bilateral insula and right medial orbitofrontal cortex. Conjunction analysis of the FDG-PET data did not detect any significant shared correlations with the PCC/Precun seed in the two groups. On rs-fMRI, disease severity was negatively correlated with connectivity between PCC/Precun and a cluster in left temporal pole. **Conclusion:** Our findings suggest disrupted BOLD connectivity in SAD between PCC/Precun and subcortical structures as well as disrupted metabolic connectivity between this seed and brain regions implicated in the fear circuit. The negative correlation between disease severity of SAD and BOLD connectivity between PCC/Precun and left temporal pole is interesting in light of the latter region's purported role as a store for social conceptual information. Differences in biological signal origin likely explain differences in RFC defined on fMRI and FDG-PET, highlighting the complementary value of these techniques.

OP615

Cerebral dopamine release and glutamatergic transmission relate to different subjective effects of acute alcohol: an in vivo multimodal imaging study

G. Leurquin-Sterk[1], J. Ceccarini[1], C. L. Crunelle[2,3], A. Weerasekera[4], B. de Laat[4], U. Himmelreich[4], G. Bormans[5], K. Van Laere[1,4]; [1]Department of Nuclear Medicine & Molecular Imaging, University Hospitals Leuven, KU Leuven – University of Leuven, Leuven, BELGIUM, [2]Toxicological Center, University of Antwerp, Antwerp, BELGIUM, [3]Department of Psychiatry, University Hospital Brussels, Brussels, BELGIUM, [4]Biomedical MRI/MoSAIC, Department of Imaging and Pathology, KU Leuven - University of Leuven, Leuven, BELGIUM, [5]Laboratory for Radiopharmacy, KU Leuven – University of Leuven, Leuven, BELGIUM.

AIM: Converging preclinical evidence has linked both extrastriatal dopamine release and glutamatergic transmission via the metabotropic glutamate receptor 5 (mGluR5) to the rewarding properties of alcohol intake. To date, direct human evidence is lacking on how and where in the brain these effects occur. This study aimed to assess whether the rewarding effects of alcohol intake in healthy humans are related to both extrastriatal dopamine release and baseline cerebral mGluR5 availability. **METHODS:** Eleven non-smoking male subjects (age = 40.1 ± 12.2 years), who were social drinkers verified by history and quantitative hair analysis, were included in the study. Mesocorticolimbic dopamine release upon monitored intravenous alcohol administration and mGluR5 availability were measured on two days using a single-session D_2/D_3 receptor ^{18}F-fallypride positron emission tomography (PET) and a ^{18}F-FPEB PET, respectively. Additionally, baseline and post-alcohol glutamate-glutamine levels in the anterior cingulate cortex were measured using magnetic resonance spectroscopy. Neuroimaging data were related to the subjective rewarding effects of alcohol. **RESULTS:** Intravenous alcohol induced significant dopamine release in various extrastriatal regions ($p < 0.05$, Bonferroni corrected), which correlated with the 'liking' and 'wanting' subjective effects for the anterior cingulate, orbitofrontal and left ventromedial prefrontal cortices (r range 0.60 - 0.86; $p < 0.05$, uncorrected). In contrast, baseline mGluR5 availability was positively associated with the 'high' effect of alcohol in dorsolateral, ventrolateral and left ventromedial prefrontal cortices, and in the medial temporal lobe, left thalamus and left caudate nucleus (r range 0.61 - 0.67; $p < 0.05$, uncorrected). Although glutamate-glutamine levels were not affected by alcohol intake, baseline anterior cingulate glutamate levels were negatively associated with the alcohol 'high' effect ($r = -0.80$; $p < 0.003$). **CONCLUSION:** These data reveal new mechanistic neurobiological accounts for alcohol effects on human behavior. We found the first *in vivo* evidence that alcohol-induced dopamine release is related to alcohol 'liking' and 'wanting' effects in specific prefrontal areas underlying value processing and motivation. In contrast, our findings suggest that mGluR5 availability in distinct subcortical-prefrontal-temporal regions is related to the 'high' effect of alcohol.

OP616

Exploration of the concept of 5-HT1A receptor biased agonists: a PET-MRI study

B. Vidal[1], M. Villien[2], S. Fieux[1], D. Le Bars[2,3], A. Newman-Tancredi[4], N. Costes[2], L. Zimmer[1,2,3]; [1]Université Claude Bernard Lyon 1, Lyon Neuroscience Research Center, INSERM, CNRS, Lyon, FRANCE, [2]CERMEP - Imaging Platform, Bron, FRANCE, [3]Hospices Civils de Lyon, Lyon, FRANCE, [4]Neurolixis Inc., Dana Point, CA, UNITED STATES.

Aim: In neuropharmacology, the recent concept of "biased agonism" implies the capacity of highly specific agonists to target specific intracellular pathways in specific brain areas. In the context of serotonin pharmacotherapy, 5-HT1A receptor biased agonists could be of great interest to optimize pharmacological treatments of several neuropsychiatric disorders. The aim of this study was to bring additional support to this concept thanks to simultaneous fMRI and PET molecular imaging. We compared two biased agonists, F13640 (a drug-candidate for the treatment of L-DOPA-induced dyskinesia) and F15599 (a drug-candidate for the treatment of breathing deficits in Rett syndrome), at different doses, in anaesthetized cats. The drug

occupancy was measured by PET imaging with [18F]MPPF, a 5-HT1A receptor radiotracer, after administration of both agonists and was correlated with the consequent brain activation patterns (pharmaco-MRI).Materials and methods: PET and fMRI data were acquired simultaneously using a Siemens Biograph mMR hybrid camera (CERMEP-Imaging Platform). [18F]MPPF was injected in a 90-min perfusion (bolus followed by a constant infusion) in isoflurane-anesthetized cats. After a post-injection equilibrium period of 50 min, F13640 or F15599 was injected i.p. The 5-HT1A receptor occupancy was quantified by comparing [18F]MPPF binding potential values, before and after the pharmacological challenge. Thirty minutes after the beginning of the PET acquisition, continuous T2* EPI MRI acquisitions (TR = 2s) were performed to measure the BOLD signal. The fMRI session was divided into 20 minutes of baseline and 20 minutes after drug injection. A voxel based analysis of the fMRI data was performed at an individual level, followed by a second-level analysis, in a block design using a General Linear Model (GLM) approach. This PET-MRI protocol was replicated for each cat (n=4) with increasing concentrations of F13640 and F15599 (0.04 - 0.08 - 0.16 mg/kg ip).Results: PET and fMRI data, taken together, showed clear differences between the two agonists in terms of binding and subsequent activation patterns. F13640 displayed similar affinities for presynaptic and postsynaptic 5-HT1A receptors and elicited BOLD modifications in multiple brain regions. In comparison, F15599 showed a preference for postsynaptic receptors, with little capacity to elicit 5-HT1A activation in the raphe nucleus.Conclusions: This study is the first simultaneous exploration of a drug 5-HT1A receptor occupancy and its consequences in terms of brain activation. PET-fMRI represents a powerful tool in neuropharmacology and opens new ways to address the innovative concept of biased agonism.

OP617

The Effect of Brain-Derived Neurotrophic Factor (BDNF) Polymorphism Val66Met on Central Serotonin Transporter (5-HTT) Availability and body mass index (BMI) in Adults: A [^{11}C]DASB-PET Study

M. Drabe*[1,2], P. Hinderberger*[1,2], M. Rullmann[1,2], J. Luthardt[1], Y. Böttcher[2], G. Becker[1], M. Patt[1], M. Blüher[2], R. Regenthal[3], T. Ploetz[3], O. Sabri[1,2], S. Hesse[1,2]; [1]Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [2]Leipzig University Medical Center, IFB AdiposityDiseases, Leipzig, GERMANY, [3]Institute of Clinical Pharmacology, University of Leipzig, Leipzig, GERMANY.

Background: BDNF is currently being discussed as a potential modulator of weight control. Val66Met, a single nucleotide polymorphism (SNP) of the BDNF-encoding gene, leads to impaired intracellular trafficking and reduced activity-dependent secretion of the mature peptide. It has been suggested that a connection exists between Val66Met and body weight. However, current literature renders ambiguous about the exact effect of their relationship in which brain 5-HT is believed to have a regulatory role as well. The aim was therefore to investigate the influence of Val66Met genotype on body weight as well as 5-HTT availability (as a proxy for 5-HT tone) in selected brain regions in highly obese and normal-weight individuals. **Methods:** 29 non-depressed obese (mean BMI, 36.7±10.4 kg/m^2, 8 men; mean age, 37±10 years; range, 21-59 years) and 14 normal-weight (mean BMI, 22.5±2.6 kg/m^2; 5 men; mean age, 36±7 years; range, 21-49 years) were scanned with dynamic PET and 484.1 ±9.9 MBq [^{11}C]DASB. TaqMan assay was performed for targeted BDNF SNP genotyping. Statistical analyses of 5-HTT binding potential BP_{ND}, Val66Met genotype and body-mass-index were first carried in both volume-of-interest (VOI) and voxel-based approach. **Results:** A significant increase of BP_{ND} in the anterior cingulate cortex (p = 0.02) and medial prefrontal cortex (p = 0.03) were found in Met carriers compared to the homozygous Val/Val group. Additionally, a general linear model was then applied to account for covariates (e.g., age, sex, sunshine duration) which revealed an increased age-corrected BMI for Met-carriers compared to the homozygous Val genotype (p = 0.04). **Conclusion:** In our study sample, Val66Met genotype was associated with *in-vivo* 5-HTT availability and BMI. Whether such associations in regions important for reward processing, personality, and decision-making are linked to trait characteristics and neurobehavioral models has to be determined by further studies in human obesity.

OP618

Imaging drug-drug interaction using PET: investigating the impact of diazepam on buprenorphine-induced respiratory depression

D. Vodovar[1,2,3], G. Pottier[1], S. Auvity[1], B. Mégarbane[2,3], I. Buvat[1], F. Caillé[1], **N. Tournier**[1]; [1]IMIV, CEA, Inserm, CNRS, Univ. Paris-Sud, Université Paris Saclay, CEA-SHFJ, Orsay, FRANCE, [2]INSERM UMRS 1144, Paris-Diderot University, Paris, FRANCE, [3]Assistance Publique - Hôpitaux de Paris, Paris, FRANCE.

Aims: Buprenorphine (BUP) is a partial mu-opioid receptor (MOR) agonist with "ceiling effect" that is supposed to prevent respiratory depression during pain management or opioid maintenance therapy. However, fatal respiratory depression with typical opioid toxidrom has been reported mainly when BUP has been co-ingested with benzodiazepines such as diazepam (DZP). In rats, we previously demonstrated that DZP (20 mg/kg s.c) or BUP (30 mg/kg i.p) did not lead to respiratory depression while their combination resulted in severe respiratory depression. Based on *in-vitro*/*ex-vivo* experiments, we hypothesized benzodiazepine-induced alterations in MOR affinity/density, which may provide a mechanistic explanation for the interaction between DZP and BUP *in vivo*. **Methods:** The *in vivo* effects of acute DZP exposure on BUP brain kinetics and affinity were investigated using [^{11}C]BUP PET imaging (~37 MBq, 90 min) in Sprague Dawley rats. Baseline brain [^{11}C]BUP kinetics (vehicle, n=4) were compared to kinetics obtained *i)* after displacement with unlabeled pharmacological BUP dose (0.3 mg/kg) administered at 20 min after [^{11}C]BUP (n=3) and *ii)* pre-treatment with DZP (20 mg/kg s.c) administered 15 min before PET (n=4). SUV-normalized [^{11}C]BUP PET images were co-registered in a template to generate time-activity curves (TACs) in several brain regions. ^{11}C-BUP binding potential (BP_{ND}) was estimated using the simplified reference-tissue model (SRTM) using the cerebellum as the reference region. **Results**: Baseline [^{11}C]BUP brain kinetics in the cerebellum (SUV_{90min}= 0.29±0.07) was influenced neither by the displacement (SUV_{90min}= 0.24±0.02) nor by DZP pretreatment (SUV_{90min}= 0.38±0.05) which makes it possible to use the cerebellum as reference tissue region. In the striatum, a MOR-rich region, baseline SUV_{90min}= 0.89±0.26 was significantly decreased by displacement (SUV_{90min}= 0.51±0.10; $p<0.05$), showing the reversibility of [^{11}C]BUP binding, but not by DZP-pretreatment (SUV_{90min}= 0.90±0.13). Kinetics modeling indicated that [^{11}C]BUP BP_{ND} was not influenced by DZP pretreatment in all tested regions including the striatum, frontal cortex, midbrain, pons, amygdala and medulla. **Conclusion:** [^{11}C]BUP brain kinetics, reported for the first time in rodents, corresponds to the known distribution of MOR in the rat brain and can be described using SRTM. [^{11}C]BUP BP_{ND} was not influenced by DZP, indicating the absence of any measurable regulation of BUP affinity for MOR *in vivo*. Our results indicate that respiratory depression attributed to BUP/benzodiazepine combination observed in patients may result from the synergistic effects of these two drugs on respiratory function rather than from alteration of MOR availability or affinity for BUP. Dominique Vodovar received a joined grant from CEA and AP-HP.

OP619

Baseline binding potential of [11C]raclopride at true transient equilibrium predicts magnitude of amphetamine-stimulated dopamine release

Y. Kumakura, **A. Gjedde**; University of Copenhagen, Copenhagen N, DENMARK.

Objectives: Quantitation of binding of [11C]raclopride in human brain is challenged by extreme changes of synaptic concentration of endogenous dopamine after intravenous administration of amphetamine. We used the exact approach of True Equilibrium Bolus Estimation (TREMBLE, Soelling et al., 1997; Wong et al, 1998) to quantify binding of tracer raclopride at true transient equilibrium by simple rearrangement of differential kinetic equations. We tested the hypothesis that baseline binding (BPND) of raclopride predicts the receptor occupancy by stimulated dopamine release in relation to baseline dopamine in young healthy volunteers. Methods: We selected PET data of 23 males and 14 females aged 19-29 years (mean 22.4; SD 3.1) from a cohort of 84 subjects (Kuwabara et al., 2012). Subjects underwent two consecutive 90-min PET sessions with [11C]raclopride. A high specific activity intravenous bolus injection was administered at the beginning of each scan. The first scan was preceded at 5 min by i.v. injection of saline; the second scan was preceded at 5 min by 0.3 mg/kg AMPH. Arterial blood was sampled at rapid intervals initially, with increasing intervals. Selected samples were analyzed by HPLC for radioactive plasma metabolites. The imaging protocol included as many as 30 acquisitions, frame durations increasing from 15 sec to 6 min. First, the raw time-activity-curves (TACs) of striatum and reference tissues were interpolated and resampled every 0.1 min. Then, we employed the Savitzky-Golay polynomial filter (Savitzky and Golay, 1964) to calculate first-order differential terms by numerical differentiation. We analyzed the filtered noise-attenuated TACs with TREMBLE to obtain BPND at the time of the transient true equilibrium (TEQ). Linear regression analysis was performed between baseline BPND (BPND{b}) and receptor occupancy (%). Outliers that exceeded 2 SDs were excluded from final analysis. Results: Mean and SD estimates of baseline BPND for caudate and putamen were 3.36 ± 0.38 and 4.09 ± 0.46, respectively. Mean estimates of amphetamine BPND were 3.25 ±0.39 and 3.50±0.31. Mean estimates of RO (%) were 2.3±14.9 and 13.2±13.0, meaning significantly smaller "displacement" in caudate. The slopes of linear regression analysis were significantly non-zero, at the significance levels of $P<0.0002$ for caudate, and $P<0.0001$ for putamen. We observed negative RO estimates in some subjects with the lowest baseline BPND. Conclusions: We conclude that the sensitivity of D2 receptors to saturation appears to be associated inversely with the degree of receptor occupancy at baseline, as predicted by the baseline binding potential obtained with this novel kinetic approach.

Performances of the collapsed cone superposition algorithm for the dosimetry of Lu177-PRRT

A. Dieudonné[1], M. Sanchez-Garcia[1], I. Gardin[2], O. Hentic[3], M. Palazzo[3], P. Ruszniewsky[3], R. Lebtahi[1]; [1]Department of Nuclear Medicine, Beaujon University Hospital, HUPNVS, APHP, Clichy, FRANCE, [2]Department of Nuclear Medicine, Henri Becquerel Cancer Center and Rouen University, QuantIF – LITIS [EA 4108], Rouen, FRANCE, [3]Department of Gastroenterology, Beaujon University Hospital, HUPNVS, APHP, Clichy, FRANCE.

The collapsed cone superposition algorithm (CCS) has been recently implemented for photon emitters (Sanchez-Garcia *et al*., Phys Med Biol 2015). The objective is to compare CCS 3D-dosimetry of ^{177}Lu peptide receptor radionuclide therapy (PRRT) with other methods. **Methods:** We compared CCS with dose-kernel convolution with a simple density correction (DKCd) and without correction (DKC) in the case of ^{177}Lu-PRRT, taking Monte Carlo simulations (MCS) as reference. The clinical case was a patient treated by ^{177}Lu-PRRT for a neuroendocrine cancer with 1 lung lesion and 3 bone lesions: 2 in the iliac crest and 1 in the sacrum. The absorbed dose-rate (ADR) in Gy.h^{-1} was calculated from SPECT/CT data acquired 24h after injection of ^{177}Lu-octreotate. Regions of interest (ROIs) were drawn on normal tissues: lung, bone marrow, liver, kidneys and spleen, and on the 4 lesions. All calculations were done through the software tool VoxelDose. MCS were run with 10^7 histories on a 40 nodes cluster. The comparison was done in terms of relative difference ΔADR at the region level and Spearman correlation ρ_{sp} between ΔADR and mass density at the voxel level. Additionally, *p,* the probability of having no correlation was calculated. **Results:** For CCS, ΔADR were below 1% at the region level. At the voxel level, no or very low correlation existed between ΔADR and density (ρ_{sp}<0.12, p<0.01, p=0.96 for kidneys and 0.7 for sacrum lesion) showing the good performances of the algorithm whatever the tissue density. For DKC, ΔADR was between -1.5 and 0% for soft-tissue organs, between 2.4 and 10% for bone lesions, -8.6% for the lung lesion and -68% for lung. A correlation of ΔADR with density was found in lung and bone lesions (ρ_{sp}>0.5, p<0.01). For DKCd, ΔADR was between -1.5 and 0% for soft-tissue organs and all lesions, except for one iliac lesion (ΔADR=-4%) and the lung (ΔADR=23%). A correlation was found between ΔADR and density in lung (ρ_{sp}=0.25, p<0.01) and bone lesions (-0.43<ρ_{sp}<-0.25, p<0.01), showing that this method is sensitive to tissue density even in case of a density correction. **Conclusion:** CCS provided the best agreement with MCS, making it a clinically relevant alternative to DKC for ^{177}Lu-PRRT, while being less computationally demanding than MCS. The absorbed dose rate calculated with DKC was in very good agreement with MCS in soft-tissues, but underestimated the dose in lung. DKCd improved the agreement in lung, but with an overestimation.

OP632

Estimation Precision of Time-integrated Activity Coefficients: A Comparison of a Physiologically Based Pharmacokinetic and an Analytical Model in Peptide Receptor Radionuclide Therapy

J. Sachs[1], C. Maaß[2], F. Mottaghy[3], G. Glatting[1]; [1]University Heidelberg, Medical Faculty Mannheim, GERMANY, [2]Massachusetts Institute of Technology, Cambridge, MA, UNITED STATES, [3]RWTH Aachen University, Aachen, GERMANY.

Aim: The aim of this study was to (1) determine time-integrated activity coefficients (TIACs) and their coefficients of variance (CVs) in peptide receptor radionuclide therapy (PRRT) with ^{111}In-DTPAOC in 15 patients using an analytical model with (a) a mono- and (b) a biexponential function and to (2) compare them to their corresponding estimated TIACs and CVs obtained using a physiologically based pharmacokinetic (PBPK) model. **Materials and Methods:** Fifteen patients with proven neuroendocrine tumors (NETs) were investigated. Planar whole-body scans using a double-head γ-camera (ECAM, Siemens, Erlangen, Germany) were performed at 45 min, 4 h, 1, 2 and 3 or 5 d and serum measurements were taken at 5 min, 0.5, 1, 2, 4 h and 1, 2, 3 or 5 d after injection of ^{111}In-DTPAOC. An analytical model with mono- and bi-exponential functions was set up in MATLAB (Version: R2015a, The MathWorks, Natick, Massachusetts, USA) and fitted to the data, including a start value search and the calculation of the coefficients of variance (CVs). The precision (described by the CVs) of the estimated TIACs for tumour and kidneys were compared to the corresponding values resulting from a PBPK model. **Results:** CVs of TIACs for (1a) the mono-exponential fit were 19 ± 6 % (median: 20 %, min: 7 %, max: 35 %) for kidneys and 28 ± 22 % (median: 22 %, min: 3 %, max: 77 %) for tumour and (1b) the bi-exponential fit 37 ± 51 % (median: 27 %, min: 2 %, max: 199 %) for kidneys and 14 ± 20 % (median: 5 %, min: 0 %, max: 62 %) for tumour. The corresponding results (2) from the PBPK model were 8 ± 3 % (median: 6 %, min: 5 %, max: 14 %) for kidneys and 12 ± 10 % (median: 10 %, min: 2 %, max: 46 %) for tumour. **Conclusion:** The use of exponential functions in the calculation of TIACs is a common way to determine absorbed doses in PRRT. However, CVs (i.e. the precision) for tumour and kidneys may be significantly larger compared to the CVs obtained using a PBPK model. Thus, the results obtained from exponential functions should be interpreted cautiously.

OP633

Can the cumulative kidney dose be predicted on the basis of the first cycle in the standard Lu-177-octreotate treatment?

V. Reijonen, J. Heikkonen, H. Mäenpää; Helsinki University Hospital Cancer Center, Helsinki, FINLAND.

Aim: We studied how well the kidney dose calculated from the first cycle of ^{177}Lu-octreotate predicts the cumulative dose from the following cycles. **Materials and methods:** 40 patients (24 males, 16 females; age 29-69 y) with metastatic neuroendocrine tumours treated in the Helsinki University Hospital, Finland, received ^{177}Lu-octreotate according to the standard protocol (7.4 GBq administered four times at eight week intervals) with amino acid solution to decrease renal uptake. The kidneys of the patients were scanned using either Symbia T2 or Intevo T6 SPECT/CT (Siemens Healthcare) at 24 hours after each treatment and at 168 hours after the first and third treatment. The activities in the left and right kidney were determined from SPECT images with defining kidney volumes from the axial CT slices, and the mean absorbed dose to the whole kidney was then calculated based on a method utilising OLINDA® software. **Results:** The median administered activity was 7479 MBq (range 6839-8761 MBq) in cycle 1, 7481 MBq (6026-8790 MBq) in cycle 2, 7478 MBq (7220-8352 MBq) in cycle 3 and 7445 MBq (6600-8752 MBq) in cycle 4. The mean kidney dose divided by the administered activity was 0.45 Gy/GBq (0.20-0.77 Gy/GBq) in cycle 1, 0.43 Gy/GBq (0.17-0.78 Gy/GBq) in cycle 2, 0.44 Gy/GBq (0.17-0.73 Gy/GBq) in cycle 3 and 0.45 Gy/GBq (0.17-0.73 Gy/GBq) in cycle 4. A paired-samples T-test indicated that there was not a significant difference in kidney dose per activity in the first cycle and the three following cycles; t(39)=1.26, p=0.215. When cumulative kidney dose was then calculated based on the kidney dose per activity in cycle 1 and the total activity administered to the patient (thus simulating that patient is imaged only in cycle 1 and the total kidney dose from the rest of the cycles is estimated based on this) and compared to the results based on dosimetric imaging in every cycle, the highest overestimation was 32% (19.4 Gy vs. 14.7 Gy) and underestimation 22% (10.2 Gy vs. 13.2 Gy). For altogether 15

patients the difference in the cumulative kidney dose was higher than 10 %, and for five patients higher than 20 %. **Conclusion:** Estimating the cumulative kidney dose on the basis of the first cycle can lead to considerable inaccuracy for a significant number of patients.

OP634

Development of a PBPK model of arginine biokinetics in humans to optimize kidney protection during peptide receptor radionuclide therapy

L. D. Jimenez, D. Hardiansyah, G. Glatting; Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, GERMANY.

Aim: To develop a physiologically based pharmacokinetic (PBPK) model of the arginine biokinetics in humans to allow optimization of kidney protection during peptide-receptor radionuclide therapy (PRRT). **Methods:** Serum arginine data after intravenous injection of L-arginine with infusion rates similar to the one used in PRRT (<0.5 g/min) were collected from 3 different studies (4 datasets in total). The collected information were used to develop a PBPK model consisting of a central serum compartment, a compartment for all the organs excluding the kidneys (remainder) and a detailed five compartment model for the kidneys. The kidney compartments were: vascular, interstitial space, apical membrane, intracellular space and basolateral membrane. Metabolic clearance of arginine in the remainder compartment was considered in the model as well as arginine synthesis in the kidneys and arginine excretion through the urine. Affinity parameters of the arginine to its main transporters in the apical and basolateral membranes in the renal tubular cells were also considered. Bayesian values were used for parameter estimation. Data from a study where a ^{111}In-DTPAOC pre-therapy bolus was co-injected with a 120 minute intravenous infusion of 25 g of lysine and 25 g of arginine (LysArg) were used to optimize the radiopharmaceutical injection schedule. A proportional relationship between the interstitial concentration of arginine and the inhibition of ^{111}In-DTPAOC uptake by the kidneys was assumed. A similar behavior of arginine and lysine in the body was also assumed. The area under the curve (AUC) of the ^{111}In-DTPAOC after interaction with arginine in the interstitial space was used to determine the optimum injection schedule. **Results:** According to our model, the predicted optimum injection time for ^{111}In-DTPAOC is at 28.3 ±2.0 min after the start of the co-infusion of LysArg. Additionally, the predicted optimal distribution for the 50 g of LysArg is approximately over 210 min with peptide injection at 65.8±1.8 min which would yield a reduction of 6.4±0.8% in the AUC when compared to a typical PPRT protocol. **Conclusions:** A PBPK model for arginine was successfully developed and used for optimization of kidney protection during PPRT. The currently-used peptide injection at minute 30 after amino acid infusion seems to be optimal according to our prediction. Additionally, a distribution of the 50 g of the kidney protective solution over 210 minutes may present a slight decrease of the AUC (also decreasing the absorbed dose in the kidneys) and may reduce possible adverse effects due to the amino acid infusion.

OP635

Design and Fabrication of Kidney Phantoms for Internal Radiation Dosimetry using 3D Printing Technology

J. Tran-Gia, S. Schlögl, M. Lassmann; University of Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY.

AIM: Currently, the calibration of gamma cameras using phantoms of variable sizes and shapes is impeded by the lack of suitable, commercially available phantoms. Therefore, the aim of this study was to design and manufacture a set of kidney dosimetry phantoms using 3D printing techniques for obtaining phantom-specific SPECT/CT calibration factors. **MATERIALS AND METHODS:** A set of kidney phantoms between 9 ml and 123 ml was designed based on the data provideded by MIRD Pamphlet 19 (Bouchet et al., JNM 2003) in Autodesk Inventor 2016 (CAD) and exported to the STL format. After conversion to machine-readable G-code, 3D printing was performed using the FDM-based Renkforce RF1000. The phantoms were coated with an epoxy casting resin for waterproofing and chemical stability. To examine the influence of the kidney geometry on image quantification, a set of spheres matching the kidney volumes was additionally produced. SPECT/CT acquisitions (Siemens Symbia T2) were performed with Tc-99m (0.90 MBq/ml), Lu-177 (0.99 MBq/ml) and I-131 (0.26 MBq/ml). The kidneys/spheres were mounted in a water-filled body phantom (IEC61675-1). A bottle of the same specific activity was placed next to the phantom as attenuation-free reference. After data acquisition, a CT-based VOI analysis was performed to determine calibration factors and examine their dependence on the VOI size. **RESULTS AND DISCUSSION:** A set of refillable, waterproof and chemically stable kidneys and spheres was successfully manufactured. Average calibration factors of 186.3 $MBq^{-1}s^{-1}$ (Tc-99m), 26.9 $MBq^{-1}s^{-1}$ (Lu-177) and 90.2 $MBq^{-1}s^{-1}$ (I-131) were obtained in the attenuation-free reference. For the largest phantom (adult), the VOIs had to be enlarged by 1.2 mm (Tc-99m), 2.5 mm (Lu-177) and 4.9 mm (I-131) in all directions to obtain calibration factors comparable to the attenuation-free reference bottle. This isotope-dependency of the VOI size can be explained by spill-out effects which are in turn dependent on the resolution of the collimator used (Tc-99m: LEHR, Lu-177: MELP, I-131: high-energy). While decreasing calibration factors were observed for decreasing phantom volumes (average percentage difference between reference and kidney phantom: 8.6% (8.6 ml), 4.6% (24.2 ml), 2.4% (44.4 ml), and 0.1% (122.9 ml), the difference between corresponding sphere/kidney pairs was small (<1.1% for all ages). The volume-dependent systematic deviation of the calibration factors results from partial volume effects. **CONCLUSION:** The presented 3D printing setup holds the potential for the design and fabrication of a wide range of anthropomorphic phantoms with an accuracy sufficient with respect to the resolution of clinically available SPECT/CT systems.

Comparative Dosimetric Evaluation on the course of PRRT using non carrier added LU-^{177} DOTATATE (i.a., i.v), non carrier added LU-^{177} DOTATOC (i.v.) and carrier added LU-^{177} DOTATATE (i.v.)

M. Paphiti[1], R. V. McCready[1], E. Z. Dimitriadi[1], **G. S. Limouris**[2]; [1]Royal Sussex County Hosp, Brighton, UNITED KINGDOM, [2]National and Kapodistrian University of Athens, Athens, GREECE.

Aim: Peptide receptor radionuclide therapy using radiolabelled somatostatin analogues is a well defined treatment option for patients with neuroendocrine tumours. It is aimed to compare patients treated with n.c.a.^{177}Lu-DOTATATE (i.a., i.v.) to those treated with n.c.a ^{177}Lu- DOTATOC and c.a. ^{177}Lu-DOTATATE, i.v. infused. **Methods:** Three groups of twelve patients with liver disseminated GEP-NETs were included in the study; n.c.a. ^{177}Lu-DOTATATE /^{177}Lu- DOTATOC and c.a. ^{177}Lu- DOTATATE were administered in a dosage of 7.3±2.3 GBq per session to each patient. Cycles did not exceed 6-fold in total. Amino-acid infusions were in parallel applied for nephroprotection. Planar scintigraphic images for the three groups were obtained at 24, 48, 96 and 120 hrs post injection. ROIs were drawn for tumour and critical organs to determine residence time and radionuclide uptake. Dosimetric calculations were performed using the patient specific scintigraphic data by the OLINDA /EXM/ 1.0 code. **Results:** Intravenous infusions of n.c.a. peptides were reached their max uptake to tumour lesions up to 20 hrs p.i. whereas the c.a. ones showed their max uptake peak at 24 hrs p.i. Intra-arterial infusions of n.c.a. DOTATATE resulted immediately, just after the end of the infusion with a tumour absorbed dose 3 folds higher than the i.v. one.

For i.v. infused n.c.a. DOTATATE / DOTATOC absorbed doses for a liver tumour of 10gr spherical mass were 33.0 mGy/MBq and 13.0 mGy/MBq, respectively and for blood and kidneys 0.030 mGy/MBq / 0.034 mGy/MBq and 0.46 mGy/MBq / 0.66 mGy/MBq. For i.v. infused c.a. DOTATATE, tumour dose was 4.4 mGy/MBq and for blood and kidneys 0.1 mGy/MBq and 0.9 mGy/MBq. **Conclusion:** Intra-arterial infusions with n.c.a. ^{177}Lu-DOTATATE reached its tumour max uptake immediately and 3 fold higher than the i.v. one. Intravenous infusions with n.c.a. ^{177}Lu- DOTATATE /^{177}Lu-DOTATOC showed approximately the same dosimetric results whereas for c.a. ^{177}Lu- DOTATATE the absorbed dose in tumour was markedly lower but higher in critical organs.

Intrinsically ^{89}Zr-labeled Gd_2O_2S:Eu nanoprobes for in vivo PET and γ-ray-induced radioluminescence imaging

W. Cai[1], Y. Zhan[2], F. Ai[3], F. Chen[1], J. Liang[2], T. E. Barnhart[1], J. Tian[4]; [1]University of Wisconsin-Madison, MADISON, WI, UNITED STATES, [2]Xidian University, Xi'an, CHINA, [3]Nanchang University, Nanchang, CHINA, [4]Chinese Academy of Sciences, Beijing, CHINA.

Objective: Cerenkov luminescence imaging (CLI) is a non-invasive imaging technique showing immense promise for clinical translation. However, weak signal intensity and poor tissue penetration depth are two shortcomings that limit its clinical applications. γ-ray-induced optical luminescence imaging, combining the merits of CLI with optical imaging, has the capacity to overcome the current limitations of CLI. In this study, Gd_2O_2S:Eu nanoparticles, radiolabeled with ^{89}Zr, were optimized for in vivo sentinel lymph node (SLN) mapping using PET and γ-ray-induced optical luminescence imaging. M**ethods:** Uniform, cubic and mono-dispersed Gd_2O_2S:Eu nanoparticles (diameter ~20nm) were synthesized using a thermal decomposition method. These highly biocompatible and water-soluble nanoparticles were prepared using a single polythylene glycol (PEG) modification. The nanoparticles were comprehensively characterized, before undergoing chelator-free radiolabeling with ^{89}Zr, for in vivo SLN mapping in BALB/c mice. Extensive in vitro, in vivo, and ex vivo experiments were performed to evaluate the pharmacokinetics, stability, and toxicity of these nanoparticles. **Results:** Highly biocompatible and water-soluble ^{89}Zr-Gd_2O_2S:Eu nanoparticles were successfully synthesized, using chelator-free technology, for in vitro and in vivo lymph node mapping. The nanoparticles were successfully excited by γ-rays emitted from ^{89}Zr in vitro after hydrophilic modification. Upon subcutaneous injection of ^{89}Zr-Gd_2O_2S@PEG nanoparticles (40 μL, ~2.26 MBq) into the left foot pad of normal BALB/c mice, serial PET scans were performed. Accumulation of ^{89}Zr-Gd_2O_2S@PEG in the popliteal lymph node was found to be 8.6±4.1, 13.4±3.3 and 4.4±1.7 percentage of injected dose per gram of tissue (%ID/g) at 0.5, 2, and 6 h post-injection, respectively (n=3). Moreover, the accumulation of ^{89}Zr-Gd_2O_2S@PEG in lymph nodes was clearly detected by -ray excited optical luminescence imaging at 0.5 and 2 h post-injection regardless of open filter (detecting both Cerenkov signal of ^{89}Zr and γ-ray-induced luminescence signal) or 620 nm filter (detecting only γ-ray-induced luminescence signal, but NOT Cerenkov signal of ^{89}Zr). Quantitative analysis further illustrates that the intensity of luminescence from the ^{89}Zr-Gd_2O_2S@PEG in 620 nm filter was 10-fold lower than that in open filter, but the potential application in vivo is prominent compared with CLI. Ex vivo studies corroborated our findings in vivo, providing additional evidence that ^{89}Zr-Gd_2O_2S@PEG nanoparticles may be successfully employed for SLN mapping with γ-ray-induced optical luminescence. **Conclusion:** This study successfully employed ^{89}Zr-labeled europium-doped Gd_2O_2S nanoparticles for SLN mapping with PET and γ-ray-induced optical luminescence imaging, improving upon the current limitations of CLI in vivo and providing a new path for the development of dual-modality PET/optical imaging technologies.

OP639

How the chemical structure of cyanine dyes influences the in vivo properties of receptor targeted tracers - exemplified using hybrid cRGDyK-analogues

T. Buckle, D. M. van Willigen, S. J. Spa, S. van der Wal, M. M. Welling, N. S. van den Berg, F. W. B. van Leeuwen; LUMC, Leiden, NETHERLANDS.

Background: The success of fluorescence-based image guided surgery is directly linked to the specific (*in vivo*) characteristics of the tracer used. Although often missing, systematic and quantitative assessment of tracer-affinity and -kinetics is critical. Using hybrid imaging labels that contain both a radiolabel and a fluorescent dye we systematically evaluated the effect of the composition of cyanine dyes with different substituents and wavelengths on the molecular imaging properties of an RGD-based targeting vector. **Methods:** Hybrid labels containing a DTPA chelate, a range of nine Cy5-dyes, a Cy3-dye or a Cy7-dye were synthesized together with reference compounds. These hybrid labels were subsequently conjugated with the $\alpha_v\beta_3$-integrin targeting c[RGDyK] peptide. Affinities (Kd) were determined *in-vitro* using GEβ_3 cells. *In vivo* biodistribution of the tracers was assessed in 4T1 tumor bearing Balb/c nude mice (n=6/group) using ^{111}In (%ID/g and SPECT). For the most optimal structure the optimal dose (range 0.1-1 nmol) for fluorescence imaging was determined as well as the optimal tracer administration-imaging window (4h or 24h). *In vivo* SPECT findings were complimented by *in-* and *ex vivo* fluorescence imaging using a clinical grade fluorescence endoscope. Detectability and in depth signal penetration of the different dyes was also assessed. **Results:** Affinities raged between 21.9 and 142.3 nM. %ID/g findings and SPECT imaging, demonstrated that the dye structure heavily influenced the *in vivo* kinetics. Only one dye (Cy5-Methyl(SO3)) showed improved kinetics over the no-dye-containing hybrid reference compound. This dye also outperformed its Cy3-Methyl(SO3)- and Cy7-Methyl(SO3)-derivatives by providing e.g. lower liver and kidney retention and a two-fold higher signal-to-background ratio. While SPECT imaging was possible at all doses, *in vivo* fluorescence imaging was optimal at 1.0 nmol. Superior signal-to-background ratios were obtained at the 24h time-interval. The Cy5 derivative also showed the best *in vivo* visibility and tissue penetration using fluorescence imaging. **Conclusion:** *In vivo* tracer properties were significantly influenced by the chemical composition of the cyanine dyes used. This suggests that functionalization of a targeting vector with a fluorescent dye requires extensive structural optimization. The RGD-peptide merely provides a proof-of-concept and the same kind of tracer optimization should be applied during the development of other fluorescent (receptor-targeted) imaging tracers.

CEA-targeted dual-modality imaging with Indium-111-DTPA-labetuzumab-IRDye800CW can detect occult pulmonary metastases in a CEA-expressing tumor model

M. Hekman[1], M. Rijpkema[1], D. Bos[1], E. Oosterwijk[1], D. Goldenberg[2], P. Mulders[1], O. Boerman[1]; [1]Radboudumc, Nijmegen, NETHERLANDS, [2]Immunomedics, Morris Plains, NJ, UNITED STATES.

OBJECTIVES: Intraoperative dual-modality imaging can help the surgeon distinguish tumor from normal tissue. This technique may prove particularly valuable if small (occult) tumors need to be removed that are difficult to detect with the naked eye. The humanized anti-CEA monoclonal antibody, labetuzumab (hMN-14), can be used as a tumor-targeting agent in colorectal cancer (CRC), since CEA (carcinoembryonic antigen) is overexpressed in approximately 95% of CRC. Dual-labeled labetuzumab, labeled with both a near-infrared fluorescent dye (IRDye800CW) and a radioactive label (Indium-111), can be used to perform dual-modality imaging. This study aimed to assess whether intraoperative dual-modality imaging using Indium-111-DTPA-labetuzumab-IRDye800CW can detect CEA-expressing pulmonary micrometastases. **METHODS:** Pulmonary GW-39 human colonic carcinoma microcolonies were induced in athymic BALB/c mice by intravenous injection of 100 μL of a 10% GW-39 cell suspension obtained from subcutaneous tumors. At 4, 11, 18, and 25 days after tumor cell injection, mice (n=7 per time point) were injected i.v. with Indium-111-DTPA-labetuzumab-IRDye800CW (10 μg, 25 MBq). Three days later, mice were euthanized and the lungs were fixed by intratracheal injection of 4% formalin. Then microSPECT/CT images and optical images were acquired. Finally, the biodistribution of the dual-labeled tracer was determined. Formalin fixed sections of the lungs were analyzed using fluorescence imaging, autoradiography and immunohistochemistry. **RESULTS:** Submillimeter pulmonary tumor colonies could be visualized with both microSPECT and fluorescence imaging from the first week of tumor growth, before they became visible with the naked eye. After three weeks of tumor growth, pulmonary tumors could be resected by using fluorescence imaging. Mean uptake of the dual-labeled tracer in tumor nodules was 17.2 ± 5.4 %ID/g and 17.0 ± 8.3 %ID/g in weeks 3 and 4, respectively. Immunohistochemical analysis of the tumorous lungs showed that the distribution of the radioactive and fluorescent signal co-localized with CEA-expressing tumor nodules. **CONCLUSION:** Dual-modality imaging after injection of Indium-111-labetuzumab-IRDye800CW can be used to detect submillimeter CEA-expressing pulmonary colonies, before they become visible with the naked eye. A clinical study will be initiated to evaluate the feasibility of CEA-targeted intraoperative dual-modality imaging in CRC patients with peritoneal carcinomatosis scheduled for cytoreductive surgery and HIPEC.

OP641

Characterization of a triple-modality anti-PSMA targeting agent for immuno-SPECT/CT, near-infrared fluorescence imaging and targeted photoimmunotherapy of PSMA-expressing tumors

S. Lütje[1], S. Heskamp[2], M. Hekman[2], S. Ekim[2], M. Gotthardt[2], A. Bockisch[1], O. C. Boerman[2]; [1]Clinic for Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [2]Department of Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim: The prostate specific membrane antigen (PSMA) was shown to be overexpressed on prostate cancer as well as in the neovasculature of other malignancies, which renders it a target for imaging and therapy of cancer. Targeted photodynamic therapy (tPDT) is a highly selective cancer treatment approach based on targeting molecules conjugated to photosensitizers which can induce cell destruction upon exposure to near-infrared (NIR) light. Here, the development and *in vivo* characterization of the multi-modality anti-PSMA targeting agent ^{111}In-DTPA-D2B-IRDye700DX is described for both pre- and intra-operative tumor localization, image-guided surgery, as well as for eradication of tumor tissue by PSMA-targeted PDT. **Materials and methods:** The anti-PSMA monoclonal antibody D2B was conjugated with IRDye700DX and DTPA and subsequently radiolabeled with ^{111}In. To determine the optimal dose and time point of tPDT, BALB/c nude mice with PSMA-expressing s.c. LS174T-PSMA xenografts received 3, 10, or 30 μg of the conjugate intravenously (8 MBq/mouse, n=5 per group) followed by μSPECT/CT and NIR fluorescence imaging at 24, 48, 72, and 168 h p.i.. Tumor growth and overall survival of 3 mice treated with 30 μg of the conjugate followed by 30 min of NIR light irradiation at 72 h p.i. was compared to mice that did not receive any treatment. The tumor lesions were resected under image-guidance using intraoperative NIR fluorescence imaging and stained for marker for double strand DNA breaks (H2AX and 53BP1). **Results:** PSMA$^+$ tumors were clearly visualized both with SPECT/CT and NIR fluorescence imaging. Highest tumor accumulation was observed in mice treated with 30 μg at 72 h p.i., which was confirmed by quantitative analysis of the SPECT data (73 ± 10% ID/g) and biodistribution studies at 168 h p.i. (52 ± 16% ID/g). tPDT with 30 μg of the tracer and irradiation at 72 h p.i. caused significant inhibition of tumor growth in the treatment group compared to the control tumors: Median survival in the treatment group was significantly improved from 12.6 to 23.3 days. **Conclusion:** These studies provided proof-of-principle that ^{111}In-DTPA-D2B-IRDye700DX enables pre- and intra-operative visualization of PSMA$^+$ tumors with radionuclide and fluorescence imaging, image-guided surgery and PSMA-targeted PDT.

OP642

Two different approaches to treat tumor-positive resection margins using targeted radioactive imaging and fluorescence-guided surgery

M. A. Stammes[1], H. J. M. Handgraaf[2], A. B. Chan[3], C. J. H. Velde, van de[2], A. L. Vahrmeijer[2], L. de Geus-Oei[2]; [1]LUMC/Percuros, Leiden, NETHERLANDS, [2]LUMC, Leiden, NETHERLANDS, [3]Percuros, Leiden, NETHERLANDS.

Aim: By using a targeted multimodal probe with both a radioactive and near-infrared (NIR) fluorescent moiety, radioactive imaging can be used to obtain a total body overview and to locate tumors prior to surgery. During surgery, the fluorescence signal can exactly show the surgeon the boundaries of the tumor. Nowadays, the translation of pre-operative imaging to the intraoperative situation is often challenging. Surgeons therefore mostly needs to rely on visual inspection and palpation when discriminating between healthy and tumor tissue. Consequently, tumor positive resection margins are still too high. The aim here is to show proof of concept for two probes, one with an antibody as targeting moiety and the second with a small molecule. Materials & Methods: For the first approach, trastuzumab-DTPA is coupled to the NIR fluorophore IRDye800CW and subsequently labelled with ^{111}In-Cl. For the second approach, cRGD-IRDye800CW-TCO in combination with Tz-DOTA is used, in here DOTA was also labelled with ^{111}In-Cl. The labelled product was intravenously injected in nude mice bearing subcutaneous HT-29 human colon cancer tumors on the back. Images were performed at different timepoints post injection using the uSPECT, IVIS Spectrum, Pearl Impulse and Artemis. After the last imaging time point, mice were sacrificed and several tissues were excised, weighed, and counted for radioactivity to determine the percentage of the injected dose per gram (%ID/g). Results: Both *in vivo* fluorescence and radioactive images showed the same location of the probe. In addition, the *ex vivo* results, obtained with the gammacounter, confirmed that the majority of the probe was located in the tumor (22.1%$^+$/_ 10.9% ID/g for ^{111}In-DTPA-CW800-Trastuzumab and 12.2%$^+$/_ 1.2% ID/g for ^{111}In-DOTA-Tz-TCO-CW800-cRGD). In general, the most optimal tumor-to-background ratio was found at 96h post injection for ^{111}In-DTPA-CW800-trastuzumab (combined FLI/RA TBR of 5.6$^+$/_ 0.8) and already at 6h for ^{111}In-DOTA-Tz-TCO-CW800-cRGD (combined FLI/RA TBR of 4.8 $^+$/_ 2.0). Conclusion & discussion: These proof of concept preclinical experiments show that trastuzumab as well as cRGD coupled to IRDye800CW and ^{111}In-Cl can be visualized in a colorectal cancer model. Nevertheless, it still is a preclinical model and needs clinical validation. Trastuzumab is already a well-known clinical available antibody and cRGD is in the middle of the process of clinical translation. Furthermore, the Artemis is also being used in the surgical theatre. We therefore do not foresee major hurdles in further translating these promising constructs.

OP643

Hybrid detection modalities for intraoperative detection of multimodal tracers

G. H. KleinJan[1,2], D. Hellingman[2,3], N. S. Van den Berg[1,2], M. N. Van Oosterom[1], K. Hendricksen[2], S. Horenblas[2], R. A. Valdes Olmos[1,2], F. W. B. Van Leeuwen[1]; [1]Leiden University Medical Centre, Leiden, NETHERLANDS, [2]The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [3]Oncovison, Valancia, NETHERLANDS.

Introduction Multimodal tracers for image-guided surgery purposes gain more interest. An example of such a hybrid (multimodal) tracer is indocyanine green (ICG)-^{99m}Tc-nanocolloid (fluorescent and radioactive) which is a clinically applied during sentinel node (SN) procedures. Detection of these signals require both gamma and fluorescence detection modalities in the operating theater. A logical step would be to combine/integrate both modalities as such to create a hybrid detection modality for intraoperative guidance. This clinical feasibility study evaluates the combination of a commercially available fluorescence camera (FC) with a gamma-ray detection probe (GP) or a portable gamma camera (GC). **Methods** Two clip-on devices were designed and 3D printed. With these clip-on devices the FC could be attached to the GP (FC-GP) or GC (FC-GC) resulting in true hybrid detection modalities. The FC-GP and FC-GC were evaluated in five and six patients with penile cancer scheduled for SN biopsy, respectively. Logistics and data interpretation for both combined modalities were evaluated. During the operation, fluorescence-guided and radioguided SN detection rates were scored at distances varying from 0-30cm. **Results** The 3D designed clip-on system helped to successfully attach the FC to the GP and GC. Upon coupling of the devices, it was easy to place and replace them during surgery. Acoustic feedback produced by the GP provided directional guidance towards the 9 SNs in the FC-GP combination. Here gamma detection rates were 55.6% at 30cm and 20cm, and 88.9% at 10cm and 100% at 0cm. For the fluorescence detection these values were 77.8%, 77.8% and 100% for 30cm, 20cm and 10cm, respectively. Fluorescence detection at 0cm was not possible; here the camera was out of focus. In the evaluation of the FC-GC *in vivo,* all 10 SNs could be visualized with the GC. The fluorescence detection was 80% at 30cm and 20cm and 90% at 10cm working distance. **Conclusion** The current study provides a proof-of-concept for the generation of a hybrid imaging modality that allows combined intraoperative gamma and fluorescence imaging. Overall gamma tracing was best for the rough localization (30-10cm range) of the SNs, while fluorescence provided more detailed visualization within the 10cm range.

Automated grading of Glioma based on MET-PET and patient-derived features utilizing multi-layer machine learning approaches

L. Papp[1], N. Pötsch[1], M. Mitterhauser[1], W. Wadsak[1], T. Beyer[2], M. Hacker[1], T. Traub-Weidinger[1]; [1]Medical University of Vienna, Division of Nuclear Medicine, Vienna, AUSTRIA, [2]Medical University of Vienna, Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA.

Introduction [^{11}C]Methionine (MET) is well established in PET imaging of glioma. Several quantitative features can be used to characterize the amino acid metabolism in these brain tumours. Our goal was to establish a novel machine learning approach to automatically generate a classification algorithm that is based solely on MET-PET and patient-derived features. **Materials and Methods** This study relates to a cohort of 160 glioma patients who underwent MET-PET between 2000-2013 prior to therapy. Tumour grading was based on the WHO-2007 classification and histopathology. To date, 30/160 patients were analysed: astrocytoma grade 2 (10 patients), astrocytoma grade 3 (10) and glioblastoma multforme (GBM, 10). Delineation of the tumour and a contra-lateral background region was performed manually in consensus by two experienced physicians using the Hybrid-3D software (Hermes Nuclear Diagnostics, Stockholm, Sweden). Tumour-to-background ratios (TBR) were calculated over each tumour voxel value for normalization. Several general features (mean, variance, minimum, maximum, volume), textural grey-level co-occurrence matrix (GLCM) derived features (homogeneity, entropy, contrast, dissimilarity, uniformity, correlation), textural neighbourhood grey-tone difference matrix (NGTDM) derived features (coarseness, contrast, busyness), and patient-derived features (age, Karnofsky score) were calculated for each normalized tumour regions. A novel multi-layer machine learning algorithm was implemented to automatically select relevant features for building a classification model for automated grading. The first layer selected the subset of features by a combined simulated annealing and genetic algorithm mimicking natural selection, crossover and mutation. The second layer determined weights for each residual feature of the first layer by a Nelder-Mead optimization method. Tumour classification was based on multiple Gaussian kernel functions - one for each feature of the three possible grades - to perform clustering across the selected features. Sensitivity and specificity were calculated for the machine learning derived classification results with histopathological grading serving as reference-standard. **Results** Sensitivity and specificity of the automated grading algorithm were 90% and 94% (grade 2 gliomas), 97% and 98% (grade 3), and 89% and 94% (grade 4), respectively. The following features were selected as relevant for tumour classification: [^{11}C]MET-PET TBR-derived: volume (general), homogeneity, entropy, contrast, correlation (GLCM) as well as patient-derived: age, Karnofsky score. **Conclusions** The present study demonstrates that joint analysis of heterogeneous image and patient-based features serve as a stable predictor of histology-derived grading.

OP649

[11C]Methionine PET as Prognostic Parameter in Newly Diagnosed Glioma Patients

N. Pötsch, A. Wöhrer, J. Furtner, D. Wilhelm, M. Weber, I. Rausch, A. Haug, G. Karanikas, M. Mitterhauser, W. Wadsak, M. Hacker, T. Traub-Weidinger; MEDICAL UNIVERSITY OF VIENNA, Vienna, AUSTRIA.

Background: [11C]Methionine (MET) PET is well established in glioma imaging. Nevertheless, only few publications with small study population exist regarding MET PET and prognosis in glioma patients. *Methods:* A total of 160 glioma patients (89 men, 71 women, mean age: 45, range 18 - 84 years) were included in this study, who underwent a MET PET prior to any therapy between 2000 and 2014 at the Medical University of Vienna. The PET scans were evaluated visually (focal, focal with a branch, multifocal with branches, areal or visually negative) and semiquantitatively by SUV tumor to background (T/N) ratios. Following T/N ratios were evaluated: $T/N_{standard}$ (i.e. SUV_{max}/SUV_{mean}), T/N_{peak} (i.e. SUV_{peak}/SUV_{mean}), T/N_{max} (i.e. SUV_{max}/SUV_{max}) and T/N_{pp} (i.e. SUV_{peak}/SUV_{peak}) and related to patients´ survival. *Results:* Our patient group was evenly distributed between low (LGG) and high grade gliomas (HGG) (46%, 54%) according to the latest WHO classification (2007). Visually negative PET scans were predominantly found in LGG (82%). Focal pattern with a branch was observed in 78%, a multifocal pattern with branches in 70% of HGG. Patients with areal uptake pattern showed longest mean survival times (114 ± *15 months)*, followed by visually negative tumors (103 ± *9* months), whereas multifocal pattern with branches was associated with the worst prognosis (44 ± *6* months). $T/N_{standard}$ ratio, by means of the AUC of a ROC-curve performed slightly better than other evaluated T/N ratios distinguishing LGG from HGG. $T/N_{standard}$ ratio thresholds of 2.1 for differentiating LGG from HGG (AUC: 0,79) and 3.5 for separating grade III from GBM (AUC: 0,77) were found applicable. Significant survival differences were seen for these 3 threshold based groups ($p < 0.001$). Furthermore, the mean time to event (death [n=63] or lost to follow-up) was 47 months. Independent of histopathology, using the median $T/N_{standard}$ ratio of 2.4 as cut-of, mean survival differed significantly ($p<0.01$; mean survival:123 months ± *9* versus 66 ± *7* months). Additionally, multivariate testing showed WHO grading, surgical approach, tumor crossing midline, parietal tumor localisation, $T/N_{standard}$ ratio value and histology as prognostic parameters by decreasing order of significance ($p < 0.001$ to $p = 0.041$). *Conclusion:* This analysis of a large population of newly diagnosed glioma demonstrates the impact of MET PET as prognostic marker on survival by visual as well as by semiquantitative analysis.

OP650

3D analysis of glioma heterogeneity with pseudo-kinetic and pharmacokinetic model parameters in dynamic 18F-FET PET

L. Vomacka, N. L. Albert, E. Mille, B. Suchorska, M. Unterrainer, A. Gosewisch, P. Bartenstein, G. Böning; University of Munich, Munich, GERMANY.

Objectives: Glioma grading with dynamic 18F-FET PET is typically performed by analysis of tumour 18F-FET uptake over time based on mean time-activity-curves delineated on late summation images (20-40min. p.i.). The aim of this work was to investigate tumour heterogeneity with quantitative parameters derived from pseudo-kinetic and pharmacokinetic models in dynamic 18F-FET PET (0-40 min p.i.). Methods: For each of the 42 patients with glioma (WHO2: 12; WHO3: 17; WHO4: 13) one blood volume-of-interest (VOI; 55% iso-contour) and one tumour VOI (SUV&gt1.8xbackground) were segmented. Furthermore, within each tumour VOI, sub-VOIs including voxels with similar time-to-peak (TTP) were defined. Kinetic parameters for the entire tumour VOI and the TTP-dependent sub-VOIs were derived from Patlak-plot, RE-plot, 2- and 3-compartment models (2CM, 3CM), and a linear fit to the late frames (15-40 min). Results: The differentiation between low grade (WHO grade 2) and high grade (WHO grade 3 and 4) glioma (p&lt0.01) was successful with TTP, SUV at TTP, linear fit (slope and intercept), Patlak-plot (VT), RE-plot (VT and intercept), 2CM (K1 and k2), and 3CM (k4, K1/k2 and k3/k4). No significant differences were found for the remaining parameters. None of the parameters allowed for the differentiation of grade 3 and 4 glioma (p&gt0.1). The analysis of each tumour's TTP-dependent sub-VOIs showed that approximately 65% of the voxels of each high grade tumour volume had a maximum activity between 5 and 20 min p.i. (3CM: K1/k2=0.7, k3/k4=1.3), whereas only 15% of the voxels exhibited a peak activity after 30 min. p.i. (3CM: K1/k2=0.7, k3/k4=3.7). In the low grade glioma, 55% of the voxels presented their maximum activity later than 30 min. p.i. (3CM: K1/k2=0.4, k3/k4=3.2). However 22% of the voxels in low grade glioma revealed a peak between 10 and 20 min. p.i. (3CM: K1/k2=0.4, k3/k4=2.5). Conclusion: Areas with early peak uptake could be detected with a voxel-based analysis within histologically proven WHO grade 2 gliomas, supporting the identification of tumour heterogeneities. In combination with other parameters, e.g. a high uptake rate, this observation might raise suspicion for the presence of aggressive sub-areas. Whether this may have an impact on clinical procedures and patient's prognosis has to be further investigated in future studies.

OP651

Comparison of F18-Fluorodopa, F18-Fluorocholine and F18-Fluorodeoxyglucose PET/CT for detection of recurrence in patients with primary brain tumors

A. Sharma, M. Singh, A. Garg, M. Tripathi, S. Gupta, H. KP, C. Bal; ALL India Institute of Medical Sciences, New Delhi, INDIA.

Objectives- Recurrence in brain tumors is notoriously difficult to distinguish from radiation necrosis on routine Magnetic Resonance Imaging (MRI). Unlike necrotic tissue, the recurrent tumor is metabolically active. Positron Emission tomography (PET/CT) can provide this additional metabolic information (glucose metabolism by F18-FDG, lipid metabolism by F18-FluoroCholine, amino-acid metabolism by F18-Fluorodopa) over structural information provided by MRI and thus can aid in diagnosis. Methods- 11 post-op patients (mean age 34 years; M:F 6:5) suspected for recurrence (6 grade II, 3 grade III, 2 grade IV) were included. Of these 6 had equivocal findings on MRI. They underwent F18-FDG PET/CT (40 min post 8-10 mci IV injection), F18- Fluorocholine PET/CT (70 min post 5-7 mci IV), F18 Fluorodopa PET/CT (20 min post 3-5 mci IV) on 3 separate days with in a period of 15 days. Any uptake more than the contralateral normal brain parenchyma was considered positive and tumor to normal SUVmax (T/N) ratios were calculated. The scans were anonymized and nuclear medicine physician reporting the scans was also blinded to patient history as well as other PET/CT scans and MRI. Results- 12 lesions were documented (4 frontal, 4 parietal, 2 temporal, 2 cerebellar). One patient had multifocal tumor. 5 patients had surgery, 1 stereotactic biopsy (5 showed conversion to grade IV, one ischemic changes). Other 5 were followed up for average 9.8 months (6-11 months; one patient died after 6 months). Of these 3 had follow up MRI, 1 died due to clinical worsening and 1 was diagnosed with clinically progressive recurrent disease. All the lesions showed 100 percent concordance on F18-fluorocholine and F18-fluorodopa PET/CT. F18-FDG was able to diagnose 7 lesions correctly (4 true positive, 3 true negative) but 5 were false negative. F18-Dopa and F18-Choline diagnosed 9 lesions correctly (8 true positives, 1 true negative) but 2 were false positives and 1 was false negative. T/N ratios were higher for F18-choline (14.17) than F18-Dopa(3.18), but neither these ratios nor SUVmax showed any correlation with tumor grade or proliferative indices(mib-1). Conclusion- F18 Fluorocholine is as efficient as F18 Fluorodopa in diagnosis of recurrent brain tumors, but provides better tumour visualisation (higher T/N ratios). Both of these agents provide more information than F18-FDG, particularly in patients with low grade tumors or in patients with recurrence with extensive radiation changes.

OP652

^{18}F-fluoromethylcholine (FMC) PET/CT and proton magnetic resonance spectroscopy; imaging and tissue biomarkers of cell membrane turnover in primary brain gliomas - a pilot study

M. Grech-Sollars[1,2], K. L. Ordidge[2,1], B. Vaqas[2], L. Honeyfield[2,1], S. Khan[2], S. Camp[2], D. Towey[3], D. Peterson[2], F. Roncaroli[4], K. S. O'Neill[2], T. Barwick[2,1], A. D. Waldman[5,1]; [1]Imperial College London, London, UNITED KINGDOM, [2]Imperial College Healthcare NHS Trust, London, UNITED KINGDOM, [3]Northampton General Hospital NHS Trust, Northampton, UNITED KINGDOM, [4]The University of Manchester, Manchester, UNITED KINGDOM, [5]The University of Edinburgh, Edinburgh, UNITED KINGDOM.

Background: Choline is a biomarker of interest in gliomas and relates to cell membrane turnover- a hallmark of aggressive tumour behaviour. Pilot C-11/ F-18 choline PET studies show differential uptake between benign and malignant tumours, however the cellular and molecular basis of this uptake and MRS-visible choline containing compounds (Cho) is not well understood. Choline kinase (CHK) α phosphorylates choline, an essential step in membrane synthesis, and is known to be expressed by malignant tumours, including prostate, lung and brain. Here we investigate the relationship between choline metabolism detected in vivo using MRS and PET, and tissue markers of choline synthesis and glioma proliferation. Method: Prospective pilot study of 14 patients with suspected primary glioma underwent multimodal 3T MRI (including multi-voxel MRS) and dynamic 45 minute list mode ^{18}F-FMC PET/CT with venous sampling prior to surgery. Time activity curves were generated and tumour SUVmax and tumour to background ratio (TBR: SUVmax tumour/ SUVmean contralateral white matter) were assessed. Co-registered PET and MRI data were used to identify regions of high and low choline and targeted biopsies were performed using a surgical planning tool. Immunohistochemistry for expression of CKα expression in this biopsied tissue is being performed. Results: All tumours showed increased tracer uptake relative to contralateral white matter. Metabolite analysis showed fast metabolism of choline, with steady state being reached after 20 minutes. Significant differences in TBR were found between WHO grade IV (11.7-44.0, mean 25.5) and WHO grades I, II & III (5.2-13.8, mean 8.2) tumours in ^{18}F-FMC uptake (t-test, $p<0.05$) and between WHO grades IV&III and grades I&II using Cho/Cr ratios on MRS (t-test, $p<0.05$). Combining PET and MRS data showed spatial concordance between regions of high PET uptake and highest Cho/Cr ratio, however there was no correlation between the actual levels of uptake (TBR) and the Cho/Cr ratio in these regions. Furthermore, regions of contrast enhancement on MRI showed high uptake on PET. CKα expression assays are pending. Conclusion: There was significantly higher choline uptake in grade IV gliomas compared to other grades. Combining ^{18}F-FMC uptake and Cho/Cr ratio on MRS may help further distinguish between high and low grade glioma. Correlation between CKα expression in tissue and imaging markers will probe the molecular basis of this uptake/signal.

OP653

Overall survival and progression free survival in patients with primary brain tumors after treatment. Is ^{18}F FDOPA PET/CT a prognostic factor in these patients?

A. Chiaravalloti[1,2], A. Fiorentini[1], V. Villani[3], C. Carapella[4], A. D'Elia[5], P. Sannino[2], M. Zinzi[6], N. Urbano[1], G. Grillea[6], E. Palombo[1], O. Schillaci[1,7]; [1]Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY, [2]IRCCS Neuromed, Pozzilli, ITALY, [3]Neuro-Oncology Unit, Regina Elena National Cancer Institute of Rome, Rome, ITALY, [4]Division of Neurosurgery "Regina Elena" National Cancer Institute of Rome, Rome, ITALY, [5]Department of neurosurgety, IRCCS Neuromed, Pozzilli, ITALY, [6]IRCCS Neuromed, Rome, ITALY, [7]IRCCS Neuromed, Pozzilli, AUSTRIA.

Aim: to investigate the progression free survival (PFS) and the overall survival (OS) in a populations affected by primary brain tumors (PBT) evaluated with [18 F]-L-dihydroxyphenylalanine (^{18}F FDOPA) Positron Emission Tomography/Computed Tomography. **Materials and methods**: 124 subjects with PBT (65 women and 59 men, mean age 45 ±10 years old) underwent ^{18}F FDOPA PET/CT after treatment. According to WHO score, 7 were grade I, 51 were grade II, 37 were grade III and 29 were grade IV.The strategy of treatment adopted for grade IV was radiotherapy (RT) plus continuous daily temozolomide, followed by six cycles of adjuvant. For grade III we used RT followed by chemotherapy (CHT) with temozolomide or lomustine and procarbazine 60 mg/m2 orally on days 8 to 21. Grade II where subjected to standard adjuvant temozolomide treatment while grade I where subjected to surgery only. Intervals from surgery, CHT and RT were 42.28 (±39.24), 17.05 (±30.1) and 24.7 (±32.4) months respectively. PET/CT was scored as positive or negative when pathological uptake was identified and, in particular, when an area of focal tracer uptake superior to the background was visually detected. Data concerning OS were collected and PFS was established according to clinical criteria. **Results**: Patients were observed for a mean of 24 months. Median OS was 13 months in positive PET/CT scans and 27 in PET/CT negative scans. OS curves were significantly different ($P<0.0001$ in Mantel-Cox test and Gehan-Breslow-Wilcoxon test). At 12 months, the survival proportions were 82% in subjects with a negative PET/CT scan and 28% in subjects with a positive PET/CT scan. The hazard ratio resulted equal to 4.62 (95% CI of ratio: 11,99 to 106.1). Median PFS was 4 months in positive PET/CT scans and 25 in negative PET/CT scans. PFS curves were significantly different ($P<0.0001$ in Mantel-Cox test and Gehan-Breslow-Wilcoxon test). At 12 months, the progression proportions were 14% in subjects with a negative PET/CT scan and 85% in subjects with a positive PET/CT scan. The hazard ratio resulted equal to 4.51 (95% CI of ratio: 13.03 to 43.74). **Conclusions**: a positive ^{18}F FDOPA PET/CT scan is related to a poor OS and PFS in subjects with PBT. This imaging modality could be considered as a prognostic factor in these subjects.

OP654

Value of F-DOPA PET in the long term follow up of radionecrotic brain metastases after radiosurgery: comparison with MRI

F. Cicone[1], L. Carideo[1], C. Scaringi[2], A. Romano[3], A. Bozzao[3], G. Minniti[2], F. Scopinaro[1]; [1]Unit of Nuclear Medicine, Sant'Andrea Hospital, "Sapienza" University of Rome, ROME, ITALY, [2]Unit of Radiation Oncology, Sant'Andrea Hospital, "Sapienza" University of Rome, ROME, ITALY, [3]Unit of Neuroradiology, Sant'Andrea Hospital, "Sapienza" University or Rome, ROME, ITALY.

Aim. To analyse the value of sequential F-DOPA PET/CT scans in the long term follow-up of predominantly radionecrotic brain metastases after stereotactic radiosurgery. Comparison with MRI-derived parameters is given. **Materials and Methods.** Eighty-one patients with previously irradiated brain metastases who underwent F-DOPA PET at our institution for differential diagnosis between radionecrosis (RN) and progression (PD) were screened. Inclusion criteria were i) initial negative or borderline uptake values (rSUV) defined according to a previously published method, ii) availability of repeated F-DOPA scans over an observational period >12 months. Standard patient monitoring in this setting includes repeated MRI and F-DOPA scans every 3-6 and 6-12 months, respectively. F-DOPA PET/CT consisted of a 20 min acquisition starting 15 minutes after tracer injection. rSUV was calculated as the ratio between the lesion SUVmax and the SUVmax of the controlateral background. Tumor maximal transverse diameter (Dmax) was calculated on contrast-enhanced, T1-weighted sequences; tumour volumes were calculated by assuming a spherical geometry with Dmax as diameter. Cerebral blood flow (rCBV) was derived from perfusion-weighted images and quantified

relative to the normal controlateral white matter. ΔrSUV, ΔDmax and ΔVol were calculated between first and last time point imaging; PD vs RN group comparisons were made with two-tailed Student's t test. **Results.** Twenty patients (12 F, 8 M) with a total of 70 F-DOPA scans were included. Median follow-up was 30.5 months (range:13-51). So far, 4 (20%) patients have died because of intracranial (n=3) or extracranial (n=1) PD. Eleven (55%) metastases remained in histologically confirmed (n=5) or unconfirmed RN, while 9 (45%) showed a slow PD (n=3 histological confirmations) over time. All PD showed a steady rSUV increase over time; however, F-DOPA was false positive in one case of histologically confirmed RN. In two RN, there was an increase of rSUV followed by a subsequent slight decrease. An increase in Dmax was observed in all patients but two cases of RN. rCBV was falsely negative in 2 (22%) PD and falsely positive in 5 (45%) RN. Initial rSUV did not differ between groups (p=0.75), while final rSUV and ΔrSUV were significantly different between PD and RN (p<0.001 and p=0.006, respectively). All MRI derived parameters were not significantly different between PD and RN (all p>0.25). **Conclusion.** F-DOPA PET/CT is a reliable tool to assess the evolution over time of predominantly radionecrotic brain metastases after stereotactic radiosurgery. In this setting, performances of MRI including perfusion-weighted imaging are lower.

OP655

Prognostic significance of molecular and imaging biomarkers in primary brain tumors

E. Lopci[1], M. Riva[1], L. Olivari[2], F. Raneri[2], A. Bizzi[3], B. Fernandes[1], P. Navarria[1], F. Pessina[1], M. Roncalli[4], L. Bello[1], A. Chiti[4]; [1]Humanitas Clinical and Research Hospital, Milano, ITALY, [2]University of Milan, Milano, ITALY, [3]Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, ITALY, [4]Humanitas University, Milano, ITALY.

Purpose: We evaluate the relationship between carbon-11-methionine PET (11C-METH PET) metrics with molecular biomarkers in patients affected by brain gliomas candidate to surgery. **Materials and Methods**: A consecutive series of 109 patients with pathologically proven gliomas (M:F=64:45; median age 43 years; 40 LGG, 69 HGG), referred to our Institution from March 2012 to January 2015 for tumor resection and submitted to pre-operative 11C-METH PET, was analyzed. The trial was registered at www.clinicaltrials.com (NCT02518061). Semi-quantitative metrics for 11C-METH PET included SUVmax, SUVratio to normal brain and metabolic tumor volume (MTV). Imaging findings were correlated to disease outcome expressed in terms of progression-free survival (PFS), and compared to other clinical-biological data, comprising IDH1 mutation, 1p/19q co-deletion and MGMT promoter methylation. The cohort was monitored for a mean period of 16.7 months (median 13 months). **Results**: In all patients, tumors were identified on 11C-METH PET: median SUVmax 3.3, median SUVratio 2.3, and median MTV 9.6 cm3. We observed a statistically significant difference for SUVmax, SUVratio and MTV values based on tumor grade (p<0.001). According to molecular analyses, IDH1 resulted mutated in 49 patients, 1p/19q co-deleted in 58 patients and MGMT promoter methylated in 74 patients. A statistically significant correlation between SUVmax and SUVratio and IDH1 mutation was observed (p<0.001). Relapse or progression was documented in 48 cases (median PFS 8.7 months). A statistically significant correlation was observed for SUVmax and SUVratio, tumor grade, IDH1 mutation, 1p/19q co-deletion and MGMT-promoter methylation to PFS. **Conclusions**: 11C-METH PET metrics significantly correlate with histological grading and IDH1 mutation status in primary brain tumors. Grading, molecular biomarkers, SUVmax and SUVratio resulted prognostic factors to PFS in this cohort of patients candidate to surgery.

In Vitro Bioactivity Evaluation of Synthesized ^{18}F-FDG-Grayanotoxin-Gadolinium Nanoparticles

T. S. Akkaya, **P. Unak**, O. K. Guldu, I. Ince; Ege University, İzmir, TURKEY.

Introduction: Grayanotoxin III (GTX-III) compounds can be found naturally in *Rhododendron ponticum L.* (Ericaceae family) and "mad honey". This natural toxic compound can cause depolarization on the cell membrane by inhibiting the voltage gated sodium channels (VGSCs) which are also associated with cancer cells. Recently, magnetic nanoparticles and radioisotopes are widely used and helpful for diagnostic and targeted therapy against cancer disease. **Methods:** In this study, we extracted GTX-III compounds from the leaves and flowers of the forest rose and mad honey. The extracted compound then conjugated with Gadolinium nanoparticles (GdO@Si-NP). Synthesized Gadolinium nanoparticles were conjugated and radiolabelled with 2-deoxy-2-(F-18) floro-D-glucose (18F-FDG). Besides, after conjugation of Grayanotoxin-III with GdO@Si-NP bioactivity of the conjugation products were investigated by applying to Human Breast Adenocarcinoma (MCF7) and Human Prostate Adenocarcinoma (PC3) cell lines and evaluated together with the MR image contrasts. GTX-III compounds were extracted from dried leaves and flowers of the forest rose and then purified by High Performance Liquid Chromatography (HPLC). However, GTX-III separated from the mad honey with solid phase extraction (SPE). GTX-III compounds were identified with Liquid Chromatography - Mass Spectrometry (LC-MS) and Nuclear Magnetic Resonance (NMR) spectroscopy. Gadolinium nanoparticles were synthesized by co-precipitation and they were modified via silication of nanoparticles. Size and characterization of the nanoparticles were determined with Dynamic Light Scattering (DLS) and Scanning Electron Microscopy (SEM). By using 1, 1'carbonyldiimidazole/N-Hydroxysuccinimide (CDI/NHS) conjugation method, synthesized GdO@Si-NP were conjugated with GTX-III compounds. Bioactivity of the conjugated nanoparticles was investigated by applying cytotoxicity and incorporation tests on PC3 and MCF7 cell lines. Incorporation values were evaluated with MR image contrast of the PC3 and MCF7 cell cultures. Conjugation of ^{18}F-FDG with GTX-III coupled GdO@Si-NP, was carried out with CDI/NHS method. **Results and Discussion:** GTX-III compounds extracted from forest rose and mad honey, showed significant cytotoxic effect to MCF7 and PC3 cell lines. However, GdO@Si-NP decreased the cytotoxicity to MCF7 while increasing PC3 cells. It was shown that incorporation studies can be carried out by using Gadolinium NP contrasts of MCF7 and PC3 cell lines, which was determined with calibrated MR images. Besides, ^{18}F-FDG was conjugated to GTX-III-GdO@Si-NP with a good yield by using CDI/NHS method. **Conclusion:** As a result of the study, the synthesized ^{18}F-FDG-GTX-III-GdO@Si-NP compounds have the potential of being used as theranostics for prostate and breast cancers. **Keywords:** *Rhododendron ponticum L.,* Mad Honey, Grayanotoxin, Gadolinium nanoparticles, MCF7, PC3, Breast cancer, Prostate cancer, MRI, ^{18}F-FDG, Radiolabeling

OP669
Intrinsically radioactive metal-organic frameworks (MOF) nanomaterials as a novel PET-guided drug delivery nano-vector

H. Hong, D. Chen, D. Yang, H. Wu, W. Lu; University of Michigan, Ann Arbor, MI, UNITED STATES.

Aim: Porous metal-organic frameworks (MOF) nanomaterials, which are built from metal ions/clusters bridged by organic linkers, have been successfully employed as drug delivery vehicles attributing to their enormous porosity, high surface area, and good biocompatibility. Different imaging "labels" have also been incorporated into MOFs and used for MRI, CT, or optical imaging. However, *in vivo* PET imaging with MOF has not been achieved. The aim of this study is to produce an intrinsically radioactive MOF nanoparticle based on the ^{89}Zr-hybrid UiO-66 nanostructure. Nucleolin, a selective tumor cell surface marker, was selected as the target-of-interest in this study. *Materials and Methods*: ^{89}Zr-incorporated MOF nanoparticle (^{89}Zr-MOF in abbreviation) was synthesized via a solvothermal method using $^{89}ZrCl_4$ as a precursor. Further functionalization was conducted via a pyrenyl-PEG derivative. F3 peptide, a strong binding agent for nuclelolin, was introduced as a tumor-targeting ligand. The structure of ^{89}Zr-MOF was characterized by TEM and DLS. The stability, targeting efficacy and specificity, and tissue distribution of these ^{89}Zr-MOF conjugates were systematically investigated. *Results:* ^{89}Zr-MOF has an isotope loading capacity of up to 20 GBq/mg. These ^{89}Zr-MOF nano-conjugates had diameters of ~ 100 nm based on TEM and hydrodynamic diameters of ~ 240 nm based on DLS. Superior radiochemical stability was achieved with ^{89}Zr-MOF conjugates: > 99.99% ^{89}Zr stayed within the structure of ^{89}Zr-MOF after a 120 h incubation with

mouse serum at 37°C. Flow cytometry and fluorescence microscopy examination confirmed the targeting specificity of F3 peptide attached ^{89}Zr-MOF conjugates against cellular nucleolin. Potent and persistent uptake of ^{89}Zr-MOF@Py-PEG-F3 in orthotopic MDA-MB-231 tumors (nucleolin^{+}) was witnessed (~8 %ID/g at 4 h post-injection) when compared with non-targeted MOF (^{89}Zr-MOF@Py-PEG, ~2 %ID/g at 4 h post-injection). Histology evaluation also confirmed the accumulation of ^{89}Zr-MOF@Py-PEG-F3 in tumor correlated well with nucleolin expression pattern while they were non-specifically captured in liver and spleen. In addition, these GO conjugates can serve as good drug carriers with satisfactory drug loading capacity (e.g. for doxorubicin, 1,000mg/g). Enhanced drug delivery efficiency in MDA-MB-231 tumors was demonstrated in DOX-loaded ^{89}Zr-MOF@Py-PEG-F3 by fluorescence imaging. Toxicity evaluation (body weight, major tissue histology evaluation, and blood biochemical assays) confirmed the safety of these ^{89}Zr-MOF conjugates.*Conclusion*: This is the first PET study using a MOF nanomaterial as the imaging contrast agent. This ^{89}Zr-MOF based nanoplatform can serve as a useful tool for early tumor detection and PET-guidable delivery of therapeutics into a variety of tumors.

OP670

Evaluation of Co-57 labelled Layered Double Hydroxide as a Tumor Imaging Agent

J. Park[1], J. Lee[1], T. Kim[2], J. Oh[2]; [1]Korea Atomic Energy Research Institute, Jeongeup, KOREA, REPUBLIC OF, [2]Yonsei University, Wonju, KOREA, REPUBLIC OF.

Aim : Layered double hydroxide (LDHs) have various advantages as drug delivery carrier, especially for anticancer therapy. They have layer-by-layer stacking structure between positively charged metal hydroxide nanolayers. Most imaging moieties are generally introduced at outer surface of nanomedicine, and thus they can be detached inside the biological system when administered, resulting in false-tracing of nanomedicine. Therefore, it is feasible that imaging moieties are introduced inside of LDHs and it leads to be more stable in vivo than those of outer surface of nanomaterials. In this study, we directly incorporated radioisotope Co-57 into LDH nanomaterial and both in vitro cellular uptake and in vivo biodistribution test were performed. Material and Method : We synthesized LDH particles consisting of Mg-Al hydroxide framework with homogenous particle size of ~150 nm through coprecipitation-hydrothermal treatment. LDHs were characterized with XRD. SEM and Zetasizer. Co-57 was incorporated to lattice of LDH framework by treating LDHs with 880 μCi of $^{57}CoCl_2$ solution per 5 mg of LDH in 150°C hydrothermal condition for 2 h. The resulting mixture was cooled down at room temperature, and then centrifuged to remove free Co-57 under 10,000 rpm for 5 min. Comparision of cellular uptake using LDHs in 3 different cell lines {CT-26 (Mouse colon), MCF-7 (Breast cancer), HepG2 (Liver hepatocellular carcinoma)}. CT-26 bearing balb/c mice of 5 weeks old weighing 25-30 g were used for the biostudies of [^{57}Co]LDHs . Results and Conclusion : we prepared uniform size and morphology MgAl-LDHs and successfully incorporated radioisotope Co-57 into LDH frameworks through hydrothermal assisted substitution reaction preserving physical properties of LDH nanoparticles. We found that Co-57/LDH exhibited significantly high cellular uptake in CT-26 and HepG2 cell lines, suggesting efficient radioactivity delivery capacity of LDH nanoparticles. In vivo biodistribution result of Co-57/LDH with CT-26 xenografted balb/c mice showed that LDH nanoparticles could deliver radioactivity to tumor with relatively high tumor-to-organ ratios for clearance organs like liver, kidney and spleens. Thus it concluded that LDH could be utilized to deliver radionuclide for diagnosis activity to tumors avoiding serious clearance and biological removal. Successful demonstration of in vitro/in vivo tumor targeting with Co-57/LDH makes them suitable nanoplatforms for tumor theragnostics.

OP671

PS-b-PEO polymeric micelles: dependence of biodistribution and tumor uptake on micellar dose and size

C. Santini[1], A. Laan[2], M. de Jong[1], A. Denkova[2], M. Bernsen[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]TUDelft, Delft, NETHERLANDS.

Introduction. PS-b-PEO are amphiphilic block copolymers able to aggregate in stable polymeric micelles. They are easy to load with different agents and tunable in size, resulting in an extremely versatile vehicle for the delivery of encapsulated drugs. Size is considered one of the main factors influencing biodistribution of nanoparticles including tumor delivery efficiency. In contrast, little is known on the biological role of the applied dose, for instance regarding saturation limits of different tissues and, as a consequence, the potential therapeutic efficacy and toxicity. This study is the first assessing the biodistribution and tumor uptake of PS-b-PEO micelles of two different sizes, applied at two different doses, in tumor-bearing mice. With this study we aim to elucidate the potential of the newly developed carrier for therapeutic use. **Materials and Methods.** PS-b-PEO micelles, of size (radius) of 89 nm or 50 nm, were synthetized and radiolabeled with ^{111}In at doses 1.7 mg/mL (~1.9 MBq/mL) and 7 mg/mL (~1.1 MBq/mL) using a one-step co-solvent evaporation method. Four combinations were obtained: big micelles at high and low dose (BMH and BML, respectively) and small micelles at high and low dose (SMH and SML). Groups of 5 tumor-bearing mice were injected with 200 μL of a given preparation. Mice were subjected to SPECT/CT at 0.5, 24 and 48 hrs post-injection, followed by ex vivo-based biodistribution analysis. **Results.** Images and biodistribution studies showed highly comparable distribution patterns of the four micelle combinations in terms of % injected activity per gram of tissue (% IA/g) with tumor uptake up to 5% IA/g, and high clearance levels in spleen and liver in average 55% and 19% IA/g, respectively. However, due to size and concentration differences in the micellar formulations, considerable differences were found in terms of absolute amount of polymer reaching the various organs. The differences were consistent in every tissue including tumor, and suggest that, at the applied dose, BM might incur in a saturation mechanism, which is not reached by SM at the doses tested. **Conclusions.** PS-b-PEO micelles are extremely versatile and valuable tool for therapeutic applications, by being easy to radiolabel and tunable in size. Next to size, we have here determined nanoparticle-specific, dose-dependency on biodistribution. This indicates that the dose is also an important parameter to consider when applying nanoparticles in drug delivery.

OP672

Gold nanoparticles labelled with ^{211}At conjugated to substance P and trastuzumab - new radiopharmaceuticals for alpha particle therapy

A. Bilewicz[1], L. Dziawer[1], P. Koźminski[1], M. Pruszynski[1], A. Majkowska-Pilip[1], A. Stolarz[2], K. Szkliniarz[3], J. Jastrzębski[2], G. Celichowski[4], J. Grobelny[4], E. Tomaszewska[4]; [1]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [2]Heavy Ions Laboratory, University of Warsaw, Warsaw, POLAND, [3]Department of Physics, Silesian University, Katowice, POLAND, [4]University of Lodz, Lodz, POLAND.

Aim: Among the others α-emitting radionuclide ^{211}At has attractive properties for use in targeted radionuclide therapy, especially for small tumours and cancer metastasis. ^{211}At is produced via ^{209}Bi(α,2n)^{211}At nuclear reaction and has a 7.2 h half-life - a sufficient time for its production, synthetic chemistry, transportation and medical application. However, many astatine compounds that have been synthesized are unstable *in vivo*, providing motivation for seeking other ^{211}At labeling strategies. In our work we propose to utilize formation of strong bond between metallic gold and astatine to bind

the ^{211}At to two biomolecules, peptide substance P and trastuzumab. **Materials and methods:** The gold nanoparticles with diameter of 5 and 20 nanometers were synthesized by Turkevich methods. The nanoparticles were characterized by SEM, STEM and DLS technique. The obtained gold nanoparticles were conjugated to substance P 5-11 (short peptide fragment having high affinity to NK1 receptors on the glioma cells) and trastuzumab (antibody having affinity to Her2 receptor). In first step polyethylene glicol with disulfide or thioctic acid with N-succinimidyl ester as a linkers were conjugated with biomolecules. After twenty four hours product was purified, lyophilized and spontaneously bound to gold nanoparticles. The obtained bioconjugates were labelled with ^{211}At produced in cyclotron at the Heavy Ion Laboratory, University of Warsaw. Before labeling astatine was reduced to At^- using 0.01 M Na_2SO_3 solution. Stability of the obtained radiobioconjugates were tested in biological fluids: sodium chloride, cysteine, glutathione and human serum for 2, 4 and 19 hours. **Results:** The Au- PEG-Substance P (5-11) and Au- PEG-trastuzumab bioconjugates were successfully synthesized. The HPLC analysis has shown that bioconjugates are covalently attached to the gold surface. using the thiol approach. The labeling yield of ^{211}At was higher than 99%. The ^{211}At bioconjugates were very stable in human blood serum and cerebrospinal fluid. Less than 0.1% of the ^{211}At radioactivity was found in solution. Also agglomeration of the nanoparticles was not observed. In-vitro biological studies indicate that ^{211}At- Au- PEG-Substance P (5-11) radiobioconjugate exhibits high affinity and cytotoxicity to the human glioma T98G cell line while ^{211}At-Au- PEG-trastuzumab to the SKOV3 ovarian cell line. **Conclusion:** We have shown that gold nanoparticles labelled with ^{211}At functionalized with substance P and trastuzumab presents a prospective solution for the use of the ^{211}At as a therapeutic tool for targeting glioma cells and HER2 positive breast and ovarian cancers. This work was supported by National Science Center of Poland (Grant 011/01/M/ST406756).

Synthesis, preparation and characterization of 99mTc-PEI-MP: a potential radiopharmaceutical for the diagnosis of bladder cancer

S. M. Ferreira[1], A. M. Abrantes[2], M. Laranjo[2], J. Casalta-Lopes[3], A. C. Gonçalves[4], A. B. Sarmento-Ribeiro[4], J. Zeevaart[5], W. Louw[5], C. Pais[6], I. Dormehl[7], M. F. Botelho[2]; [1]Biophysics Unit, Faculty of Medicine, University of Coimbra; Centre of Molecular and Environmental Biology, School of Sciences, University of Minho; Nuclear Medicine Course, School of Allied Health Technologies of Porto's Polytechnic Institute, Coimbra, Braga, Porto, PORTUGAL, [2]Biophysics Unit, Centre of Investigation on Environment, Genetics and Oncobiology; Institute for Biomedical Research on Light and Image; Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [3]Biophysics Unit, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [4]Centre of Investigation on Environment, Genetics and Oncobiology; Applied Molecular Biology and Hematology Group; Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [5]Radiochemistry Department, NECSA, Pretoria, SOUTH AFRICA, [6]Centre of Molecular and Environmental Biology, School of Sciences, University of Minho, Braga, PORTUGAL, [7]Department of Internal Medicine, University of Pretoria, Pretoria, SOUTH AFRICA.

Introduction and Aim: Polyethyleneiminomethyl phosphonic acid (PEI-MP) was initially synthesized for palliative therapy of bone metastases after suitable radiolabelling. Biodistribution studies with radiolabelled PEI-MP, demonstrated that the bladder wall was a critical organ, demonstrating the affinity of PEI-MP to bladder cells and possibly to bladder cancer cells. The aim of this work was to reconstitute the cold kit of PEI-MP to be radiolabelled with technetium-99m and to characterize the ^{99m}Tc-PEI-MP in terms of hydrophilic character and *in vitro* cellular uptake. **Material and Methods:** PEI-MP was synthesized by condensation of polyethyleneimine (PEI), phosphorous acid and formaldehyde in the presence of hydrochloric acid. The reconstitution of the PEI-MP labelling kits were performed by adding 500 mg of PEI-MP/25 ml of water and 0.05 ml of $SnCl_2.2H_2O$ (pH = 5.0-6.0). The volume of this solution was adjusted with water and 1ml was dispensed into sterile vials, and then lyophilized. $Na^{99m}TcO4$ (1739 to 1850 MBq) was added to the PEI-MP kit, and left to stabilize at room temperature for 15 minutes. The radiochemical purity of ^{99m}Tc-PEI-MP was evaluated hourly until 5 hours after the radiolabelling, using ascendant thin-layer chromatography (ITLC-SG/acetone and Whatman 3MM/citrate buffer). To determine the hydrophilicity of ^{99m}Tc-PEI-MP, it was calculated the 1-octanol/water partition coefficient (log $P_{o/w}$), hourly until 4 hours after radiolabelling. For cellular uptake and retention studies human cell line of transitional cell carcinoma of the bladder (ATCC® CRL1472™) was used. Cellular uptake and retention studies were performed using ^{99m}Tc-PEI-MP and ^{99m}Tc-Pertechnetate. Cell samples were collected during 4 hours, centrifuged to separate supernatant and pellet. Subsequently, the radioactivity of each portion was counted to determine percentage of uptake and retention. **Results:** The radiochemical purity of ^{99m}Tc-PEI-MP (89-92%) demonstrated to be high. The partition coefficient of ^{99m}Tc-PEI-MP ranged between -3.28 and -3.82, demonstrated the water solubility of ^{99m}Tc-PEI-MP. The maximum uptake of ^{99m}Tc-PEI-MP (1.16), demonstrated to be significantly higher ($p=0.001$, 5%) than ^{99m}Tc-Pertechnetate (0.27). The minimum retention of ^{99m}Tc-PEI-MP (3.89), demonstrated to be significantly higher ($p<0.001$, 5%) than ^{99m}Tc-Pertechnetate (1.03). **Conclusions:** The high radiochemical purity of ^{99m}Tc-PEI-MP revealed the stability of the kit formulation. The ^{99m}Tc-PEI-MP demonstrated its hydrophilic character that could be an advantage in terms of unnecessary liver and fat tissue uptake, and a faster kidney-uptake *in vivo*. The high value of uptake and retention of ^{99m}Tc-PEI-MP, demonstrated the affinity of PEI-MP to bladder cancer cells, revealing that ^{99m}Tc-PEI-MP could be an excellent agent for imaging in vivo.

OP674

Lanthanum phosphate nanoparticles as carriers for ^{225}Ac, ^{223}Ra & ^{225}Ra for targeted alpha therapy

S. Mirzadeh[1], J. V. Rojas[2], M. F. McLaughlin[3], J. D. Woodward[1], D. Robertson[3], S. Kennel[4]; [1]Medical Radioisotope Program, Oak Ridge National Laboratory, Oak Ridge, TN, UNITED STATES, [2]Department of Mechanical and Nuclear Engineering, Virginia Commonwealth University, Richmond, VA, UNITED STATES, [3]Department of Chemistry and University of Missouri Research Reactor, University of Missouri, Columbia, MO, UNITED STATES, [4]Graduate School of Medicine, University of TN, Knoxville, TN, UNITED STATES.

Targeted alpha therapy (TAT) has the potential for killing micrometastases with minimum collateral damage to surrounding healthy tissue. *In-vivo* generator radionuclides, such as ^{225}Ac, ^{223}Ra, and ^{225}Ra are of special interest as they emit multiple α-particles during their decay. Utilizing appropriate carriers capable of retaining both the parent radioisotope as well as daughter products is important for the effective delivery of the radioisotope to the tumor site while mitigating global *in vivo* radiotoxicity. In this work, $LaPO_4$ core and core+2 shells nanoparticles (NPs) (NPs with 2 layers of cold $LaPO_4$ deposited on the core surfaces) were synthesized containing either ^{223}Ra or ^{225}Ra/^{225}Ac and the retention of the parents and daughters within the NPs *in vitro* was investigated. XRD and TEM analysis revealed that the NPs crystallized with mean diameters of 3.4 and 6.3 nm for core and core+2 shells, respectively. The core $LaPO_4$ NPs retained up to 88% of ^{223}Ra over 35 days. In the core+

2 shells NPs, the retention of ^{223}Ra and its daughter, ^{211}Pb, was improved to >99.9% over 27 days. The retention of ^{225}Ra/^{225}Ac parents was >99.98% and ~80% for the ^{221}Fr and ^{213}Bi daughters over 35 days for the core+2 shells NPs. Conjugation of $LaPO_4$ NP's to mAb 201B was achieved using a lipoamide polyethylene glycol (dPEG)-COOH linker with gold-coated $La_{0.5}Gd_{0.5}\{^{225}Ac\}PO_4$ NPs. The conjugates showed an antibody-mediated uptake of 30% injected dose/organ in the target lung, vasculature which was enhanced to 47% when the reticuloendotheilial system was temporarily paralyzed. Further, the core-shell NPs retained a large fraction of the daughter products at the target site without compromising the tumoricidal properties of the α-radiation; retention of the ^{213}Bi daughter in endothelial tissue was over 70% at 1 h and about 90% at 24 h post-injection. In a model of lung metastases, treatment of mice with lung-targeted $La\{^{225}Ac\}PO_4$ NPs reduced EMT-6 lung tumor colonies significantly over control treatments. In conclusion, the high *in vitro* retention of both parents and daughters suggest that $LaPO_4$ NPs are potentially effective carriers of Ac and Ra isotopes, and the NPs-antibody construct is indeed stable in vivo with very high antibody-directed uptake.

Production yield and isotopic purity of medical Sc radioisotopes formed by proton, deuteron and alpha particle beams

M. Sitarz[1], K. Szkliniarz[2], R. Walczak[3], J. Jastrzębski[1], J. Choiński[1], A. Majkowska[3], A. Stolarz[1], A. Trzcińska[1], W. Zipper[2], A. Bilewicz[3]; [1]Heavy Ion Laboratory, University of Warsaw, Poland, POLAND, [2]Institute of Physics, University of Silesia, Katowice, Poland, POLAND, [3]Institute of Nuclear Chemistry and Technology, Warsaw, Poland, POLAND.

Aim. Recently there has been steadily growing interest in the medical applications of Sc radioisotopes. This is due to the convenient half-life of ^{43,44g}Sc, the prospect of using ^{44m}Sc as an in vivo ^{44m}Sc/^{44g}Sc generator and the therapeutic properties of ^{47}Sc which represents an ideal theranostic pair for the β^+ emitting ^{44}Sc or ^{43}Sc radioisotopes. The production efficiency and impurities generated in the formation of these radioisotopes by p, d and α projectiles are determined. *Materials and methods.* These Sc radioisotopes were produced using α particles from the K=160 heavy ion cyclotron and protons and deuterons from the medical PETtrace p/d cyclotron at the Heavy Ion Laboratory, University of Warsaw. Higher energy protons from the C30 cyclotron at the NCNR in Świerk were also employed. The targets were in $CaCO_3$ form, natural and enriched, mixed with graphite powder in various proportions. After target irradiation the properties of the produced radioisotopes were first investigated at HIL via gamma-ray spectroscopy techniques and subsequently transported to the Institute of Nuclear Chemistry and Technology in Warsaw for further chemical investigations. *Results.* A 20-30 MeV α-particle beam can produce from a cheap, easily affordable $^{nat}CaCO_3$ target the prospective PET radioisotope ^{43}Sc with an activity of about 100 MBq/μAh and isotopic purity better than 10^{-3}. ^{44g}Sc is produced by the (p,n) reaction at 16 MeV on a 95% ^{44}Ca target with a yield of 700 MBq/μAh and isotopic purity better than 10^{-4}. ^{44m}Sc can be produced by a 29 MeV α-particle beam on a 68% ^{42}Ca target with a yield of **4** MBq/μAh. It can also be formed using a 16 MeV proton beam: for 50 μA proton intensity, 12 h irradiation and 48 h cooling time its activity will be about 1 GBq without the directly produced ^{44g}Sc activity. The (p,2n) reaction on a 96% ^{48}Ca target in the energy range 30-16 MeV and 10 μA beam intensity produces after 6 h irradiation 6.4 GBq of the therapeutic ^{47}Sc (see R.Walczak et al., abstract at NRC9, Finland and this conference). The ^{48}Sc contamination is 16% of this activity at EOB and decreases with target cooling time. *Conclusions*. All medically interesting Sc radioisotopes can be produced via the accelerator route with intensities and purities acceptable for clinical applications. However, cyclotrons accelerating α particles and protons to energies of about 30 MeV are in some cases necessary. Support by NCBiR grant PBS3/A9/28/2015 is acknowledged.

OP676

Nuclear Medicine Eye Dosimetry: Preliminary Results from a UK Nuclear Medicine and PET/CT centre

G. Havariyoun, M. N. Branco, P. Clinch, E. Kalogianni, A. Mistry, D. Ruiz, G. Vivian; King's College Hospital NHS Trust, London, UNITED KINGDOM.

Introduction In light of the recently recommended occupational exposure limit of 20mSv per year for the lens of the eye, an eye dose measurement study for Nuclear Medicine (NM) Technologists at a UK NM and PET/CT centre was initiated[1-2]. **Aim** The aim of the project was to determine whether there would be any concerns regarding the new exposure limit to the eye for the technologists due to the high dose rates experienced in PET/CT. **Methods** Seven Li-F Thermo-Luminescence $H_p(3)$ Eye Dosimeters (TLDs) with a dose range of 0.15mSv to 20mSv and an energy detection range of 16keV to 662kev were allocated to NM Technologists to be worn above the right eye. The headbands were worn for a one-month period in addition to the routinely issued body and finger dosimeters. Technologists were involved in both PET/CT and routine NM procedures. A monthly rota is implemented to rotate technologists on a weekly basis. Two of the seven bands were to be worn at all times by the two PET/CT operators. The other five bands were allocated to 5 individual technologists. The number and types of procedures carried out by the five technologists during this period was audited. **Results** A total number of 109 PET/CT procedures were carried out during the above mentioned period. Both headbands worn throughout all 109 PET/CT procedures had readings below the lower dose limit of the TLDs. All but one of the five headbands worn throughout a mixture of routine NM and PET/CT procedures had readings below the lower dose limit of the TLDs and were hence set to 0mSv. Only one headband had a reading of that equal to the lower limit (0.15mSv). **Conclusions** The new recommended annual eye dose limit of 20mSv would lead to a monthly limit of 1.6mSv. Preliminary results indicate that this is not exceeded with the current practice. We believe that the radiation protection measures in place such as use of an automatic radiopharmaceutical dispenser, staff rota and appropriate use of shielding has contributed to these low eye dose measurements. The results will be further validated with phantom measurements and longer use of eye dosimeters. **References** 1. Intercomparison of radionuclide calibrators in Belgian hospitals

C. Saldarriaga Vargas[1], L. Struelens[1], S. Rodríguez Pérez[1], K. Baete[2], S. Pommé[3], J. Paepen[3], R. Van Ammel[3]; [1]Belgian Nuclear Research Centre (SCK-CEN), Mol, BELGIUM, [2]UZ Leuven Gasthuisberg, Leuven, BELGIUM, [3]Institute for Reference Materials and Measurements, Geel, BELGIUM.

Radionuclide calibrators are used in nuclear medicine to determine the amount of activity in a radiopharmaceutical. Their response not only

depends on the characteristic emissions of the particular radionuclide, but also on geometrical characteristics of the chamber and sample. Commercially available activity calibrators are typically calibrated inside the factory, thus establishing traceability for specific measurements. After commissioning, periodic quality control of the chamber is carried out by means of long-lived reference sources, like *e.g.* Co-57, Cs-137 or Ba-133. However, there is an increasing demand to investigate the accuracy of activity calibrator measurements for clinical isotopes using an SI-traceable standard solution. An intercomparison exercise has been performed of radionuclide calibrator measurements of F-18, In-111 and Tc-99m in 15 Belgian hospitals, involving 37 radionuclide calibrators. Four sessions were held in different geographical regions between December 2013 and February 2015. For each radionuclide a 10 ml Greer vial and a 10 ml syringe filled with 3 ml of stock solution were prepared. For both vial and syringe, an average activity at start was prepared of 100 MBq for Tc-99m, 15 MBq for In-111 and 115 MBq for F-18. The reference values for the massic activity of the solutions were provided by the Joint Research Centre of the European Commission in Geel following two traceability chains to the SI-unit Becquerel. For Tc-99m, about 90% of the calibrators are within +/-5% of the reference value for vial and syringe. A maximum underestimation of 16% is observed. For F-18, about 70% of the measured activities are within +/-5% of the reference for both containers. All results are correct within +/-10% for the F-18 vial. For In-111 the results are worse, with only 40% of the results within +/-5% of the reference value for the vial and none for the syringe. Whereas 80% comply within +/-10% for the vial measurements, this is true only for 6% of the syringe measurements. For 30% of the calibrators, the In-111 syringe measurements overestimated the activity by more than 30%, up to a maximum deviation of 70%. This intercomparison exercise demonstrates that there is significant room for improvement in the activity measurements of clinical radionuclides. Traceability is best established by a systematic calibration of the radionuclide calibrator for each relevant nuclide, using well characterized standards in identical, reproducible geometrical conditions as applied in daily practice. Such measures are recommended to comply with the growing need for quantitative accuracy in nuclear medicine.

OP678

Measurement of Hg-197 and Hg-197m by a dose calibrator

R. Freudenberg, M. Vogel, M. Andreeff, J. Kotzerke; University Hospital Dresden, Dresden, GERMANY.

Aim: Radiomercury isotopes Hg-197m and Hg-197 are two prospecting isotopes for theranostic applications in nuclear medicine. Hg-197m (half life: 23.8 hours) decays by electron capture (8.9 %) to Au-197 (stable) or by internal transition to Hg-197 (half life: 64.1 hours). The mercury isotopes are produced by proton irradiation of a gold target using a cyclotron. At the end of bombardment the ratio of both radionuclides is approx. 1:1. By solid state spectroscopy it is possible to estimate the activities of both isotopes inside a radioactive probe separately. But it is challenging to do the same by a dose calibrator due to the transient equilibrium and the missing spectroscopic features of an ionization chamber. Method: At first we calibrated an HPGe solid state detector (Canberra GC2018-7500SL, Meriden, USA) by reference sources to measure absolute activities of Hg-197m and Hg-197. Additionally, a geometric model of the HPGe detector was constructed to perform Monte Carlo simulations using Geant4 to verify the calibration procedure. In the next step, we created reference source (vials, syringes) of different sizes containing Hg-197/Hg-197m solutions to cross calibrate a dose calibrator (MED Isomed 2010, Dresden, Germany). The radiomercury solutions were measured with and without shielding to determine both activities separately. Therefore we tested shielding of different materials and thickness to optimize the accuracy of measurement. Results: The Monte Carlo simulations revealed a good accordance to the HPGe measurements of calibration sources. Hence we were able to estimate Hg-197(m) activities within 95 % accuracy by using the HPGe. We created vials containing total activities between 5 and 20 MBq within a volume between 2 and 10 ml as well as 1 ml, 2 ml, 5 ml and 10 ml syringes with different volumes. We present the results of dose calibrator measurements by using plastic, aluminum, copper and lead shielding to differentiate between Hg-197 and Hg-197m. Conclusion: Based on our results it is possible to upgrade the isotope table in the dose calibrator to measure Hg-197 and Hg-197m routinely. Hence it would be possible to measure radiomercury when it is successfully translated to clinical applications.

OP679

Radiation exposure in 177Lu-PSMA & the possibility of applying outpatient treatment rules

M. Abuqbeitah, M. Demir, N. Yeyin, L. Uslu, B. Vatankulu, L. Kabasakal, K. Sönmezoğlu; Istanbul University, İstanbul, TURKEY.

Aim: The aim of this study is to develope outpatient treatment protocol for new-emerging 177Lu-PSMA therapy and to evaluate the related radiation safety .Materials and Methods: This study analyzed the dose rate of 23 patients treated by 200 mCi 177Lu-PSMA at different distances (0.0, 0.25, 0.50, 1.0 and 2.0 m) in various time points (0, 1, 2, 4, 18, 24, 48 and 120 h) after infusion. Blood samples were withdrawn from 17 patients within the same group in 3, 10, 20, 40, 60, and 90 min and 2, 3, 24 h after infusion. Different 7 patients were asked to collect urine until 24 h and gamma well counter used for samples counting. Family members were invited to wear optically stimulated luminescence (OSL) dosimeter whenever they are in proximity of patients up to 4-5 days. Total dose of medical team including radiopharmacist, physicist, physician, nurse, and nuclear medicine technologist was estimated by electronic personnel dosimeter (EPD). Finger dose was determined using ring thermoluminescent dosimeter (TLD) for radiopharmacist and nurses.Results: Dose rate at 1 m after 4 and 6 h was 23±6 μSv/h and 15±4 μSv/h respectively. Mean total dose to 23 caregivers was 202.3±42.7 μSv (120-265 μSv). Nurses and radiopharmacist had a total dos of 6 and 4 μSv per patient respectively, whereas physicist and physician dose was 2 μSv/patient. Blood distribution and early eliminatiion half life was 0.41±0.1 h and 5.1±1 respectively. 7 patients excreted a mean of 45% (range: 32%-65%)of the initial activity during 6 hours following administration. Conclusion: Our study supports 177Lu-PSMA as a safe modality to be performed within outpatient treatment protocol, since dose rate decreases below the determined threshold after approximately 5 hours to < 30 μSv/h and after 6 hours degrades to 20 μSv/h.

OP680

First Ex-Vivo experience of Radioguided Surgery Technique with beta- radiation in a meningioma patient

C. M. Grana[1], R. Faccini[2], M. Schiariti[3], M. Colandrea[1], M. E. Ferrari[1], S. Papi[1], E. Solfaroli Camillocci[2], P. Ferroli[3], S. Morganti[4], M. Cremonesi[1], S. Fracassi[1], S. M. Baio[1], L. Gilardi[1], A. P. Rocca[1], L. L. Travaini[1]; [1]European Institute of Oncology, Milano, ITALY, [2]Dip Fisica Sapienza Università, Roma, ITALY, [3]Istituto Neurologico Besta, Milano, ITALY, [4]INFN, Roma, ITALY.

Introduction**:** Radioguided surgery (RGS) is a technique aimed at assisting the surgeon to reach a complete resection of the tumoral lesion, while minimizing the amount of healthy tissue removed. Established methods make use of a gamma-emitting tracer with a gamma detecting probe. Since gamma radiation can travel through large amounts of tissue, any uptake of the tracer in nearby healthy tissue represents a non-negligible background, strongly limiting and often preventing the use of this technique. Aim: To overcome these limits and extend the range of

applicability of RGS, it was suggested to use pure beta- emitting radioisotopes, as 90Y, which are characterized by a penetration of only few millimeters of tissue. This novel approach allows to develop a new probe which, detecting electrons and operating with low radiation background, provides a clearer delineation of the margins of lesions. We started on evaluating tumors expressing somatostatin receptors, where we can study the uptake of 90Y-DOTATOC, as in brain (meningioma and glioma) and neuroendocrine tumors. These studies started from PET images with 68Ga-DOTATOC and, assuming that the biodistribution of the tracer did not change when labeled with 90Y, with a simulation program (FLUKA) estimated the signal rate on the probe. Materials and Methods: A 68 years female patient with radiological diagnosis of meningioma, after giving written informed consent, received a 68Ga-DOTATOC/PET, two weeks prior to surgery. PET revealed that the tumor had an average SUV of 2.3. Twenty-four hours before surgery, the patient was injected with 300 MBq of 90Y-DOTATOC. Before surgery the probe was placed in proximity to the skin of the patient in several spots to estimate the level of background. Results: After surgery, that was performed as routine clinical indicated, the extracted tumor and the attached dura were sectioned in 7 samples. Then the probe was put in contact with each sample to measure its activity: all the samples identified by the probe as malignant were actually of tumor tissue, as histologically routine detected. Conclusions: This first ex-vivo RGS test proved that administering 4MBq/kg of 90Y-DOTATOC, induced on the probe a signal that allows to discriminate very strongly between tumor and nearby healthy tissues. Now we are enrolling a second meningioma patient. Further developments of the probe could further increase its sensitivity, in order to reduce the dose for a given administered activity.

Prognosis value of FDG-PET Parameters at Diagnosis and after Induction in Patients with Mantle Cell Lymphoma, Interim Results from the LyMa-PET Project, a LYSA study

C. Bailly[1], T. Carlier[1], M. Meignan[2], C. Gallazzini Crepin[3], A. Beriollo Riedinger[4], A. Devillers[5], F. Kraeber Bodere[1], S. Le Gouill[1], C. Bodet Milin[1]; [1]University Hospital, Nantes, FRANCE, [2]University Hospital, Creteil, FRANCE, [3]University Hospital, Grenoble, FRANCE, [4]Cancer Center, Dijon, FRANCE, [5]Cancer Center, Rennes, FRANCE.

OBJECTIVES: Positron emission tomography using 18F-fluoro-2-deoxy-glucose (FDG-PET) has emerged as an important predictor of clinical outcome in lymphomas. Yet, its role and its prognostic value in mantle cell lymphoma (MCL) is less well defined as its utility for assessing disease burden and response to therapy remains unclear. The objective of the study was to analyse whether quantitative indices derived from FDG-PET at diagnosis and after induction can provide prognostic value for untreated MCL patients. Our work is an ancillary study of the prospective phase III Lyma trial (Le Gouill et al. ASH 2014 ; ASH 2015) (NCT00921414). Herein, we present the first results performed from the database of first planed interim-analysis. METHODS: FDG-PET of 94 MCL patients have been independently and centrally reviewed by 2 lymphoma expert nuclear physicians. Quantitative metrics including SUVmax, SUVmean, SUVpeak, total lesion glycolysis (TLG) were extracted from the area with the highest uptake, at diagnosis and before ASCT (iPET). Whole-body functional volume and whole-body TLG (TLGwb) were derived considering all detected lesions at diagnosis. Visual analysis with Deauville scale was also performed at iPET. The best cut-off values were determined for each metric using X-tile® analysis. Prognostic value was assessed using univariate analysis by Kaplan-Meier estimates of progression-free survival (PFS). RESULTS: The studied population did not differ from the entire Lyma cohort (n=299). At diagnosis, univariate analysis showed a prognostic value on PFS of 4 metrics: SUVmax ($p<0.001$), SUVmean ($p< 0.001$), SUVpeak ($p<0.001$) and TLG ($p=0.03$). The prognostic value of SUVmax was reinforced when combined with MIPI. Indeed, patients can be separated in 3 prognostic groups including a group of patients with a very good outcome (low SUVmax plus MIPI inter/low). Whole-body functional volume and TLGwb were not associated with PFS. Results of iTEP showed that SUVmax, SUVpeak, SUVmean but also ΔSUVmax, ΔSUVpeak, ΔSUVmean before ASCT were predictive of PFS. FGD-PET before ASCT's analysis according to Deauville scale (positivity cut-off: Deauville score ≥4) was not associated with PFS. CONCLUSION: The LyMa-PET project is the largest study addressing the question of FDG-PET in a homogeneously treated population of MCL. Results show a strong prognostic value on PFS of quantitative parameters such as SUV_{max} determined on FDG-PET at diagnosis and after induction in MCL untreated patients. Update results and patients' outcome according to randomization arms will be presented for the time of the meeting.

OP682

18F FDG-PET/CT In Gastric Malt Lymphoma: A Bicentric Experience To Establish Correlations With Histological And Morphological Features

D. Albano[1], P. Ferro[2], M. Bertoli[1], M. Spallino[2], G. Bosio[1], M. Picchio[2], F. Bertagna[1], F. Fallanca[2], L. Gianolli[2], R. Giubbini[1]; [1]Spedali Civili Brescia, Brescia, ITALY, [2]IRCCS San Raffaele Scientific Institute, Milano, ITALY.

Aim: gastric mucosa-associated lymphoid tissue (MALT) lymphoma is the most common extranodal MALT lymphoma. The role of 18F-FDG PET/CT in evaluating this type of lymphoma is still controversial. In literature the detection rate of 18F-FDG PET/CT in patients with gastric MALT is variable (9-77%) and the reason of this heterogeneity is not still clear. Our aim was to compare the metabolic behavior of gastric MALT with epidemiological, histopatological, Ann Arbor staging and gross morphological features. **Materials and methods**: sixty seven patients (26 female, 41 male; median age: 60 years; age range, 27-83) from two center (Department of Nuclear Medicine of Spedali Civili Brescia and of IRCCS San Raffaele Scientific Institute) with histologically-confirmed diagnosis of gastric MALT who underwent a 18F-FDG PET for initial staging before any treatment were included. PET images were qualitatively and semi-quantitatively analyzed by measuring the maximum standardized uptake value (SUVmax), lesion-to-liver SUVmax ratio and lesion-to-blood pool SUVmax ratio and compared with epidemiological (age,sex), histological (presence of gastritis, ulcer, H. pylori infection, plasmacytic differentiation and Ki67 index) and morphological (diameter max lesion, superficial or mass-forming lesions) characteristics. Proliferative activity expressed by Ki-67 was evaluated in 60 patients. Forty nine patients were stage I, 4 stage II, 4 stage III and 10 stage IV. **Results**: thirty five patients had positive18F-FDG-PET/CT showing 18F-FDG uptake (average SUVmax was 8.9 ± 6.7; lesion-to-liver SUVmax ratio 3.7 ± 2.6; lesion-to-blood pool SUVmax ratio 4.8 ± 3.3) at the corresponding gastric lesion; the remaining 32 were not 18F-FDG-avid. 54 (81%) patients had gastritis, 32 (49%) had gastric ulcer, 28 (42%) had H. pylori infection. Thirty four MALT (51%) presented with superficial gastric lesion, while 33 (49%) with mass forming lesions; plasmacytic differentiation was present in 9 patients (13%); median diameter maximum measured with morphological imaging like CT or endoscopy was 1.7 cm (range:0.2-8.7 cm). 18F-FDG avidity was significantly associated with morphological features (mass forming and high maximum diameter), Ann Arbor stage and Ki67 index ($p<0.001$). SUVmax, lesion-to-liver SUVmax ratio and lesion-to-blood pool SUVmax ratio correlated significantly with Ki67 index ($p<0.001$) and no other features. **Conclusions**: 18F-FDG avidity was noted in 52% of gastric MALT lymphoma and this avidity is correlated with gross morphological characteristics, tumor stage and Ki-67 index. SUVmax, lesion-to-liver SUVmax ratio and lesion-to-blood pool SUVmax ratio are correlated only with Ki-67 index.

OP683

Interobserver Agreement of Interim ^{18}F-FDG PET/CT in Diffuse Large B-Cell Lymphoma (DLBCL): Impact of Baseline Imaging Modality and Disease Localization

C. N. Burggraaff[1], A. C. Cornelisse[1], J. M. Zijlstra[1], O. S. Hoekstra[1], H. C. W. De Vet[1], P. J. Lugtenburg[2], F. Celik[3], J. E. Huijbregts[4], A. I. J. Arens[5], B. De Keizer[4], On behalf of the HOVON imaging working group; [1]VU university medical center, Amsterdam, NETHERLANDS, [2]Erasmus MC Cancer Institute, Rotterdam, NETHERLANDS, [3]Deventer Ziekenhuis, Deventer, NETHERLANDS, [4]university medical center Utrecht, Utrecht, NETHERLANDS, [5]Radboud university medical center, Nijmegen, NETHERLANDS.

Aim: International guidelines recommend ^{18}F-FDG PET/CT for staging and for end-of-treatment response assessment in DLBCL patients. The role of interim ^{18}F-FDG PET/CT (iPET) in DLBCL is less clear. Our aim was to assess the interobserver agreement of iPET using the Deauville 5-point scale (DS) in patients with DLBCL as a function of the baseline imaging modality (^{18}F-FDG PET/CT or CT only) and of the localization of residual ^{18}F-FDG uptake. *Materials and methods*: iPET scans of DLBCL patients were collected from the HOVON84 study, an international multicenter randomised controlled trial. Patients received R-CHOP immuno-chemotherapy and were randomized to receive rituximab intensification in the first four cycles or not. iPET was made after 4 cycles. Scans were scored according to the DS by two central reviewers from a pool of ten experienced nuclear medicine physicians. Reviewers were blinded to clinical outcomes. DS results were dichotomized (DS 1-3: 'negative', DS 4-5: 'positive'). Besides Cohen's kappa we calculated the agreement separately for the positive and the negative scores, expressed as positive agreement (PA) and negative agreement (NA). Definition of positive agreement: given one reviewer scores positive, the probability that another reviewer scores positive as well.(de Vet et al. BMJ 2013). *Results:* 488 iPET scans were reviewed centrally; a baseline ^{18}F-FDG PET/CT was available in 76%, and CT in the remaining cases. Kappa for iPET interobserver agreement was 0.65, NA was 92.1% and PA was 72.5%. Kappa and PA of the 369 iPET cases with a baseline ^{18}F-FDG PET/CT available were 0.68 and 75.6% versus 0.52 and 60.9% in the 119 iPET cases with only a baseline CT scan for reference (p=0.10 and 0.16, respectively). Negative agreement for involved localizations was 97.8-100%. Lowest positive agreement was observed for mediastinal and mesenterial lymph nodes, spleen, GI and skeletal localizations (30.0-65.2%). *Conclusion:* Availability of a baseline ^{18}F-FDG PET/CT seems to give a better interobserver agreement of iPET, although not statistically significant. Despite reasonable kappas, the relatively low PA indicates that observer agreement needs to be improved before iPET can be used in treatment escalation trials in DLBCL patients. These data can help to set the agenda for further training and research on iPET interpretation.

OP684

FDG PET-CT parameters in the therapy evaluation of patients with Hodgkin's lymphoma

M. Tuncel[1], T. M. Kutluk[2], P. Ö. Kıratlı[1], B. Aydın[2], B. Erbas[1], C. Akyüz[2]; [1]Hacettepe University, Department of Nuclear Medicine, ANKARA, TURKEY, [2]Hacettepe University, Department of Pediatric Oncology, ANKARA, TURKEY.

Aim: FDG PET-CT is the modality of choice for staging and therapy response evaluation of patients with Hodgkin's lymphoma(HL). However the optimal quantitative or qualitative parameter that predicts therapy response and prognosis is a matter of debate. In this study we aimedto compare the accuracy of several FDG PET-CT parameters in the evaluation of patients with HL. Material and method: FDG PET-CT was performed in 70 pediatric patients with HL (mean age:12.6±4, range:4-20 yrs) at baseline(1) and after 2-3rd cycles of chemotherapy(interim)(2). End of therapy imaging(3) was available in 50 patients. The median follow-up was 31 months(6-60). Images were interpreted according to the Deauville 5-point score(DS), Revised DS(that accepts milimetric residual upper cervical lymph node with DS ≥4 as DS:1) and SUVmax of the lesion, total tumor volume(TTV) and total lesion glycolysis (TTVxSUVmean). Percentage change(%Δ) of these quantitative parameters were measured. The ROC curves were obtained to determine the AUC values and the optimal cut-off of parameters to predict relapse. Results: Interim FDG PET-CT was normal in 77%(54/70) of patients. DS4-5 was in 23%(16/70) of group. Six patients had progression or relapse during follow-up. SUV2[0.6 ±1.2 vs 7.3 ±7.4, p=0.001], SUV3[0.6 ±1.6 vs 6.9 ±9.3, p=0.001], TTV2 [1.9 ±8.6 vs 31.2 ±46.3, p=0.0001]]and TLG2[3 ±13 vs 133 ±190, p=0.0001] values were different in remission and relapse sub-groups. The AUC values were 0.83(p=0.008) for SUV2, 0.936(p=0.02) for SUV3, 0.77(p=0.027) for TTV2, 0,78(p=0.021) for TLG2, 0.78(p=0.026) for %ΔSUV2, 0.73(p=0,08) for %ΔTTV and 0.73(p=0.087) for %ΔTLG respectively. The best cut-off values were 2.7, 6.5, 16, %55, %96 and %97 with a sensitivity and specificity of 93% and 71.4% for SUV2, 95% and 66.7% for TTV2, 98% and 66.7% for TLG2, %94.2 and 66.2 for %ΔSUV2, 94% and 60% for %ΔTTV, 94% and 60% for %ΔTLG respectively. Progression free survival(PFS) in patients with DS 1-3 was better than in patients with DS 4-5 (Log-rank, p=0.002) According to ROC analysis, revisedDS performed better than DS(AUC:0,83 P=0,005 vs AUC:0,78 p=0,017). Patients with values below the cut-off of SUV2, TTV2, TLG2, %ΔSUV2, %ΔTTV and %ΔTLG had longer PFS than patients with higher values (Log-rank, p=0.005, p=0.0001, p=0.0001, p=0,016, p=0,0001 and p=0.012). Conclusion:FDG PET-CT was useful for the evaluation of pediatric patients with HL. Interim Revised DS 4-5 and high TTV2 and TLG2 were the best predictors of shorter PFS. Our results should be confirmed in further studies with larger number of patients.

OP685

Evaluating early interim fluorine-18 fluorodeoxyglucose PET/CT with SUVmax-based criteria for predicting the outcome in DLBCL

Y. Fan[1], **Y. Zhang**[2], Z. Yang[1], N. Zhou[1], C. Liu[1], Z. Ying[1], J. Zhu[1], X. Wang[1]; [1]Peking university cancer hospital, Beijing, CHINA, [2]Peking university cancer hospital & Institute, Beijing, CHINA.

Purpose: To investigate whether the SUV_{max}-based criteria could be a superior method for evaluating early interim PET compared with the Deauville five-point scale (5-PS) and reduction rate of the maximum standardized uptake value (ΔSUV_{max}) criteria.**Methods:** A total of 119 patients with DLBCL underwent ^{18}F-FDG PET/CT at baseline (PET0) and after two chemotherapy cycles (PET-2) were enrolled in this study. PET-2 were evaluated with the SUV_{max}-based, 5-PS, and ΔSUV_{max} criteria. The optimal threshold of the SUV_{max}-based criteria was calculated via reproducibility and prognostic analyses using the liver SUV_{max} as reference. Using the three criteria, prognostic factors were compared by the survival analysis. Uni- and multivariate analyses of outcomes were performed using clinical variables and PET-2.**Results:** The optimal threshold for the SUV_{max}-based criteria is 1.6 fold of the liver SUV_{max}. The Cohen's *k* values for reproducibility of the SUV_{max}-based criteria were above 0.90 and were superior to the 5-PS or ΔSUV_{max} interpretation. Using the SUV_{max}-based criteria, the 3-year progression-free survival (PFS) and overall survival (OS) were 75.1% and 78.6%, respectively, for patients with a positive residue compared with 15.8% and 36.9%, respectively, for patients with a negative residue ($P < 0.001$). The SUV_{max}-based criteria demonstrated a slight superior prognostic value compared with the other two criteria. Uni- and multivariate

analyses revealed that the PET-2 viewing via SUV_{max}-based criteria was an independent predictor for PFS (P<0.001) and OS (P = 0.003).**Conclusion:** Together, these data indicate that early interim ^{18}F-FDG PET/CT effectively predicts the outcome in patients with DLBCL using the SUV_{max}-based criteria.

OP686

Baseline Metabolic Tumour Volume to Predict Outcome in Diffuse Large B Cell Lymphoma: Which Method?

F. Rahman[1], N. G. Mikhaeel[1], L. C. Gormsen[2], J. T. Dunn[3], T. C. El-Galaly[4], H. Ilyas[3], D. Smith[1], H. Møller[5], L. J. Petersen[6], M. H. Vendelbo[2], A. Elsner[7], S. F. Barrington[3]; [1]Department of Clinical Oncology, Guy's and St Thomas' Hospital, London, UNITED KINGDOM, [2]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, DENMARK, [3]PET Imaging Centre at St. Thomas' Hospital, King's College, London, UNITED KINGDOM, [4]Department of Hematology, Aalborg University Hospital, Aalborg, DENMARK, [5]Cancer Epidemiology, Population and Global Health, King's College, London, UNITED KINGDOM, [6]Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, [7]Hermes Medical Solutions, Stockholm, SWEDEN.

Aim: Baseline total Metabolic Tumour Volume (tMTV) has been reported to be prognostic in Diffuse Large B Cell Lymphoma (DLBCL) using two methods, which have differing complexity and delineation time. The aim of this study was i) to determine whether the methods accurately predicted progression free survival (PFS) using commercial software in an unselected population of patients with DLBCL and ii) if measurement of MTV in the bulkiest lesion(s) could be used as a surrogate for tMTV. Methods: Consecutive patients with DLBCL staged with 18F Fluorodeoxyglucose PET-CT and treated with RCHOP(-like) chemotherapy were included from two institutions from UK and Denmark. Tumour was segmented with Hermes Medical Hybrid 3D viewer© software using the standardised uptake value (SUV) ≥ 2.5 (MTV2.5) and ≥ 41% of maximum SUV (MTV41%). Tumour volume(s) were edited to exclude physiological uptake and summed to calculate tMTV. The MTV of the lesion with the greatest overall bulk (MTVbulk) and the sum of the two bulkiest lesions above and below the diaphragm (MTVsum) were also measured. Correlation between methods was tested using Pearson's, and Kendall-tau rank correlation. Receiver operator characteristics (ROC) analysis was performed to determine the optimal threshold to predict PFS for each method. Kaplan-Meier analysis was used to examine the association between MTV and PFS using these thresholds. Results are available from 246 patients, median follow up 43.8 months (range 0.62-121.6 months). Mean tMTV2.5 (sd) was 969±1301 cm^3. Mean tMTV41% (sd) was 295 ±465 cm^3. Total MTV2.5 and tMTV41% correlated strongly (R=0.79) and ranked patients in similar order (Tau=0.75). MTVbulk and MTVsum also correlated strongly with total MTV using both methods. [MTVbulk2.5 vs. tMTV2.5 R=0.84; MTVsum2.5 vs. tMTV2.5 R=0.86. MTVbulk41% vs. tMTV41% R=0.93; MTVsum41% vs. tMTV41% R=0.94.] Optimal cut-offs were 426cm^3 (tMTV2.5) and 99cm^3 (tMTV41%). Using the derived cut-offs to separate patients into high and low MTV, the six methods were all predictive of PFS, with tMTV2.5 being the most significant (log rank=23.3, p<0.00). 5y-PFS was 79% vs. 50% for patients with low and high tMTV2.5 respectively and 75% vs. 51% for low and high bulkMTV2.5 respectively. Conclusions: Baseline MTV predicts PFS in DLBCL using both published methods, but the optimal threshold is dependent on the method used. The MTV of the bulkiest lesion predicted PFS almost as well as the total MTV. This would reduce the time needed to measure MTV making it feasible for routine reporting.

OP687

The Oncology Biomarker Qualification Initiative (OBQI): Multi-institutional Demonstration Using FDG-PET in Non-Hodgkin's Lymphoma

J. Zhang[1], N. C. Hall[2], H. Schoder[3], L. P. Schwartz[4], W. H. Wilson[5], G. Kelloff[6], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Philadelphia VA Medical Center, Philadelphia, PA, UNITED STATES, [3]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES, [4]Columbia University, New York, NY, UNITED STATES, [5]National Institutes of Health, Bethesda, MD, UNITED STATES, [6]National Cancer Institute, Bethesda, MD, UNITED STATES.

Purpose: OBQI was initiated in January 2006 in USA via an FDA-NCI-CMS consortium to quality new cancer biomarkers. The Imaging and Radiation Oncology Core (IROC) Ohio served as one of the six NCI-designated quality assurance centers and managed this multi-institutional project with the goal to qualify FDG-PET as an imaging biomarker in non-Hodgkin's lymphoma. This presentation is to introduce, evaluate and demonstrate the overall experiences within this clinical trial and the established quality assurance workflows and standards. **Methods**: To ensure consistent and objective imaging biomarker assessment for treatment response, a standardized workflow supporting such multi-institutional clinical trials was established to manage the continuum from trial initiation to closure. Four advanced components of imaging performance and protocol compliance from site credentialing to central review analysis were implemented and evaluated. 15 itemized criteria within 4 categories in data quality control were established and standardized. A 'heat-mapping' approach for quantitative data assessment was developed and utilized for effective trial performance and quality control management. All imaging aspects of this trial was coordinate between the Imaging Committee of the NCI network group and the responsible Imaging Core Lab. **Results**: Within 5 years patient enrollment and data accrual for this biomarker study, a total of 173 patients with 538 PET/CT studies from 57 specifically credentialed institutions within the US were included in the assessment. The overall data compliance rate was at the start of the trial ~50% and improved to greater than 90% due to the implemented quality control procedures. The QC scoring system found for the 538 studies 92% were rated compliant, 5% acceptable and 3% noncompliant. Focusing on 173 accessible patients found 92% were compliant, 7% acceptable and 1% noncompliant. The most common imaging protocol deviations were uptake time, scanner consistency and timing of follow up. The blinded reader assessment found a 92% agreement in quantitative biomarker analysis (discrepancies: PC2 positive 5%, PC2 negative 3%, PC6 0%). **Conclusion**: We report on the established best practices and experiences in quality assurance workflows, site credentialing strategies, imaging protocol standards and central imaging review for the national biomarker initiative. Our experience should lead to refined best clinical imaging trial practices and strengthen the effort to establish validated PET Biomarker capabilities not only for lymphoma but for all clinical trials.

Somatostatin Receptor Expression in Lymphomas: ^{68}Ga-DOTANOC PET/CT Imaging and Immunohistochemical Analysis

T. Ruuska[1,2,3], Y. Escala-Ramirez[4,5], S. Vaittinen[1,6,3], M. Gardberg[6,3], E. Alanne[2,3], A. Kiviniemi[7,3], I. Jambor[7,1], P. Marjamäki[8,1], J. Kemppainen[9,8,3], S. Jyrkkiö[2,3], H. Minn[2,3]; [1]University of Turku, Turku, FINLAND, [2]Department of Oncology and Radiotherapy, Turku, FINLAND, [3]Turku University Hospital, Turku, FINLAND, [4]Department of Radiology, Madrid, SPAIN, [5]University of Madrid, Madrid, SPAIN, [6]Department of Pathology, Turku, FINLAND, [7]Department of Radiology, Turku, FINLAND, [8]Turku PET Centre, Turku, FINLAND, [9]Department of Nuclear Medicine, Turku, FINLAND.

INTRODUCTION: ^{68}Ga-DOTANOC PET/CT is routinely used to image neuroendocrine tumors (NETs). Incidentally we saw a patient whose pancreatic diffuse large B-cell lymphoma (DLBCL) mimicked NET in ^{68}Ga-DOTANOC-PET/CT. This prompted us to determine somatostatin receptor (SSTR) status in patients with lymphoma at ^{68}Ga-DOTANOC PET/CT and by immunohistochemical analysis of SSTR subtypes 2, 3 and 5 ($SSTR_{2,3,5}$). **METHODS:** 21 patients with newly diagnosed lymphoma were referred to ^{68}Ga-DOTANOC and FDG PET/CT prior any treatment. Tracer uptake was evaluated visually by two nuclear medicine specialists. Maximum standardized uptake values (SUVmax) were determined from 14 lymph node and two extranodal regions (if any) with highest uptake in each patient. Lesions were then graded with Deauville score (1-5) in FDG PET/CT and modified Krenning score (0-4) in ^{68}Ga-DOTANOC PET/CT, respectively. $SSTR_{2,3,5}$ status was analyzed from routine biopsies of lymphomatous tissue and matched to corresponding PET/CT findings. **RESULTS:** 20/21 patients had FDG-positive lymphoma (Deuville score ≥ 3). Uptake of ^{68}Ga-DOTANOC was regarded as positive if modified Krenning score was ≥ 2 (uptake less or equal to liver) and resulted in 14 of 21 (67%) patients having ^{68}Ga-DOTANOC-positive lymphomas. Highest ^{68}Ga-DOTANOC SUVmax values were seen in Hodgkin's lymphoma of nodular sclerosis subtype and DLBCL (median 9.8 and 9.7, respectively). Both cases showed strong $SSTR_2$ immunopositivity in tumor cells. Some patients had $SSTR_2$ immunopositivity predominantly in endothelial and dendritic cells and follicular centers of lymph nodes contributing to a positive PET/CT with probably low tumor-specific uptake. $SSTR_3$ and $SSTR_5$ were mainly negative in all lymphoma subtypes. **CONCLUSION:** According to this pilot study, ^{68}Ga-DOTANOC PET/CT is positive in some lymphoma subtypes which express SSTRs. These tumors may be amenable to treatments targeting SSTR and present a potential risk to be classified as NET if representative tumor sample is not available.

The role of ^{18}F-FDG PET/CT in the diagnosis and response to medical treatment of inflammatory aneurysms of abdominal aorta. A prospective pilot study

M. Lavalle[1], V. Alberti[2], S. Annunziata[1], L. Leccisotti[1], M. Orrico[2], S. Ronchey[2], N. Mangialardi[2], A. Giordano[1]; [1]Institute of Nuclear Medicine, Università Cattolica Sacro Cuore, Roma, ITALY, [2]Institute of Vascular Surgery, Presidio Ospedaliero San Filippo Neri, Roma, ITALY.

Aim: Normal aortic wall contains few inflammatory cells in contrast to aneurysm of abdominal aorta (AAA) tissue, which demonstrates a progressive accumulation of inflammatory cells from relatively non-inflammatory (niAAA) to inflammatory AAA (iAAA). Computed tomography (CT) sensitivity in identifying iAAA is ~83% and medical treatment with steroids can lead to regression of the inflammation without a reduction in aneurysm size. To date, limited data are available on the role of metabolic imaging in iAAAs by ^{18}F-FDG PET/CT. Therefore, the aim of this pilot study is to evaluate prospectively the role of ^{18}F-FDG-PET/CT in iAAA diagnosis and response to medical treatment. **Methods**: We prospectively evaluated 6 patients (all male, mean age 65±6 yrs) with symptomatic iAAA (mean diameter 7.17±1.93 cm). Five male patients with asymptomatic niAAA undergone ^{18}F-FDG-PET/CT for oncological purposes were included as age and size-matched controls. All patients with iAAA underwent ^{18}F-FDG-PET/CT before and after steroid treatment for three months. In all patients AAA SUVmax and target to background ratio (TBR) were calculated (a VOI was placed on the area of most intense aortic wall ^{18}F-FDG uptake and the superior cava vein was used for background). All PET parameters were compared with serum inflammation levels. After steroids, clinical examination, especially a prompt reversal of symptoms, was used as response criteria in iAAA patients. **Results**: All iAAAs showed significantly increased FDG uptake before steroid therapy compared to asymptomatic niAAAs (mean SUVmax 9.61±2.43 *vs.* 2.28±0.23, mean TBR 5.49 ±1.60 *vs.* 1.40±0.31; $p<0.05$). After medical treatment, all PET parameters significantly decreased in all iAAAs compared to baseline values (mean SUVmax 3.29±1.12 and mean TBR 1.58±0.49; $p<0.05$). Mean SUVmax and TBR reductions were respectively 65±12% (range 50%-79%) and 69 ±11% (51%-83% range). Mean C-reactive protein value slightly decreased after steroid therapy without reaching statistical significance (7.70±3.43 vs. 5.84±1.22 mg/dl after steroids; p=n.s) and mantaining levels higher than laboratory cut-off in all iAAAs. All iAAAs were considered responders to medical treatment by clinical examination. **Conclusions**: The preliminary

data of this prospective pilot study show that all symptomatic iAAAs exhibit highly increased ^{18}F-FDG uptake compared to asymptomatic niAAAs. Moreover, ^{18}F-FDG uptake changes seems to correlate with clinical response to steroid therapy more than serum inflammation parameters suggesting that PET/CT may become a useful method of monitoring response to medical treatment.

OP694

Correlation of tissue to blood standard uptake ratio (SUR) derived from static 18F-FDG-PET scans with the metabolic uptake rate derived from dynamic 18F-FDG-PET scans for quantification of lung inflammation in experimental ARDS

A. Braune, L. Oehme, T. Kiss, T. Bluth, J. Kotzerke, M. Gama de Abreu; University Hospital Carl Gustav Carus at the Technische Universität Dresden, Dresden, GERMANY.

AIM: PET imaging using 18F-FDG followed by mathematical modelling of the pulmonary metabolic uptake rate of 18F-FDG (ki) is goldstandard for the assessment of pulmonary inflammation in acute respiratory distress syndrome (ARDS). However, dynamic PET requires 60-75min and covers only a 15cm cranio-caudal field of view. It has been shown in experimental ARDS in dogs, the the tissue to blood standard uptake ratio (SUR), derived from the last 300s-frame of a 58min dynamic 18F-FDG-PET scan, highly correlated with ki measurements [Chen DL et al., JNuclMed2004]. In this study we investigated whether ki measurements also correlate with SUR derived from static 18F-FDG-PET in experimental ARDS, which would allow a much faster acquisition of the whole lung. We also investigated, whether the 15cm cranio-caudal field of view of dynamic PET was representative for inflammation of the whole lung. METHODS: Lung injury was induced by saline lavage and ventilation with high tidal volumes in 8 pigs. After injury (day1) and after 24h of mechanical ventilation (day2) 18F-FDG uptake was quantified as kiP using the Patlak analysis of dynamic PET frames 15-75min after 18F-FDG injection. Mean kiP values were calculated for 5 isogravimetic subregions (ROIs15cm) along the ventro-dorsal gradient of the captured 15cm cranio-caudal lung field. Immediately after dynamic PET scanning and 77-80min after 18F-FDG injection, static 18F-FDG-PET scans of the whole lung were obtained. Mean SUR values (SUR15cm) were calculated for the same ROIs as used for kiP analysis, thus covering only a 15cm cranio-caudal lung field, using plasma activity measurements at the timepoint of static PET scanning. In addition, mean SUR values (SURwholeLung) were calculated for 5 ROIs using the ventro-dorsal expansions of ROIs15cm but the whole cranio-caudal lung dimensions. Correlation of kiP and SUR15cm and of SURwholeLung and SUR15cm were investigated by means of linear regression of all ROI on day1 and day2, respectively, and coefficients of determination (r2) were compared. RESULTS: SUR15cm linearly correlated with kiP within all ROIs, both on day1 and day2 (r2=0.8581 and 0.9643, respectively). SUR15cm highly correlated with SURwholeLung, both on day1 and day2 (r2=0.9069 and 0.9909, respectively). CONCLUSION: Compared to dynamic PET and Patlak analysis, SUR determined with static PET is a valuable alternative for determination of pulmonary inflammation. It allows assessment of inflammation of the whole lung within a much shorter time range. In this ARDS study the inflammation within a 15cm cranio-caudal lung field was representative for inflammation of the whole lung.

OP695

The diagnostic value of F-18-FDG PET/CT in patients suspected for LVAD infection

N. Avramovic[1], A. Dell'Aquila[2], J. Sindermann[2], M. Schäfers[1], C. Wenning[1]; [1]Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY, [2]Department of Cardiac Surgery, University Hospital Münster, Münster, GERMANY.

Continuous-flow left ventricular assist device (CF-LVAD) is a new gold standard in supporting end-stage heart failure patients, bridging them to heart transplantation. Infection is one of the major complications associated with LVAD implants. The goal of this study is to evaluate the potential impact of F-18-FDG PET/CT in the diagnosis of infection in patients with implanted CF-LVAD. We examined 57 patients with an implanted LVAD who underwent an F-18-FDG PET/CT, who were either suspected to have a driveline infection or the infection of the LVAD itself or who received PET/CT for other reasons. Three groups were compared: Group A (n=21) consisted of patients suspected of LVAD/driveline infection due to positive blood cultures and/or leukocytosis or elevated CRP but without wound healing disorder; Group B (n=30) included patients with clinically apparent wound healing disorder; a control group (n=6) consisted of patients without signs of infection who received PET/CT for other reasons. First, PET/CT was graded visually as positive or negative in order of pathological uptake along the driveline and/or the device. Second, uptake was measured quantitatively (SUVmax) in the attenuation corrected images at the driveline skin penetration point and at the subcutaneous portion of the driveline. A semi-quantitative target-to-background ratio (TBR) using the uncorrected PET images was calculated in order to measure the activity around the LVAD aggregate. Out of 21 patients in Group A 13 (62%) had a positive finding in PET/CT. 27 of 30 patients (90%) in Group B were graded positive in PET/CT. In the Control group, 1 of 6 patients was falsely positive. At the driveline skin penetration point we observed significantly higher SUVmax in Group A (4,23±0,67 vs. 2,02±0,84, p=0,02) and Group B (6,57±0,78 vs. 2,02±0,84, p<0,001) compared to controls. At the subcutaneous portion of the driveline only Group B showed significantly higher SUVmax (8,66±0,89 vs. 3,09±0,19, p<0,001). The TBR of the aggregate did not differ significantly. The area under the ROC curve was 0,744 at the driveline skin penetration point and 0,768 at the subcutaneous portion of the driveline. Sensitivity/specificity (Group B as reference) was 90%/83%. F-18-FDG PET/CT is a valuable tool in the diagnosis of infection in the patients with CF-LVAD at the driveline skin penetration point and at the subcutaneous portion of the driveline. However, the identification of the infection around the LVAD aggregate may be challenging. Finally, F-18-FDG PET/CT might be useful in guiding therapeutic decisions.

OP696

Respective role of ^{18}F-FDG PET/CT and WBC SPECT/CT in the diagnosis of cardiac implantable electronic devices infection.

J. CALAIS, A. TOUATI, N. GRALL, K. BENALI, B. MAHIDA, F. HYAFIL, B. IUNG, X. DUVAL, D. LE GULUDEC, F. ROUZET; Hopital Bichat, Paris, FRANCE.

Rationale: Although the role of nuclear imaging in the management of cardiovascular infections is acknowledged, its diagnostic value in CIEDs infection remains debated and nuclear techniques have not been included in the recently issued ESC/EANM joint guidelines. Some studies showed good diagnostic values of both FDG PET/CT and radiolabelled WBC scan in patients with high prevalence of the disease. The aim of the study was to evaluate the respective role of both techniques in a population with intermediate prevalence of CIEDs infection. Methods: Our institution's database has been reviewed for a 3-year period to identify patients with a suspicion of CIEDs infection who underwent both FDG PET/CT and radiolabelled WBC scan in a time span of <1 month. Whole-body PET/CT was acquired 1 h after injection of FDG. SPECT/CT acquisitions were performed 4 and 24 hours after reinjection of 99mTc-HMPAO labelled WBC, included planar and SPECT/CT. The final diagnosis of CIEDs infection was based on the modified Duke classification after 3-month follow-up (rated as: definite, possible or rejected) with the addition of positive culture of the extracted material and clinically patent pocket infection as major criteria for infection. The readers of FDG PET and WBC SPECT were blinded to the results of the other technique and to the patients' clinical record. Each scan was rated for diagnosis of infection as positive

or negative. Results: 48 consecutive patients were included (age 70±11 years; female: 50%; prosthetic heart valve: 60%; Staphylococcus species: 38%). Thirty-two (67%) patients were receiving antibiotic therapy at the time of imaging (mean duration >1 month). The final diagnosis of CIED infection was: definite in 29%, possible in 23% and rejected in 48%. The diagnostic sensitivity, specificity, PPV, NPV and accuracy of FDG PET were respectively: 71%, 82%, 71%, 82%, 78% and of WBC SPECT: 50%, 100%, 100%, 76%, 77%. WBC SPECT was always negative when FDG PET was negative. By combining FDG PET as a first line modality with WBC SPECT only when PET was positive, the diagnostic sensitivity, specificity, PPV, NPV and accuracy were respectively: 70%, 100%, 100%, 57%, 79%. Conclusion: In a study population with intermediate prevalence of CIEDs infection, FDG PET has a good overall diagnostic value although the sensitivity may have been decreased by prior antibiotherapy. WBC SPECT is highly specific of infection and thus strongly supports CIED extraction when positive.

OP697

Does antibiotic treatment effect the diagnostic accuracy of F18-FDG PET/CT studies?

O. Kagna, M. Kurash, Z. Keidar, O. Israel; Rambam Health Care Campus, Haifa, ISRAEL.

Introduction: F18-FDG PET/CT plays a significant role in the assessment of various infectious processes. Patients with suspected or known sites of infection are often referred for FDG imaging while already receiving antibiotic treatment. To the best of our knowledge the effect of antibiotic treatment on the uptake of FDG is not yet well established. Current study aims at assessing the impact of antibiotic therapy on the detectability rate of infectious processes by FDG PET/CT. Methods: FDG PET/CT studies of 105 consecutive hospitalized patients (71M, age 18-88 years) evaluated for fever of unknown origin (n=64) and suspected vascular graft infection (n=41) were analyzed. The presence and duration of antibiotic treatment prior to performing the FDG-PET/CT study was recorded. The final diagnosis of an infectious process was based on microbiological and pathological as well as on clinical and radiological data available at follow-up. Results: Ten of the 64 patients who presented with FUO were diagnosed as having a non-infectious process and were excluded from further analysis. Thus the final study population included 95 patients. FDG-PET/CT was true positive and diagnosed an infectious process in 49 of the 95 patients (51%). Furthermore there were 31 (33%) true negative and 15 (16%) false positive FDG-PET/CT studies. Sixty-nine of the 95 patients (73%) received antibiotic treatment prior to the PET/CT study for a period ranging from 1 to 73 days (mean 9.57± 13.23 days). Forty patients with true positive studies (82%) were under antibiotic therapy. No false negative results were found among the whole population of 95 patients included in this study group. Conclusion: PET/CT correctly identified increased FDG uptake compatible with infection in more than half of the study population including 82% of the patients who were on antimicrobial therapy prior to the study. No false negative results were found in this study group including 73% of patients receiving antibiotic treatment over a wide range of duration. Current results in a group of 95 patients suggest that antimicrobial therapy appears to have no clinically significant impact on the diagnostic accuracy of FDG PET/CT performed for evaluation of known or suspected infectious processes.

OP698

^{18}F-FDG PET/CT For Prosthetic Valve Endocarditis And Cardiac Device Infection Diagnosis: An Additional Tool

A. Jiménez-Ballvé, C. Sánchez-Enrique, M. J. Pérez-Castejón, M. Martínez de Bourio, A. Ortega-Candil, I. Vilacosta, D. Vivas, M. E. Fuentes-Ferrer, J. L. Carreras-Delgado; Hospital Clinico San Carlos, Madrid, SPAIN.

Aim: The aim of this study was to assess the usefulness of FDG PET/CT in the diagnosis of prosthetic valve endocarditis (PVE) and cardiac device infection (CDI) as an additional tool to the modified Duke criteria and echocardiography, as both seems to have limitations for these challenging diagnosis. Materials and methods: We performed a prospective study including 41 patients with infection suspiction (PVE/CDI) from November-2012 to January-2015. PET/CT was considered positive when FDG uptake was present in the region of interest in both PET images (corrected and non-corrected); and negative if there was no uptake or did not persist in the non-corrected images. Histopathologic result was considered the gold standard in patients who underwent cardiac surgery. Those without surgery, final diagnosis was established according to clinical consensus of the endocarditis team. Results: In the 41 PET/CT studies, we analyzed 62 foci with infection suspicious, 42 PVE (27 mechanical and 15 biological) and 20 CDI. Duke criteria classified 28 (45%) foci as definitive endocarditis and 34 (55%) as possible endocarditis. Echocardiography was positive in 30 (48%) foci; PET/CT was positive in 40 (65%); we obtained a final diagnosis of infection in 32 (52%) foci. PET/CT had a sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) and area under de curve (AUC) of 100%, 73%, 80%, 100%, 0,86, respectively; and Duke criteria had 84% Se, 96% Sp, 96% VPP, 85% VPN and 0,90 AUC. Both tools presented statiscally significant differences of Se (p<0,020) and Sp (p<0,011), with a similar AUC (p=0,49) and a moderate Kappa Index (0,56). Echocardiography had 75% Se, 80% Sp, 80% VPP, 75% VPN and AUC of 0,78. Kappa Index between PET/CT and echocardiography was moderate (0,43). When only using transesophageal echocardiography data just before PET/CT, Se, Sp, VPP, VPN and AUC were 55%, 96%, 94%, 67% and 0,76, respectively; with a low Kappa Index (0,38) with PET/CT. Additionally, PET/CT detected systemic septic emboli in 12 patients (29%) (8 spleen, 3 lung parenchyma, 3 spondylodiscitis, 1 liver and 1 kidney) and in 6 patients (15%) we detected incidental malignancies leading to changes in therapeutic management. Conclusion: ^{18}F-FDG PET/CT seems to be a promising diagnostic tool for prosthetic valve endocarditis and cardiac device infection with high sensitivity in infection diagnosis as well as detecting systemic septic emboli. It has become an imaging technique complementary to echocardiography in the new modified criteria for the diagnosis of endocarditis.

OP699

Potential role of WBC-SPECT/CT to assess antibiotic treatment

J. Dubreuil[1], I. Morelec[2], A. Skanjeti[2], M. Moret[3], P. Michon[3], D. Matanza[4], M. Fraysse[4], C. Thivolet[3], J. Vouillarmet[3]; [1]CHU Lyon Sud, Pierrre-Bénite, FRANCE, [2]Nuclear Medicine - Hospices Civils de Lyon, Lyon, FRANCE, [3]Endocrinology - Hospices Civils de Lyon, Lyon, FRANCE, [4]Radiopharmacy - Hospices Civils de Lyon, Lyon, FRANCE.

Background : Diabetic foot osteomyelitis (DFO) is a frequent complication of diabetes, and an important risk factor of amputation. However, the duration of antibiotic therapy is difficult to define in the absence of a marker to diagnose osteomyelitis remission at the end of the treatment. The aim of this study is to evaluate the performance of Tc99m-White Blood Cell (WBC)-SPECT/CT to diagnose DFO remission. **Material and methods:** Patients with DFO proved were included and scheduled to perform a WBC-SPECT/CT at the end of antibiotic treatment. WBC-SPECT-Ct included planar acquisitions at 2h and 20h post-injection and a SPECT-CT at 20h.All exams were retrospectively read by 2 nuclear physicians, blind to clinical results, with consensus (IM and JD). Successful treatment of DFO was defined by absence of DFO relapse in the same site within 1 year. **Results:** Sixty patients were included in this study between March 2010 and April 2015. Nine were excluded of analysis due to absence of follow-up or absence of SPECT-CT. Median activity injected was 437 MBq, and median labelling yield was 82%. Of the 51 patients included in the analysis, 9 (17.6%) showed DFO relapse during follow-up. Sensitivity, specificity, negative predictive value, positive predictive value and accuracy of WBC-SPECT/CT to predict relapse of DFO in the same area were 77.8%, 83.7%, 94.7%, 50% and 82.6% respectively.

Conclusion: These preliminary results confirm the potential role to assess treatment of DFO especially due to his high negative predictive value. This exam could be used in the future to decrease the duration of DFO treatment.

OP700

SPECT-based semi-quantitative assessment of ^{123}I-SAP scintigraphy in patients with amyloidosis

R. W. J. van Rheenen, B. P. C. Hazenberg, W. Noordzij, R. A. J. O. Dierckx, R. H. J. A. Slart, A. W. J. M. Glaudemans; UMCG, Groningen, NETHERLANDS.

INTRODUCTION: ^{123}I-Serum Amyloid P (SAP)-scintigraphy is used to image the extent and distribution of amyloid deposition in patients with systemic AA, AL and ATTR amyloidosis in a non-invasive manner. In the context of follow-up and inter-observer agreement, the standard visual assessment method has proven to be suboptimal. The aim of this study was to develop a SPECT(-CT) organ/blood pool ratio-based quantitative assessment system with clear cut-off values to define organ involvement with a high specificity. **MATERIAL & METHODS:** Between January 2009 and January 2016 in 145 patients with amyloidosis a ^{123}I-SAP with SPECT(-CT) was performed to evaluate the extent and distribution of the amyloidosis. In all patient's amyloidosis had been proven by means of a fat biopsy. The patients were divided in four groups: AL type (n=86), AA type (n=20), ATTR type (n=18), AL localized type (n=21). A fived disease-control group without amyloidosis (n=24) was used to calculate the reference cut-off values for each organ ratio. The validity of these new values was tested by comparing ratio-based results to visual grading as well as to clinical parameters. **RESULTS:** Based on data of the control group the following cut-off ratios were calculated: liver 1.0, spleen 1.5, and kidney 1.1. When comparing ratio-based organ results to visual grading of the organs, normal values within the reference range were present in all amyloidosis patients visually graded 0. Values above the reference range were present in patients visually graded 2 or higher. Normal values, however, were often found in spleens and kidneys visually graded 1. When comparing organ values to the respective clinical parameters, modest correlations were found for liver values and Alkaline Phosphatase ($r = 0.33$; $p=0.028$), kidney values and eGFR ($r = -0.21$; $p=0.032$), and kidney values and proteinuria ($r = 0.45$; $p=0.04$). This correlation was not present using the standard visual grading. **DISCUSSION & CONCLUSIONS:** The ratio-based assessment of SAP-scintigraphy enables us to obtain a very specific, although less sensitive organ evaluation of liver, spleen and kidney compared with our current visual assessment of these organs. Besides, the ratio-based method hints at a physiologically increased SAP binding within the spleen of controls. The amount of SAP binding in kidney and liver somewhat reflects clinical disease and probably the amyloid load of these organs. The latter may indicate utility of this quantitative method for monitoring patients with amyloidosis during the course of their disease and especially for assessing the effect of treatment.

Distinguishing breast tumor from normal breast using textural indices in FDG-PET

S. Boughdad[1], C. Nioche[2], F. Orlhac[3], L. Champion[1], J. Alberini[1], I. Buvat[2]; [1]Institut Curie-Hôpital René Huguenin, Saint-Cloud, FRANCE, [2]IMIV CEA, Inserm, CNRS, UnNiv Paris Sud, CEA-SHFJ, Orsay, FRANCE, [3]IMIV CEA, Inserm, CNRS, UnNiv Paris Sud, CEA-SHFJ, IGR, Orsay, FRANCE.

Introduction: Breast cancer (BC) is the most common cancer in women in western countries. Previous studies have shown a significant correlation between histological data and SUV or textural indices (TI) measured from PET images. However, little is known about textural characteristics of normal breast tissue. We assessed TI in normal breast tissue in comparison to BC to define "normal" values for those index. Method: Normal breast tissue group (NBT group) was defined from a population of 112 women who underwent a F18-FDG-PET/CT in our institution for initial staging of various cancers (discarding BC, endometrial, or ovarian cancers) for comparison to our BC sample population consisting of 58 patients. SUV (max, mean and peak), TLG (total lesion glycolysis, mL) and TI (homogeneity, entropy, LRE, SRE, LGZE and HGZE) were measured in a tumor volume of interest (T-VOI) in the BC group obtained using a threshold method (40% of SUVmax). The same VOI was mirrored in the contralateral breast (CL-VOI). A VOI with a volume identical to the average volume of T-VOI in our BC group was then drawn on both breasts of the NBT group (B-VOI) to derive "normal" SUV and TI. A ROC analysis was performed to assess SUV and TI performances for distinguishing normal breast tissue and BC. Results: Fifty-four T-VOI were drawn in the BC group and 54 VOI were drawn in the contralateral breast of this group. Patients with bilateral breast cancer were excluded. A total of 224 VOI were drawn in the NBT group. The SUV and TI measured in the T-VOI significantly differ from those measured in the CL-VOI in the BC group and from those measured in the B-VOI from the NBT group (table 1). There was no significant difference between SUV and TI in the CL-VOI of the BC group and in the B-VOI of the NBT group using a Mann-Withney test ($p>0.05$ for SUV and TI except for SRE and LRE). Conclusion: Our study showed significant differences in SUV and textural indices between BC and NBT. For the first time, "normal" TI values in non-pathological breast tissues are reported and might be useful for early detection of BC in seemingly normal breast tissues, especially in contralateral breast of patients with unilateral BC at initial staging.

EPW02

Preoperative prediction for invasive components in breast ductal carcinoma in situ with FDG PET/CT

H. Hwang, L. Kim; Hallym Sacred Heart Hospital, Anyang-si, KOREA, REPUBLIC OF.

Objectives: Preoperative diagnosis of ductal carcinoma in situ (DCIS) on needle biopsy specimen is limited role in treatment decision because it can provide only partial information for the entire tumor tissue. The limited specimens obtained from biopsy frequently resulted in underestimation of invasive components. This study investigated the role of FDG PET/CT to predict invasive cancer components in ductal carcinoma in situ at core needle biopsy. Methods: This retrospective analysis focused on 85 biopsy confirmed DCIS patients (age: mean 50.3±10.2) who performed F-18 FDG PET/CT preoperatively, and underwent curative surgery, between 2009 July to 2015 December. We analyzed FDG PET/CT, visually and semiquantitatively, and assessed histopathologic characteristics. We evaluated the areas under the receiver operating characteristic curve (AUC) for SUVmax. After surgery, final pathology was categorized as pure DCIS (DCIS-P), DCIS with microinvasion (DCIS-MC), DCSI and invasive ductal carcinoma (IDC) (DCIS-MX), or IDC. DCIS-MX and IDC were classified as invasive components. Results: Final pathology confirmed 48 DCIS-P, 13 DCIS-MC, 12 DCIS-MX, and 12 IDC. AUC of SUVmax for invasive components was 0.758 (CI: 0.652-0.844) at the cutoff value of SUVmax to predict underestimation of invasive component was 2.1 (sensitivity: 83.33%, specificity: 62.30, $p<0.0001$). SUVmax was significantly correlated with pathologic IDC size ($p=0.0001$), PET axillary LN uptake ($p=0.0004$), and pathologic LN metastasis ($p=0.001$). The pathologic invasive components was significantly correlated with SUVmax ($p<0.0001$), and mildly correlated with PET axillary LN uptake ($p=0.031$), but not correlated with PET tumor size ($p=0.22$) and nuclear grade at preoperative needle biopsy ($p=0.63$). Conclusions: The SUVmax of primary tumor on preoperative FDG PET/CT was most important to predict the invasive components in casesof DCIS at core needle biopsy.

Performance of a newly developed parallel detector PEM in detection of small breast cancer less than 2 cm

M. Itoh[1], S. Itoh[2], H. Hirakawa[3], F. Yano[1], M. Soma[1], R. Sugai[1], I. Odano[1], M. Tashiro[4], H. Sato[2], A. Yoshikawa[5], S. Yamamoto[6], A. Yanai[7]; [1]Sendai Medical Imaging Center, Sendai, JAPAN, [2]Furukawa Scintitec Corporation, Iwaki, Fukushima, JAPAN, [3]Tohoku Kosai Hospital, Sendai, JAPAN, [4]Cyclotron RI Center, Tohoku University, Sendai, JAPAN, [5]Institute for Material Science, Tohoku Univ., Sendai, JAPAN, [6]Graduate School of Medicine, Nagoya Univ., Nagoya, JAPAN, [7]Graduate School of Medicine, Tohoku Univ, Sendai, JAPAN.

Aim of the Study A high resolution wide field of view positron mammograph (PEMGRAPH) comprised of novel scintillation crystals, praseodymium-doped lutetium aluminium garnet,Pr;LuAG, was developed under collaboration of Tohoku University and Furukawa Ltd,Japan. Its clinical utilities were evaluated in detection of small breast cancers less than 2 cm as compared with whole-body PET/CT, Siemens Biograph. **Subjects and Methods** The PEMGRAPH is comprised of two 140×200 mm^2 (field of view) opposing detectors made of Pr:LuAG scintilation blocks coupled with position-sensitive PMTs (Hamamatsu H8500). The Spatial resolution was 2.1 mm FWHM in the directions parallel to the detector faces. The time resolution and energy resolution were 3.1 ns FWHM and 11.6 % FWHM (at 511 keV), respectively at the center of the detector block. The peak count rate was 51.4 kCPS using a flood phantom having 35.7 kBq/ml ^{18}F-solution. Eighty-one subjects having biopsy or cytology proven breast cancer before operation participated the study. The inclusion criteria was as follows; subjects who has breast cancer less than 2 cm in size and agreed to participate with a written informed consent. The tumor volume and its position relative to the nipple were measured by ultrasound in the same day prior the injection of FDG. ^{18}F-FDG was injected via cubital vein at the amount of 3.7 MBq/kg. After 75 minutes of uptake time whole body isotope distribution was measured using a PET/CT, Siemens Biograph 16 for two minutes at each couch position. Then PEM images were obtained in the mediolateral direction with subjects sitting on an electric driven up-down chair. Breast images tangential to the chest wall was also obtained with 15 cm detector separation in case of the tumor was close to the pectoral muscles. Scan time was between 3 to 5 minutes at each position. **Results** Twenty-eight breast tumors were not detected by PET/CT in which 15 tumors were detected by PEM The detection sensitivity was

66.3%, 75.9% and 84.3% for PET/CT, PEM and the both combined respectively. PEM missed 7 cases which were detected by PET/CT. In cases of breast tumors less than 1.0 cm the sensitivity were 36.8%, 57.9%, and 68.4% for PET/CT, PEM and the both combined respectively. **Conclusion** The detection sensitivity by FDG molecular imaging for UICC T_1 breast cancer was 84% if PET/CT and PEM were combined in this study. The chest wall scanning with PEM was useful for tumors close to the pectoral muscles.

5 Year-Follow-up: Value and Efficacy of Sentinel Lymph Node Diagnostics in Patients with Penile Carcinoma with Non-Palpable Inguinal Lymph Nodes

U. Lützen, M. Marx, M. Zuhayra, Y. Zhao, M. Jüptner, K. Jünemann, M. Naumann; Universitätsklinikum Schleswig-Holstein, KIEL, GERMANY.

Introduction and Aim For some years, sentinel lymph node excision (SLNE) has been described as a minimally invasive method for lymph node staging in patients with a penile carcinoma and non-palpable inguinal nodes in the guidelines of the German Society of Nuclear Medicine (DGN), the European Association of Urologists (EAU) and the European Society for Medical Oncology (ESMO). However, this method is rarely used in Germany due to the initial unreliable results and the methodical demands associated with the application of radioactive tracers as well as the radiation burden. The aim of this study was to validate the reliability and morbidity of this method. **Material and Methods** We recorded all cases of lymph node recurrence and complications in patients with initially non-palpable inguinal lymph nodes and histologically negative sentinel lymph nodes in a prospective approach. We calculated the rates of false negative findings and morbidity as qualitative criteria. Inguinal regions with palpable lymph nodes and/or evidence of metastases were not considered here in accordance with the expert society guidelines. **Results** 28 patients with histologically negative sentinel lymph nodes in 47 groins with non-palpable inguinal lymph nodes were included in this study. There were 17 T1(a/b) stages, 8 T2 and 3 T3-stages. Tumor differentiation was good in 4, moderate in 22 and poor in 2 patients. During a median follow-up of 68 (4-131) months, we observed one case of bilateral lymph node recurrence as well as one case of prolonged inguinal lymphorrhea, which could be managed conservatively. Per inguinal region, the false negative rate was 4.25% and the morbidity rate was 2.12%; seen per patient the rates were both 3.57%. **Conclusions** SLNE under use of radioactive tracers is a reliable method of lymph node staging in patients with penile carcinoma and non-palpable inguinal lymph nodes. Its higher methodical complexity is justified by high reliability and low radiation exposure for both patient and medical staff as well as low morbidity rates.

EPW05

Development and evaluation of a high sensitivity gamma imaging probe for axillary sentinel lymph node mapping

M. Georgiou[1], G. Loudos[2], E. Fysikopoulos[3], E. Lamprou[4], K. Mikropoulos[3], A. Shegani[5], P. Georgoulias[1]; [1]Department of Nuclear Medicine, Medical School, University of Thessaly, Larissa, GREECE, [2]Technological Educational Institute of Athens, Athens, GREECE, [3]BioEmission Technology Solutions, R&D, Athens, Greece, Athens, GREECE, [4]Department of Medical Physics, Medical School, University of Patras, Patra, GREECE, [5]Institute of Radioisotopes and Radiodiagnostic Products, NCSR "Demokritos", Athens, GREECE.

***Aim*:** Sentinel lymph node (SLN) mapping is very important for the recognition and the dissection of the first lymph nodes (LN) that drain the breast tumor. The detection of the lymph nodes using blue-dyes and acoustical gamma probes can be improved with a gamma imaging probe acquiring real-time images. The aim of this work is the construction and performance evaluation of "λ-eye", a gamma imaging probe, optimized in terms of sensitivity for Sentinel Lymph Node (SLN) mapping. ***Methods*:** The optimization of "λ-eye" was based on theoretical calculations, presented in a previous published work of our group. The system was constructed based on these results and was evaluated using phantoms and performing animal studies. All critical parameters for the evaluation of gamma imaging probes were measured according to similar studies for the characterization of small gamma imaging devices. The systems' spatial and energy resolution, sensitivity, count rate performance Integral (IU) and Differential Uniformity (DU) in the Useful-Field-of-View (UFOV) and in the Central-Field-of-View (CFOV) were measured using phantoms. Finally, a proof-of-concept animal experiment was carried out for the imaging of the lymph nodes of normal mice using a clinical and a novel radiotracer. ***Results*:** The energy resolution of individual scintillator pixels was found equal to 22%±1.6%, while the system's total energy resolution was measured 36%±2%. The spatial resolution was 2.2mm at 2mm source-collimator distance and ~10mm at 50mm respectively. The sensitivity of the system was measured to be ~1.5cps/kBq. The values of the IU in the UFOV and in the CFOV were found to be 5.2% and 1.7%, while the DU was measured equal to 2.1% and 0.75% respectively. Finally, clear visualization of the lymph nodes of the mice was obtained using both radiotracers. ***Conclusion*:** The "λ-eye", dedicated for SLN mapping, provides a combination of high sensitivity (~1.5cps/kBq) and good spatial resolution (~6mm FWHM @ 20mm and ~10mm FWHM @ 50mm distance), which makes it an appropriate tool for fast and accurate real-time intraoperative imaging of the lymph nodes.

EPW06

Lymphoscintigraphy for sentinel node identification after neo-adjuvant therapies in breast cancer: feasibility

S. M. Baio, L. Gilardi, S. L. Fracassi, M. Colandrea, L. Travaini, P. Rocca, G. Corso, B. Ballardini, P. Veronesi, V. Galimberti, C. M. Grana, F. Bassi, P. Maisonneuve, N. Rotmensz; European Institute of Oncology Milan, Milano, ITALY.

Introduction Neo-Adjuvant Treatment (NAT) is a consolidated approach for the care of locally advanced Breast Cancer (BC). The main objective of NAT is to obtain a tumour down-staging with a cytoreductive surgery that may comprise the sentinel lymph-node biopsy (SNB). To date, the role of SNB in patients receiving NAT still remains controversial, as it has been theorized that systemic chemotherapy as local radiotherapy are responsible to alter lymphatic drainage causing a false negative rate in the SN detection during lymphoscintigraphy. In fact, some institutes discourage the SNB after NAT, due to the high failure of SN identification rate. **Aim** The aim of this study was to assess the SN identification rate at lymphoscintigraphy and its technical feasibility after NAT. **Materials and Methods** Between 2000 and 2013, 444 consecutive patients (median age 44 years) affected by primary locally advanced BC were enrolled in this study. All individuals were eligible for NAT, including hormone therapy alone, chemotherapy alone, or chemotherapy plus hormone therapy. All patients gave informed consent and use of anonymized data was approved by the Institute's Review Board. Lymphoscintigraphy was performed as already described: a subdermal injection of the radiotracer, 99mTc-labeled human albumin colloid particles was performed 2-20 hours before surgery in correspondence of the skin projection of the tumour. Planar images of involved breast and axillary regions were acquired 15-30 min post-injection. The images showed a single area or, less frequently, two or multiple hot spots, corresponding to the SNs. After the acquisition of the last scan, the skin projection of these hot spots were marked with a suitable pen. During surgery the SN was identified by a gamma ray detection probe. This method allows the surgeon to remove the sentinel node and to send it for histopathological examination. **Results** Almost one sentinel node was identified during lymphoscintigraphy in

430 cases. The detection rate at lymphoscintigraphy was 96.9% (95% CI, 94.8-98.1%). Considering the correlation between specific treatments and sentinel node identification rate, we verified that the detection rate did not vary significantly (p=0.53) according to the type of neo-adjuvant therapies administered to the patients. **Conclusion** Our results demonstrated that lymphoscintigraphy for sentinel node identification is a safe and feasible procedure after neo-adjuvant therapies, independently of treatment types.

EPW07

Radioguided surgery in non palpable lung lesions. Our preliminary experience

M. Salcedo-Pujantell[1], I. Navales[2], I. Bello[3], E. Pallissa[4], J. Blanco-Cano[1], D. Varona[4], M. Deu[3], M. Simó-Perdigó[1], J. Castell-Conesa[1]; [1]Hospital Universitari Vall d´Hebron. Nuclear Medicine, Barcelona, SPAIN, [2]Hospital Universitari Vall d´Hebron. Nuclear Medicine. Institut de Diagnòstic per la Imatge, Barcelona, SPAIN, [3]Hospital Universitari Vall d´Hebron. Thoracic Surgery, Barcelona, SPAIN, [4]Hospital Universitari Vall d´Hebron. Radiology, Barcelona, SPAIN.

AIM: Radioguided resection of ground glass opacities and deep small solid lung nodules by video-assisted thoratic surgery (VATS) is a demanding scenario. Even though this procedure is well documented and there´s enough clinic evidence about its utility, it has not become widespread yet. We report our initial experience implementing this technique in our center. **MATERIAL AND METHODS:** We prospectively added our first 14 patients (60,54± 18,79 years, 4W): 9pts were referred for suspected malignancy of a solitary lung lesion based on a radiological follow-up (7 pure ground-glass opacity, 1 subsolid and 1 solid nodule) whereas the others 5pts had solid nodule that were suspected to be pulmonary metastases of known previous extrathoracic malignancies. The mean size of the solid nodules was 6mm, and for the ground glass opacities/subsolid pulmonary lesions were 14mm. Intralesional percutaneus 99mTc-MAA CT-guided injection was performed in all patients. Subsequent gamma probe localization of the lesion was performed during VATS (Dylon Navigator GPS). **RESULTS:** Regarding the injection procedure, there were no significant complications. Only minor asymptomatic hemorrages in the needle path and small pneumothorax were seen in some patients. There were no cases of pleural diffusion. The whole procedure, including the scintigraphy (planar and/or SPECT images), was completed in an average time of 74m, this allowed for the surgery to be performed on the same day. The detection rate at surgery was 100%. Only in the first patient an intentional thoracotomy was chosen by the thoracic comitee in order to test the gamma probe localization technique. In the other 13pts a two incisions VATS was performed, and just one case required conversion to a thoracotomy because the nodule was too deep to securely resect it. After wedge resection, histological examination showed malignancy and margins free of tumour in all lesions (5 metastases and 9 lung primary adenocarcinomas). In 7pts with lung primary adenocarcinomas a completion lobectomy was performed, (the remaining 2 pts had not enough cardiopulmonary reserve to stand a lobectomy). **CONCLUSIONS:** Radioguided surgery is a reliable procedure that allows the identification and resection of nonpalpable lung lesion, such as ground glass opacities, subsolids and small deep nodules by VATS. While it requires a good interdisciplinary communication, this technique can be done in one day step. Even though we have only performed it on 14 patients, we found it easy to learn. Excellent detection rate and the lack of surgical complications, encourages us to recommend this technique.

EPW08

Phase II study of prophylactic radiotherapy in cN0 HNSCC patients based on sentinel node(s) SPECT/CT

E. Longton[1], G. Lawson[2], B. Bihin[3], S. Deheneffe[1], I. Mathieu[4], J. Installé[4], T. Vander Borght[5], M. Laloux[6], J. Daisne[1]; [1]Clinique et Maternité Sainte-Elisabeth, Radiation Oncology, Namur, BELGIUM, [2]CHU Dinant-Godinne, Head and Neck Surgery, Yvoir, BELGIUM, [3]Namur Research Institute for Life Sciences Narilis, Unit of Biostatistics, Namur, BELGIUM, [4]Clinique et Maternité Sainte-Elisabeth, Nuclear Medicine, Namur, BELGIUM, [5]CHU Dinant-Godinne, Nuclear Medicine, Yvoir, BELGIUM, [6]Clinique et Maternité Sainte-Elisabeth, Head and Neck Surgery, Namur, BELGIUM.

Purpose/Objectives: Due to a risk of 18 to 45% of occult nodal metastases in cN0 HNSCC patients, prophylactic neck irradiation is often mandatory. Anyway, it leads to a large irradiation of normal tissues because bilateral drainage is the rule in only 30 to 50 % of individuals. Moreover, 15 to 30 % of the tumors drain in unpredicted nodal basins (risk of geographical miss). SPECT/CT lymphoscintigraphy of sentinel lymph nodes (SLN) could help individualizing prophylactic irradiation levels in cN0 patients and, hence, reduce irradiated volume and improve quality of life (QoL). This ongoing prospective phase II study investigates its oncological safety. Materials and Methods: Twenty-seven patients with newly diagnosed cN0 SCC of the oral cavity, oropharynx, larynx or hypopharynx were included. All patients were imaged with SPECT/CT after 99mTc nanocolloid injection around the tumor. The neck levels containing up to four hottest SLN were identified and selected for prophylactic irradiation (CTVn-LS) by volumetric modulated arc therapy. A comparative virtual planning was performed with volumes selected according to international guidelines (CTVn-IG). QoL was assessed using EORTC C30 and HN25 scales. Results: Migration was observed in all of the 27 patients (one with gamma probe only) with an average of 3.1 sentinel nodes detected per patient. CTVn-LS was totally encompassed by CTVn-IG in all patients but two with an unpredicted drainage in homolateral retropharyngeal levels. More than half of the patients has only a unilateral drainage. CTVn-LS and related PTV were systematically smaller than IG ones, by a factor of two on average. This led to significant dose decrease in identified OAR as well as remaining volume at risk. With a median follow-up of 30 months, no regional relapse was observed while 3 patients had a local one (11%). Crude overall survival rate is 89%. Conclusions: SPECT/CT lymphoscintigraphy of SLN allows individualizing prophylactic node CTV in cN0 HNSCC patients eligible for definitive radiotherapy. Both CTV and PTV are significantly reduced, which results in a significant dose decrease in OAR. At a median follow-up of 30 months, no regional relapse was observed but further follow-up and recruitment are necessary to ensure the oncological safety.

EPW09

18F-FDG PET-CT and DWI-MRI in staging cervical cancer patients: role of metabolic and volumetric parameters

C. Crivellaro[1,2], P. A. Bonaffini[3], M. Cuzzocrea[1], L. Baratto[1], E. De Ponti[4], F. Elisei[2], A. Buda[5], L. Guerra[2], P. Guglielmo[1], S. Sironi[3], C. Landoni[1]; [1]University Milan-Bicocca, Milan, ITALY, [2]Nuclear Medicine, ASST-San Gerardo, Monza, ITALY, [3]Radiology, University Milan-Bicocca, Milan, ITALY, [4]Medical-Physics, ASST-San Gerardo, Monza, ITALY, [5]Gynaecology-Oncology, ASST-San Gerardo, Monza, ITALY.

Aim. To evaluate the role of metabolic and volumetric parameters obtained in pre-operative PET and MRI studies of patients with cervical cancer. **Materials and Methods.** 29 females (range 28-76 years) with histologically proven cervical cancer were enrolled. Before surgery (hysterectomy, bilateral salpingo-oophorectomy and lymphadenectomy), all patient underwent to both a ^{18}F-FDG PET-CT and pelvic 1.5T MRI scan,including DWI (*b*: 0-1000 mm^2/sec). On PET images, SUVmax and SUVmean, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of cervical lesions were calculated, using an iterative threshold segmentation. On MRI scan, ADC values and DWI tumor volume were considered. All parameters were statistically analysed and correlated to

histological analysis (parametrial and lymphovascular invasion, tumor grade, nodes metastases) and relapse (by using Kruskal-Wallis test). **Results.** In G3 lesions, SUVmax (mean 13.5 g/ml), MTV (mean 21.6 ml), TLG (mean 164 g), DWI-V (mean 34.6 ml) were significantly higher than SUVmax (9.2 g/ml; p=0.02), MTV (6.5 ml; p=0.001), TLG (50.5 g; p=0.005) DWI-V (11.1ml; p=0.04) of G2 lesions, respectively. A significant association was found between the presence of LN metastases (7/29 pts, incidence 24%) and SUVmax (p=0.09), MTV (p=0.02) and DWI-V (p=0.002), respectively. Mean ADC value of cervical cancer was significantly lower ($0.85\pm0.12x10^{-3}mm^2/sec$) than normal myometrium ($1.15\pm0.20x10^{-3}mm^2/sec$). No other statistically significant differences were obtained, in particular no correlations were found between PET and MRI parameters and relapse (median follow-up 48 months). **Conclusion.** At metabolic and DWI-MRI parameters analysis, SUVmax, MTV, TLG and DWI-V were significantly higher in G3 lesions. SUVmax, MTV and TLG were correlated to the presence of nodal metastases, while none of these parameters was predictor of recurrence.

EPW10

Detection of extraregional tumor recurrence with ^{18}F-FDG-PET/CT in patients with recurrent gynecological malignancies being considered for pelvic exenteration

U. Metser; University of Toronto, Toronto, ON, CANADA.

Background: Pelvic exenteration may be offered as a salvage procedure for patients with central recurrent or persistent gynecologic cancer, including cervical, endometrial, vaginal, or vulvar cancer. This procedure is the only potential curative therapy for these patients but is associated with significant morbidity and mortality; therefore, appropriate patient selection, and exclusion of extra-regional metastases is paramount. **Objective:** To compare the detection rate of extraregional metastases in patients with recurrent gynecological malignancies being considered for pelvic exenteration with FDG-PET/CT (=PET) compared to conventional imaging. **Methods:** A retrospective review was performed of all patients in a provincial database with recurrent gynecological malignancies being considered for pelvic exenteration that underwent restaging with PET between March 2011 and October 2014. Findings on PET and conventional imaging (CT ± pelvic MRI) were abstracted. Disease sites were classified according to location (regional nodal metastases, extra-regional nodal metastases, peritoneum or other distant sites) and diagnostic certainty (definitive or equivocal). The proportion of patients positive for extraregional recurrence was calculated for PET and conventional imaging. In addition, the proportion of patients with indeterminate lesions only was calculated for each modality and the sites of indeterminate findings were tabulated. **Results:** There were 85 patients (median age, 50 years; range: 30-81) with carcinoma of cervix (n=51), endometrium (n=18), vagina (n=6), or vulva (n=10). Extraregional recurrence was detected in 8/85 (9.4%) and 24/85 (28.2%) patients on conventional imaging and PET, respectively (p=0.0017). The greatest impact of PET compared to CT was in detection of extraregional nodal metastases, including above the diaphragm (27 vs. 6 nodal basins, respectively). There were 61 equivocal lesions on CT in the entire patient cohort and 22/61 (36%) were above the diaphragm. PET was positive in only 12/61 (20%) of CT equivocal lesions and negative in 44/61 (72.1%). PET had significantly fewer examinations equivocal for extraregional recurrence versus CT (6/85 [7.1%] and 29/85 [34.1%], respectively; p<0.001). **Conclusion:** In patients with recurrent gynecologic malignancies being considered for pelvic exenteration, PET identifies significantly more extraregional recurrence than conventional imaging. PET also results in fewer equivocal lesions. The impact of these results on patient management and outcome should be confirmed in future prospective trials.

Initial experience with aggressive treatment of metastastic prostate cancer using 3 cycles of 7.4 GBq [177Lu]-PSMA every 4 weeks

A. R. Haug[1,2], S. Shariat[3], H. Eidherr[1,2], C. Vraka[1,2], W. Wadsak[2], M. Mitterhauser[2], G. Kramer[3], M. Krainer[4], H. Duan[1,2], M. Hacker[1,2], M. Hartenbach[1,2]; [1]University of Vienna, Vienna, AUSTRIA, [2]Division of Nuclear Medicine, University of Vienna, Vienna, AUSTRIA, [3]Department of Urology, University of Vienna, Vienna, AUSTRIA, [4]Department of Internal Medicine I, University of Vienna, Vienna, AUSTRIA.

Aim: Treatment with [177Lu]-PSMA has emerged as treatment option in metastatic prostate cancer. However, so far treatment schemes have been adopted mainly from experiences based on PRRT of NET. Given the more aggressive biological features of metastatic prostate cancer, a more aggressive treatment might be more appropriate. Materials and methods: We have treated 15 patients (mean age 69 years) with intended 3 cycles of [177Lu]-PSMA every 4 weeks. 14/15 were castration resistant, 7/15 resistant to chemotherapy. All patients have been examined with [68Ga]-PSMA PET/MRI to validate PSMA expression of all metastatic lesions. We monitored haemoglobin (Hb), platelets (Pl), leucocytes and creatinine for assessment of toxicity. The highest toxicity grade during therapy was reported and additional toxicity grade 3 months after the last cycle. Scintigraphy of the salivary glands using $99mTcO_4$ before treatment, and after the third cycle has been used to assess salivary toxicity. For treatment response we evaluated PSA values before the first and after the third cycle. For RECIST based response 12/15 patients were examined with [68Ga]-PSMA PET/MRI 4 weeks after the last cycle. Results: 12/15 patients were treated with all 3 cycles; In 2/15 treatment was stopped after the second cycle due to progressive disease, in 1/15 patient treatment was stopped due to PSA response (-52%) and minimal tumor load. 11/15 patients (73%) had a decreasing PSA (mean -53%), 6/15 (40%) with a decline of more than 50%. According to RECIST 5/12 patients showed PR (42%), 4/12 SD (33%) and 3/12 PD (25%). Treatment was excellent tolerated with no grade 2 toxicity. 1/15 patients showed an increase of Hb toxicity of grade 0 to 1; 2/15 had an increase of Pl toxicity from grade 0 to 1 and 4/15 of leucocytes toxicity, which resolved after 3 months, respectively. We experienced no toxicity regarding creatinine. We did not experience any relevant loss of function neither in scintigraphic monitoring of the salivary glands nor from patient reports. Conclusion: In the presented small preliminary patient cohort aggressive [177Lu]-PSMA treatment was safe and effective. As our reported response rates are comparably high, treatment with high doses every 4 weeks might better reflect the more aggressive nature of castration resistant metastatic prostate cancer.

EPW12

Predictors of better response to radioligand therapy of metastatic castrate-resistant prostate cancer with 177Lu-PSMA-617

J. Ferdinandus, E. Eppard, S. Kürpig, F. Gärtner, R. Fimmers, A. Yordanova, S. Hauser, M. Essler, G. Feldmann, H. Ahmadzadehfar; University Hospital Bonn, Bonn, GERMANY.

Aim: Radioligand therapy (RLT) with 177Lu-PSMA-617 (Lu-PSMA) (prostate-specific membrane antigen) is a novel targeted therapy for metastatic prostate cancer. In this study we evaluated the effect of different pretherapeutic parameters on therapy response measured by PSA two months after RLT. **Methods:** RLT was performed in 40 hormone and/or chemo refractory patients with distant metastases and progressive disease (mean age: 71.4 y/o). 68Ga-PSMA PET/CT was performed in all patients

one to two weeks prior to RLT. SUV max and mean were determined by region of interest. SUV values were recorded for up to five bone and lymph node lesions as well as for relevant normal organs such as liver and spleen as background for the calculation of lesion/background. CBC, renal and liver functions, different previous therapies, pain medication and SUVs were evaluated. **Results:** All patients were treated with a mean of 6 GBq. PSA was controlled two months after RLT. A proportion of 67.5% showed a PSA decline, with 45% and 35% showing a decline of more than 30% and 50%, respectively. In the univariate analysis, older age, a lower Gleason score, a lower number of platelets, lower CRP, no need for pain medication and lower LDH reflected a positive impact of better therapy response; however, multivariate analysis revealed that the most significant independent factors were the number of platelets and no need for pain medication. The response was independent of the amount of PSMA uptake, previous therapies with enzalutamide, abiretarone, Ra-223 and chemotherapy, and other measured factors. **Conclusion:** RLT with Lu-PSMA is an effective therapy in hormone-refractory patients. The metastases should be just PSMA-positive but the response is independent of the amount of PSMA expression. A better treatment response was observed in older patients with a lower Gleason score as well as in patients with platelets in the lower normal limit and without regular need for pain medication.

EPW13

PSA-response and acute toxicity with 4, 6 or 7.4 GBq/cycle of ^{177}Lu-PSMA-617 in patients with mCRPC

H. Rathke[1], F. L. Giesel[1], F. Paul[1], K. Kopka[2], W. Mier[1], U. Haberkorn[1], C. Kratochwil[1]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]Division of Radiopharmaceutical Chemistry, German Cancer Research Center (dkfz), Heidelberg, GERMANY.

Aim: PSMA targeting radionuclide therapy (PSMA-RLT) with ^{177}Lu-PSMA-617 is an upcoming treatment option for patients with mCRPC and presents promising dosimetry. However, the bone-marrow reserve might be reduced after previous chemotherapy and tolerance limits have to be interpreted with care; thus making it difficult to define the optimal treatment regime based on dosimetry only. Here we retrospectively report our empiric dose escalation experience. **Methods:** Patients (n=30) with PSMA-positive tumor phenotype were selected with PSMA-imaging. The PSMA-RLT was performed bi-monthly with single fraction treatment activities of 4 GBq, 6 GBq or 7.4 GBq (n=10, respectively). The treatment regime was applied to 10 consecutive patients, respectively before the treatment activity was escalated. After each cycle blood cell count, clinical symptoms and tumor markers were checked at least every 4 weeks. **Results:** All patients tolerated the first therapy cycle well. The only G3/4 hematological toxicity was observed with 4 GBq in a patient with diffuse type red marrow infiltration which consecutively was considered a contra-indication against ^{177}Lu-PSMA-RLT; thereafter no dose limiting hematological toxicity was observed even in the 7.4 GBq group. Initial PSA-response (> 50% decrease in comparison to baseline) was observed in the 4 GBq-group in 4 of 10 patients, 3 of 10 in the 6 GBq and 5 of 10 in the 7.4 GBq-group. However, with 4 GBq only 2/10 intention-to-treat (ITT) patients could accomplish 3-cycles per protocol before PSA re-progression. In the 6 GBq and 7.4 GBq group out 5/10 patients could stay per protocol and were still in PSA-response after 3 cycles (6 month follow-up). In our cohort 70% of patients were pre-treated with chemotherapy. **Conclusions:** If patients with diffuse red marrow infiltration are excluded a priori, the maximum tolerated dose is not reached with treatment activities of up to 7.4 GBq and bi-monthly repetition, even in a patient collective with previous chemotherapy. A positive dose-effect relationship in regard to response duration emphasizes that escalation to even higher treatment activities is warranted.

EPW14

Treatment response according to PSA changes in patients undergo more than one cycle of 177Lu-PSMA-617 therapy

S. Wegen, E. Eppard, S. Kürpig, M. Essler, A. Yordanova, S. Hauser, H. Ahmadzadehfar; University Hospital Bonn, Bonn, GERMANY.

Aim: Radioligand therapy (RLT) with 177Lu-PSMA-617 (Lu-PSMA) (prostate-specific membrane antigen) is a novel targeted therapy for metastatic prostate cancer. About 70% of patients show PSA decline after the first cycle. The aim of this study was to evaluate the treatment response considering PSA changes after the second cycle and to determine whether the patients without any response after the first cycle show a good response to further treatments. **Methods:** One hundred five RLT were performed in 39 hormone and/or chemorefractory patients (2-5 cycles; median: 3 cycles) with distant metastases and progressive disease (mean age: 72 y/o). Gleason-Score was 6-10 (median: 9). Mean PSA was 798 ng/ml (range: 4.7-5910). The median interval between the therapy cycles was 2 months. The PSA level was measured every 4 weeks after each cycle; however, the PSA value 8 weeks after each cycle was considered for the evaluation of therapy response. **Results:** The median administered activity was 6.0 GBq per cycle. Two months after the first cycle, 26/39 patients (66.7%) showed a PSA decline. All 39 patients received the second cycle independent of the treatment response. Two months after the second cycle, 21 patients (53.8%) showed a PSA decline compared to baseline PSA prior to the first cycle. The patients who did not show any treatment response according to PSA changes after the first cycle did not show any positive response after the further cycles, either. **Conclusion:** The patients without any PSA-decline after the first cycle did not show a PSA decline after the further cycles. However, this does not mean that these patients did not profit from RLT. This should be evaluated in a long-term follow-up with measurements of the overall survival of both groups in comparison to patients who did not receive any RLT.

EPW15

Dosimetry for Lu-177-PSMA therapy of patients with mCRPC: A comparison of 3D SPECT and 2D planar methods

A. Delker[1], A. Gosewisch[1], S. Rieger[1], H. Ilhan[1], W. Fendler[2], F. Gildehaus[1], P. Bartenstein[1], G. Böning[1]; [1]University of Munich, München, GERMANY, [2]UCLA, Los Angeles, CA, UNITED STATES.

Aim: In nuclear medicine the new radioligand Lu-177-DKFZ-PSMA-617 was developed for the treatment of patients with mCRPC. In a recent dosimetry study an elevated tracer uptake in the intestine was observed in the majority of patients which in planar images superimposes the kidneys. In this study we compared two approaches for planar 2D dosimetry with the 3D dosimetry calculations based on quantitative SPECT. Methods: For 8 patients an anterior and posterior planar image with a subsequent SPECT image acquisition was performed at 1h, 24h, 48h and 72h after administration of 3.7 GBq Lu-177-PSMA. Quantitative 3D SPECT was regarded as overlay-free reference. The kidney dose was determined by fitting and integrating the activity signal of the co-registered Images by use of an exponential function and subsequent multiplication of the accumulated activity with the kidney specific S-value. Two methods for planar dosimetry were investigated: In the first method (planar1), according to the MIRD concept, all images were corrected for scatter and attenuation and calibrated with the known activity. In the second method (planar2) the effective half-life of each kidney was determined from the posterior planar acquisitions which were only corrected for scatter, and adjusted to an overlay-free fully calibrated data point from quantitative SPECT before calculating the dose. Results: The mean estimated dose was 1.46 ± 0.53 Gy for SPECT, 3.89 ± 2.03 Gy for planar1 and 1.48 ± 0.56 Gy for planar2. A significant difference (t-test $p < 0.001$) and no correlation (Pearson rho = 0.43) was observed between SPECT and planar1. No significant difference ($p = 0.92$) and a

very strong correlation (rho = 0.96) was observed with planar2. Conclusions: In Lu-177-PSMA therapy we noted an overestimation of kidney dose from anterior and posterior planar images compared to the corresponding 3D dosimetry. This observation can be addressed to extra-renal activity in the intestine which apparently has an emphasized effect onto the anterior view. Solely utilizing the posterior view and consequently omitting attenuation correction improved planar dosimetry, provided that appropriate calibration of the time-activity curve is performed. Although we used quantitative SPECT for this purpose, the application of other calibration methods based on the planar data may be feasible.

EPW16

PSMA Radioligand Therapy (PRLT) using Lu-177 PSMA I&T and Lu-177 PSMA-617: Intra-individual comparison of kinetics and dosimetry

C. Schuchardt, H. R. Kulkarni, S. Wiessalla, M. Shahinfar, A. Singh, R. P. Baum; THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, BAD BERKA, GERMANY.

Aim: PRLT using Lu-177 labeled PSMA ligands is a promising therapy option for metastasized castrate-resistant prostate cancer (mCRPC). Goal of the study was the intra-individual comparison of the kinetics and mean absorbed dose in organs and tumor lesions in PRLT using Lu-177 PSMA I&T und Lu-177 PSMA-617. **Methods:** Four patients (P1-P4) suffering from mCRPC were enrolled (intense PSMA expression verified before using Ga-68 PSMA PET/CT). Three patients (P1-P3) initially received Lu-177 PSMA I&T (P1-P3: 5, 6, 5.4 GBq respectively), in the following cycle PSMA-617 (6.4 GBq each patient). P4 was treated using 6 GBq Lu-177 PSMA 617 in the first cycle, followed by 7.4 GBq Lu-177 PSMA I&T in the next cycle. The kinetics were determined by means of planar whole body scintigraphies plus SPECT/CT acquisitions and dose estimations performed according to MIRD-scheme (OLINDA/EXM). For intra-individual comparison, the following parameters were analyzed: effective half-life, uptake and mean absorbed dose. **Results:** P1: PSMA-617 showed a higher uptake, longer half-life and higher mean absorbed dose for all normal organs. In contrast, the analyzed bone lesion demonstrated a higher uptake, longer half-life and higher tumor dose when using PSMA I&T for therapy. P2: The half-life of PSMA-617 was longer in normal organs, the uptake of both ligands in kidneys (similar doses) and parotid glands was comparable, but the dose to parotid glands was higher for PSMA I&T. In opposition to P1, a longer half-life, higher uptake and therefore a higher tumor dose was found for a bone lesion in case of PSMA-617. P3: Regarding normal organs and a bone metastasis, a longer half-life, higher uptake and higher doses were determined for PSMA I&T. P4: Therapy using PSMA-617 revealed higher uptake, and dose, as well as longer half-lives for whole body and parotid glands. The renal parameters were comparable. A higher uptake and longer half-life were also found for the lymph node metastasis for PSMA-617. **Conclusions:** These first comparative investigations demonstrate the different kinetics of Lu-177 PSMA I&T and Lu-177 PSMA-617 which represent higher uptake in normal organs for therapy using PSMA-617. Due to the different biodistribution and mean absorbed doses to normal organs and tumor lesions, individual dosimetry should be performed.

EPW17

Impact of treatment delay in Radium-223 Dichloride therapy of metastatic castration-resistant prostate cancer patients

M. Ø. Fosbøl, S. Holm, P. M. Petersen, G. Daugaard, J. Mortensen; Rigshospitalet, Copenhagen, DENMARK.

Aim: A global temporary shortage of Radium-223 Dichloride ($^{223}RaCl_2$) occurred for 7 weeks in the fall of 2014 due to production irregularities. The objective of this study was to assess the impact of treatment delay due to non-disease related causes in $^{223}RaCl_2$ therapy of patients with metastatic castration resistant prostate cancer (mCRPC). **Materials and methods**: Retrospective cohort study of mCRPC patients who initiated $^{223}RaCl_2$ therapy in the period from March to November 2014. End points were number of completed $^{223}RaCl_2$ cycles, overall survival (OS) and hematological toxicity defined as grade 2-4 anemia, leucopenia or thrombocytopenia according to Common Terminology Criteria for Adverse Events 4.0 (CTCAE). Bone scintigraphy, hematological status, PSA and alkaline phosphatase were evaluated prior to first dose and after 3rd and 6th treatment, respectively. Follow-up period was 17 months after first $^{223}RaCl_2$ dose. **Results:** 30 consecutive patients initiated $^{223}RaCl_2$ therapy in the time period. Median age 70 years (range 51-82 years), median baseline PSA 172 μg/l (range 18-2098) and alkaline phosphatase 181 U/l (range 29-1850). 23 patients (77%) had extensive metastatic disease with ≥ 20 bone metastases or superscan. 17 of 30 patients were affected by delivery problems. Median delay was 4 weeks (range 3-9 weeks). Five of the 17 patients did not recommence $^{223}RaCl_2$ therapy, four patients due to progressive disease and one patient for reasons not related to $^{223}RaCl_2$ therapy or prostate cancer. For the 13 patients not affected by delivery delay mean number of completed treatment cycles was 3.5 (SD 1.9) vs. 4.5 cycles (SD 1.5) in the delay group. Median OS from the first $^{223}RaCl_2$ dose was 9.0 months (95% CI 5.9-11.5) for the patients without delivery delay and 15.1 months (95% CI 8.2-21.9) for the patients impacted by treatment delay (Hazard ratio 0.62, P =0.304). There was no significant difference in frequency or severity of hematological toxicity. Hematological toxicity grade 2 occurred in 6 (46%) of the patients without delivery delay vs. three patients (17.6%) of the patients affected by delivery issues (P=0.09). For Grade 3 toxicity the numbers were 2 (15%) vs. 5 (29%) (P=0.36). No cases of grade 4 hematological toxicity were observed. **Conclusion**: Results from this small retrospective cohort do not suggest that a short treatment pause due to non-disease related causes has negative impact on number of completed treatment cycles or overall survival in mCRPC patients receiving $^{223}RaCl_2$ therapy.

EPW18

Radium-223 dichloride treatment for prostate cancer with bone metastases: A symptomatic outcome review of 12 months experience

H. H. Lee[1], N. C. McAddy[1], P. O'Sullivan[1], P. Crawley[1], S. Beesley[2], M. Naji[1]; [1]Nuclear Medicine Department, Maidstone and Tunbridge Wells NHS Trust, Maidstone, UNITED KINGDOM, [2]Oncology Department, Maidstone and Tunbridge Wells NHS Trust, Maidstone, UNITED KINGDOM.

Background Radium-223 dichlorid (Ra-223) is an alpha emitting radipharmaceutical that has been approved under the National Institute of Health and Care Excellence (NICE) guidelines for the treatment of patients with castration-resistant prostate cancer (CRPC) and symptomatic bone metastasis. Bone metastases disrupt the normal balance of bone formation by osteoblasts and bone resorption by osteoclasts, which in many cases, are associated with significant pain. This has a direct impact on patients' morbidity, mortality as well as quality of life. Ra-223 has shown to be an effective therapy that targets osteoblastic bone lesions to prolong survival and life expectancy in CRPC. In this study we reviewed the symptomatic outcome of the treatment and effect on pain score and quality of life. **Methods** 43 Patients, who commenced Ra-223 treatment between March 2015 and January 2016, were prospectively reviewed. They were asked to rate their severity of pain and the impact on quality of life at three time points (pre-treatment, mid treatment and at the end of treatment). Pain scores and overall quality of life scores were given on a scale of 0 to 10. Data were analysed to look for whether there is a clinical and symptomatic improvement during and following a full course of treatment. Ra-223 is given as an intravenous injection each month over a total period of 6 months. **Results** In 8 patients the treatment course was abandoned due to clinical deterioration or death. In most patients, who completed a full 6-month course of treatment, there was a measurable pain improvement. The

effect on quality of life was somewhat variable; it was improved in some patients but it remained stable or deteriorated in others. **Conclusion** The current regime of treatment with Ra-223 for symptomatic bone metastasis for CRPR has shown a favourable symptomatic outcome in the majority of patients. The pain score has reduced in most patients and quality of life has also improved in some patients, however, a small minority of patients felt that their quality of life has deteriorated despite an improvement in pain score. This may be related to the general progression of the disease and occasionally patients were being referred late for this particular treatment. Nonetheless, in our experience Ra-223 treatment has been generally well-tolerated and resulted in symptomatic improvement in most patients.

EPW19

Correlation between Bone Lesion Dosimetry and Pain Outcome in Patients (pts) with Castration-Resistant Prostate Cancer (CRPC) undergoing ^{223}Ra-dichloride Therapy

G. A. Follacchio[1], V. Frantellizzi[1], M. Pacilio[2], B. Cassano[1], R. Pani[1], R. Pellegrini[1], G. De Vincentis[1]; [1]Sapienza University, Rome, ITALY, [2]San Camillo-Forlanini Hospital, Rome, ITALY.

Aim. ^{223}Radium is an alpha-emitting radiopharmaceutical indicated in CRPC pts with symptomatic bone metastases. We recently confirmed the feasibility of bone lesion dosimetry in pts treated with ^{223}Ra. Aim of this work was to evaluate correlation between Cumulative Absorbed Dose to bone lesions and pain outcome in pts undergoing ^{223}Radium therapy. **Patients and methods.** 59 pts affected by mCRPC undergoing ^{223}Radium treatment in our institution were evaluated for bone lesion dosimetry on the basis of baseline ^{99m}Tc-diphosphonate bone scan acquired a month before first ^{223}Ra administration. Pts presenting relevant bone lesions characterized by a Tumor/Soft Tissue Contrast Ratio (TST-CR)≥10 were enrolled. Pts with lesions with TST-CR<10 and pts with low compliance due to an ECOG Performance Status>2 were excluded. Pts underwent serial planar static images based on ^{223}Ra γ-emitting component (double-peak acquisitions on thoracic or pelvic district, energy window centred at 84 and 164 keV, each 20% wide, MEGP collimator, 256x256 matrix, acquisition time 30') acquired after 24h, 48h and 7 days from first ^{223}Ra administration. Absorbed Dose (D) to bone lesions with the highest uptake was calculated, accounting for all radioactive decay daughters, and Cumulative D_{RBE} was obtained by multiplying D for α-particles RBE (=5) and for the number of administered ^{223}Ra cycles. Pain scores during ^{223}Radium treatment were acquired through Brief-Pain Inventory 0-10 Numeric Rating Scale at baseline and after every ^{223}Ra cycle. **Results.** 10/59 pts were studied. On the basis of pain outcome, pts were classified in improved pain score (4/10), constant pain score (3/10) and pts with worsening pain (3/10). A total of 10 lesions were selected over 10 pts. Mean Cumulative D_{RBE} to lesions resulted: 73 Gy for the first group of pts, 43 Gy for the second group and 36.5 Gy for the third group. **Conclusions.** Bone lesion dosimetry in pts undergoing ^{223}Ra therapy was feasible in pts with bone scan TST-CR≥10. As general trend, the bone pain outcome seems to improve with increasing of the Mean Cumulative D_{RBE} to bone lesions with the highest uptake. Clinical trials are currenlty evaluating the possibility to rechallenge ^{223}Ra treatment and to modulate ^{223}Ra dosage. This preliminary results suggest that dosimetric assessment in patients undergoing ^{223}Ra treatment could lead to a personalized therapeutic approach. Statistical significance of the observed trend will be studied in a larger number of patients.

EPW20

First Italian Multicentre Experience in using Ra-223 in patients with metastatic castration resistant prostate cancer (mCRPC)

S. Mazzarri[1], G. Boni[1], C. Cianci[2], L. Galli[2], A. Farnesi[2], P. Ghidini[3], F. Monari[4], F. Massari[5], E. Borsatti[6], C. Gobitti[7], R. Bortolus[7], L. Fratino[8], A. G. Morganti[4], S. Fanti[3], D. Volterrani[1]; [1]Regional centre of Nuclear Medicine, AOU Pisa, Pisa, ITALY, [2]Medical Oncology Division, AOU Pisa, Pisa, ITALY, [3]Nuclear Medicine, Policlinico Sant'Orsola, Bologna, ITALY, [4]Radiotherapy, Policlinico Sant'Orsola, Bologna, ITALY, [5]Medical Oncology Division, Policlinico Sant'Orsola, Bologna, ITALY, [6]Nuclear Medicine Unit, CRO-IRCCS, Aviano, ITALY, [7]Radiation Oncology Department, CRO-IRCCS, Aviano, ITALY, [8]Medical Oncology Division, CRO-IRCCS, Aviano, ITALY.

Aim: Radium-223 is a novel bone-targeted α-emitter associated with a survival benefit. We present first Italian multicentre experience in using Ra-223 in mCRPC patients . Material and methods: Data from mCRPC patients submitted to Ra-223 treatment over 3 years (August 2013 - February 2016) were retrospectively collected. Information included Gleason score, age, prior treatments, bone symptoms, analgesic requirements, imaging and blood results. Ra-223 (50 kBq/kg) was administered every 4 weeks, up to the recommended 6 therapy cycles. Endpoints assessed included Overall Survival, pain score using Visual Analog scale (VAS), side effects, skeletal related events (SREs), disease biomarkers (PSA & ALP levels) and haematological parameters. Results: 90 patients received Ra-223 in three Italian Radiotherapy/Nuclear Medicine Departments. Up to April 2016 only Pisa Nuclear Medicine Department data are available, while analysis of data from other centres is still ongoing. Median age was 69 yr (range 52-85 yr). Median follow-up was 8,6 months (range 1-18 months). Mean Gleason score was 7. All patients received 3 previous lines of treatment on average. All bone scans showed foci of abnormal uptake. CT scans was used to exclude visceral involvement and the presence of pathologic lymph nodes with a diameter ≥ 3 cm. 16/32 pts completed the recommended 6 cycles, of whom: 5 had bone pain reduction, 3 had worsening, 8 had absence of bone pain, remaining stable and not requiring analgesia. 16 pts stopped treatment : 3 cases of delay due to lack in radiopharmaceutical supplies, 9 developed extra skeletal disease/skeletal progression, 3 deteriorated clinically, 1 experienced SRE during treatment. About non-haematological toxicity we observed 3 cases of G3 anorexia, 3 cases of G1 diarrhoea, 2 cases of G2 asthenia. No patients developed SREs during follow-up. Concerning haematological toxicity, bone marrow failure resulted in 8 cases of G2 anaemia, 6 cases of G3 anaemia, 2 cases of G2 leucopoenia, 1 case of G2 thrombocytopenia. Regarding biomarkers, median ALP decline was 50%, median LDH decline was -5%, 32% of pts showed a reduction in PSA level. OS mean is at the present date about 8 months, and median OS has not been achieved yet. Conclusion: Ra-223 has a major impact on serum ALP levels, with negligible effect on PSA levels. Therefore, ALP appears to be a useful biomarker of therapy response. Haematological and non-haematological side effects were acceptable. Stability in pain or palliative effects occurred in the majority of pts.

Hepatic nodules characterization with FCH-PET/ceCT : preliminary results

J. Dubreuil[1,2], A. Skanjeti[1,2], P. Rousset[3,2], C. Houzard[1], O. Guillaud[4], F. Giammarile[1], C. Houzard[1], O. Dumortier[4], P. Valette[3]; [1]Nuclear Medicine - Hospices Civils de Lyon, Lyon, FRANCE, [2]Equipe Mixte de Recherche 3738, Lyon, FRANCE, [3]Radiology - Hospices Civils de Lyon, Lyon, FRANCE, [4]Hepatology - Hospices Civils de Lyon, Lyon, FRANCE.

Background: The diagnostic of hepatocellular carcinoma (HCC) is a challenge for medical imaging. MRI is the gold standard, however its accuracy is limited, especially in small tumors. The aim of

this study was to evaluate the potential of fluorocholine (FCH)-PET to diagnose HCC. **Material and method:** Twenty-six cirrhotic patients were prospectively included in this observational study. FCH-PET/CT was performed with enhanced triple phase CT after IV contrast injection (ceCT). MRI and PET were realized within 3 months (median interval: 24 days). Gold standard was considered Liver Imaging Reporting and Data System (LI-RADS) classification based on MRI. A total of 77 liver nodules were classified as follows: 45 HCC (LI-RADS 4-5) and 32 negative lesions (LI-RADS 1 to 3). All hepatic nodules were recorded by a nuclear physician blinded to MR results and classified using the LI-RADS classification based on ceCT. FCH uptake higher than background (on visual analysis) was used as an ancillary feature to favor HCC. Each nodule was matched between both techniques for comparison. McNemar test was used to compare the performances of ceCT, FCH-PET, and FCH-PET/ceCT. Correlation coefficient was used between FCH uptake and size of HCC. **Results:** The sensitivity, specificity an accuracy were respectively 75.6%, 87.5%, 80.5% for ceCT, 73.3%, 84.4%, 77.9% for FCH-PET and 82.2%, 81.3%, 81,8% for FCH-PET/ceCT. FCH-PET/ceCT was superior to ceCT (p=0.03) and FCH-PET (p=0.03). There was no difference between ceCT and FCH uptake (p=1). FCH uptake was positive in 3 of 4 HCC nodules (75%) inferior to 10 mm, 16 of 22 (72,7%) HCC nodules with size between 1 and 2 cm and in 14 of 18 (77,7%) HCC nodules with size superior to 20 mm. No correlation was observed between size of HCC and FCH uptake (r= 0.10). **Conclusion:** These preliminary results confirm the potential interest of FCH-PET/ceCT in HCC, in particular shows the significant and synergic improvement of diagnosis produced by FCH-PET and contrast enhanced CT acquired in "one stop shop". Furthermore, the size of the nodules does not seem to impact significantly the sensitivity of FCH-PET.

EPW22

Recurrent bladder carcinoma: clinical and prognostic role of 18F-FDG PET/TC

P. Alongi[1], R. Gentile[2], A. Stefano[3], G. Russo[3], S. Baldari[2], M. Gilardi[3], M. Midiri[4]; [1]San Raffaele G.Giglio Institute, Cefalù, ITALY, [2]University of Messina, Messina, ITALY, [3]IBFM-CNR, Cefalù, ITALY, [4]DIBIMEF - University of Palermo, Palermo, ITALY.

Aim: the performance of 18F-FDG-PET/CT (FDG-PET) for the restaging of patients (pts) with bladder carcinoma (BC) were shown in the literature in a small number of studies. Furthermore, its prognostic role remains still undefined. The aims of this retrospective study were to evaluate the accuracy, the effects on treatment decision and the prognostic value of FDG-PET/CT in pts with suspicious of recurrent BC. **Materials and Methods:** data from 41 pts affected by BC, who underwent FDG-PET for suspicious of recurrent disease were collected. The diagnostic accuracy of visually interpreted FDG-PET was obtained by considering histology (n=8), other diagnostic imaging modalities (ceCT in 38/41 pts and MRI in 15/41 pts) and clinical follow-up (n=41pts). Semi-quantitative PET values were calculated by using a graph-based method. Progression-free survival (PFS) and overall survival (OS) were assessed by using Kaplan-Meier method. The risk of progression (Hazard Ratio-HR) was computed by Cox regression analysis by considering all available variables. **Results:** suspicious of recurrent BC was confirmed in 20/21 pts with a positive FDG-PET scan. Overall, the sensitivity, specificity, positive predictive value, negative predictive value and accuracy of FDG-PET were 87%, 94%, 95%, 85%, 90%. AUC was 0.9 (95%IC 0.8-1; p<0.05). Likelihood ratio analysis results were as follows: LH+=14.5; LH-=0.13. FDG-PET findings influenced significantly the therapeutic management in 12 patients (modified therapy in 7 PET positive pts; watch and wait in 5 PET negative pts). After 2 years of follow-up, PFS was significantly longer in pts with a negative vs. a positive FDG-PET scan (85% vs 24%, p<0.05). Moreover, a negative study was associated with a significantly longer OS than a positive one (88% vs 47% after 2 years and 87% vs 25% after3 years, respectively; both p<0.05). Furthermore, a positive PET scan was associated with an increased risk of disease progression (HR=12.4; p=0.001). At semi-quantitative PET analysis, thresholds SUVmax>6 and TLG>8.5 were recognized as the unique values predicting significantly (p<0.05) the PFS rate (2 year PFS rate for SUVmax<6 vs SUVmax>6= 62% vs 15%; 2 year PFS rate for TLG<8.5 vs TLG>8.5= 66% vs 18%). **Conclusion:** FDG-PET/CT has a valuable diagnostic performance in pts with suspicious of recurrent BC and provided a change in treatment decision in about 30% of cases. Moreover, FDG-PET showed an important prognostic value in assessing the risk of disease progression and survival outcomes in this setting of pts.

EPW23

^{18}F-FDG PET/CT in the evaluation of adrenal masses in patients with oligometastatic state non-small cell lung cancer: a histopathologic comparison after laparoscopic adrenalectomy

Y. Kordan[1], **F. Sen**[2], O. Kaygisiz[1], G. Ozmerdiven[1], I. Yavascaoglu[1]; [1]Uludag University Department of Urology, BURSA, TURKEY, [2]Uludag University Department of Nuclear Medicine, BURSA, TURKEY.

Aim: Adrenal glands comprise one of the most common site for an oligometastatic involvement of non-small cell lung cancer (NSCLC). Patients with such limited metastatic site has the opportunity to be treated surgically and improved survival rate. First-line staging of NSCLC patients with ^{18}F-FDG PET/CT (PET/CT) has made an increase in the frequency of adrenal mass detection. However the accurate diagnosis of the lesion, whether benign or malignant, is challenging and preoperative imaging with combined PET/CT help to avoid the patient from aggressive treatment modalities. We aimed to determine the reliability of PET/CT for characterizing the mass in the adrenal glands in patients with oligometastatic NSCLC by comparing results after adrenalectomy. Materials and Methods: This was a retrospective study of all laparoscopic adrenalectomy performed with curative intent between March 2004 and January 2014 in our clinic. Patients who had histologically proven NSCLC with detected adrenal masses on staging PET/CT scans were included in the study. Patients who were staged without PET/CT or patients who received chemotherapy before imaging were excluded. Patient demographics, analysis of both PET and CT components of adrenal lesions on PET/CT and histopathogical results after adrenalectomy were determined. The intensity of FDG uptake expressed as a standard uptake value (SUV) with ratio of SUV in adrenal mass to normal liver uptake was recorded. These parameters were compared statistically between benign and malignant pathologies. Results: A total of 22 patients met the inclusion criteria. All but three were females. The mean age was 58.3± 8.35. Metastasis was found in 16 of the adrenal masses (72.7%). SUVmax and SUV ratio values were found significantly higher in the metastatic group (p=0.001 and p=0.009, respectively).The HU value in CT was greater than 10 in all the patients. No metastasis was found in patients with adrenal mass SUV max smaller than 3, all the patients with SUVmax greater than 4.1 were found to have metastases. There was only one patient with SUV ratio less than 1. The smallest SUV ratio among the adrenal metastases was 1.07. Using ROC curve analysis the best SUV ratio threshold to differentiate benign and metastatic adrenal lesions was 1.2 with a sensitivity of 87.5% and specifity of 83.3%. Conclusion: When evaluating the adrenal masses of patients with NSCLC, PET/CT can reliably predict adrenal metastases and oligometastatic state and aid decision making by means of follow-up or surgical resection.

EPW24

Circulation Tumor Cells in Resected Nonsmall Cell Lung Cancer: The Association With Early Relapse and 18F-FDG PET Uptake

C. Ramos-Font[1], A. Rodríguez-Fernández[1], C. Bayarri-Lara[1], D. de Miguel-Pérez[2], M. J. Serrano[3], E. Triviño-Ibáñez[1], R. Sánchez-Sánchez[1], M. Gómez-Río[1], J. M. Llamas-Elvira[1]; [1]COMPLEJO HOSPITALARIO UNIVERSITARIO DE GRANADA, GRANADA, SPAIN, [2]GENYO. Centre for Genomics and Oncological Research: Pfizer / University of Granada, GRANADA, SPAIN, [3]1.-GENYO. Centre for Genomics and Oncological Research: Pfizer/University of Granada. 2.-Integral Oncology Division, San Cecilio Clinical University Hospital, GRANADA, SPAIN.

Objective: More than 20% of lung cancer patients develop recurrence, even after curative resection. It is hypothesized that relapse may arise from dissemination of circulating tumor cells (CTCs). The present study investigated the association between CTCs and primary tumor 18F-fluorodeoxyglucose (FDG) uptake on PET scan. Secondly, we evaluated the influence of CTCs detection on recurrence rate in surgically resected nonsmall cell lung cancer (NSCLC). **Methods:** In this single center prospective study, blood samples for CTCs analysis were obtained from 102 patients with previously untreated, stage IIIA NSCLC both before and one month after radical resection. CTCs were isolated using inmunomagnetic techniques. CTCs presence was correlated with standardized uptake value (SUVmax) measured on preoperative FDG PET/TC. Recurrence and disease free survival (DFS) analysis was performed. **Results**: CTCs were detected in 39.2% of patients before surgery and in 27.5% one month after surgery. In the 85% (34 out of 40) of patients with CTCs at baseline showed a decrease in CTC count after surgery. CTC presence after surgery was significantly correlated with SUVmax on PET scan, pathological stage and with surgical approach. But only SUVmax on PET was an independent predictor of CTC presence after the operation in multivariate analysis (HR=3.71, 95% CI 1.3210.37, p=0.013). 36 patients (35.3%) experienced recurrence during a median follow up period of 19 months. CTCs presence after surgery was significantly associated with early recurrence (p=0.006) and with a shorter DFS, with a 1 year DFS rate of 52.1% compared to 79.1% for CTC negative group (log rank test p=0.005). In multivariate analysis CTCs presence after surgery was associated with a shorter DFS, independently of disease staging. **Conclusion**: Detection of CTCs one month after radical resection might be an useful marker to predict early recurrence in stage III NSCLC. SUVmax value of the primary tumor on preoperative PET scan was associated with CTsC presence one month after the operation.

EPW25

Correlation of metabolic information on FDG-PET with the tissue expression of immune markers in patients with non-small cell lung cancer (NSCLC) candidate to upfront surgery

E. Lopci[1], L. Toschi[1], F. Marchesi[1], F. Grizzi[1], D. Rahal[1], L. Olivari[2], G. Castino[1], S. Marchetti[2], N. Cortese[1], M. Alloisio[1], P. Allavena[3], A. Santoro[3], A. Chiti[3]; [1]Humanitas Clinical and Research Hospital, Milano, ITALY, [2]University of Milan, Milano, ITALY, [3]Humanitas University, Milano, ITALY.

Purpose: Eliciting antitumor T-cell response by targeting the PD-1/PD-L1 axis with checkpoint inhibitors has emerged as a novel therapeutic strategy in non-small cell lung cancer (NSCLC). The identification of predictors of sensitivity or resistance to these agents is therefore needed. Herein, we investigate the correlation of metabolic information on FDG-PET with tissue expression of immune-checkpoints and other markers of tumor-related immunity in resected NSCLC patients. **Materials and Methods:** All patients referred to our Institution for upfront surgical resection of NSCLC, who were investigated with FDG-PET prior to surgery, were consecutively included in the study. From January 2010 to May 2014, 55 patients (stage IA-IIIB; M:F=42:13; mean age 68.9 years) were investigated. Sampled surgical tumor specimens were analyzed by immunohistochemistry (IHC) for CD68-TAMs (tumor-associated macrophages), CD8-TILs (tumor infiltrating lymphocytes), PD-1-TILs and PD-L1 tumor expression. The immunoreactivity was evaluated and scores compared with imaging findings. FDG-PET images were analyzed to define semi-quantitative parameters: SUVmax and SUVmean. Metabolic information on FDG-PET were correlated with tissue markers expression, and both with disease-free survival (DFS) considering a median follow-up of 16.2 months. **Results:** Thirty-six adenocarcinomas (ADC), 18 squamous cell carcinomas (SCC), and 1 sarcomatoid carcinoma were analyzed. All tumors resulted positive at FDG-PET: median SUVmax 11.3 (range: 2.3-32.5) and SUVmean 6.4 (range: 1.5-13) resulted both significantly higher in SCC compared to other NSCLC histotypes (p=0.007 and 0.048, respectively). IHC demonstrated a median immunoreactive surface covered by CD68-TAMs of 5.41% (range: 0.84-14.01%), CD8-TILs of 2.9% (range: 0.11-11.92%), PD-1 of 0.65% (range: 0.02-5.87%), and PD-L1 of 0.7% (range: 0.03-10.29%). We found a statistically significant correlation between SUVmax and SUVmean with the expression of CD8 TILs (rho=0.31; p=0.027) and PD-1 (rho=0.33; p=0.017 and rho=0.36; p=0.009, respectively). The other tissue markers correlated as follows: CD8 TILs and PD-1 (rho=0.45; p=0.001), CD8 TILs and PD-L1 (rho=0.41; p=0.003), CD68-TAMs and PD-L1 (rho=0.30; p=0.027), PD-1 and PD-L1 (rho=0.26; p=0.059). With respect to patients' outcome, SUVmax, SUVmean and disease stage showed a statistically significant correlation with DFS (p=0.002, 0.004 and <0.001, respectively).**Conclusions:** The present study shows a direct association between metabolic parameters on FDG-PET and the expression of tumor-related immunity markers, suggesting a potential role for FDG-PET to characterize the tumor microenvironment and select NSCLC patients candidate to checkpoint inhibitors.

EPW26

Role of F-18 FDG PET/CT in non-conjunctival origin ocular adnexal mucosa-associated lymphoid tissue (MALT) lymphomas, in comparison with orbital MRI

H. Park[1], J. Kim[2], S. Kim[1], J. O[1], S. Yang[1], S. Cho[1]; [1]Seoul St. Mary's Hospital, Seoul, KOREA, REPUBLIC OF, [2]Taean Health center and County Hospital, Seoul, KOREA, REPUBLIC OF.

Purpose: Despite the widespread use of F-18 fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) in the diagnosis and response assessment of patients with lymphoma, few studies have assessed its value in ocular adnexal lymphomas. The purpose of this study was to evaluate the role of FDG PET/CT in staging of non-conjunctival origin ocular adnexal MALT lymphomas (OAML), and to compare its diagnostic sensitivity to magnetic resonance imaging (MRI). Methods: FDG PET/CT of 124 patients with pathologically proven OAML between January 2009 and February 2016 were retrospectively reviewed. The patients with MALT lymphoma originating from conjunctiva were excluded. Total 50 patients with non-conjunctival origin OAML were assessed. Maximum standardized uptake value (SUVmax) was measured for all lesions. Sensitivity for primary tumor detection was compared to MRI. Results: Ten patients had bilateral OAML and total 60 OAML lesions were analyzed. MRI was missing in one patient. The tumor locations were: eyelid, 9; lacrimal gland, 18; orbit, 33. Fifty lesions (83.3%) showed perceptible FDG uptake with mean±SD SUVmax 4.8 ±2.4 (range 2.0~11.1). The mean SUVmax according to tumor location were: eyelid, 3.7±1.1 (2.8~5.3); lacrimal gland, 3.6±1.4 (1.4~6.4); orbit, 5.7±2.6 (2.0~11.0). Mean SUVmax among the 3 locations were statistically different (p=0.010 by Kruskal-Wallis test). The sensitivity was

calculated as 83.1% (49/59) for FDG PET/CT and 89.8% (53/59) for MRI, which were statistically comparable (p=0.219 by McNemar's test). Seven of 50 patients (14%) were upstaged by detect on of extraocular lesions by FDG PET/CT (1 kidney and lung, 1 tonsil, 4 cervical LNs, 1 sacral foramen). Conclusion: Non-conjunctival origin OAML showed perceptible FDG uptake in 83.3% of the lesions, with comparable sensitivity to that of MRI. FDG PET/CT detected extraocular lymphoma involvement in 14% of the patients. FDG PET/CT performed for non-conjunctival origin OAML has a role in guiding the therapeutic plan.

EPW27

The Prognostic Utility of Pre-Treatment 18F-FDG-PET for Salvage Re-Irradiation in Head and Neck Cancer Patients

K. Musaieva[1], O. Solodyannikiva[2], Y. Kmetyuk[1]; [1]All-Ukrainian Center of Radiosurgery, Kyiv, UKRAINE, [2]National Cancer Institute, Kyiv, UKRAINE.

Background. Statistical image features from hybrid PET/CT scans were studied for their potential to predict clinical outcome of salvage re-irradiation treatment. We analyzed tumor metabolic features from pre-treatment 18F-FDG-PET scans as related to clinical outcomes in patients treated with intensity modulated radiotherapy (IMRT) for recurrent squamous cell carcinoma of head and neck (HNSCC). Materials and Methods. Pretreatment PET/CT scans and after treatment PET/CT scans (2.5 to 4.5 months) of 11 patients (9 males, 2 females) who underwent re-irradiation for recurrent HNSCC, were retrospectively evaluated. Semi-quantitative analysis of PET/CT were performed. Metabolic response was assessed using PET response criteria for solid tumors (PERCIST). None of the patients underwent a salvage surgery. Multiple statistical image features related to the standard uptake value (SUV) were computed: metabolic tumor volume, maximum SUV, mean SUV, total lesion glycolysis (TLG), whole-body total lesion glycolysis, whole-body metabolic tumor volume. The correlation between the image features and local control and overall survival was calculated. Results. Between 2012 and 2015 eleven patients with recurrent HNSCC underwent IMRT re-irradiation; interval since previous radiation is 21.5 months (3-72). Complete tumor metabolic response (CMR) was achieved in 5 patients (45.5%). Six patients failed to achieve CMR: progressive metabolic disease was in 4 patients (36.4%); stable metabolic disease in one patient (9.1%); one patient had partial metabolic response (9.1%). The median follow-up time was 18.2 months; by the time of this report three patients who failed to achieve CMR died. Out of the calculated image features, only pre-treatment tumor TLG (individual tumor volume multiplied by its mean SUV) correlated with tumor metabolic response in the early PET/CT follow-up: mean tumor TLG in the group with CMR was 71.74; while the mean tumor TLG in the group who failed to achieve CMR was 224.75. Also dividing the patient population based on the median tumor TLG showed a split of the Kaplan-Meier survival curves. Conclusions. The tumor TLG of pre-treatment PET/CT scans has important information on the failure risk to achieve CMR in recurrent HNSCC patients. It is necessary to obtain additional patients data to validate these results and to find correlations of the calculated image features with metabolic outcome, local control, progression-free survival and overall survival.

EPW28

The Role Of 18F-FDG PET/CT In Diagnosis And Staging Of Gastric Cancer

E. ARSLAN[1], F. D. CAN TRABULUS[2], S. BAYRAK[2], H. E. PASAOGLU[3], N. DURSUN[3], T. F. CERMIK[4]; [1]ISTANBUL RESEARCH AND EDUCATIONAL HOSPITAL CLINIC OF NUCLEAR MEDICINE, ISTANBUL, TURKEY, [2]ISTANBUL RESEARCH AND EDUCATIONAL HOSPITAL CLINIC OF GENERAL SURGERY, ISTANBUL, TURKEY, [3]ISTANBUL RESEARCH AND EDUCATIONAL HOSPITAL DEPARTMENT OF PATHOLOGY, ISTANBUL, TURKEY, [4]SAKARYA SCHOOL OF MEDICINE,NUCLEAR MEDICINE DEPARTMENT, SAKARYA, TURKEY.

OBJECTIVES: Accurate initial assessment for the stage of disease is important for treatment selection and prognosis in gastric cancer. 18F-FDG PET/CT has been shown to be an important tool in the evaluation of gastric cancer. AIM: The aim of this study was to evaluate the role of 18F-FDG PET/CT in the staging of gastric cancer in comparison to histopathological results. MATERIALS AND METHOD: One hundred forty three patients (mean age:60.7 ±10.9 y) who underwent 18F-FDG PET/CT for primary staging of gastric cancer between May 2010 and December 2015 were included the study. Seventy one patients have been diagnosed by endoscopic and remaining 72 patients with surgical histopatological results. 18F-FDG PET/CT findings of primary lesions, lymph nodes and metastatic organs were compared with pathological results and/or follow-up imaging methods. RESULTS: In TNM staging of the patients 8 (11%), 7 (10%), 19(26%) and 38 (53%) were staged as T1, T2, T3 and T4, and 14 (20%), 9 (13%), 17(24%), 30(42%) and 2 (1%) were N0, N1, N2, N3a and N3b respectively. Distant metastasis was found in 57 (40%) patients (37 liver, 8lung, 7bone-bone marrow and 5multi-organ). Distant metastatic patients' primary tumor SUV max was calculated as 13.0±9.1.There was no statistically significant difference between distant metastatic and non-metastatic groups (p>0.05). According to analysis of histopathological types of primary tumors, SUV max of adenocarcinoma was calculated as 12.9±9.0, invasive adenocarcinoma as 13.1±9.1, signet ring cells carcinomaas 12.8±8.4 and mucinous adenocarcinoma as 12.2±8.6. There were no statistically significant differences between these groups (p>0.05). Fifty-five of 72 patients diagnosed lymph node metastasis with histopathological examination. In comparison with histopathological results 18F-FDG PET/CT was true positive (TP), false positive (FP), false negative (FN), true negative (TN) in 43, 6, 12 and 11patients respectively. Sensitivity, specificity, accuracy, positive predictive value (PPV) and negative predictive value (NPV) of 18F-FDG PET/CT were calculated as 78%, 65%, 75%, 88% and 48% respectively. CONCLUSION: Despite the low NPV of 18F-FDG PET/CT in detecting nodal metastasis of gastric carcinoma, relatively high sensitivity and PPV might contribute to accurate initial staging. Also our results suggested that 18F-FDG PET/CT has demonstrated a prominent role in detection of distant metastasis in initial staging of gastric cancer.

EPW29

The diagnostic usefulness of ^{18}F-FDG PET/CT in radiological suspected cases of cholangiocarcinoma

B. R. Mittal, R. Kumar, A. Jois, A. Sood, A. Bhattacharya; Postgraduate Institute of Medical Education & Research, PGIMER, CHANDIGARH, INDIA.

Objective: This retrospective study was performed to evaluate the diagnostic yield of ^{18}F-fluorodeoxyglucose positron emission tomography-computed tomography (^{18}F-FDG PET/CT) in radiological suspected cases of cholangiocarcinoma Material and Methods: In this retrospective study, we evaluated data of patients with radiological suspicion of cholangiocarcinoma and who were referred for whole body ^{18}F-FDG PET/CT from January 2011 to December 2015 to assess the disease status. The PET/CT images were evaluated by two experienced nuclear medicine physicians. Abnormal FDG uptake on PET images were correlated with the morphological abnormalities on corresponding contrast enhanced CT images and considered positive. The imaging results were compared with histopathological examination, clinical or imaging follow up. **Results**: A

total of 63 patients (32 males, 31 females) aged 29-78 years (median age of 56.7) data was analysed retrospectively. PET/CT results revealed positive findings in 47/63 patients (74.6%) while 16/63 patients (25.4%) were PET negative. Out of 47 PET positive patients, the intrahepatic lesions were localized in 29 patients while extra-hepatic lesions in 18 patients. On comparing with histopathological examination, FDG PET/CT was true positive (TP) in 43 patients, false positive (FP) in 4 patients, true negative (TN) in 15 patients and false negative (FN) in one patient. The overall sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of FDG PET/CT for detection of malignant bile duct diseases was 97.7% (95% CI-87.9% -99.9%), 78.9% (95% CI-54.4% - 93.9%), 91.5% (95% CI-79.6% - 97.6%), 93.7% (95%CI- 69.7% - 99.8%) and 92.1% respectively. The sensitivity and PPV of FDG PET/CT for detection of intrahepatic disease was 100%, 93.10% respectively (TP-27, FP-2, FN-0 and TN-0) while for extra-hepatic disease 94.1% and 88.8% respectively (TP -16, FP-2, FN-1 and TN -0). By ROC curve analysis we found that SUVmax >3.6 had a sensitivity 100% and specificity 74.1% (AUC 0.843) for detection of intrahepatic lesions but for detection of extra-hepatic lesion SUVmax >7.1 had a sensitivity 75% and specificity 100% (AUC 0.781) respectively. FDG-PET detected distant metastatic lesions in 13 patients not found by other imaging studies and regional lymph nodes were noticed in 41 patients. **Conclusion**: FDG PET/CT had shown a high diagnostic performance in radiological suspected cholangiocarcinoma and promising tool in differentiating intra hepatic and extra-hepatic cholangiocarcinoma. FDG PET/CT also helps in detection of hidden distant metastases and can help in treatment planning.

A New Method for Submillimeter Desktop Small-Animal SPECT Imaging using Tilted Detector

N. Zeraatakr[1], A. Rahmim[2,3], S. Sarkar[4,5], **M. Ay**[1,4]; [1]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Radiology, Johns Hopkins University, Baltimore, MD, UNITED STATES, [3]Department of Electrical and Computer Engineering, Johns Hopkins University, Baltimore, MD, UNITED STATES, [4]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Research Center for Science and Technology in Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: During last decade, the role of molecular imaging in small-animal models has been highlighted in a variety of applications including pharmaceutical studies, radiopharmaceutical research, and exploring new approaches in cancer therapy. SPECT systems based on pinhole/multi-pinhole collimators with a rotating gantry (or static gantry with a closed-structure multi-pinhole collimator) are the most common design used. In this work, we introduce a new system for desktop small-animal SPECT imaging considering the primary goal of Submillimeter spatial resolution. **Materials and Methods**: The system consists of a detector equipped with a pinhole collimator. The detector-collimator set can rotate underneath a desk (imaging desk) with a tilt angle. The imaging desk has a determined region for placing the object to be scanned. The head acquires data in a step-and-shoot manner by rotating around the object underneath the desk maintaining its tilted angle. To evaluate the performance evaluation of the system, it was modeled using GATE Monte Carlo simulation. Also, some complicated phantoms including MOBY phantom were simulated, analytically. The acquired data were then reconstructed using an MLEM-based developed algorithm: Finite-Aperture-Based Circular Projection. For all GATE simulations in the current work, pinhole diameter of 1 mm, pinhole-to-object distance of 18.5 mm, pinhole-to-detector distance of 300 mm, and tilt angle of 30° were applied. The data were reconstructed using 3 iterations. **Results**: The sensitivity was calculated as ~200 cps/MBq. Also, submillimeter tomographic spatial resolution with appropriate variation throughout the field-of-view (CV% of 9%) was obtained. The noise was quantified as 5.6% in terms of STD%. Non-uniformity was computed as about 25%. Moreover, using submillimeter pinhole diameter, images of the MOBY phantom were reconstructed with acceptable quality. **Conclusion**: The introduced system can provide images with comparable quality to the conventional small-animal SPECT systems while proposing a desktop method for tomographic scan. The system can be manufactured as a low-cost one regarding the application of simple design of the detection and mechanics. The dedicated image reconstruction algorithm developed for the system showed appropriate performance despite of complex geometry of the system.

EPW32

Feasibility of Ultra-low Dose Canine Imaging Using a Next Generation Digital PET System

M. I. Menendez, J. Zhang, K. Binzel, A. Siva, M. I. Knopp, M. Tweedle, T. Rosol, C. L. Wright, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

Aim: Molecular imaging using ^{18}F-FDG positron emission tomography (PET) in veterinary subjects and patients is an important clinical and translational research tool. While imaging at as low as reasonable achievable doses (ALARA) is current practice in human patients, imaging at the lowest possible dose is even more critical to reduce staff exposure and to avoid the need for longer isolation housing. Veterinary subjects are imaged under anesthesia and therefore only physiologic motion needs to be considered. Associated with a project to develop and validate ultra-low human PET imaging, we initiated this pre-clinical project to demonstrate and validate the ability to perform ultra-low dose FDG using a next generation solid state, digital PET detector human PET/CT system. **Materials and Methods:** PET/CT imaging of anesthetized, healthy, skeletally mature beagles was performed using a next generation digital photon counting PET/CT system (Vereos, Philips) (dPET) that has excellent sensitivity and time of flight timing resolution (325ps). Combined dynamic and whole-body imaging over 110 min with a 120s per bed position acquisition time was acquired starting with injection and event data were recorded in listmode. A specialized reconstruction and *in silico* simulation computational environment was previously developed and utilized. Our current human standard of care dose is 3.5 - 7 MBq/kg. Canine dosing was performed and simulated in the range from 1 to 10 MBq/kg. Images were qualitatively analyzed by experienced blinded reader review and quantitatively by 3D ROI placement on reference tissues and SNR assessments. **Results:** Imaging was performed using 6 canine subjects with an average weight of 15 kg, evaluating total dose ranges from 15 to 111 MBq. In parallel, simulated lower dose whole-body scans were reconstructed in 10% dose reduction increments down to the 15 MBq. The quantitative analysis found consistent (less than 10% variability) SUV_{max} values when using the previously developed adaptive reconstruction approach over the assessed dosing range down to 1.0 MBq/kg. Visual quality was rated assessable for all dose ranges of 1.5 MBq/kg or above. **Conclusion:** Ultra-low dose canine FDG PET imaging can be accomplished at 1.5 MBq/kg using a digital PET/CT system and optimized reconstructions approaches. The considerable dose reduction supports increased opportunities of FDG PET for veterinary applications as the post procedure radiation dose has been a limiting factor necessitating subsequent isolation housing or undue exposures to support staff. Furthermore it creates new in vivo benchmark data for human patient dose reduction efforts.

EPW33

A Study on the Effect of Attenuation Correction in image Quantity in Small-Animal SPECT System

S. Khorasani Gerdekoohi[1,2], N. Vosoughi[1], K. Tanha[3], M. Assadi[3], M. Ay[2,4]; [1]Department of Energy Engineering, Sharif University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Persian Gulf Nuclear Medicine Research Center, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Medical Physics and Biomadical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Photon attenuation as an inevitable degradation factor affect the accuracy of quantitative measurements in single photon emission computed tomography (SPECT) images. Various attenuation correction methods have been evolved to compensate this degradation. We proposed a Chang based attenuation correction algorithm and then evaluated its effect on SPECT images of HiReSPECT scanner which developed in our department. Phantom and animal studies were performed to validate our method. *Materials and methods:* A post-processing Chang attenuation correction algorithm developed using extracting object contour from emission data. In our study due to small size of objects a uniform attenuation map with attenuation coefficient of water in 140 keV was used. Then a matrix calculated slice-by-slice and multiplied by reconstructed image to compensate the attenuation. Uniform cylindrical phantoms with various volumes from 1ml to 30ml and known activities were scanned to evaluate the influence of attenuation correction on different volumes of objects. Additionally, we scanned the NEMA NU-2008 image quality phantom and analyzed its uniform region and hot rods activity concentration before and after applying attenuation correction. At the end we performed rat renal scans (n=8 kidneys) to examine the validity of our correction method in non-uniform distribution of attenuating tissues in animal body. After each scan rat's kidneys were removed and counted with a dose calibrator to attain absorbed activity. Afterwards comparison of corrected and non-corrected images confirmed. Data analysis was done by drawing region of interests (ROI) in two ways: (a) manual ROIs for phantom images because of their simple shape and absence of background activity and (b) an iso-contour based ROI drawing for animal images. *Results:* In cylindrical phantoms, applying attenuation correction caused a reduction of 2.2% in relative error for phantom with 7mm diameter; whereas, it reduced the relative error 15.9% for 30mm phantom. So attenuation correction becomes more important when the size of the object and its self attenuation rises. In image quality phantom, applying attenuation correction improved the recovery coefficient (RC) 8% for hot rod with diameter of 2mm (smallest detected hot rod) and 19% for 5mm diameter hot rod (biggest one). Furthermore, relative error of activity concentration in uniform region reduced from -15% to 5% after correction. In animal studies, the quantitative error improved from -22.8% to +3.5% on average by applying attenuation correction. *Conclusion:* These results show that in small animals, a uniform attenuation map using only emission data can promise an acceptable image quantitative accuracy.

EPW34

A high-resolution hybrid gamma-optical camera for intraoperative imaging

J. E. Lees[1], S. L. Bugby[1], M. S. Alqahtani[1], L. K. Jambi[1], N. S. Dawood[1], A. H. Ng[2], A. C. Perkins[2]; [1]University of Leicester, Leicester, UNITED KINGDOM, [2]University of Nottingham, Nottingham, UNITED KINGDOM.

Introduction The development of compact low profile gamma-ray detectors has allowed the production of a small field of view, handheld imaging device which could be used at the patient bedside and in operating theatres. The combination of an optical and a gamma camera, in a co-aligned configuration, provides an optical image overlaid with a scintigraphic image. This innovative introduction of hybrid imaging offers assistance in localising the site of uptake in procedures such as sentinel node detection. The hybrid camera concept can be extended to a multi-detector design which provides depth estimation of the gamma-emitting source. **Materials and Methods** The hybrid camera consists of a 1500 μm thick CsI(Tl) columnar scintillator coupled to an electron multiplying CCD with a tungsten pinhole collimator which gives a 40mm x 40mm nominal field of view for the 8mm x 8mm CCD detection area. An optical camera is aligned so as to provide the same field of view as the gamma camera. Optical and gamma images are taken simultaneously and fused to produce dual-modality images providing information from the gamma camera within an optical context. Images were obtained in laboratory simulations using a range of bespoke phantoms. Clinical images from patients attending the nuclear medicine clinic were also taken. **Results** The characteristics of the hybrid camera compared favourably with other portable SFOV cameras currently in use. High quality images from phantoms show that the hybrid system is particularly suited for sentinel lymph node detection. Experimental simulations demonstrated the ability to differentiate between adjacent hot sources (1:100 activity ratio) in close proximity, as would be required for differentiation of sentinel nodes from the injection site. Estimation of depths of radioisotope sources in a simple phantom were also achieved. We report on clinical results from lymphoscintigraphy, thyroid imaging and lacrimal drainage studies that show that the site of uptake could be visualised in the patient. **Conclusion** The hybrid camera has been used to produce dual-modality images in both laboratory simulations and in the clinic. In addition we have shown that the hybrid camera concept can be extended to estimate the position and depth of radionuclide distribution within an object.

EPW35

Portable hybrid gamma-near-infrared fluorescence imaging

S. L. Bugby[1], J. E. Lees[1], A. H. Ng[2], M. S. Alqahtani[1,3], L. K. Jambi[1,4], M. A. Stammes[5,6], H. J. M. Handgraaf[5], A. C. Perkins[2]; [1]University of Leicester, Leicester, UNITED KINGDOM, [2]University of Nottingham, Nottingham, UNITED KINGDOM, [3]King Khalid University, Abha, SAUDI ARABIA, [4]King Saud University, Riyadh, SAUDI ARABIA, [5]LUMC, Leiden, NETHERLANDS, [6]Percuros, Leiden, NETHERLANDS.

Introduction: The first clinical study of targeted hybrid near-infrared (NIR) fluorescent-radioactive tracers was recently published. In addition, ICG-^{99m}Tc-nanocolloid is already being used by some centres for sentinel lymph node biopsy. Once exposed, the NIR fluorescence reporter can be imaged at very high resolutions while the radioactive component allows imaging at depths which would not be possible in NIR. Visualisation of NIR fluorescence during surgery requires a dedicated NIR camera, several of which are available commercially. Gamma detection may be carried out with a separate portable gamma camera or with a non-imaging probe. We describe a portable hybrid NIR-gamma small field of view camera, capable of displaying co-aligned images from both modalities which can be fused into one image or viewed separately. This study is a preliminary investigation of the performance of the fluorescence component of this camera, including phantom studies and first images from a preclinical pilot study. ***Materials and Methods:*** The hybrid camera consists of a 1.5mm thick CsI:Tl columnar scintillator coupled to an electron multiplying CCD. A 1.0mm diameter pinhole collimator gives a 40mm x 40mm nominal field of view for an 8mm x 8mm detector area. A fluorescence camera was aligned to provide the same field of view as the gamma camera with an LED ring as the excitation source. The performance of the fluorescence imaging was quantified in this study for the fluorophores ICG and IRDye800CW (CW800) using a number of phantom experiments.

Images are also presented for a preclinical study of a targeted hybrid tracer (cRGD-CW800-TCO + TCO-DOTA-^{111}In) in mice with HT29 colorectal cancer xenografts. These images have been used for a qualitative comparison between the hybrid camera and commercially available fluorescence imaging systems (Artemis, Quest; Pearl Impulse, LICOR). ***Results and conclusions***: The hybrid camera prototype has been shown to successfully image the dual NIR-gamma tracers tested. With further development, this camera could be used intraoperatively, offering the benefits of high resolution surface NIR fluorescence imaging and the depth penetration of gamma imaging in a single imaging system.

EPW36

From compound library to lead compound selection via established ^{99m}Tc radiochemistry, high-throughput preclinical SPECT/CT imaging and automated analysis

S. Macholl[1], C. Finucane[1], S. Mather[1], J. Hesterman[2], D. Scully[2], E. Jouannot[3]; [1]inviCRO Ltd., London, UNITED KINGDOM, [2]inviCRO LLC, Boston, MA, UNITED STATES, [3]Sanofi-Aventis R&D, Chilly-Mazarin, FRANCE.

Feasibility and application of preclinical high-volume, high-throughput SPECT/CT imaging including automated analysis is presented, by example of a study comprising 25 tumor-targeting proteins. Radiochemistry: Each study day, 2 proteins were radiolabeled by ^{99m}Tc tricarbonyl technology followed by iTLC+HPLC for QC. Imaging: Tumor tissue was inoculated into mice in staggered batches. For each radiotracer, 3 mice were injected iv (20 nmol/kg; 100 MBq) and imaged simultaneously (Bioscan NanoSPECT/CT): whole-body SPECT scans at 1h, 4h, 24h (and 48h in pre-selected compounds) post-injection. For 10 preselected compounds, dynamic SPECT was done at 0-2 h p.i. Whole-body CT scans accompanied SPECT scans giving 291 scans in total. Reconstructed SPECT and CT images were split into single animals and analysed in VivoQuant (inviCRO). All data were stored on an iPACS study management system. Absolute radiotracer uptake in Bq was measured in tumor, skeletal muscle, heart, blood (left ventricle), liver and kidneys by manual and semi-automated segmentation. %ID, %ID/mL, SUV and %ID/mL ratio data were automatically generated and plots of all study data created by a Matlab script. QC images were generated automatically and inspected to verify injection quality, ROI placements and intersubject reproducibility. Ex vivo: Animals were dissected after imaging, tissue weights automatically stored into a spreadsheet, and this imported automatically into Matlab together with gamma counts (LKB-Wallac) to calculate and plot absolute radiotracer uptake in Bq, %ID, %ID/g, SUV and %ID/g ratios via Matlab script. QC included outlier detection. Results: A total of 507 single animal SPECT images were acquired for the 25 proteins in 5 weeks. Labeling quality was excellent and consistent for all compounds (radiochemical purity=(98.0±1.6)%). The analysis workflow was applied within hours to every incoming dataset and an updated set of plots generated comprising finally >3500 ROI and >1000 tissue data. SPECT/CT images clearly visualized uptake in tissues such as tumor (except controls), kidneys and liver, even at 48 h p.i. Tumor uptake was 0.5 to 13 %ID/mL. Intersubject variability for any compound was typically 10% COV. Conclusion: The large data set of tumor, blood, background and systemic uptake/clearance data from 75 mice and for 25 compounds allowed identification and ranking of lead compounds, with all experiments and analysis taking 3 months. QC results and a high level of automation throughout provide confidence in the data set. For even larger compound libraries, radiolabeling could be expedited and the number of imaging time points reduced to increase weekly throughput.

Relationship Between 18F-FDG PET/CT Diagnostic Accuracy And Stimulated Thyroglobulin Levels In High/Intermediate Risk Differentiated Thyroid Carcinoma

E. TRIVIÑO-IBÁÑEZ[1,2], M. MUROS[1], E. TORRES-VELA[1], N. TESTART[1], A. GONZÁLEZ-JIMÉNEZ[1], R. SÁNCHEZ-SÁNCHEZ[1], M. BERMÚDEZ-MORALES[1], J. LLAMAS-ELVIRA[1]; [1]Complejo Hospitalario Universitario de Granada, Granada, SPAIN, [2]IBS, Granada, SPAIN.

INTRODUCTION: Multiple studies in the literature have analyzed the relationship between thyroglobulin (Tg) plasma levels and diagnostic accuracy of 18F-FDG PET/CT in the context of patients with TENIS Syndrome (elevated thyroglobulin and negative 131I-whole body scan). However, there is very little data available on the influence of Tg levels in the early evaluation with 18F-FDG PET/CT of patients with intermediate-high risk differentiated thyroid carcinoma (DTC) recurrence. PATIENTS and METHODS: A prospective study was carried out (June 2007 to December 2013) on 81 patients with high/intermediate risk of recurrence DTC, treated with surgery and radioiodine ablation (RIA). Our patient selection was not based exclusively on TNM classification and included broad risk criteria (ATA guidelines 2015, etc.), such as locoregional invasion, inadequate high Tg value and aggressive histological subtypes. We performed 18F-FDG-PET/CT just before or immediately after radioiodine ablation. We confirmed 18F-FDG- PET/CT results with other imaging techniques, pathology reports, first year whole body scans, neck ultrasounds or follow-up. RESULTS: 81 patients with high/intermediate-risk of recurrent DTC. Forty-one (50.6%) had positive uptake in 18F-FDG PET/CT, with negative 131I WBS. Sensitivity, specificity and diagnostic accuracy of PET/CT were 92.5%, 90.2% and 91.4% respectively. Considering Tg stimulated levels at the time of the ablative therapy with 131I, we observed a progressive increase in sensitivity and positive predictive value (PPV) of 18F- FDG PET/CT study. So with levels of Tg≤10 ng/mL the sensitivity was 92.8% and PPV 80%, with Tg>10 and ≤ 100 ng/mL sensitivity was 100% and PPV 80%, whereas above 100ng /mL both parameters values reach 100%. For ROC curves analysis, false positive and false negative cases of 18F-FDG PET/CT were excluded. The cutoff value of stimulated thyroglobulin at the time of ablation that showed a better relationship sensitivity/specificity was 9.3ng/ml, discriminated correctly to 83 % of patients with a sensitivity of 70.3% and a specificity of 86.1%.CONCLUSIONS: The diagnostic accuracy of 18F-FDG PET/CT in high/intermediate-risk of recurrent DTC is positively related with stimulated thyroglobulin levels. The cutoff value of stimulated thyroglobulin with best sensitivity/specificity relationship is 9.3ng/ml.

EPW38

Could Disappearance of Anti-thyroglobulin Antibody Predict Disease Persistence in Differentiated Thyroid Carcinoma Patients With Positive Anti-thyroglobulin Level After Total Thyroidectomy And Radioiodine Ablation

P. Lee[1], Y. Huang[1], S. Lee[2], L. Juan[2], Y. Hsu[2]; [1]Department of Nuclear Medicine, Koo Foundation Sun-Yat Sen Cancer Center, Taipei, TAIWAN, [2]Department of Internal Medicine, Koo Foundation Sun-Yat Sen Cancer Center, Taipei, TAIWAN.

Background: Serum thyroglobulin (Tg) serves as an important marker in monitoring patients with differentiated thyroid cancer treatment. However, serum Tg measurement may be interfered by the presence of anti-Tg antibodies (TgAb), thus limiting the usefulness of Tg in surveillance of patients with positive TgAb. Recent articles demonstrated that TgAb may be used as a surrogate marker of disease persistence or response to treatment. The aim of this study was to evaluate if the disappearance of serum TgAb after ablation could predict disease persistence

in patients with differentiated thyroid carcinoma after thyroidectomy and radioiodine ablation. *Materials and Methods:* A retrospective review was performed on differentiated thyroid carcinoma patients who underwent total thyroidectomy and radioiodine ablation from 2006 till 2013, and were positive for TgAb before ablation. The change of serum TgAb before ablation (TgAb1) and after ablation (TgAb2), tumor pathologic status, patients' sex and age were all recorded. TgAb was considered positive or negative on the basis of specific assay cutoff values at our hospital. All of these parameters were correlated with disease persistence at 10-20 months after ablation. Disease persistence was defined as appearance of disease by diagnostic radioiodine scan, neck sonogram or stimulated Tg level of >1ng/ml. *Results*: A total of 53 patients with positive TgAb1 were included in this study. At 10-20 months after radioiodine ablation, 36 patients (67.9%) had persistent disease. TgAb2 was positive in 34 patients (64.2%) while TgAb2 declined to negative in 19 patients (35.8%). Of these 19 patients with negative TgAb2, disease persistence was still noted in 11 patients (57.9%). In the positive TgAb2 group, disease persistence was noted in 25 of 34 patients (73.5%). There was no statistical difference between TgAb2 negative and TgAb2 positive group (p=0.242). However, younger patients had a higher risk of persistent disease as compared to elder patients (mean age 40.3y/o vs 49.1y/o, p=0.014). Other parameters, such as sex, tumor number, extra-thyroidal extension, lymphovascular invasion, margin involvement, and lymph node involvement were non-predictive of persistent disease. *Conclusion*: Our results indicated that disappearance of serum TgAb2 at 10-20 months after ablation could not predict disease persistence in differentiated thyroid carcinoma patients after total thyroidectomy and radioiodine ablation. However, younger patients were more likely to have a higher rate of persistent disease.

EPW39

Investigation of the effect of BRAF^{V600E} mutation on the clinical outcome in the group of patients with papillary thyroid carcinoma

M. Hartmanova[1], K. Taborska, P. Sykorova, T. Kracmerova, P. Vlcek, S. Dvorakova[2], V. Sykorova[2]; [1]University Motol Hospital, Prague, CZECH REPUBLIC, [2]Department of Molecular Endocrinology, Institute of Endocrinology, Prague, CZECH REPUBLIC.

This pilot study included 50 patients with papillary thyroid carcinoma (PTC) after total thyreoidectomy or operation for relapse of the disease between 11/2006-1/2011. Parts of the frozen thyroid tissue were examined for the presence of BRAF^{V600E} mutation. All patients have been followed-up annually. In 2016, after receiving the results of the genetic screening, we were able to assess the clinical outcome both in patients with positive and with negative BRAF ^{V600E} mutation findings. **Aim and methods**: The research was focused on the evaluation of the amount of remission or recidive of the PTC in both groups on the basis of: clinical examination, cervical ultrasonography, suppressed and stimulated level of thyreoglobulin, presence of Tg antibodies and diagnostic or post-therapeutic whole-body 131I scintigraphy. Patients were considered to have complete remission if the clinical examination and ultrasonography were negative and suppressed level of hs (high sensitive) Tg was <0,2ug/l or the level of stimulated hsTg <2ug/l. **Methods**: We divided the patients into two groups according to the presence or absence of BRAF^{V600E} mutation and into groups considering their age(<45 years and older) and clinical stage. Then in each group of patients we assessed the number of iodine ^{131}I administration and number of patients in remission or with persistent disease. **Results**: In the BRAF positive group (together 18 patients), there were one patient in the stage I and 2 patients in higher clinical stages, who have persistent disease inspite of repetitive radioiodine treatment. In the BRAF negative group (together 32 patients) all patients who were in stage I, even if they were treated repetitively, all reached complete remission. Only one out of 6 patients of higher clinical stage did not reach remission. Alhough there were more patients of higher clinical stage in the BRAF negative group, the number of recidives was lower than in the BRAF positive group, where the majority of patients in higher clinical stage did not reach remission. Together, there were 33% BRAF^{V600E} positive and 77% BRAF^{V600E} negative patients in the group younger than 45 years. In the patients of the age 45 and older there were 41% BRAF^{V600E} positive and 59% BRAF negative. **Conclusion**: In conformity with previous published studies we demonstrated that the presence of BRAF^{V600E} somatic mutation is more common in elderly patients and is connected with more significant radioiodine resistance and higher risk of relapse of the PTC.

EPW40

Second Primary Cancer Risk Estimates in Differentiated Thyroid Carcinoma Patients Treated with Radioiodine

N. L. Correa[1], L. V. de Sá[2]; [1]Instituto Estadual de Diabetes e Endocrinologia, Rio de Janeiro, BRAZIL, [2]Instituto de Radioproteção e Dosimetria - CNEN, Rio de Janeiro, BRAZIL.

Introduction: An increase in the incidence of second primary cancers (SPC) is the most feared late effect that can occur in differentiated thyroid carcinoma (DTC) patients treated with radioactive iodine (RAI). The decision to treat a patient with RAI should therefore incorporate a careful risk-benefit analysis. The objective of this work is to adapt the risk estimation models developed by the Biological Effects of Ionizing Radiation Committee (BEIR VII) to local epidemiological characteristics to access the carcinogenesis risk from radiation in a population of Brazilian DTC patients treated with RAI. Absorbed radiation doses in critical organs were also estimated to determine whether they exceeded the respective thresholds for deterministic effects. **Material and Methods**: 416 DTC patients treated with RAI were retrospectively studied. Four organs were selected for absorbed dose estimation and subsequent calculation of carcinogenic risk: kidney, stomach, salivary glands and bone marrow. Absorbed doses were calculated by dose factors (absorbed dose per unit activity administered) previously established based on standard human models. The lifetime attributable risk (LAR) of incidence of cancer as a function of age, gender, and organ specific dose was estimated according to BEIR VII mathematical models, relating it to the activity of RAI administered in the initial treatment. **Results**: The salivary glands received the greatest absorbed doses of radiation (1,567 ± 0,431 Gy), followed by the stomach (1,022 ± 0,738 Gy), kidney (0,315 ± 0,089 Gy) and bone marrow (0,184 ± 0,050 Gy). None of these, however, surpassed the threshold for significant deterministic effects for a single administration of RAI. The LAR for stomach cancer incidence was by far the highest, followed in descending order by the salivary glands, leukemia and kidney cancer. The LAR for stomach cancer and leukemia incidence after RAI demonstrates a substantial reduction of risk for lower activities administered, especially in younger patients. **Conclusion**: RAI in single administration is extremely safe in terms of deterministic effects, because even high administered activities do not result in absorbed doses that exceed the thresholds for significant tissue reactions. The BEIR VII mathematical models allow a feasible quantification of SPC risk, demonstrating a marked decrease in risk for younger patients with the administration of lower RAI activities and suggest that only the smallest effective activities should be administered in low-risk DTC patients.

EPW41

Association Between 18F-FDG PET/CT and Thyroglobulin Doubling-Time in Differentiated Thyroid Carcinoma

G. Costa[1], P. Lapa[1], H. Martins[1], A. Albuquerque[1], J. Pedroso de Lima[1,2]; [1]Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL.

Aim: Serum thyroglobulin doubling-time (Tg-Dt) and 18F-2-fluoro-2-deoxy-D-glucose (18F-FDG) PET/CT were recently proposed as important additional prognostic tools in differentiated thyroid carcinoma (DTC). Faster Tg-Dt and higher 18F-FDG uptake are associated with shorter survivor rates.We aimed to evaluate the relationship between Tg-Dt and the 18F-FDG PECT/CT results. **Material and methods**: We review 64 PET/CT scans with 18F-FDG, performed in DTC patients (55 female, 9 male; 57.1±12.7 years). All patients were previously submitted to surgery and, at least, one course of radioiodine therapy. Indications for 18F-FDG PET/CT were elevated thyroglobulin (Tg) level in combination with negative 131I whole-body scintigraphy (WBS), unfavourable tumour histology or known distant metastases by any imaging modality. For Tg-Dt calculation, we collected 2 or 3 consecutive Tg measurements (always under suppressed TSH), taken before 18F-FDG PET/CT. Excluding the administration of levothyroxine, no thyroid carcinoma specific therapeutic procedure was done during that time. Tg-Dt was calculated by exponential curve fitting to the available data using nonlinear regression and the results were categorized in 3 groups: fast (Tg-Dt<1 year); slow (1<Tg-Dt<3 years); very-slow (Tg-Dt>3 years or negative value).18F-FDG PET/CT were classified as true-positive (TP), true-negative (TN), false-positive (FP) and false-negative (FN) according to the histologic or clinical follow-up. PET/CT results were also analysed, based on the Tg-Dt. **Results**: Thirty two 18F-FDG-PET scans were classified as positive and 32 as negative. Of these, 31 were TP and 18 TN (sensibility=69%; specificity=95%; accuracy=76%). Regarding Tg-Dt, we found 26 patients (40.6%) with a fast, 7 (10.9%) with slow and 31 (48.4%) with very-slow Tg-Dt. Most of the TP cases had a fast Tg-Dt (n=21; 67.7%) and most of the TN scan had a very-slow Tg-Dt (n=15; 83.3%). **Conclusion**: Our study shows a clear association between 18F-FDG results and Tg-Dt, suggesting that glycolytic metabolism is also linked to the Tg production rate.

EPW42

68Ga-DOTA-TATE PET-CT in differentiated thyroid cancer patients: comparison with 18F-FDG PET-CT

B. Vatankulu, B. Akovalı, S. Sağer, M. Halaç, L. Kabasakal, K. Sönmezoğlu; İstanbul University Cerrahpaşa Medical Faculty, İstanbul, TURKEY.

Aim: We aimed to investigate the role of Ga-68 PET/CT in the patients with differentiated thyroid cancers (DTC) who had negative iodine- 131 (I-131) scan and elevated thyroglobulin (Tg) level and also to compare with FDG PET/CT. **Materials and method:** A total of 32 patients with DTC diagnosis who had negative I-131 scan and increased Tg level during follow-up were included in this study. All patients underwent both Ga-68 and FDG PET/CT imaging. The mean interval between the two scans was 14±3 days. PET/CT images were analyzed on a lesion-by-lesion, location-by-location and on a patient-by-patient basis. All lesions detected by PET/CT were divided into 4 groups as local, nodal, pulmonary or skeletal lesion. Final diagnosis was made by histopathological results, serial Tg measurement and clinical/radiological follow-up (at least 6 months). **Results:** While Ga-68 DOTA-TATE PET/CT detected recurrent/metastatic lesion in the 67% (21/32) of the patients, FDG PET/CT demonstrated in the 74% (23/32) of the patients. There was no statistically significant difference in the diagnostic ability between the two methods (p= 0,248). According to patient based analysis, the sensitivity and specificity was found to be 72,4% and 100% for Ga-68 PET/CT and 89% and 91% for FDG PET/CT. A total of 92 lesions were found by both imaging methods. Sixty-four of these were shown by Ga-68 PET/CT and 79 of the 92 lesions were detected by FDG PET/CT. Both methods were concordant in 60/92 lesions. There was high consistency in the detection of nodal metastasis between the 2 test (κ=0.89). On the other hand, it's lower for the pulmonary and skeletal lesions (κ=0.65). Ga-68 PET/CT changed therapy management in 21/32 patients while FDG PET/CT changed management in 18/32 patients. **Conclusion:** We found that Ga-68 and FDG PET/CT had similar accuracy in the detection of DTC recurrence/metastasis according to patient based analysis. However, lesion based analysis showed that FDG PET/CT detected more lesion than Ga-68 study. Ga-68 PET/CT is a proper imaging technique for selecting DTC patients who are candidates for peptide receptor radionuclide therapy.

EPW43

Peptide receptor radionuclide therapy in non-neuroendocrine tumours - a field report

B. Nilica; Universitätsklinik für Nuklearmedizin Innsbruck, Innsbruck, AUSTRIA.

Purpose: To present observed impact of Peptide receptor radionuclide therapy (PRRT) in non-neuroendocrine tumours (non-NET) showing overexpression of somatostatin receptors (SSTR). *Methods:* On database research we found 50 patients who underwent PRRT with a progressive, histologically proven tumour other than NET but still SSTR-positive in 68Ga-DOTA-TOC PET which had no other convincing conservative option for treatment left. *Results:* All 50 patients showed tumour-progression and after evaluation with 68Ga-DOTA-TOC PET for SSTR-positive lesions were treated with PRRT. The main proportion were thyroid cancer (total 29, initially differentiated 17, medullary thyroid cancer 7, poorly differentiated / anaplastic 5) followed by paraganglioma (7), neuroblastoma (3), medulloblastoma (2), phaeochromocytoma, breast cancer, meningioma, merkel-cell carcinoma, mesothelioma, prostate cancer of possible neuroendocrine origin, sarcoma, thymoma, urothelial cell carcinoma (each 1). 43 Patients received one substance (e.g. 177Lu-DOTA-TATE) only, 7 patients two different treatment substances (e.g. 177Lu-DOTA-TATE or 90Y-DOTA-TOC). Of those 7, 5 patients were switched to another substance after fulfilling one full course of treatment (4 applications). Two patients switched due to problems of availability. The number of single applications ranged from 1 up to 16 treatments (median 3.5, mean 3.9), cumulative doses ranged inpatient from 759 MBq to 63190 MBq (median 14.6 GBq, mean 17.0 GBq), the age at first application from 3 to 87 years. The time between first and last application (40 patients more than one treatment) was up to 107 months in one case, median 6.5, mean 13.1, standard deviation 20.0. Taken together 31 patients were on treatment for 0.5 years (60%), 8 for one year, 5 for 2, 4 for 3.5 years and one for 5.4 and another one for 9 years. *Conclusion:* Patients with SSTR-positive progressive non-NETs with no or little conservative therapeutic options (side effects, contraindications) may benefit from PRRT. 40% of the patients treated by PRRT with SSTR-positive non-NETs were on treatment-course for more than 6 months with little side effects and remarking good quality of life in a palliative setting, suggesting that PRRT may offer a possible therapeutic option for these patients.

EPW44

^{177}Lu-DOTA-TATE therapy in patients with NETs: Response to treatment and long-term survival update

E. Demirci[1], O. Erdem Şahin[2], M. Ocak[3], A. Aygün[2], I. Uslu[2], L. Kabasakal[2]; [1]Department of Nuclear Medicine, Sisli Etfal Training and Research Hospital, istanbul, TURKEY, [2]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, istanbul, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University,, istanbul, TURKEY.

Aim: We report the long-term survival results of patients with metastatic neuroendocrine tumors who were treated with ^{177}Lu-DOTA-TATE. Additionally, our secondary aim was to evaluate prognostic indicators. **Materials and Methods:** 234 patients with metastatic or inoperable well differentiated NETs who underwent ^{177}Lu-DOTA-TATE treatment during period of 2010-2015 included in this retrospective study. Response to

treatment evaluated according to RECIST criteria. Progression-free survival (PFS) and overall survival (OS) rates were calculated. **Result:** Patients were treated with an average 5.04 administrations and 4.45 ±0,9 GBq of ^{177}Lu-DOTA-TATE. All patients had diagnosis of NET with primary localization of pancreas (n=90), non-pancreatic GEP-NET (n=45), lung (n=34), paraganglioma-pheochromocytoma (n=18) and other sites (n=12). In 34 patients primary tumor could not be identified. In 135 (57.9%) patients Grade 1 or 2 hematologic toxicity occurred after 36.5% and 52.9% of first cycle and second cycle (salvage) of treatment, respectively. Grade 3 hematologic toxicity occurred 0.6% and 1.2% after first and second cycles, respectively. Among 183 patients who had completed first cycle of treatment, 63 (27%) patients had progression, 37 (15.9%) patients had stable disease, 77 (33%) patients had partial response and 6 patients (2.6%) had complete response. Median overall survival rate was calculated 35 months (95% CI: 28,4- 41,5) and 54.7 months (95%CI:51,7-58,1) for all patients and for patients who had treated with at least 3 administration of ^{177}Lu-DOTA-TATE, respectively. Grade I NETs had a median survival of 51.3 months (%95 CI:44,9-57,7), grade II NETs had a median survival of 34.4 months (95% CI:28,3-40,5) and grade III NETs had a median survival of 16.6 months (95% CI: 4,2-29). Overall survival rates according to primary site was 48.5 months for pancreas, 56.1 months for non-pancreatic GEP-NETs, 38.8 months for paraganglioma-pheochromocytoma, 43.5 months for lung and 38.4 months for unknown primary and 19.8 months for other sites. Patients who had bone metastasis had lower OS and PFS than those who did not (OS: 40.4 vs 54; p<0,005). Patients who had stable disease or partial response after first cycle of treatment had a comparable survival rates with no statistically significant difference (OS: 57.7 vs 55.6; p>0,05). However, patients who had progressive disease had significantly lower OS rates of 24.6 months with %95CI of 8.3- 21.5 (p<0.001). **Conclusion:** Treatment with multiple cycles of ^{177}Lu-DOTA-TATE PRRT is safe and effective for patients with metastatic NETs. Response to treatment, progression free and overall survival rates compare favorably to the limited number of alternative treatments.

EPW45

Measurement of kidney absorbed dose using ^{177}Lu-DOTATATE in paediatric neuroblastoma

M. Aldridge[1], J. Gains[2], A. Smith[1], J. Bomanji[1], M. Gaze[2]; [1]Institute of Nuclear Medicine, UCLH, London, UNITED KINGDOM, [2]Radiotherapy, UCLH, London, UNITED KINGDOM.

Introduction Neuroblastoma has been shown to express somatostatin receptor subtype 2 (sstr-2) as demonstrated by ^{68}Ga-DOTATATE imaging. Peptide receptor radionuclide therapy (PRRT) with ^{177}Lu-DOTATATE is therefore an option for therapy. However, avoidance of renal toxicity is essential for safety and a dose constraint is set at 23Gy for the kidneys. **Aims** In this study we calculate kidney absorbed dose for each fraction of treatment and cumulative dose to ensure safe tolerability of treatment. **Methods** Children with relapsed or refractory high-risk neuroblastoma were assessed for suitability for in-patient PRRT with ^{177}Lu-DOTATATE as assessed by ^{68}Ga-DOTATATE PET/CT. The intention was to administer 4 fractions of treatment. The administered activity of the first fraction of ^{177}Lu DOTATATE is weight-based (75MBq/Kg). Activity for subsequent administrations at 8 to 12 week intervals depends on the whole-body radiation dose received and the haematological and renal toxicity from previous administrations. Administered activity was escalated to 100MBq/Kg if whole body dose was <0.5Gy with minimal haematological and renal toxicity. Whole-body dose was determined by ceiling-mounted scintillation probe monitoring, performed regularly by carers over 4 days; and planar imaging, performed using a GE D670 gamma-camera at 6 time points with whole body and SPECT/CT imaging for critical organ dosimetry. **Results** 15 patients have been treated, with 36 fractions administered. Mean age was 6.2 years (range 1 - 16 yrs). 7 patients received 4 fractions of treatment, 1 patient received 2 fractions of treatment and 7 patients received a single fraction. Patients who received a single fraction of treatment were contraindicated for additional fractions due to disease progression and not toxicity. All patients receiving more than one fraction were escalated to 100MBq/Kg. 14/15 patients had imaging data appropriate for accurate dosimetry calculations. Mean whole body absorbed dose was 0.28Gy/fraction (range 0.19 - 0.38). Mean kidney dose was 4.02Gy/fraction (range 1.5 - 6.7). For those seven patients completing 4 fractions of treatments, mean cumulative kidney dose was 16.7Gy (range 12.0 - 22.6). Monitoring of GFR during and after treatment demonstrated no renal toxicity, although long-term data is yet to be obtained. **Conclusions** Treatment was well tolerated. No children exhibited renal toxicity and therefore PRRT in children with neuroblastoma is a safe therapeutic technique. As the cumulative kidney dose ranged from <50% to <100% of the kidney dose constraint of 23Gy, it is possible that personalised dose escalation based on the actual renal dose received might lead to better oncological outcomes.

EPW46

Can PET/CT 68Ga-DOTA-peptides uptake predict the absorbed dose in peptide receptor radionuclide therapy (PRRT)?

A. Filice[1], F. Fioroni[2], E. Grassi[2], A. Tartaglione[1], A. Fraternali[1], M. Asti[1], C. Carnaghi[3], N. Fazio[4], A. Frasoldati[5], A. Versari[1]; [1]Nuclear Medicine Unit IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [2]Medical Physics Unit, IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [3]Medical Oncology Unit Humanitas Cancer Center, Milano, ITALY, [4]Unit of Gastrointestinal Medical Oncology and Neuroendocrine Tumors, European Institute of Oncology, Milano, ITALY, [5]Endocrinology Unit IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY.

Purpose: it is well known that dosimetry was until now focused to normal organs in order to limit side effects while the absorbed dose-tumor response relationship has not been settled. However, knowledge about this relationship it'is becoming crucial for a better understanding of PRRT. The purpose of this work is to demonstrate whether is possible to predict absorbed dose on the basis of PET/CT 68Ga-DOTATOC uptake. **Methods**: in our center a prospective PRRT clinical trial is ongoing. The dosimetric evaluation is performed at the first cycle of treatment. From 03/2014 to 11/2014, the first 20 consecutive patients were enrolled. We evaluated 50 lesions in the first 20 patients: liver (38), lymph node (7), and bone (5) and assessed the relationship between the PET/CT 68Ga-DOTATOC baseline uptake, in terms of SUV max, and the absorbed dose (Gy) at the end of the treatment. **Results**: in our experience highest SUV max doesn't match always with highest absorbed dose. In a high number of lesions in the liver the absorbed dose is greater than SUV max, while in the lymph node and bone lesions SUV max is often greater than absorbed dose, perhaps because the kinetics in this tissues is more rapid than in the hepatic lesions. The mean values for absorbed dose (Gy) and SUV max in all lesions were respectively 132 (range 1-522) and 36 (range 6-89). If we consider the lesions according to the different localization, the mean absorbed dose values (Gy) are: liver 179 (range 24-522), lymph node 54 (range 4-270) and bone 38 (range 1-116).Mean SUV max values are respectively: liver 36 (range 8-89), lymph node 34 (range 10-89) and bone 37 (range 6-47). The mean kidney biological effective dose value (BED) was 26 Gy (range 11-48) and the tumour-to-kidney dose ratio was 5 (range 1-15). **Conclusion**: there is little attention to the relationship between uptake at PET/CT 68Ga-DOTATOC baseline and absorbed dose but this is a very important aspect in PRRT because probably a better understanding of this relationship could give us the elements to be able to predict the therapeutic response. In our experience in a high number of liver lesions the absorbed dose is greater than SUV max while in the other tissues the data are more inhomogeneous. The kinetics of the radiopharmaceutical is important because the behavior is different in various tissues depending on many factors. More studies are needed to confirm these data.

Effective radiation dose estimate in volunteers recruited for renal transplant

I. Maamoun[1], **M. Khalil**[2]; [1]Intensive Care Unit (ICU), Faulty of Medicine, Cairo University Hospitals, Cairo, EGYPT, [2]Department of Physics (Medical Biophysics), Faculty of Science, Helwan University, Cairo, EGYPT.

Aim: One of the categories that receive little attention in estimating radiation doses are kidney donor volunteers. They need comprehensive diagnostic examinations before clinical decision is made. Among those diagnostic testing are renal scintigraphy, CT renal angiography, and x-ray imaging. The aim of this work was to elaborate on the average effective dose received by this particular subjects group. **Methods**: Twenty patients (12 M and 8 F) who were considered potential kidney donors were retrospectively analyzed. All patients had undergone renal scan using Tc-99m labelled DTPA, CT renal angiography and planar x-ray imaging. DTPA scintigraphy was performed using an average dose of 3.1±0.7 mCi. Scan parameters were 180 frames, 10 sec/frame and Lasix was co-injected with the tracer. The CT renal angiography protocol consisted of five phases namely non contrast phase, arterial phase, cortico-medullary phase, nephrographic phase and excretory phase. CT dose index (CTDIvol) and dose length product (DLP) were obtained from the scanning protocol performed for each patient. The scan length was determined using a scout image covering 400mm±10mm in the abdominal and pelvis regions. CT scan was performed using 16 CT scanner, helical pitch of 24, detector collimation of 1.0 mmx16, slice thickness of 1.0mm and 0.75 sec/rotation. The average mAs was 16386.8±3140.7 and the average total scan time was 83.8±17.0 sec. Contrast agent was injected before the arterial phase within 15-20 sec using 100-120ml of 350 mg/ml iodine solution. Planar x-ray image was taken at the end of the CT scan using 100-160 mAs at 70-80 kV tube voltage. All data were tabulated, descriptively summarized in terms mean±SD and statistically analysed. **Results**. On average, the effective dose measured due to renal scintigraphy was 0.53±0.03mSv. However, a significant increase in effective dose calculations was revealed from CT angiography. The average CTDIvol was 203.7 ±32.5 mGy and DLP calculations were 3268.3±604.3 Gy.cm These measures resulted in a significantly higher effective dose of 49.0±9.0 mSv. Effective dose due to x-ray planar imaging was on average 0.7±0.2 mSv. **Conclusion**: Volunteer subjects who are recruited for donating kidneys are receiving a considerably high radiation effective dose. CT angiography is the potential player in this scenario and substantial efforts should be made toward dose reduction in clinical routine. Follow up of this patient category using nuclear or radiological imaging modalities would cause an incremental radiation burden. This will be further investigated in future studies.

EPW48

Simulation of ^{90}Y microspheres in Selective Internal Radiation Therapy (SIRT) reveals different heterogeneity profiles for glass and resin microspheres

J. Hemmingsson[1], J. Högberg[2], J. Svensson[1], J. Mölne[1], M. Rizell[1], P. Bernhardt[1]; [1]The Sahlgrenska Academy at The University of Gothenburg, Gothenburg, SWEDEN, [2]Department of Medical Physics, Linköping University Hospital, Linköping, SWEDEN.

Aim: Selective internal radiation therapy (SIRT) can supply normal tissue in the liver with radiation doses exceeding tolerance without causing toxicity, an effect possibly explained by microsphere clustering causing heterogeneity in the distribution. Using a simulation of microspheres transported through a simplified arterial structure, the aim of this study has been to evaluate how the number of injected microspheres affect the dose distribution. Materials and methods: The simulation was based on observations in biopsies and autoradiographies from resected liver tissue receiving ^{90}Y-SIRT. Individual microspheres, with diameter and density from literature, were followed through a simplistic bifurcations model in which three parameters were introduced and optimised to obtain results consistent with observations: an artery coefficient of variation, a reduction parameter for the arterial diameter and a distribution volume parameter for the arterial tree. In the model the arterial diameter decreases for higher artery generations and the probability of microsphere clustering increases successively in the artery tree. After simulation a ^{90}Y dose kernel was applied to the 940 cm^3 sized 3D-matrix of microspheres and the dose distribution throughout the matrix was evaluated using varying resolutions and computing the coefficient of variation (CV). A smaller number of simulated microspheres (10^5) corresponds to the higher activity/sphere found in glass spheres while a larger number (10^7) resembles resin spheres. Results: As the number of microspheres increase from thousands to 10^6 the CV of the absorbed dose decrease from over 80 % to 32 % in a volume corresponding to a lobuli (2 mm^3) and at 10^6 microspheres a plateau was reached. The simulation was consistent with biopsy and autoradiography observations regarding the formation of clusters. A large majority of the clusters contain few microspheres and a minority of the clusters are significantly more numerous in microspheres. Conclusion: For the high microsphere concentrations used with resin microspheres the CV of the absorbed doses was constant (32 %) while for the lower microsphere concentrations used for glass spheres the CV varied between 90 % and 40 %. These results implies that small scale dosimetry for ^{90}Y-SIRT differs between resin and glass spheres.

EPW49

Improved dose-volume histograms for Y90-PET based dosimetry with partial volume effect and noise compensations by means of region sub-segmentation

M. Sanchez-Garcia[1], J. Strydhorst[2], H. Levillain[1], I. Gardin[3], P. Buyssens[3], T. Carlier[4], R. Lebtahi[1], I. Buvat[2], A. Dieudonné[1]; [1]Department of Nuclear Medicine, Beaujon University Hospital, HUPNVS, APHP, INSERM 1149, Clichy, FRANCE, [2]Imagerie Moléculaire In Vivo, IMIV, CEA, Inserm, CNRS, Univ. Paris-Sud, Université Paris Saclay, CEA-SHFJ, Orsay, FRANCE, [3]Department of Nuclear Medicine, Henri Becquerel Cancer Center and Rouen University Hospital, & QuantIF – LITIS [EA 4108], Rouen, FRANCE, [4]Department of Nuclear Medicine, University Hospital of Nantes, CRCNA-UMR 892 INSERM 6299 CNRS, Nantes, FRANCE.

Partial volume effects (PVE) and noise in ^{90}Y-PET images propagate in the absorbed dose calculation, producing biased dose-volume histograms (DVH). We propose a method to compensate for these effects. **Materials and methods**: The method consists in segmenting the region of interest (ROI) into sub-regions using super-voxels (SVs) defined by an eikonal region growing (ERG) (Buyssens P *et al*. Image Vision Comput 2014). The SVs are generated on an image filtered using a median filter and are assumed to contain a homogeneous activity distribution to remove the noise. The optimal number of SVs n_{opt}, is defined by the user. Geometric transfer matrix (GTM) inversion is then applied for PVE compensation. The absorbed dose computation is done on the corrected image. A realistic voxelized phantom was built using patient data. Lung and normal liver had uniform activity distribution. The liver lesion was divided into 4 sub regions, each with uniform activity. A 30-minute acquisition ($5.4x10^{12}$ decays) with a Biograph mCT (Siemens) scanner was simulated using GATE and reconstructed using Siemens software (VG50, 2 iterations, 21 subsets, PSF modelling, TOF). Two median filters were tested: 2x2x2 (med2) and 3x3x3 (med3). For each, the calculation was performed with n_{opt}, the optimal number of SVs, n_{opt}*-1* and n_{opt}*+1*. The resolution used for PVE compensation was a 3 mm FWHM. Theoretical, uncorrected and corrected DVHs were compared in terms of doses covering 5%, 20%, 50%, 80% and 95% of the lesion volume (D5, D20, D50, D80 and D95

respectively). **Results and discussion**: The uncorrected DVH deviated from the theoretical for D5, D20, D50, D80 and D95 by 15.2%, -7.5%, 7.1%, -20.7% and -38.1% respectively. With med2, n_{opt}=5. Using 4 SVs did not improve DVH estimates. Using 5 or 6 SVs resulted in a similar improvement with 5.7%, 0.4%, -6.7%, 9.1% and -10.2% errors. With med3 filter, n_{opt}=4. Using 3 SVs did not improve DVH estimates. For 4 and 5 SVs the results were improved similarly with 5.8%, 2.1%, -8.3%, -9.2% and -10.5% errors. These results show that the pre-filtering did not matter much when using the optimal number of SVs. Yet, for a given filter, the accuracy of the dose estimates depended on the number of SVs. **Conclusion**: We propose an approach to improve the DVH estimates in ^{90}Y-PET dosimetry, based on ROI segmentation using super-voxels and region-based PVE compensation.

EPW50

DNA Damage in Blood Lymphocytes after Personalised Peptide Receptor Radionuclide Therapy with High Activities

U. Eberlein[1], R. A. Werner[1], C. Lapa[1], C. Bluemel[1], M. Peper[2], A. K. Buck[1], H. Scherthan[2], M. Lassmann[1]; [1]University of Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology, Munich, GERMANY.

Objectives: Radiation-induced DNA double strand breaks (DSBs) cause, in their vicinity, the phosphorylation of the histone H2AX (then called γ-H2AX) and the accumulation of the 53BP1 protein that binds to and signals damaged chromatin at a DSB site. This leads to the formation of microscopically visible nuclear foci containing both markers, which thus mark radiation-induced DSBs. The aim of the study is to analyse the dose- and time-dependency of the DNA damage in blood lymphocytes in patients after a personalised high-activity ^{177}Lu-DOTATATE treatment. **Methods:** We investigated multiple blood samples of three patients up to 96h after peptide receptor radionuclide therapy (activity range: 14.4GBq-19.3GBq). The average frequencies of radiation-induced foci (RIF) containing both γ-H2AX and 53BP1 fluorescence were determined in the nuclei of two-colour immunostained γ-H2AX/53BP1 lymphocytes isolated from peripheral blood samples of patients before and after therapy. The foci containing both DSB markers were scored manually in a fluorescence microscope equipped with a red/green double-band-pass filter by an experienced observer. The individual background focus rate was determined in a sample taken prior to therapy. The results were compared to a previous patient study (Eberlein et al, EJNMMI 2015) and an in-vitro calibration curve (Eberlein et al, PlosOne 2015). **Results:** Blood samples of 3 patients receiving a personalised high activity therapy were evaluated for γ-H2AX and 53BP1. Compared to the standard therapy (7.7GBq) the absorbed dose to the blood after 48 h is higher (mean: 186mGy vs. 78mGy). In the first four hours after administration of the radiopharmaceutical there is a strong increase of the number of RIF/cell; the RIF/cell values are in accordance to the in-vitro calibration. The maximum foci numbers range from 0.8 RIF/cell to 1.1 RIF/cell. At t=4h the mean standard therapy RIF/cell values normalised to the blood dose (0.019 RIF/cell/mGy) are higher than those of the high-activity patients (0.012 RIF/cell/mGy). 72 hours after application the patient who received the highest activity and the highest absorbed dose to the blood still shows increased levels of RIF/cell. For the two other patients the foci levels decrease similarly compared to the patients receiving a standard therapy (7.7GBq). **Conclusions:** This study provides a first RIF/cell analysis of Lu-DOTATATE patients receiving higher activities compared to the standard Lu-DOTATATE therapy. With the exception of the data of one patient at a late time-point the results are in accordance with our previous results.

EPW51

Effect of activity heterogeneity on the absorbed doses from Y-90 therapies

A. Divoli, J. Gear, I. Murray, G. Flux; Royal Marsden Foundation Trust, Sutton, UNITED KINGDOM.

Aim: Heterogeneous uptake is often observed in tumours treated with Y-90 therapies. A common uptake pattern observed in both PRRT and SIRT administrations is a ring of uptake, surrounding an inner section without activity. Generally, absorbed doses are calculated based on S-factors provided by OLINDA for spheres of various sizes. The aim of this work was to use Monte Carlo simulations to calculate the S-factors and the corresponding absorbed doses of typical heterogeneous tumours and to compare the results with those calculated when heterogeneity is ignored. **Material and methods:** Spherical "shell" lesions were simulated using two concentric spheres. Input files for the MCNPX2.5.0 Monte Carlo code were created with spherical lesions 40 and 50 mm in diameter with inner spheres of 20, 25, 30 and 40mm and lesion densities of 1.05g/cm^3. The spectrum of Y-90 with all emissions was incorporated into the code as given by MIRD. Lesion geometries were voxelised into 0.5 mm bins and energy depositions at each voxel were recorded enabling the production of dose maps, dose volume histograms and segment specific S-factors. Typical cumulated activity values from patient data were used to translate the results into absorbed doses. **Results:** S-factors were generated for active areas of the lesion, non-active and for the whole lesion. As the percentage of non-active to active tumour increased a decrease in segment S-factor was observed. This decrease resulted in an increasing difference (10 - 50%) from the uniform model S-factors given by Olinda for the equivalent volume. This difference can be attributed to the deviation of the shell segment from a spherical shape and more absorbed dose being deposited outside the active segment. The observed cross irradiation from the active outer shell to the cold inner was not insignificant (up to 85%) and varied according to the size of the inner region; the smaller the inner region the larger the cross dose. It is therefore important to determine if the dose to the lesion as a whole or just to the active part is to be reported. **Discussion**: The heterogeneity of lesion uptake can cause errors in absorbed dose of up to 50% if not correctly accounted for. Further work is planned to study segmental S values under a larger variety of geometries aiming to provide S-factor values for these structures.

EPW52

A successful Y-90-microspheres radioembolization of the spleen in a case of primary myelofibrosis splenomegaly

A. Fernandes[1], A. Oliveira[1], N. Silva[2], J. Pereira[1], P. Morgado[3]; [1]Nuclear Medicine Department - Hospital de São João, Porto, PORTUGAL, [2]Radiology Department - Hospital de São João, Porto, PORTUGAL, [3]Interventional Radiology Department - Hospital de São João, Porto, PORTUGAL.

Introduction: Primary myelofibrosis (PMF) is a rare clonal disorder originated from the neoplastic transformation of early hematopoietic stem cells (50 to 60% of the patients presenting the JAK2 V617F mutation). Common clinical manifestations include splenomegaly, severe anaemia and cytopenias. Radioembolization with Y-90-microspheres of liver tumours (primary or metastatic), via the hepatic arterial route, is a safe, effective, established treatment, based on the fact that hepatic tumours typically have arterial vascularization (whilst normal hepatic parenchyma depends on portal irrigation). Due to its good results and low toxicity, this approach is rapidly expanding throughout the Nuclear Medicine and the Interventional Radiology communities, with different applications being sought after - treatments directed at the spleen, lungs and kidneys have been published. There is no ideal option for treating severe, symptomatic splenomegaly. The decision to use Radioembolization in this case was to provide an option with less associated morbidity and mortality than the alternatives - splenectomy, JAK inhibitors and external radiation therapy. **Case report:** We report a successful case of radioembolization with Y-90-glass microspheres of the spleen, in a 63-year-old, Caucasian woman, with primary myelofibrosis (with the JAK2 V617F mutation). The patient was experiencing increasing abdominal discomfort and night sweats, associated with an enlarging splenomegaly (23 cm, cranio-caudal), as well as the need for repeated, but ineffective, platelet transfusions - at the time of

evaluation for radioembolization, her platelet counts were <10X10*9/L. The treatment was well tolerated, with no adverse events reported from radiation exposure. Follow-up, 16 weeks after the treatment, revealed a significant reduction of the spleen volume (43%), and its clinical effectiveness, with increasing platelet counts, without the need for further transfusions. **Conclusion:** We propose that, in carefully selected patients with primary myelofibrosis, radioembolization may be a viable alternative for the treatment of splenomegaly. The successful clinical and radiological responses suggest that achieving the necessary absorbed dose in the spleen is technically feasible and safe.

EPW53

Effect of image noise, respiratory motion, and motion compensation on quantitative accuracy of 90Y PET/CT based 3D absorbed doses following 90Y-microsphere therapy

W. Siman[1], O. Mawlawi[1], J. Mikell[1], F. Mourtada[2], **S. C. Kappadath**[1]; [1]UT MD Anderson Cancer Center, Houston, TX, UNITED STATES, [2]Christiana Care Health System, Newark, DE, UNITED STATES.

Aim: The liver is subject to motion due to respiration. Typical 90Y PET acquisitions 10-30 min/bed following SIRT introduce respiratory motion blur of in vivo 90Y activity concentration (AC); AC is proportional to absorbed dose. Our aim is to quantify the effects of image noise and motion blur on 90Y PET/CT 3D absorbed-dose distributions using AC volume histogram (ACVH) metrics; ACxx is the minimum AC that covers xx% of the tumor volume. We also investigated the efficacy of motion compensation using quiescent-period gating (QPG) as a function of tumor size and motion amplitude. **Materials and Methods**: An IEC phantom with SBR of 9.6 was prepared using 18F (0.8 kBq/mL background) to simulate clinical 90Y PET/CT (600 kBq/mL background) such that 47 s/bed with 18F corresponded to 30 min/bed with 90Y. List-mode PET data (GE D690) was acquired for 300 s/bed (high-count dataset) when the phantom was static and subject to periodic 1D-motion that simulated respiration with amplitudes of 1cm, 2cm, 4cm. PET emissions were binned into 6 independent datasets of shorter durations 47s-to-8s (100%-to-17%) to assess the effect of image noise on ACVH. PET acquisitions during motion was gated in real-time (RPM, Varian Medical System) and sorted into multiple phases to assess the effect of motion and QPG on ACVH. Images were reconstructed using 3D-OSEM with TOF and PSF corrections. **Results**: Decreased scan times increased the apparent non-uniformity of tumor doses by increasing the dispersion of ACVH metrics; these effects were severe for tumors <17mm. AC20-AC60 was less sensitive (errors <10%) to decreased scan times compared to AC80-AC90. ACmean errors were <10% when scan time reduction was >50% (>15 min/bed) for tumors >17mm. Respiratory motion decreased the observed AC and skewed ACVH distribution to lower values; with degree of severity that depended on motion amplitude and tumor diameter. AC20-AC80 for 37mm/17mm tumors decreased by -20%/-30% and -50%/-55% for motion amplitudes of 2cm and 4cm. QPG that used 40-50% of respiratory phase were effective for improving AC quantification; AC20-AC80 showed errors <20% for motion amplitudes <4cm. **Conclusion**: Biases and non-uniformities in absorbed dose estimates were introduced by 90Y PET image noise and respiratory motion; mean dose errors <10% were possible only for >15 min/bed and tumors >17mm; AC80-AC90 were more sensitive than AC30-AC70. QPG techniques using 40-50% of respiratory phase was successful at reducing errors. Research support: NIH/NCI R01 CA138986.

Optimizing Re-188 SPECT/CT: quantitative imaging for image-based dosimetry

P. L. Esquinas Fernandez[1], C. F. Uribe[2], J. Tanguay[1], M. Gonzalez[3], C. Rodríguez-Rodríguez[1], U. Häfeli[1], A. Celler[1]; [1]University of British Columbia, Vancouver, BC, CANADA, [2]British Columbia Cancer Research Centre, Vancouver, BC, CANADA, [3]Vancouver Coastal Health Authority, Vancouver, BC, CANADA.

AIM: ^{188}Re is a promising isotope for radionuclide therapies, including trans-arterial radioembolization (TARE). The accuracy of image-based dosimetry calculations for ^{188}Re therapies relies on the quantification of activity using SPECT/CT. Our aim was to 1) optimize collimator, energy-windows settings and quantitative ^{188}Re SPECT reconstruction, and 2) evaluate the accuracy of ^{188}Re image-based dosimetry estimates. The methodology developed in this study will be applied to dose calculations for 40 patients undergoing TARE with ^{188}Re. **MATERIALS AND METHODS:** Experiments were performed using SymbiaT (Siemens) SPECT/CT camera with Medium Energy (ME) and High Energy (HE) collimators. A thorax phantom (with lungs and spine) containing six spheres (2mL-20mL) and two bottles (34mL-196mL) filled with ^{188}Re (3.8 MBq/mL) was scanned with three configurations: (A) empty phantom, (B) filled with water and (C) filled with ^{188}Re solution with signal-to-background ratio ~7. Images were reconstructed using OSEM with attenuation, triple-energy window (TEW) scatter, and resolution recovery corrections. TEW was investigated using two sets of scatter windows. The sources were segmented using 1% threshold (air and water) and 40% threshold (hot-water). Quantification accuracy was evaluated by the percent difference between the reconstructed and the true activities for each source. Using these activities and CT-based volumes, the average absorbed dose-rates (AADR) for the spheres and bottles were estimated using OLINDA. Additionally, the voxelized S-Value (VSV) dose-map was calculated and AADR was estimated using again CT-based volumes. These AADR were compared to the "truth" calculated using the digital version of our phantom. **RESULTS:** The mean accuracy of activity quantification in A and B configurations was 7% (range 0.7%-12.5%) for both collimators. Images obtained with the ME collimator, however, had to be corrected for high dead-time. The 40% threshold resulted in underestimation of the true activity by >15% for both collimators. The use of wide scatter windows resulted in decreased accuracy (12% on average). For hot-water-scans, OLINDA and VSV underestimated the true dose by 27% and 19%, respectively. The results were comparable for both collimators. **CONCLUSIONS:** Our study demonstrates that ^{188}Re images reconstructed with corrections are quantitatively accurate (5.4% accuracy in total phantom activity). However, organ/tumour segmentation remains a challenge. Both 40% threshold (widely used in clinical studies) and the CT-based segmentation result in large activity underestimations. For ^{188}Re, the problem is exacerbated by poor resolution of ME or HE collimators. Since these inaccuracies strongly affect dose estimations, more research effort should be directed to accurate segmentation of nuclear medicine images.

EPW55

Comparison of Y90 and Ho166 3D-dosimetry for SIRT with collapsed cone superpostion

A. Dieudonné[1], M. Sanchez-Garcia[1], I. Gardin[2], A. Siebert[3], V. Vilgrain[3], R. Lebtahi[1]; [1]Department of Nuclear Medicine, Beaujon Hospital, HUPNVS, APHP, INSERM 1149, Clichy, FRANCE, [2]Department of Nuclear Medicine, Henri Becquerel Cancer Center and Rouen University, QuantIF – LITIS [EA 4108], Rouen, FRANCE, [3]Department of Radiology, Beaujon Hospital, HUPNVS, APHP, Clichy, FRANCE.

^{166}Ho has been proposed as an alternative to ^{90}Y for selective internal radiation therapy (SIRT). Both radionuclides disintegrate through a beta decay: ^{90}Y (E_{max}=2.28 MeV, Δ=933 keV/des, 64.1 h) and ^{166}Ho (E=1.87 MeV, Δ=665 keV/des, 26.8h). Additionally, ^{166}Ho has a photon emission (80.5 keV, 6.7%) allowing for imaging. This paper aims at comparing both radionuclides in term of dosimetry using a collapsed cone

superposition (CCS) algorithm. **Methods:** CCS takes into account tissue density heterogeneities by scaling linearly the energy deposition according to the radiological distance (Sanchez-Garcia *et al*., Phys Med Biol 2014, 2015). We compared ^{90}Y and ^{166}Ho dosimetry based on SPECT/CT data, acquired 30 min after injection of ^{99m}Tc-macroagregated-albumin, of a patient eligible for a SIRT. The VOIs were the normal liver, the lesion and the lung. All the calculations were done through the software tool VoxelDose. The absorbed dose coefficient, d in Gy.GBq^{-1}, was calculated at the voxel level. The comparison was done in terms of mean absorbed d_{mean} in each VOI, and dose-coefficient-volume histogram (dVH) indices d_{80}, d_{50}, and d_{20}, irradiating respectively 80, 50 and 20% of the VOI. Additionally, dVH indices were normalised by d_{mean}. **Results:** d_{mean} [Gy.GBq^{-1}] in the normal liver equals 5.1 for ^{90}Y and 1.6 for ^{166}Ho, while d_{80} and d_{50} [Gy.GBq^{-1}] equal 0 for both radionuclides and d_{20} respectively 4.5 and 1.4. In the lesion, d_{mean} equals 62 for ^{90}Y and 20 for ^{166}Ho, while d_{20}, d_{50} and d_{80}-values are equal respectively to 85, 53, 30 and 27, 17, 9.4 for ^{90}Y and ^{166}Ho. In the lung, d_{mean} equals 15 for ^{90}Y and 5.0 for ^{166}Ho, while d_{20}, d_{50} and d_{80}-values are equal respectively to 23, 14, 5.6 and 7.9, 4.4, 1.6 for ^{90}Y and ^{166}Ho. For dVH indices normalised to d_{mean}, results are in the same order of magnitude for both radionuclides, indeed for the lesion, d_{20}/d_{mean}, d_{50}/d_{mean} and d_{80}/d_{mean}-values equal respectively 1.4, 0.84, 0.49 for ^{90}Y and 1.4, 0.84 and 0.48 for ^{166}Ho. For the lung, the normalised indices equal 1.6, 0.92, 0.38 for ^{90}Y and 1.6, 0.90 and 0.32 for ^{166}Ho. **Conclusion:** This dosimetry comparison of ^{90}Y and ^{166}Ho using a collapsed cone superposition algorithm shows that the absorbed dose coefficient in Gy.GBq^{-1} is around 3 times greater for ^{90}Y than for ^{166}Ho, while normalised dVH indices show similar dose coverage for a given mean absorbed dose of each radionuclide.

EPW56

Monte Carlo calculated single-cell *S*-values using a stochastic atomic relaxation model for accurate nuclear data of Auger electron-emitting radionuclides

N. Falzone[1], B. Q. Lee[2], J. M. Fernández-Varea[3], A. E. Stuchbery[2], T. Kibedi[2], K. A. Vallis[1]; [1]University of Oxford, Oxford, UNITED KINGDOM, [2]Australian National University, Canberra, AUSTRALIA, [3]Universitat de Barcelona, Barcelona, SPAIN.

AIM: Auger electron- (AE) emitting radionuclides could be exploited for therapeutic purposes due to the high local energy deposition by low-energy Auger (and Coster-Kronig) electrons or may deliver an unintentional mean absorbed dose burden when used as medical imaging agents. The emission spectra of AE emitting radionuclides are essential for dosimetric calculations to quantify the biological damage to the target. The aim of this study is to compare single-cell *S*-values derived from the BrIccEmis radiation spectra of 14 AE emitting radionuclides to the corresponding MIRD data. **MATERIALS AND METHODS:** The radiation spectra of ^{67}Ga, ^{80m}Br, ^{89}Zr, ^{90}Nb, ^{99m}Tc, ^{111}In, ^{117m}Sn, ^{119}Sb, ^{123}I, ^{124}I, ^{125}I, ^{135}La, ^{195m}Pt and ^{201}Tl were taken from the unabridged nuclear decay data of the MIRD RADTABS program[2] and also generated using the BrIccEmis code, which implements a stochastic model for the atomic relaxation assuming either an isolated atom or condensed-phase approach. Dose-point kernels (DPKs) were calculated using event-by-event simulations with the general-purpose Monte Carlo (MC) code PENELOPE[3]. The simulated DPKs and appropriate geometric reduction factors were then employed to calculate cellular *S*-values. **RESULTS:** Auger yields from MIRD are consistently higher than those calculated with the BrIccEmis code. The methodology adopted by MIRD did not account for variations in orbital binding energies during atomic relaxation and thus overestimated the intensity of low-energy electrons. *S*-values from BrIccEmis relative to MIRD data are up to 18% and 10% smaller for isolated and condensed phase approximations, respectively. A decrease in *S*-values is prominent when the cell size is small and the source is assumed to be uniformly distributed in the cell nucleus, as the differences between MIRD and BrIccEmis data are most noticeable for electrons with energies below 2 keV. **CONCLUSION:** Overestimation in the total AE energy output by MIRD leads to higher predicted energy deposition by AE emitting radionuclides, especially in the immediate vicinity of the decaying radionuclides. However, the impact of different AE spectra becomes less noticeable at larger volumes (> 1 μm), and does not translate into significant differences in *S*-values. [1] Lee B et al. Comp Math Meth Med 2012; 651475. [2] Eckerman KF and Endo A, MIRD Radionuclide Data and Decay Schemes 2008. [3] Salvat F, Fernández-Varea JM, Sempau J, eds. PENELOPE-2011 OECD Nuclear Energy Agency.

Brain serotonergic and dopaminergic changes in a hot flash model with & without risperidone treatment

W. S. Huang[1], H. M. Wu[2], K. W. Chang[3], Y. Y. Kuo[4], C. Y. Shiue[5,6]; [1]Taipei Veterans General Hospital,Department of Nuclear Medicine, Taipei, TAIWAN, [2]Changhua Christian Hospital,Department of Neurology, Changhua, TAIWAN, [3]Institute of Nuclear Energy Research (INER), Taoyuan, TAIWAN, [4]National Defense Medical Center, Graduate Institute of Medical Sciences, Taipei, TAIWAN, [5]National Taiwan University Hospital, PET Center, Department of Nuclear Medicine, Taipei, TAIWAN, [6]National Taiwan University, Molecular Imaging Center, Taipei, TAIWAN.

Introduction: Hot flash remains a major problem worldwide affecting menopausal women that is thought to be related to central neurotransmitter derangement. This study observed brain serotonergic and dopaminergic changes in a hot flash model and its effects on risperidone, an antipsychotic medication using nuclear neuroimaging modalities. **Methods:** Home- made ^{18}F-Alterserin and ^{123}I-Epidepride were applied to evaluate functional changes of central 5-HT$_{2A}$ (HT$_{2A}$) and dopamine receptor-2 (D2). A hot flash rat model was created by ovariectomy (n=5) [Khajuria, 2012]. Sham operation group served as the controls (n=5). Imaging was performed using NanoPET(^{18}F-Altanserin, 37 MBq; dynamic for 60 min) or NanoSPECT (^{123}I-Epidepride, 185 MBq; 30-60 min post-injection) with or without risperidone pre-treatment (0.005mg/kg, 2 weeks prior to imaging). Rectal temperature (RT), uterine weight (UW), plasma estradiol (E2), and NO2/3 (NOx) were also measured. **Results:** Significant changes of RT, UW, E2 and NOx were found in the OVx group compared to the controls. The changes can be restored, at least in part with risperidone pre-treatment. The brain HT$_{2A}$ uptake was significantly decreased in OVX group compared to the controls and partially restored with risperidone treatment. No significant decrease of D2 uptake between OVX and control groups but significantly decreased D2 uptake was noted after risperidone treatment. **Conclusions:** The results provide insight into the interplay among menopausal hot flash, central neurotransmission and its therapeutic effect that could be reflected by nuclear receptor imaging modalities and served as a platform for drug screening. **Key Words:** Hot flush, ^{18}F-Altanserin, ^{123}I-Epidepride, 5-HT$_{2A}$ receptor, Dopamine-2 receptor.

EPW58

Evaluation of [^{18}F]BR420 and [^{18}F]BR351 as potential PET ligands for in vivo imaging of MMP-9 activity in an animal model of traumatic brain injury

S. Missault, **M. Chomet**, N. Vazquez, D. Thomae, S. Deleye, I. Blockx, P. Van Der Veken, A. Van Der Linden, L. wyffels, S. Staelens, S. Dedeurwaerdere; University of Antwerp, Wilrijk, BELGIUM.

Aim: Matrix metalloproteinase-9 (MMP-9), a zinc-dependent endopeptidase, is a modulator of the brain extracellular matrix. Increased expression and activity of MMP-9 has been reported after traumatic brain injury (TBI) and is associated with blood-brain barrier disruption and inflammation. Due to its involvement in synaptic plasticity, a role for MMP-9 in the development of posttraumatic epilepsy has been proposed. This study evaluated the potential of radiolabeled broad-spectrum MMP inhibitors [^{18}F]BR420 and [^{18}F]BR351 for *in vivo* visualisation of MMP-9 after TBI. **Methods:** Adolescent male Sprague-Dawley (SD) rats were subjected to either Controlled Cortical Impact (CCI) injury over the left parietal cortex (impact depth: 2.5mm, velocity: 4m/s, dwell time: 500ms; n=10) or sham injury (craniotomy only; n=10). Metabolite studies were performed for both [^{18}F]BR420 (IC_{50}= 7nM) and [^{18}F]BR351 (IC_{50}= 50nM) in healthy rats sacrificed at 5min and 1h post-intravenous (iv) tracer injection (35.2±0.3MBq; n=3/time point). Plasma and brain were analysed by reversed-phase HPLC and collected fractions were counted in an automated γ-counter. CCI and sham-operated rats were subjected to T_2-weighted MR imaging, followed by 60min dynamic PET-CT imaging at 7d post-injury. Rats were injected iv with either [^{18}F]BR420 (24.9±3.7MBq; n=7/group) or [^{18}F]BR351 (37.1±0.7MBq; n=3/group). After scanning, brains were resected, counted and processed for *ex vivo* autoradiography. Tracer uptake in different brain regions was quantified by region of interest (ROI) analysis using PMOD software and expressed as Standardised Uptake Values (SUV). **Results:** In plasma, [^{18}F]BR420 proved to be more stable than [^{18}F]BR351 (50.3±15.7% and 3.5±3.7% of intact tracer remaining 1h post injection (pi), respectively). However, both compounds presented a relatively fast metabolism in the brain with a polar brain penetrating metabolite (≥40%) already present for both tracers 5min pi. Furthermore, at 1h pi, only 11.4±0.3% and 6.1 ±4.1% of intact [^{18}F]BR420 and [^{18}F]BR351 were measured. However, due to low brain extraction yields (respectively 43% and 46%) those results might be misinterpreted. PET imaging revealed no difference in [^{18}F]BR420 or [^{18}F]BR351 uptake at the lesion site, in perilesional cortex, ipsilateral hippocampus, contralateral cortex and contralateral hippocampus between CCI- and sham-injured rats. Brain uptake was 0.069 ±0.012 %ID/g and 0.055±0.002 %ID/g for [^{18}F]BR420 and [^{18}F]BR351 respectively. *Ex vivo* autoradiography revealed a homogeneous tracer distribution throughout the brain. **Conclusion**: Studies are ongoing to confirm the increase of MMP-9 at this time point in our model. Due to the rather fast metabolism of these tracers, it seems unlikely that they will be suited for *in vivo* brain imaging of MMP-9.

EPW59

Preclinical validation of synthetic peptide p5 plus 14 as a multi-platform molecular imaging agent for systemic amyloidosis

S. J. Kennel[1], A. williams[1], E. B. Martin[1], T. Richey[1], A. Stuckey[1], S. Macy[1], X. Cheng[2], J. S. Wall[1]; [1]UT GSM, Knoxville, TN, UNITED STATES, [2]Oak Ridge National Laboratory, Oak Ridge, TN, UNITED STATES.

Background: Amyloid is comprised principally of protein fibrils and hypersulfated heparan sulfate proteoglycans. The fibrils can be of about 30 different proteins, but the most common are immunoglobulin light chain, transthyretin or serum amyloid protein. Systemic amyloid diseases are rare (~4,000 new cases per year in the US); thus, routine diagnosis is challenging resulting in delayed treatment and in high morbidity and mortality rates. At present, there are no routine clinical methods for imaging amyloid in these patients in the US. The glycosaminoglycans ubiquitously present in amyloid have a high degree of heparin-like hypersulfation. We have identified the heparin-reactive synthetic peptide, p5+14, as a potential amyloid-specific amyloid imaging agent. We present *in vivo* and *in vitro* preclinical data demonstrating the efficacy of ^{125}I- and ^{99m}Tc-labeled peptide p5+14 as an amyloid targeting agent. **Methods**: Peptide p5+14 was labeled with iodine-125 or biotin using standard procedures. Technetium-99m labeling was achieved by reduction with $SnCl_2$. The reactivity of ^{125}I- and ^{99m}Tc-p5+14 with amyloid was demonstrated in a pulldown assay. Binding to amyloid in formalin-fixed tissue sections was evidenced using biotinylated p5+14 or by addition of ^{125}I-p5+14 followed by microautoradiography. Specific co-localization of ^{125}I- and ^{99m}Tc-labeled peptide with amyloid *in vivo* was demonstrated in a mouse model of systemic inflammation-associated amyloidosis by using SPECT imaging and tissue radioactivity biodistribution. **Results**: Peptide p5+14 was shown by histochemistry and autoradiographic staining of patient tissue samples to react specifically with human amyloid deposits. In the solution phase pulldown assay, ^{125}I- and ^{99m}Tc-p5+14 bound synthetic fibrils, composed of distinct precursor proteins, as well as human amyloid extracts with high efficiency. Using small animal SPECT imaging, biodistribution measurements and microautoradiography we showed specific retention of radiolabeled peptide in amyloid affected organs, *in vivo*, as early as 1 h and as late as 72 h post-injection. Biodistribution data documented accumulation of ~10% injected dose per gram in the liver, spleen, and pancreas, sites of major amyloid deposition. In healthy, wild type mice the peptide was rapidly cleared via renal excretion with a whole body half-life of 1.5 h. Co-localization of the ^{125}I-labeled peptide with amyloid was documented using microautoradiography and Congo red staining. **Conclusion**: These studies demonstrate the reactivity of peptide p5+14 with numerous forms of human and murine amyloid. Given the specific localization of this radiotracer with visceral amyloid we have applied for support through the NHLBI/NIH to perform a first in man Phase 1 PET/CT imaging trial.

EPW60

Does early distribution of ^{18}F-FMISO reflect tumoral blood flow? Comparison study with quantitative ^{15}O-CO2 gas inhalation PET

T. Watabe, Y. Kanai, H. Ikeda, G. Horitsugi, K. Matsunaga, H. Kato, K. Isohashi, K. Abe, E. Shimosegawa, J. Hatazawa; Osaka University Graduate School Of Medicine, SUITA/OSAKA, JAPAN.

[Objectives] The relationship between perfusion and hypoxia in the tumor is controversial. Previous study reported flow limited delivery might affect the uptake of the hypoxic region. The purpose of this study was to evaluate the early distribution of ^{18}F-FMISO reflects the tumoral blood flow (TBF) and its relation to hypoxic region by comparing ^{18}F-FMISO and ^{15}O-gas PET. [Methods] Six male Fischer rats with subcutaneous xenograft of C6 glioma (body weight=220 ± 18 g) were investigated. Early distribution of ^{18}F-FMISO was evaluated by the 5min PET frame data after intravenous administration of ^{18}F-FMISO (67.5 ± 10.6 MBq) and hypoxic region was evaluated by late static images 3hrs post injection. The TBF was measured by quantitative steady state inhalation method of ^{15}O-CO_2 gas PET with arterial blood sampling. Multiple volumes of interest (2 mm diameter sphere) were placed on the co-registered ^{18}F-FMISO and TBF images. The correlation between early uptake of standardized uptake value of ^{18}F-FMISO (eFMISO-SUV) and TBF were compared by Spearman's test and cluster analysis, in which VOIs were classified by global or lesional threshold of each median value of eFMISO-SUV and TBF. In the group analysis, VOI values were divided into two subgroups of non-hypoxic region (less than 1.0 in late ^{18}F-FMISO SUV) and hypoxic region (more than 1.0), in which the threshold was defined based on the background muscle uptake. [Results] Total 12 tumor lesions were evaluated. Mean value of eFMISO-SUV and TBF were 1.22 ± 0.43 and 44.9 ± 27.5 (ml/100ml/min) in the non-hypoxic region, and 0.96 ± 0.27 and 31.5 ± 17.0 in the hypoxic region, respectively. There was a significant positive correlation between eFMISO-SUV and TBF ($r=0.552$, $p<0.01$) in the global analysis. In the lesional analysis, 9 of 12 lesions also showed a significant positive correlation ($r=0.50 \pm 0.12$, $p<0.01$). Cluster analysis revealed regions with high eFMISO-SUV and high TBF were dominant in the non-hypoxic region (53.4 ± 38.6% and 33.5 ± 12.2%) and regions with low eFMISO-SUV

and low TBF were dominant in the hypoxic region (35.9 ± 26.3% and 39.2 ± 8.4%) using global and lesional threshold, respectively. [Conclusions] This study demonstrated significant positive correlation between eFMISO-SUV and the TBF. Cluster analysis revealed regions with low TBF with low eFMISO-SUV were dominant in the hypoxic region, indicating negative correlation between hypoxia and perfusion. Early distribution of ^{18}F-FMISO reflects TBF in the C6 glioma, suggesting the feasibility of dynamic ^{18}F-FMISO PET for perfusion imaging.

EPW61

Evaluation of whole-body biodistribution of ^{89}Zr-labeled antibodies in cynomolgus macaque with PET

T. Sasaki[1], S. Kimura[2], A. Noda[2], Y. Murakami[2], F. Takenaka[1], S. Miyoshi[2], E. Matsuura[1]; [1]Okayama university, Okayama, JAPAN, [2]Astellas Pharma Inc, Tukuba, JAPAN.

OBJECTIVES: To develop therapeutic antibodies, a set of pre-clinical pharmacokinetic studies in non-human primates (NHPs) is required due to their difficulty for extrapolating ADME data with non-primates. In the present study, we aimed pharmacokinetic evaluations of ^{89}Zr-labeled human irreverent IgG and its metabolites, as with prior confirmed their non-specific/physiological accumulation in healthy NHPs. METHODS: Human IgG was conjugated to deferoxamine (DFO) and labeled with ^{89}Zr. The radiochemical purity was determined by size exclusion high performance liquid chromatography and thin-layer chromatography. Healthy cynomolgus macaques were injected with 9-16 MBq of ^{89}Zr-IgG; PET/CT images were acquired at 0, 1, 3, 6, and 10 days after the IgG injection and plasma was timely collected. We also analyzed with shortened antibody valiant, ^{89}Zr-Fab, in addition to ^{89}Zr-DFO and ^{89}Zr-oxalate as metabolites from ^{89}Zr-IgG. Regions of interest were drawn on organs, i.e., the heart, liver, spleen, kidneys, vertebral body, and muscles. RESULTS: The SUV in heart, vertebral body and muscle was decreased, depending on ^{89}Zr concentration in the circulation. Whereas the accumulation of radioactivity increased over time in kidneys and liver. Autoradiograph of renal sections indicated that most of radioactivity accumulated in the renal cortex. In addition, relatively high accumulation in kidney was also observed in ^{89}Zr-Fab injected macaques, and its renal autoradiograph showed the similar tendency to that of ^{89}Zr-IgG. Meanwhile, ^{89}Zr-DFO was rapidly excreted into urine, and ^{89}Zr-oxalate highly accumulated in epiphysis of long bone and vertebral body. Taken together, these data demonstrated that IgG itself and/or its metabolites physiologically accumulated in kidney and liver, although ^{89}Zr-DFO or ^{89}Zr metal did not accumulate in these organs. CONCLUSION: We demonstrated that the distribution kinetics of human IgG and its metabolites in NHPs. This preclinical pharmacokinetic study is of great significance for determining the basic distribution of ^{89}Zr-IgG using PET technique.

Imaging p53 in Pancreatic Ductal Adenocarcinoma (PDAC)

S. Koustoulidou, J. C. Knight, V. Kersemans, E. O'Neill, B. Cornelissen; Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.

Aim: Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal tumours in the UK with a five-year survival rate of merely 3%. PDAC is characterised by a complex mutational landscape with four genes being the most prevalent: KRAS, TP53, CDKN2A/p16, and SMAD4/DPC4. Mutations of the p53 tumour suppressor, described as the "guardian of the genome", appear at approximately 60% in the later stage PDAC development, which showed strong correlation with progression to invasive carcinoma characterised by severe dysplasia. The main treatment for PDAC remains, to date, surgical resection of the primary tumour. However, the outcomes remain poor, mainly due to the lack of diagnostic biomarkers for early detection, patient staging, prognosis, and therapy evaluation. Previously, we demonstrated non-invasive imaging of intranuclear targets [1], using radioimmunoconjugates coupled to cell penetrating peptides with nuclear localisation sequence. The aim of this study is to develop a p53 imaging biomarker suitable for diagnosis and patient stratification. **Materials and Methods**: Anti-p53 antibodies were evaluated *in vitro*, using a panel of cell lines derived from a genetically engineered mouse model of PDAC (KPC), with high levels of mutated p53, confirmed by western blot, flow cytometry and immunofluorescence assays. The mouse monoclonal p53 (IC12) antibody, which binds to all forms of p53, was chosen for further *in vivo* experiments. IC12 antibodies or non-specific mouse-IgG1 control antibodies were modified by the addition of pSCN-benzyl-DTPA to allow labelling with ^{111}In. The cell penetrating peptide TAT was then conjugated to the antibody to enable nuclear translocation. After *in vitro* testing, the compounds were intravenously administered to mice bearing subcutaneous allografts of the KPC-derived B8484 cell line. SPECT/CT imaging was performed 24, 48, and 72 h post injection. **Results**: *In vitro* assays confirmed the specificity of the selected antibodies. Radiolabelling yields of ^{111}In-DTPA-p53 (IC12)-TAT and the isotype control ^{111}In-DTPA-mIgG1-TAT were determined as >99% by iTLC. *Ex vivo* biodistribution analysis, performed after the last scan, revealed significantly higher radioactivity uptake in p53-expressing tumours of ^{111}In-DTPA-p53 (IC12)-TAT (7.1 ± 3.0 %ID/g) over ^{111}In-DTPA-mIgG1-TAT controls (4.9 ± 1.4 %ID/g; $p < 0.05$), confirming the ability to image p53 *in vivo*. **Conclusions**: Our findings establish the proof of principle for a non-invasive p53-expression imaging method for tumours. Even though further research is needed, this method could have major significance for cancer patient management. 1. Cornelissen, B. *et. al* (2011) Imaging DNA damage in vivo using gammaH2AX-targeted immunoconjugates, *Cancer research,* Vol. 71: 4539-49.

EPW63

Imaging of pancreatic tumours in mice using radiolabelled anti-Claudin4 antibodies

M. Mosley, J. C. Knight, S. Koustoulidou, B. Cornelissen; Oxford University, Oxford, UNITED KINGDOM.

Aim: Survival rates for pancreatic cancer patients, especially pancreatic ductal adenocarcinoma (PDAC) are particularly low, in large part because of late diagnosis and consequently untreatable metastatic disease. Identification of specific pancreatic tumour markers and the development of appropriate imaging tools provide hope for ameliorating the survival of these patients via early diagnosis and treatment. Claudin4 is increasingly expressed during early during tumour formation in PDAC, the most common type of pancreatic cancer (1). The aim of this study was to use an ^{111}In-labelled anti-Claudin4 antibody for SPECT imaging of a mouse model of pancreatic cancer. **Materials and Methods:** Claudin4-expressing PANC-1 cells (human PDAC), and Claudin4-negative HT1080 cells (human fibrosarcoma) were grown as subcutaneous xenografts in Balb/c nu/nu mice. A mouse monoclonal antibody recognizing an external epitope of human Claudin-4 (clone MAB4219) was conjugated to p-SCN-Bn-DTPA prior to labelling with ^{111}Indium (In). An isotype-matched mouse IgG (mIgG) was treated similarly and used as a negative control. Imaging agents (5 μg, 5 MBq) were injected intravenously and mice were imaged using SPECT/CT at 24, 48 and 72 hours post injection. After imaging, mice were sacrificed and selected tissues were removed, and the amount of ^{111}In in each tissue was measured using an automated gamma counter. Uptake was expressed as the percentage injected dose per gram of tissue (%ID/g). The xenograft tissue was then cryo-sectioned and its radio-label count monitored by autoradiography. **Results:** SPECT imaging of mice bearing Claudin4-positive PANC-1 xenografts showed high uptake in the xenograft after administration of ^{111}In-anti-Claudin4 (14.3±2.6 %ID/g at 72 h post injection), compared to ^{111}In-mIgG (6.3

±0.8 %ID/g; p<0.01) or Claudin4-negative HT1080 xenografts (4.3±3.0 %ID/g; p=0.001). The PANC-1 xenograft sections from mice injected with ^{111}In-anti-Claudin4 antibody showed strong signal using autoradiography, whereas xenografts removed from mice injected with control ^{111}In-mIgG did not. In a separate study, using a genetically engineered KPC mouse (a mouse model of KRAS- and p53-mutation induced PDAC), SPECT/CT imaging after administration of ^{111}In-anti-Claudin4 antibody also showed high uptake in the tumour, whose location was confirmed by FDG-PET/MRI. **Conclusions:** This study shows the potential use of ^{111}In-anti-Claudin4 antibodies as an imaging tool for the timely diagnosis of pancreatic cancer. **1.** Mosley M, Knight J, Neesse A, et al. Claudin-4 SPECT Imaging Allows Detection of Aplastic Lesions in a Mouse Model of Breast Cancer. *J Nucl Med.* 2015;56:745-751.

EPW64

PET/MRI imaging of Aminopeptidase N (APN/CD13) expression of experimental hepatocellular carcinoma using ^{68}Ga-NOTA-c(NGR)

A. Kis[1], K. N. Enyedi[2], A. Farkas[3], G. Nagy[4], I. Garai[1,4], P. Kertai[5], G. Mező[2], I. Kertész[1], **G. Trencsényi**[1,4]; [1]University of Debrecen, Department of Nuclear Medicine, Debrecen, HUNGARY, [2]MTA-ELTE, Research Group of Peptide Chemistry, Budapest, HUNGARY, [3]University of Debrecen, Department of Urology, Debrecen, HUNGARY, [4]Scanomed Ltd., Debrecen, HUNGARY, [5]University of Debrecen, Department of Preventive Medicine, Debrecen, HUNGARY.

Purpose: Aminopeptidase N (APN/CD13) plays an important role in neoangiogenic process. Our previous studies have already shown that ^{68}Ga-labeled asparagine-glycine-arginine (NGR) peptides specifically bind to APN/CD13 expressing mesoblastic nephroma (Ne/De) tumors in rats. The aim of this study was to investigate the APN/CD13 specificity of ^{68}Ga-NOTA-c(NGR) in chemically induced hepatocellular carcinoma (He/De) tumor models. Methods: c[KNGRE]-NH2 peptide analogue was labeled with Ga-68-NOTA. He/De hepatocellular carcinoma cells were used for the induction of heterotopic transplanted (subcutaneously and under the left kidney capsule) tumor models in Fischer-344 rats (n=10). Ex vivo biodistribution studies and whole body PET/MRI (nanoScan PET/MRI, Mediso Ltd, Hungary) scans were performed 90 min after intravenous injection of 6.9±0.2 MBq ^{68}Ga-NOTA-c(NGR) and two weeks after tumor cell implantation. The imaging of neoangiogenetic process with ^{68}Ga-NOTA-c(NGR) was compared with $\alpha_v\beta_3$ integrin selective ^{68}Ga-NODAGA-[c(RGD)]$_2$ tracer. Aminopeptidase N receptor expression of primary He/De tumors was verified by western blot analysis. Results: ^{68}Ga-NOTA-c(NGR) was produced with high specific activity (5.52±0.55 GBq/μmol) and radiochemical purity (95%<). Biodistribution studies with ^{68}Ga-NOTA-c(NGR) showed lower uptake in abdominal organs than using ^{68}Ga-NODAGA-[c(RGD)]$_2$. After the quantitative analysis of PET/MRI images we found that ^{68}Ga-NOTA-c(NGR) accumulation in He/De tumors (SUVmean: 1.8±0.2, Tumor/Muscle ratio: 13.43±2.1) was significantly ($p\leq$0,05) higher than the ^{68}Ga-NODAGA-[c(RGD)]$_2$ accumulation (SUVmean: 0.7±0.2, Tumor/Muscle ratio: 5.52±0.47) in the same tumor. Conclusions: In our preclinical studies ^{68}Ga-NOTA-c(NGR) showed specific binding to the APN/CD13 positive He/De tumors. Therefore, ^{68}Ga-NOTA-c(NGR) is a suitable tracer for the detection of APN/CD13 positive hepatocellular carcinoma tumors in vivo. This project was supported by the János Bolyai Research Scholarship of the Hungarian Academy of Sciences.

EPW65

Imaging EGFR In Head and Neck Cancer: Useful Prognostic and Treatment Monitoring Tool?

T. A. Burley, C. D. Martins, C. Da Pieve, L. Allott, R. Smith, D. M. Ciobota, G. Smith, K. Harrington, G. Kramer-Marek; Institute of Cancer Research, London, UNITED KINGDOM.

Aims: The human epidermal growth factor receptor 1 (HER1/EGFR) is targeted by a growing number of inhibitors. However, these drugs have shown limited success in the clinic so far, most likely due to the lack of a reliable method for patient stratification. Information about the potential biomarker status is routinely obtained *ex vivo* from biopsy specimens. However, receptor expression may be heterogeneous within and between tumours in the same patient. Therefore, an EGFR-targeted imaging biomarker could become an important tool measuring the receptor expression *in vivo* across the entire disease burden and help monitor receptor changes in response to treatment intervention. **Materials and Methods:** The ^{89}Zr was conjugated to the $Z_{EGFR:03115}$Affibody using the chelator desferrioxamine (DFO). The specificity of the radiotracer *in vivo* was investigated in mice bearing subcutaneous HNSCC and breast cancer tumours with varying EGFR expression CAL27(+++), DT562(++) and MCF7(+). Mice were injected with 100μl (1.3-3.6MBq, 1-2μg) of ^{89}Zr-$Z_{EGFR:03115}$Affibody and spiked with unlabelled Affibody. Biodistribution was undertaken 3, 24 and 48hr post tracer administration, the radioactivity within the organs was measured using a γ-counter. The *in vivo* imaging profile of the optimum dose of ^{89}Zr-$Z_{EGFR:03115}$Affibody was evaluated by PET at 3, 24 and 48hr post tracer injection. The EGFR expression and distribution of the tracer was assessed *ex vivo* by immunohistochemistry (IHC), Western blot and autoradiography. The tumour heterogeneity was further explored using texture analysis. To downregulate the EGFR level, treatment with AUY922 was performed on CAL27 and DT562 cells *in vitro* and changes in receptor expression were monitored by FACS analysis using an Affibody conjugate. **Results:** *In vivo* studies demonstrated that the radiotracer can distinguish between the xenograft models with varying EGFR expression (CAL27 3.88 ±0.18%ID/g, DT562 2.42±0.13%ID/g and MCF7 1.67±0.15%ID/g) already 3hr post injection. Tracer was eliminated quickly from the blood and normal tissues, allowing high contrast images to be acquired (24hr T:B=2.5; T:M=16.0, 48hr T:B=9.34; T:M=13.56). A strong correlation was observed between PET analysis, *ex vivo* estimates of tracer concentration and the receptor expression in the tumour tissues. Additionally, texture analysis, which consisted of extracting first, second and higher order statistics of segmented tumours, allowed differentiation of tumours with varying receptor expression. Receptor downregulation due to AUY922 treatment was confirmed by lower Affibody conjugate binding. **Conclusion**: ^{89}Zr-$Z_{EGFR03115}$Affibody can assess different levels of EGFR expression *in vivo* and has the potential to be used to stratify patients for treatment.

EPW66

Cardiac metabolic changes during doxorubicin treatment in mice

B. F. Bulten[1,2], M. Sollini[3], R. Boni[4], K. Massri[4], L. de Geus-Oei[5], H. W. M. van Laarhoven[6], R. H. J. A. Slart[7], P. A. Erba[8]; [1]Queen Beatrix Hospital, Winterswijk, NETHERLANDS, [2]Department of Biomedical and Photonic Imaging, University of Twente, Enschede, NETHERLANDS, [3]Humanitas University, Milan, ITALY, [4]Department of Translational Research and New Technology, University of Pisa, Pisa, ITALY, [5]Department of Radiology, Leiden University Medical Centre, Leiden, NETHERLANDS, [6]Department of Medical Oncology, Amsterdam Medical Centre, Amsterdam, NETHERLANDS, [7]Department of Nuclear Medicine and Molecular Imaging, University Medical Centre Groningen, Groningen, NETHERLANDS, [8]Department of Translational Research and New Technology, University of Pisa, Pisa, NETHERLANDS.

Background: Although doxorubicin is a potent antineoplastic agent, it possesses distinct cardiotoxic attributes, of which the underlying pathologic mechanisms are not fully unraveled. It is important to elucidate the complex pathophysiology on a molecular level to allow early detection of cardiotoxicity and selection of prophylactic treatment strategies. Methods: The cardiac distribution of ^{99m}Tc-sestamibi, ^{99m}Tc-Annexin V, ^{99m}Tc-glucaric acid and ^{18}F-FDG was evaluated using a gammacounter

at baseline and after one, two, three or four cycles of 15 mg/kg DOX in healthy male BALB/c mice and controls. In addition, cardiac expression of nonimaging markers (Bcl-2, Caspase-3 and -8, TUNEL, HIF-1α, p53) was assessed by Western Blot or immunohistochemy and mitochondrial membrane potential was measured. Results: A total of 200 mice (100 treated, 100 controls) was evaluated. All radiopharmaceuticals showed a significantly increased uptake compared to controls, with peak cardiac uptake after one (^{99m}Tc-Annexin V), two (^{99m}Tc-sestamibi), three (^{18}F-FDG) or four (^{99m}Tc-glucaric acid) cycles of DOX. Strong correlations (p <0.01) were observed between ^{99m}Tc-Annexin V, Caspase 3 and 8 and TUNEL and between ^{18}F-FDG and p53 and HIF-1α. Conclusions: A significantly increased uptake all radiopharmaceuticals compared to controls was observed, depicting the metabolic changes following DOX exposure. The peak of apoptosis, represented by ^{99m}Tc-Annexin V, Caspase 3, Caspase 8 and TUNEL occurred at low levels of anthracycline exposure, as well as ^{18}F-FDG uptake corresponding with HIF-1α expression, suggesting an adaptive response after low levels anthracycline exposure. The upregulation of Bcl-2 is underlined as a potential target for prophylactic therapy in AIC.

Clinical significance of focal parotid lesions incidentally identified on FDG PET/CT studies- what should we do?

K. Nakatani[1], K. Kitaguchi[2], K. Yoshino[1], T. Koyama[1]; [1]Kurashiki Central Hospital, Kurashiki, Okayama, JAPAN, [2]Kobe City Medical Center General Hospital, Kobe, Hyogo, JAPAN.

AIM: Incidental parotid lesions with significant focal uptake are often experienced in patients undergoing whole-body FDG PET/CT studies. However, their appropriate clinical decisions remain unclear, as they usually do not undergo histological confirmation of these lesions. The aim of this retrospective study was to find out the role of FDG PET/CT in the management of such incidental parotid lesions by investigating the outcome. PATIENTS AND METHODS: Our daily clinical reports between May 2012 and April 2015 were retrospectively reviewed, and a total of 232 patients were identified who had incidental focal FDG uptake in the parotid glands on the PET/CT scans. Exclusion criteria were those who underwent the scans for the work-up examination of known head and neck tumors, lymphoma, hematological malignancies, and systemic diseases that affect the salivary glands (e.g. Sjögren syndrome, IgG4-related disease), since parotid lesions in those patients should not be considered as true 'incidental' finding, and those whose follow-up period was less than one year. The confirmed diagnosis was made by histopathology or by the results of follow-up examination after one year or more. RESULTS: 60 patients (average age: 71 ± 9.6, male/female = 51/9) were enrolled as study population. Among 21 patients who underwent biopsy or surgical excision for the parotid lesions, 19 had benign results (14 with Warthin's tumor, 3 with pleomorphic adenoma, one with schwannoma, and one with intraglandular lymphadenopathy) and 2 patients had malignant parotid tumors, both of which are parotid gland metastasis (one from male breast cancer and one from esophageal cancer) with concurrent extensive visceral involvement. The remaining 39 patients had the follow-up examination, and none of the scan showed enlargement of the lesions; three of the lesions showed spontaneous regression, and the remaining 36 showed no significant change. Tumor SUVmax was 6.6 and 3.4 for the malignant cases and 1.5-26.9 (average 6.8 ± 4.5) for the benign cases. There was no case identified with primary parotid cancer in this study. CONCLUSIONS: Except for the cases with extensive visceral tumor involvement, it seems that the majority of parotid lesions incidentally identified on FDG PET/CT scans are benign, regardless of the intensity of uptake. Follow-up observations are usually considered to be sufficient in these cases as far as the patients do not have any specific symptoms.

EPW68

Lesion analysis in PERCIST: Are we doing it right?

A. BHOIL[1], B. Mittal[2], N. Singh[2]; [1]Regional Cancer Centre, Shimla, INDIA, [2]Postgraduate Institute of Medical Education and Research, Chandigarh, INDIA.

Objective: The standardized uptake value (SUV) is the most frequently used semi quantitative PET imaging parameter for response evaluation but this approach predicts metabolic activity only of single lesion. Newer response evaluation parameters a) Tumor Lesion Glycolysis (TLG) incorporating metabolic aggression and lesion volume b) Whole Body Metabolic tumor burden (MTB_{WB}) have been recently explored for response in various tumors. An effort to evaluate and compare response with different semi quantitative parameters as SUV_{peak} and TLG in single lesion, multiple lesions and total metabolic tumor burden (MTB_{WB}) in advanced NSCLC patients was made and association with the OS and PFS was analysed **Method**: Prospective serial 18F-FDG-PET /CT imaging was performed in twenty three patients (M=14, F=9, mean age=57.6 year) with Stage IIIB-IV advanced NSCLC before start of therapy, at 21 days (early) and at 42 days (late) after oral EGFR TKI treatment for response evaluation. The quantitative PET parameters as standard uptake lean body mass SUL_{peak}, SUV_{peak} , and TLG were measured in the single hottest lesion, multiple lesion (max of five) lesion and metabolic tumor burden whole body (MTB_{wb}). The TLG was calculated by fixed automated threshold while metabolic tumor volume (MTV) was calculated by automated summing of the lesions glycolysis. The SUV_{peak}, TLG and metabolic tumor burden whole body MTB_{WB} for response was compared for early response (21 days) and for late response (42 days). The overall survival and progression free survival were analyzed with Kaplan Meier analysis and log rank test. **Result:** No change in patients' response was seen when evaluated with single hottest lesion, multiple lesions and the whole body tumor load in form of summed tumor lesion glycolysis. Change in response between disease control and no disease control was seen between early imaging (21 days) (DC- 22, NDC-1) and late imaging (42 days) (DC-20, NDC-3) which remained unchanged when the lesion was measured in the terms of hottest lesion, five hottest lesion or the whole body tumor load. The overall survival (OS) in the early imaging was statistically significant (p= 0.049) compared to the late imaging (p=0.115). **Conclusion:** Single hottest lesion shows similar disease response classification and overall survival compared to the five hottest lesions and whole body tumor burden (WB_{MTB}). Late imaging offered no significant advantage compared to that of early imaging in disease response evaluation. Thus early response evaluation with single hottest lesion with SUV_{peak} should be considered in clinical work setting.

EPW69

Adrenal mass in cancer patients: Comparison of total lesion glycolysis and conventional PET/CT parameters in differentiating between benign and malignant lesions

S. GUNGOR[1], F. DEDE[2], O. KUPIK[3], M. ARPA[4], A. H. AKTAN[5], S. ASA[3], E. OZER[6]; [1]Istanbul Medeniyet University Faculty of Medicine, Department of Nuclear Medicine, ISTANBUL, TURKEY, [2]Marmara University Faculty of Medicine, Department of Nuclear Medicine, ISTANBUL, TURKEY, [3]Recep Tayyip Erdogan University Training and Research Hospital, Department of Nuclear Medicine, RIZE, TURKEY, [4]Recep Tayyip Erdogan University Training and Research Hospital, Department of Biochemistry, RIZE, TURKEY, [5]Recep Tayyip Erdogan University Training and Research Hospital, Department of Internal Medicine, RIZE, TURKEY, [6]Recep Tayyip Erdogan University Training and Research Hospital, Department of General Surgery, RIZE, TURKEY.

Objective: Benign adrenal lesions frequently encountered in oncologic imaging make difficulties in the diagnosis of metastatic disease. F18 FDG PET/CT is becoming widely used for differentiating benign from malignant adrenal masses. The purpose of this study was to determine the diagnostic performance of total lesion *glycolysis (TLG)* measured by PET/CT for characterizing adrenal masses in patients with cancer compared with conventional PET/CT parameters. Methods: A total of 48 adrenal masses in 48 patients with cancer (35 men; mean [± SD] age, 64.94 ± 10.5 years, and 13 women; mean [± SD] age, 66.38 ± 16.5 years) were retrospectively evaluated with FDG PET/CT. Diagnosis of adrenal malignant lesions was based on interval growth or reduction after chemotherapy. An adrenal mass that remained unchanged for over 1 year was the standard used to diagnose adrenal benign lesions. Metabolic (SUVmax, SUVmean, and tumor/liver SUVmax ratio), morphologic (size, Hounsfield Units (HU), and CT volume), and metabolovolumetric (total lesion glycolysis (TLG): SUVmean x metabolic tumor volume) parameters were calculated for each adrenal lesion. PET/CT parameters were assessed by using *Student t-test* and receiving operating characteristic (ROC) analysis. Results: There was a statistically significant difference between benign and malignant lesions for PET/CT parameters. All malignant lesions demonstrated FDG activity higher than liver. Among the PET/CT parameters, SUVmax, SUVmean, and tumor/liver SUVmax ratio revealed the best result in distinguishing benign and malignant lesions. The cut-off score, sensitivity, and specificity for the PET/CT parameters were presented in Table 1. Conclusion: We found that metabolic parameters showed the best result in distinguishing in benign and malignant adrenal lesions. However; TLG proposed as a new parameter in the literature did not reach the expected performance due to the negative impact of malignat but small and benign but large lesions on metabolovolumetric index. **Table 1**: The cut-off score, sensitivity, and specificity for the PET/CT parameters

EPW70

DOTATOC uptake in typical vertebral hemangiomas

N. Testart[1,2,3], M. Gauthé[1], F. Montravers[1], V. Nataf[1], J. Talbot[1]; [1]Hôpital Tenon AP-HP et Université P& Marie Curie, Paris, FRANCE, [2]Complejo Hospitalario Universitario de Granada, Granada, SPAIN, [3]IBS, Granada, SPAIN.

Bone hemangiomas are frequent benign vascular tumors, usually asymptomatic and most frequently localized in the spine. There are few documented case reports describing an increased uptake of ^{68}Ga labeled peptides (DOTA-TATE) PET/CT in bone hemangiomas. The **aim** of our study is to evaluate the DOTATOC uptake in typical vertebral bone hemangiomas, derived from a large series. PATIENTS AND METHODS We retrospectively reviewed all 68Ga-DOTATOC PET/CTs of a prospective cohort of patients who were referred to our department because of a neuroendocrine tumor. A masked image analysis of all CT scans was firstly performed independently by 2 nuclear medicine physicians in order to select patients with typical vertebral hemangioma pattern on CT i.e. "Polka Dot" appearance. The PET studies of those selected patients were secondarily analyzed, to measure SUVmax of the lesions and compare them to a healthy vertebra. A 1 cm diameter region of interest (ROI) in the liver right lobe was manually drawn to calculate the SUmax ratios lesion/liver and healthy vertebra /liver. Ccomparison of the SUVmax values and SUVmax ratios were performed by paired Student's t-test. RESULTS From the 536 patients who benefited from a DOTATOC PET/CT in our centre between February 2010 and March 2016, 16 (9 males and 7 females; mean age: 57 years [range: 29-72]) had a typical hemangioma in the spine (3% prevalence in our series). Two patients had 2 lesions. In a per lesion analysis (18 lesions), all hemangiomas had an increased uptake (mean SUVmax: 2.7 [95%CI 2.0; 3.6]; ratio: 0.36 [95%CI 0.26-0.48]), significantly higher than that of healthy vertebrae (mean SUVmax: 1.0 [95%CI 0.92-1.2] (p=0.001); ratio: 0.15 [9%5CI 0.11-0.20](p<0.001)). CONCLUSIONOur study showed an increased DOTATOC uptake in all typical vertebral hemangiomas that was statistically higher than healthy vertebral uptake. The importance of our findings lies on the fact that, in a DOTATOC PET/CT study for staging of a neuroendocrine tumour, a bone hemangioma could be a cause of false positive for bone metastases, which emphasizes the need of a thorough evaluation of CT images, looking for a "Polka Dot" appearance in any focal vertebral uptake.

EPW71

Prognostic Significance of Metabolic Parameters by 18F-FDG PET/CT in Non-Small Cell Lung Cancer

G. Eren[1], S. Asa[1], O. Kupik[1], S. Güngör[2], S. B. Asa[3]; [1]Oncology Hospital of RTE University, Rize, TURKEY, [2]Nuclear Medicine Department of Medeniyet University, İstanbul, TURKEY, [3]Physics Department of İstanbul University, İstanbul, TURKEY.

PURPOSE: We evaluated the prognostic impact of metabolic and volumetric information by 18F-FDG PET/CT in non-small cell lung cancer (NSCLC) patients. METHODS: In this retrospective study we evaluated 18F-FDG PET/CT parameters of 67 patients with newly diagnosed NSCLC who had pretreatment 18F-FDG PET/CT scans between January and December of 2014. The metabolic tumor volume (MTV) of whole-body tumor (MTV_{WB}), of primary tumor (MTV_T), of nodal metastases (MTV_N), and of distant metastases (MTV_M); the total lesion glycolysis (TLG) of whole-body tumor (TLG_{WB}), of primary tumor (TLG_T), of nodal metastases (TLG_N), and of distant metastases (TLG_M); the standardized uptake value (SUV_{max}) of primary tumor (SUV_{maxT}), of nodal metastases (SUV_{maxN}), and of distant metastases (SUV_{maxM}), SUV_{peakT}, (SUV_{meanT}) and CT volume (CT_v)of primary tumor were measured. The MTV and TLG were measured using adaptive (adp) method. Histologic subtype, sex, age, TNM stage, clinical stage were registered. Kaplan-Meier, receiver operating characteristic (ROC) curve analysis were used to detect parameters influencing survival. RESULTS: The median overall survival (OS) was 10.1 months (95% confidence interval (CI) 6.2-14.0 months). MTV_{WB} (p:0.000), TLG_{WB} (0.005), MTV_T (p:0.006), CT_v (p:0.007), SUV_{maxM} (p:0.008), TLG_M (p:0.01), MTV_M (p:0.01) , SUV_{maxN} (p:0.028), TLG_T (p:0.031) , MTV_N (p:0.033), TLG_N (p:0.038) had impact on survival statistically significantly. SUV_{maxT} (p:0.73), SUV_{peakT} (p:0.83), SUV_{meanT} (p:0.27) did not predict survival statistically significantly. Significant cut-off values (sensitivity, specificity) were 360 for TLG_{WB} (72%, 67%) , 60.5 cm3 for MTV_{WB} (72%, 81%), 29.5 cm3 for CT_v (72%, 67%). The 1 year median overall survival was 58% for for patients with TLG_{WB} (<360) and 37 % for patients with TLG_{WB} (>360) p:0.009, 67% for patients with MTV_{WB} (<60.5 cm3) and 31% for patients with MTV_{WB} (>60.5cm3) p:0.000, %64 for patients with CT_v (<29.5cm3) and 35% for those with CT_v (>29.5cm3) p:0.004. The median survival was 7.3 months in patients with distant metastases and 16.2 months in patients without distant metastases p:0.002. CONCLUSION: The metabolic tumor parameters; MTV_{WB} , TLG_{WB} , MTV_T , SUV_{maxM} , TLG_M , MTV_M , SUV_{maxN} , TLG_T , MTV_N , TLG_N and CT_v are statistically significant prognostic factors for survival in patients with newly diagnosed NSCLC. SUV_{maxT} , SUV_{peakT} and SUV_{meanT} did not influence survival statistically significantly. Further studies with larger patient populations are needed to explore these findings.

EPW72

The Role Of 18F-Fluorothymidine (18F-FLT) In Patients With Suspected Lymphoma Relapse

L. Zanoni[1], A. Broccoli[2], A. Lambertini[1], C. Pellegrini[2], V. Stefoni[2], F. Lodi[1], C. Fonti[1], R. Bonfiglioli[1], P. Zinzani[2], S. Fanti[1]; [1]Nuclear Medicine, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [2]Hematology "L. e A. Seràgnoli", Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY.

AIM: Monocentric prospective study to evaluate the role of 18F-Fuorothymidine (FLT) PET/CT in lymphoma patients (pts) following a positive or equivocal 18F-Fluorodeoxyglucose (FDG) PET/CT at end-treatment or follow-up. **MATERIALS AND METHODS**: From May 2010 to April 2016, 46 patients were enrolled, all undergoing FLT within approximately 3 weeks from a previous positive/equivocal FDG scan and, if available, biopsy confirmation to define PET results. SUVmax and Tumor-to-background-ratio (TBR, using liver SUVmean) were recorded for the most avid lesion and then compared between the recurrent/residual disease group and the group in remission, for both tracers. **RESULTS:** Pts characteristics (n=46). Age: mean 55; median 60; range 20¬76 27 males and 19 females 36 non-Hodgkin (NHL) and 10 Hodgkin lymphoma (HL) stage at diagnosis: 11 II, 10 III, 25 IV 6 pts were evaluated at end-treatment and 40 during follow-up. Only in 19/46 pts (41%) histological evidence was available. Biopsy was not an option in the remaining 27 due to practical/ethical reasons; in these cases, clinical judgment and subsequent laboratory and imaging follow-up was considered as standard of reference. Relapse/residual disease was excluded in 9 pts (20%), who were diagnosed as: 1 reactive follicular hyperplasia, 2 reactive-inflammatory tissue, 4 reactive nodes, 1 nodal sarcoid-like, 1 unspecified peri-caecal finding. 39 pts (85%) were FDG-positive, of whom 35 were true positive (TP) (90%); 32 pts (70%) were FLT-positive showing 30 TP (94%). 7 FDG pts showed inconclusive results, of whom 2 TP (29%), while 14 FLT pts were inconclusive, later showing 7 TP (50%). The majority of pts (31 pts, 67%) showed both FDG- and FLT-positivity with 29 TP (93%). 8 pts (17%) were FDG-positive but FLT-inconclusive (6 TP, 75%). 6 pts (13%) resulted both FDG and FLT inconclusive (1 TP, 17%). 1 patient (2%) was FDG-inconclusive but FLT-positive (1TP, 100%). FDG and FLT-TBR and FLT-SUVmax were significantly higher in recurrent/residual lymphoma pts than in the disease-free group (p= 0,0342 ; 0,0377; 0,0267, respectively). On the contrary no statistically significant difference was found with FDG-SUVmax (p= 0,0578). Re-staging (Ann-Arbor) according to FDG and FLT-PET images resulted concordant in 31 cases. In 1 case FLT upstaged whereas in 14 downstaged the disease-extent compared to FDG. Analyses on potential change in pts management are ongoing. **CONCLUSION:** Our preliminary data suggest that FLT might be complementary although not alternative to FDG. The elimination of inconclusive PET findings is still challenging. Further lesion/semiquantitative/ Ki67 correlation analyses are ongoing.

EPW73

The preliminary study of 18F-FLT and 18F-FDG PET/CT in predicting response to chemoradiotherapy in nasopharyngeal carcinoma

Z. Yang, Q. Shi, Y. Zhang, C. Hu, Nasopharygneal carcinoma multidisciplinary team, Shanghai Cancer Center, Fudan University, Shanghai; Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim: The main objective of this study was to explore the feasibility of 18F-Fluorothymidine (18F-FLT) and 18F-Fluorodeoxyglucose (18F-FDG) positron emission tomography/computed tomography (PET/CT) in monitoring and predicting treatment response of nasopharyngeal carcinoma (NPC). Materials and Methods: Patients with NPC of Stage II-IVB were prospectively enrolled, receiving 2 cycles of neoadjuvant chemotherapy (NACT), followed by concurrent chemoradiotherapy. Each patient underwent pre-treatment and post-NACT FLT and FDG PET/CT. SUVmax (maximal standard uptake value), SUVmean, PTV (proliferative tumor volume) and MTV (metabolic tumor volume) of primary tumor and lymph nodes were measured. Several threshold were tried to define the contouring margin around the target. Tumor response to NACT was evaluated before commencement of radiotherapy by MRI, and tumor regression at the end of radiotherapy was evaluated at 55Gy, according to RECIST 1.1 Criteria. Results: 20 patients have been consecutively enrolled into this prospective study. At the end of radiotherapy, 7 patients reached complete response while others were partial response. So far, no loco-regional recurrence or distant metastasis has occurred. After 2 cycles of NACT, both FLT and FDG parameters declined remarkably. Parameters of FDG PET were more strongly correlated to tumor regression than those of FLT PET. In both FLT and FDG PET, 70% SUVmax was the best threshold to define the contouring margin around the target. Some residual lesions after NACT showed by MRI were negative in PET/CT. Conclusion: Both FLT and FDG PET could reflect the metabolic changes of tumor and predict tumor regression more early than MRI. They may play an important role in radiotherapy target volume delineation.

EPW74

^{68}Ga-DOTATOC PET/MRI for characterization of undetermined upper abdominal tracer uptake in ^{68}Ga-DOTATOC PET/CT

A. Sabet[1], J. Cohnen[1], K. Beiderwellen[1], S. Ezziddin[2], L. Umutlu[1], H. V. Grafe[1], A. Bockisch[1], T. D. Poeppel[1]; [1]Universität Duisburg-Essen, Essen, GERMANY, [2]Universität Saarland, Homburg, GERMANY.

Purpose: High density of somatostatin receptors (sstr) in the uncinate process of pancreas along with suboptimal soft tissue contrast of CT may hinder accurate assessment of pancreatic head and the adjacent organs in PET/CT imaging with 68Ga-labelled sstr analogs. The aim of this study was to investigate the performance of simultaneous 68Ga-DOTATOC PET/MRI in patients with undetermined increased DOTATOC uptake in upper abdomen in 68Ga-DOTATOC PET/CT. **Methods:** 88 patients with well-differentiated neuroendocrine tumors (NET) and visually detectable DOTATOC Uptake were analyzed. PET/CT was followed by PET/MRI in all patients. Histopathology and follow-up served as reference standard. Diagnostic performances of the two modalities were compared. Quantitative assessments were also performed measuring standardized uptake value (SUV) parameters. Paired Students t-test was performed with a significance level of $p< 0.05$ to examine the differences in SUV_{max} between physiological and pathological uptake in both modalities. **Results:** 54/88 patients had a faint or irregular uptake with no morphologic correlate in either PET/CT, PET/MRI or during the follow up. Of 34/88 patients with focally increased uptake, PET/CT detected pancreatic tumors in 2, adjacent lymph nodes in 3, and duodenual lesion in 1 patients. PET/MRI defined corresponding pathologies in 10 of 34 patients, consisting of pancreatic tumor (n=4), adjacent lymph nodes (n=4), and duodenal lesions (n=2). Suspected uptake with no morphologic correlate proved duodenal NET in 1 patient during the follow-up. PET/MRI was superior to PET/CT in terms of sensitivity (91% vs 55%), negative predictive value (96% vs 82%), and diagnostic accuracy (97% vs 85%). The mean SUV_{max} was significantly higher in tumor lesions of uncinate process as compared to patients with physiological uptake. **Conclusions:** In this study, 68Ga-DOTATOC PET/MRI could determine the entity (physiological vs pathological) and origin (pancreatic vs extra-pancreatic) of increased DOTATOC uptake in upper abdomen in significantly more patients compared to 68Ga-DOTATOC PET/CT resulting in considerable reduction in inconclusive PET images.

EPW75

18F FACBC PET/CT for nodal staging in high risk prostate cancer: preliminary accuracy data

L. Zanoni[1], I. Bossert[1], C. Nanni[1], C. Pultrone[2], R. Schiavina[2], F. Giunchi[3], M. Fiorentino[3], C. Fonti[1], A. Matti[1], S. Ricciolino[4], F. Lodi[1], A. Porreca[5], E. Brunocilla[2], A. D'Errico[3], S. Fanti[1]; [1]Nuclear Medicine, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [2]Urology, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [3]Pathology, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [4]Nuclear Medicine, Azienda ospedaliero-universitaria Federico II, Napoli, ITALY, [5]Urology, Policlinico Abano Terme, Abano (PD), ITALY.

AIM: To evaluate the diagnostic performance of 18F-FACBC-PET/CT in nodal staging prior to lymph-node-dissection (LND) in high-risk primary prostate cancer (PCa). **MATERIALS AND METHODS**: 65 patients (pts), consecutively and prospectively enrolled, underwent 18F-FACBC-PET/CT. Inclusion Criteria were: high-risk biopsy-proven PCa; standard staging workup (including Choline-PET/CT); out of hormonal-therapy; eligible for LND. Any LN uptake greater than surrounding background was interpreted with a 5-point-scale (confidence of disease): 1-2 probably negative; 4-5 probably positive; 3 equivocal. Lesions' number, site and dimension, SUVmax and target-to-background-ratio were registered. PET/CT results were compared, on a per-patient basis, with histopathology from LND (39 pts). 26/65 pts were excluded from diagnostic-performance-analysis: 5 minimal lymphadenectomy; 3 not operated; 18 waiting for surgery. **RESULTS**: Overall pts characteristics (65pts). Age: Mean 65; Median 66; Range 47-76. PSA: Mean 10,30; Median 7,90; Range 2,56-30; BiopsyGS: 3+3 1; 3+4 3; 4+3 5; 4+4 32; 4+5 19; 5+4 4; 5+3 1. cT: T1c 6; T2n.s. 25; T2a 1; T2b 8; T2c 18; T3 7. Diagnostic-performance (39pts). Overall 913 LN were removed in 39/65 pts (60%): mean 23; median 19; range 6-49. Despite a considerable risk for LNMs predicted by Briganti-Nomogram (mean 26%; median 22%; range 3-70%), only 4 pts (10%) resulted N1. Overall 14 LNMs were counted (10 in 1 pt; 1 in 2 pts; 2 in 1 pt), all showing millimetric deposits (range 1-5 mm). *Pts characteristics:* Age: Mean 65; Median 66; Range 47-75. PSA: Mean 10,42 ; Median 8; Range 2,87-30. Biopsy-GS: 3+3 1; 3+4 2; 4+3 1; 4+4 22; 4+5 10; 5+4 3. cT: T1c 3; T2 n.s. 12; T2a 1; T2b 2; T2c 15; T3 6. pT: T2b 1; T2c 11; T3a 21; T3b 6. pGS: 3+4 1; 4+3 9; 4+4 8; 3+5 1; 4+5 14; 5+4 2; 4+3(+5) 1; 4+4(+5) 3. *PET results:* 24 pts resulted negative (21 TN, 3 FN) and 8 positive (1TP, 7 FP) with both tracers; 1 positive with FACBC (1 FP) but negative with Choline (1 TN); 6 positive with Choline (FP) but negative with FACBC (TN). Sensitivity resulted 25% with both tracers; specificity 77 vs 63%, accuracy 72 vs 59%, PPV 13 vs 7%, NPV 90 vs 88% in favor of FACBC. **CONCLUSION:** FACBC demonstrated low sensitivity, equal to Choline, but slightly better overall diagnostic performance in nodal staging. Due to small size of LNMs, PET remains not ideal. Enrolment and further analyses (region-based/semi-quantitative/uni-multivariate-logistic-regression to search for relevant predictive factors) are ongoing.

EPW76

Evaluation of Effect of Intravenous Iodinated Contrast Enhanced Computed Tomography on Diagnostic Yield of PET/CT Scan in Recurrent Head and Neck Malignancies

S. BARAI[1], A. Singh[2], S. Gambhir[2]; [1]Department of Nuclear Medicine. Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, INDIA, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, INDIA.

Aim: Iodinated contrast agents are routinely used in computed tomography (CT) and are acknowledged to provide additional information over a noncontrast CT. Iodinated contrasts are also increasingly being used in the CT component of Positron emission tomography (PET) with the assumption that contrast enhance CT will provide better diagnostic yield though the utility of contrast study for PET imaging is still being debated. Aim of the study was to evaluate the effect of contrast CT on diagnostic yield of PET/CT scan done in patients with suspected recurrent head, neck malignancies. ***Materials and Method:*** A total of 139 patients of head, neck malignancies having suspected tumour recurrence, undergoing FDG-PET scan were included in this study. Two sets of CT images were obtained. One set used standard noncontrast CT (80-130 mA, 120 kvp) for coregistration, and the other set used intravenous contrast (Iopromide 370) enhanced diagnostic quality CT (160-300mA, 120kvP) for coregistration. Two nuclear medicine physicians blinded to clinical details interpreted the results. Any difference in observation was resolved by consensus. ***Results:*** Both contrast and noncontrast PET/CT detected recurrence at the primary site in 127 patients. In 33 of 127 patients histopathology of the primary recurrent site was available for analysis. The calculated sensitivity, specificity, accuracy and positive and negative predictive values of the noncontrast PET/CT protocol for detection of recurrence at the primary site were 91.6%, 66.6%, 84.8%, 88%, and 75% respectively and that of contrast enhanced PET/CT were 91.6%, 88.8%, 90.9%, 95.6%, and 88.8%, respectively. There was no statistical difference between PET/CT and PET/CECT protocols. However when compared to noncontrast PET/CT the contrast PET/CT resulted in better tumour margin delineation, resulting in disease status upstaging in 25 patients (17.9%) and downgrading in 3 patients (2.1%). Lymph nodes were also better visualised in contrast PET/CT allowing more accurate evaluation of nodal characteristics like shape, size, and presence of hilum, enhancement and presence of necrosis resulting in upstaging in 45 patients(32.3%) and down staging in 10 (7.1%) cases. Both contrast and non contrast PET/CT performed identically while deciding the M stage (distant metastases) of the disease, however in 3(2.1%) patients additional location of distant metastases were detected by contrast PET/CT. ***Conclusion:*** The contrast enhanced PET/CT protocol demonstrated a significantly better diagnostic performance in evaluation of tumour infiltration, margin and lymph nodal involvement, resulting in change in T stage in 20% and N stage in 39.4% patients of suspected recurrent head, neck malignancies.

Effects of Carbidopa on Kinetics of 6-^{11}C-Methyl-*m*-tyrosine and 6-^{18}F-Fluoro-*m*-tyrosine into the Living Brain: A PET Study in Monkey

M. Kanazawa, H. Ohba, T. Kakiuchi, H. Tsukada; Hamamatsu Photonics K.K., Hamamatsu City, JAPAN.

Aim: We have recently developed a novel PET probe, 6-^{11}C-methyl-*m*-tyrosine (^{11}C-6Me*m*Tyr), to qualify presynaptic dopamine (DA) synthesis in the living brain (Kanazawa M., et al., *Bioorg Med Chem.* 2015;23:729). We reported that ^{11}C-6Me*m*Tyr, which has non-catechol structure, were not affected by pre-administration of carbidopa, a specific inhibitor of peripheral aromatic L-amino acid decarboxylase (AADC), at the clinical dose (Kanazawa M., et al., *J Nucl Med*. 2016;57:303). In contrast, PET measurements using 6-^{18}F-fluoro-L-*m*-tyrosine (^{18}F-6FMT), another non-catechol probe, are routinely conducted with preadministration of carbidopa. In the present study, we comparatively evaluated the effects of carbidopa on plasma metabolism and brain uptake of ^{11}C-6Me*m*Tyr and ^{18}F-6FMT in the living normal monkey (*Macaca fascicularis*). **Materials and Methods:** ^{11}C-6Me*m*Tyr was synthesized by using a rapid Pd(0)-mediated crosscoupling reaction of ^{11}C-methyl iodide and corresponding alkenyl boronate precursor (Kanazawa M., et al., *Bioorg Med Chem*. 2015;23:729). ^{18}F-6FMT was labeled by a highly enantioselective synthesis method using chiral phase-transfer alkylation as previously used for the labeling of no-carrier-added ^{18}F-FDOPA (Lemaire C., et al., *Eur J Org Chem.* 2004:2899) with minor modifications. PET scans using ^{11}C-6Me*m*Tyr and ^{18}F-6FMT were conducted in monkeys under isoflurane anesthetic state. In order to evaluate the effects of carbidopa, vehicle or carbidopa was orally administered 1 hr before the injection of ^{11}C-6Me*m*Tyr or ^{18}F-6FMT. DA synthesis rates (Ki) in the striatum were calculated by Patlak plot analysis applying the TAC in the cerebellum as an input function. In addition, the effects of carbidopa on metabolic profiles of ^{11}C-6Me*m*Tyr and ^{18}F-6FMT in plasma were assessed using radio-TLC method. **Results and Conclusion:** As previously observed using ^{11}C-6Me*m*Tyr, the striatal Ki value measured using ^{18}F-6FMT was also not affected by carbidopa at clinical dose even with the slight changes in their plasma metabolic profiles. The present study demonstrated that ^{11}C-

6Me*m*Tyr and ^{18}F-6FMT could be potential PET probes for quantitative imaging of the presynaptic DA activity without pre-administration of carbidopa in the living brain with PET.

In Vivo and In Vitro Metabolism of the new Translocator Protein PET Ligand [^{11}C]PBR170

M. Peyronneau[1], T. Bourdier[2], S. Eberl[2,3], C. Loch[2], L. Wen[2,3], D. Henderson[2], P. Lam[2], A. Mohamed[2,4], I. Greguric[5], F. Mattner[2], A. Katsifis[2,6], M. Fulham[2,3,4]; [1]IMIV, CEA, Inserm, Univ.Paris-Sud, CNRS, Université Paris-Saclay, CEA-SHFJ, Orsay, FRANCE, [2]Department of Molecular Imaging (PET and Nuclear Medicine), Royal Prince Alfred Hospital, Missenden Road, Camperdown, NSW 2050, AUSTRALIA, [3]Faculty of Engineering and Information Technologies, University of Sydney, Sydney, NSW 2006, AUSTRALIA, [4]Sydney Medical School, University of Sydney, Sydney, NSW 2006, AUSTRALIA, [5]Life Sciences, ANSTO, New Illawarra Road, NSW 2234., Lucas Heights, AUSTRALIA, [6]Faculty of Pharmacy, University of Sydney, Sydney NSW 2006, AUSTRALIA.

Aim: The 2-(6,8-dichloro-2-(4-ethoxyphenyl)imidazo[1,2-a]pyridin-3-yl)-N-(2-fluoropyridin-3-yl)-N-methylacetamide has been previously synthesized and labelled with [^{11}C] for imaging the translocator protein (TSPO) with PET [1]. During preclinical imaging evaluation of this ligand in rats and non-human primates, our aim was to investigate the in-vitro and in-vivo metabolism of PBR170 and [^{11}C]PBR170 to determine the contribution of radiometabolites to the brain uptake and to evaluate species differences. **Materials and Methods:** The *in-vitro* metabolic study was assessed by incubation with rat, baboon and human liver microsomes followed by LC/MS and MS-MS analyses. PBR170 was radiolabelled by *N*-methylation of the corresponding des-methyl precursor with [^{11}C]methyl iodide in 30-45% radiochemical yield with radiochemical purity > 98% and specific activity of 90-190 GBq/μmol. In-vivo metabolism was measured in arterial plasma samples by a validated solid phase extraction (SPE) method during dynamic brain imaging of [^{11}C]PBR170 in baboons (Papio Hamadryas) using a Biograph PET-CT. **Results:** LC-MS analyses of rat, non-human primate and human liver incubations identified 6 main metabolites generated by cytochrome P450-dependant N-demethylation, O-deethylation and hydroxylation of PBR170, forming: N-demethyl (*m/z* 459), O-deethyl (*m/z* 445), hydroxyl (*m/z* 489), N-demethyl, O-deethyl (*m/z* 431), N-demethyl, hydroxyl (*m/z* 475), O-deethyl, hydroxyl (*m/z* 461) and O-deethyl, hydroxyl, N-demethyl (*m/z* 447) derivatives of PBR170. The N-demethylated compounds (*m/z* 459 and 431) were the major metabolites in baboon and human liver microsomes whereas the O-deethylated (*m/z* 445) and hydroxylated (m/z 475) derivatives were the major metabolites in rat microsomes. In-vivo, [^{11}C]PBR170 slowly decreased in baboon plasma and contributed for more than 50% of the radioactivity 60 min after injection. The [^{11}C]N-demethylation leads to the formation of a non-radioactive N-demethylated compound, with lower affinity for the TSPO and [^{11}C]CO_2, which is excluded by the blood-brain barrier and therefore has little interference with brain measurements. O-deethylation results in non-radioactive acetate and a phenol with poor affinity for the PBR and CBR receptors. Finally, whole body PET-CT imaging, performed after 60 minutes, showed liver uptake and predominantly hepatobiliary elimination with little excretion through the kidneys. **Conclusions:** Species differences were observed in the metabolism of PBR170 between rat, non-human primate and human. In-vivo [^{11}C]PBR170 radiometabolites resulting from N- and O-dealkylation should not confound brain PET measurements.[1] Bourdier et al., Appl Radiat Isot, 2014;90:46-52.

PET Imaging of HER2 Expressing Tumors using a Novel ^{18}F labeled Affibody with a Hydrophilic Linker

M. Yang, Y. Xu, Z. Bai, D. Pan, L. Wang, J. Yan, R. Yang; Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Human epidermal growth factor receptor 2 (HER2) is a potential target for diagnosis and therapy of the tumor. ^{18}F labeled HER2 targeting affibody, $ZHER_{2:342}$, has been developed for the noninvasive assessment of HER2 status in vivo through PET imaging. However, unfavourable abdominal background and laborious multiple-step synthetic procedure may hinder the widespread use of these agents. A new hydrophilic linker, GGGRDN, is benefit to improve the pharmacokinetic quality of peptides. In the present study, modified $ZHER_{2:342}$ with the linker, $ZHER_{2:342}$-NDRGGG-Cys (denoted as $MZHER_{2:342}$), was designed and labeled using ^{18}F-Al-NOTA strategies. The imaging properties of the novel tracer were investigated in tumor models and also compared to those of unmodified counterpart. *Methods:* $MZHER_{2:342}$ and $ZHER_{2:342}$were conjugated with MAL-NOTA under standard reaction conditions. The affibody molecules were then radiolabeled with Al^{18}F complex. MicroPET imaging and biodistribution studies were performed in nude mice bearing HER2-positive human breast cancer JIMT-1 after iv injection. *Results:* ^{18}F-Al-NOTA-MAL-$MZHER_{2:342}$ and ^{18}F-Al-NOTA-MAL-$ZHER_{2:342}$ can be efficiently produced within 30 min with non-decay corrected yields of about 10% and radiochemical purities of more than 95%. PET imaging revealed that the JIMT-1 xenografts were readily visualized with high target to background contrast after administration of ^{18}F-Al-NOTA-MAL-$MZHER_{2:342}$. ROI analysis showed that the tumor uptakes were 8.75±0.83, 8.42±1.20 and 8.31±0.96 %ID/g and 1.71±0.31, 1.59±0.29 , 1.41±0.29 %ID/g at 30, 60 and 120 min after administration of ^{18}F-Al-NOTA-MAL-$MZHER_{2:342}$ and ^{18}F-Al-NOTA-MAL-$ZHER_{2:342}$ respectively. Excessive unlabeled $ZHER_{2:342}$ significantly inhibited the tumor uptakes at 60 min postinjection. The liver uptake of ^{18}F-Al-NOTA-MAL-$MZHER_{2:342}$ was about 2 %ID/g , but the corresponding values for ^{18}F-Al-NOTA-MAL-$ZHER_{2:342}$ was nearly 10% ID/g at all time points . Prominent uptake of ^{18}F-Al labeled affibodys were also observed in kidneys at early time points, suggesting that these tracers are mainly excreted through the renal-urinary routes. *Conclusions:* ^{18}F-Al-NOTA-MAL-$MZHER_{2:342}$ can be prepared simply and GGGRDN linker greatly improved the pharmacokinetic performances in vivo. ^{18}F-Al-NOTA-MAL-$MZHER_{2:342}$ is promising for detecting HER2 expression of cancers. *Acknowledgements* This work was supported by National Natural Science Foundation (51473071,81472749,81401450,21401084, 21504034), Jiangsu Province Foundation (BE2014609), Health Ministry of Jiangsu Province Fund (RC2011095,Q201406 and H201529), 333 Project of Jiangsu (BRA2015476).

Evaluation of two approaches for the [^{18}F]AlF radiolabeling of affibody $Z_{HER3:8698}$ for PET imaging of HER3 status

C. Da Pieve, L. Allott, C. D. Martins, A. Vardon, D. M. Ciobota, G. Kramer-Marek, G. Smith; Institute of Cancer Research, Sutton, UNITED KINGDOM.

Background: HER3 is a member of the human epidermal growth factor receptor (EGFR/HER) tyrosine kinase family. HER3 is involved in the establishment of malignancy and its signalling has recently been identified as a prominent mediator of resistance to HER1 and HER2-targeted therapies. Radionuclide-based molecular imaging of HER3 receptor expression could guide patient stratification for HER3 targeted therapy and more importantly could aid monitoring early tumour response to therapeutic intervention. This study aimed to develop an efficient and reproducible radiolabelling of an affibody molecule having high HER3 affinity *via* the rapid and effective aluminium-^{18}F-fluoride ([^{18}F]AlF) method for the imaging of HER3 expression *in vivo*. Materials and Methods: The HER3-targeting $Z_{HER3:8698}$ affibody (AffibodyAB, Sweden) was radiolabelled following two different strategies: a one-step radiolabelling performed at 100°C

using 1,4,7-triazanonane-1,4,7-triacetate (NOTA) as chelator for the [^{18}F]AlF complex; and a two-step alternative approach performed at room temperature based on the inverse electron demand Diels-Alder (IEDDA) reaction between a novel tetrazine functionalised 1,4,7-triazacyclononane-1,4-diacetate chelator (NODA-Tz) and a *trans*-cyclooctene (TCO) functionalised affibody. Binding affinity and specificities of the products were evaluated *in vitro*. High HER3-expressing MCF-7 tumour-bearing mice were used to assess the HER3 targeting *in vivo*. Results: NOTA-$Z_{HER3:8698}$ was radiolabelled with [^{18}F]AlF in a one-step reaction (38.8 ± 5.8 % radiochemical conversion). However, the exposure of the radioconjugate to the high temperatures required for radiolabelling formed a by-product. A purification procedure comprising of RP-HPLC followed by HLB-SPE was therefore developed to produce [^{18}F]AlF-NOTA-$Z_{HER3:8698}$ with a RCP higher than 98% and high stability. The alternative IEDDA reaction was performed by initially radiolabelling NODA-Tz with [^{18}F]AlF which was subsequently ligated to TCO-$Z_{HER3:8698}$ at room temperature to produce the [^{18}F]AlF-NOTA-$Z_{HER3:8698}$ radioconjugate. The binding affinities of both radioconjugates to HER3, using the overexpressing MCF-7 cell line, were found to be specific and in the subnanomolar range (ca 0.4-1.0 nM). Both radioconjugates display similar *in vivo* pharmacokinetic profiles when injected in MCF-7 tumour bearing mice. Tumour uptake was found to be 4.36 ± 0.92 and 4.96 ± 0.92 %ID/g for [^{18}F]AlF-NOTA-$Z_{HER3:8698}$ and [^{18}F]AlF-NODA-$Z_{HER3:8698}$ respectively at 1 h p.i. when 1 μg of protein (*ca* 0.8 MBq) was injected. Conclusions: [^{18}F]AlF radiolabelled HER3-targeting affibody molecule $Z_{HER3:8698}$ was efficiently achieved using two distinct approaches. Both radiotracers can provide specific PET imaging of HER3 expression in tumours. However, the simplicity of the synthesis and the *in vivo* data indicated [^{18}F]AlF-NOTA-$Z_{HER3:8698}$ as the most promising candidate for further investigation.

EPW81

Comparative evaluation of ^{177}Lu-HP2 and ^{111}In-HP2, secondary agents for affibody-based PNA-mediated radionuclide pretargeting

M. Altai[1], K. Westerlund[2], J. Velletta[1], H. Honarvar[1], A. Orlova[3], A. Eriksson-Karlström[2], V. Tolmachev[1]; [1]Imuunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]DIVISION OF PROTEIN TECHNOLOGY, KTH, Stockholm, SWEDEN, [3]Department of Medicinal Chemistry, Division of Molecular Imaging, Uppsala, SWEDEN.

Aim. The use of radiometal-labelled affibody molecules in targeted radionuclide therapy is hindered by the high uptake and retention of radioactivity in the kidneys. Commonly used methods for reduction of renal radioactivity were inefficient in the case of affibody molecules. We have recently developed a peptide nucleic acid (PNA) hybridization-mediated pretargeting approach to improve tumor-to-kidney radioactivity uptake ratios .The primary targeting agent is $Z_{HER2:342}$-SR-HP1 affibody-PNA chimera. An anti-HER2 $Z_{HER2:342}$ affibody molecule provides localization of PNA hybridization probe HP1 in HER2-expressing tumours. The complementary PNA HP2 probe contains DOTA and can be labelled with a variety of radiometals. In vivo proof-of-principle was demonstrated using ^{111}In-labeled HP2. The radioactivity uptake in kidneys was ca. 2-folds lower than that in the tumour. In the current study we continue the optimization of our pretargeting approach using the therapeutic low-energy beta emitter ^{177}Lu. **Methods.** DOTA-HP2 was labelled with lutetium-177 in 1M ascorbate, pH 5.5. In vitro pretargeting was studied in HER2-expressing SKOV-3 and BT474 cell lines. Biodistribution of ^{177}Lu-HP2 and ^{111}In-HP2 was compared in NMRI mice at 1, 4 and 24h p.i. To test the possibility of further reducing the kidney uptake of ^{177}Lu-HP2, two groups of mice were co-injected with kidney reabsorption blocking agents, Gelofusine and lysine. **Results.** HP2 was efficiently and stably labelled with ^{177}Lu with a yield of 99.5±0.4 % (n=5) and a specific radioactivity of 24.7 GBq/μmol. SDS-PAGE analysis demonstrated minimal radiolytic damage during labeling. In vitro, ^{177}Lu-labeled HP2 bound specifically to HER2-expressing cells pretreated with $Z_{HER2:342}$-SR-HP1 and showed high cellular retention up to 24h. In vivo, ^{177}Lu-HP2 demonstrated significantly reduced retention in the blood in comparison to ^{111}In-HP2 (0.22±0.1 vs. 0.68±0.07 %ID/g). The low blood-borne radioactivity of ^{177}Lu-HP2 resulted in lower uptake in the well-perfused liver in comparison to ^{111}In-HP2 (0.1±0.04 vs. 0,9±0.3 %ID/g). No significant difference in the kidney uptake was observed. When mice were co-injected with Gelofusine and lysine, the kidney uptake of ^{177}Lu-HP2 was reduced 3- and 2- fold, respectively. **Conclusion.** ^{177}Lu-HP2 showed both favourable in vitro pretargeting and in vivo biodistribution properties. This study demonstrates the feasibility of further development of the ^{177}Lu-labelled HP2 for affibody-based PNA-mediated radionuclide pretargeting. Studies to evaluate the feasibility of in vivo pretargeting of HER2-overexpressing SKOV-3 ovarian carcinoma xenografts using ^{177}Lu-HP2 are ongoing.

EPW82

In vivo evaluation of pharmacokinetics, tumors targeting and therapeutic efficacy of a novel format of HER3-targeting affibody molecule with prolonged blood circulation

A. Orlova[1], M. Rosestedt[1], B. Mitran[1], T. Bass[2], F. Y. Frejd[1], J. Löfblom[2], V. Tolmachev[1], S. Ståhl[2]; [1]Uppsala University, UPPSALA, SWEDEN, [2]Royal Institute of Technology, Stockholm, SWEDEN.

Aim. Surface expression of human epidermal growth factor receptor type 3 (HER3) and its heterodimerisation with other receptors of HER family is a cause of resistance of malignant tumors to anti-HER targeting therapies. We have developed affibody molecule with low pikomolar affinity to HER3 for molecular imaging of HER3 expression. The anti-HER3 affibody molecule blocks it's binding to the natural ligand heregulin, suppresses heregulin-induced HER3 phosphorylation in vitro, blocks heregulin-induced downstream signaling through the Ras-MAPK and the PI3K-Akt pathways, and demonstrates complete inhibition of heregulin-induced cancer cell growth. To increase further the therapeutic effect and to extend residence time of affibody molecule in circulation, we have developed a bivalent HER3-targeting construct containing two HER3-specific affibody molecules flanking the ABD (albumin binding domain), Z_{HER3}-ABD-Z_{HER3}. The aims of this study were to evaluate biodistribution and in vivo targeting properties of the new construct; to determine protein dose, administration pathway and injection frequency for pilot anti-HER3 therapy in murine model. **Materials and methods**. Z_{HER3}-ABD-Z_{HER3} was coupled to DOTA chelator and labelled with indium-111. Its targeting properties were evaluated in vitro in HER3-expressing cell lines and in vivo. An experimental therapy was performed in mice beating HER3-expressing xenografts, BxPC-3. **Results**. Radiolabeled Z_{HER3}-ABD-Z_{HER3} preserved high affinity to HER3 ($K_D = 1.0±0.4×10^{-10}$ M) and demonstrated HER3 specific uptake both in vitro and in vivo. The biodistribution of ^{111}In-Z_{HER3}-ABD-Z_{HER3} was quite similar after intravenous, subcutaneous and intraperitoneal injections. Biodistribution of ^{111}In-Z_{HER3}-ABD-Z_{HER3} was studied up to 168 h after intraperitoneal injection. The compound was efficiently taken up into blood circulation (7.9±0.7%ID/g blood 6 h pi). Residence time of the new affibody construct was extended by fusion with ABD in comparison to naked anti-HER3 affibody molecule (distribution phase 440-fold and elimination phase 3.5-fold). However, clearance of Z_{HER3}-ABD-Z_{HER3} was rapider than for other ABD-fused affibody molecules. Increasing of injected protein dose significantly decreased radioactivity concentrations in organs expressing mErbB3 (murine counterpart of HER3) but not concentration in blood. Based on pharmacokinetic data, the pilot anti-HER3 in vivo therapy experiment was planned and performed in mice bearing HER3-expressing BxPC-3 xenografts. The growth of xenografts in the treated group was significantly slower than in the control group and treatment was well tolerated. **Conclusion**. The novel high-affinity affibody-ABD fusion protein Z_{HER3}-ABD-Z_{HER3} provides efficient growth inhibition of HER3-expressing cancer cells in vitro and in vivo. Pharmacokinetic studies using radiolabeled construct allowed planning efficient therapy experiment.

EPW83

Imaging of EGFR Expression Using 99mTC-Labelled ZEGFR:2377 Affibody Molecule

M. Oroujeni[1], K. Andersson[2], J. Garousi[1], B. Mitran[1], A. Orlova[1], J. Löfblom[2], V. Tolmachev[1]; [1]Uppsala University, Uppsala, SWEDEN, [2]KTH-Royal Institute of Technology, Stockholm, SWEDEN.

Aim. Overexpression of the epidermal growth factor receptor (EGFR) is a driving force in proliferation of several carcinomas. Imaging of EGFR expression enables patients' stratification for hyperfractionated radiation therapy of head and neck carcinoma or for gefitinib treatment of non-small-cell lung cancer. Earlier, we have demonstrated that ^{111}In-labeled affibody molecule DOTA-ZEGFR:2377 enables specific imaging of EGFR-expressing xenografts in vivo. The use of ^{99m}Tc instead of ^{111}In permits to increase the resolution, improve sensitivity, decrease dose burden to patients and reduce costs of diagnostics. The goal of this study was to evaluate feasibility of EGFR imaging by ZEGFR:2377 affibody molecules labelled with ^{99m}Tc using C-terminal amino acid KVDC sequence as a chelator. **Materials and methods**. ZEGFR:2377 was labelled with ^{99m}Tc using a gluconate-containing kit. The labelling stability was evaluated in vitro by challenge with 300-fold molar excess of cysteine. In vitro binding specificity was checked in A431 and MDA468 EGFR-expressing cell lines using pre-saturation with non-labelled affibody molecules and anti-EGFR antibody cetuximab. The cellular processing of ^{99m}Tc-ZEGFR:2377 bound to A431 and MDA468 cells was evaluated using a modified acid wash method. Affinity was measured using LigandTracer. Biodistribution was measured in BALB/C nu/nu mice bearing A431 xenografts at 3 and 24 h after injection. In vivo specificity was checked by pre-saturation of receptors by cetuximab. Experimental imaging was performed at 3 and 24 h using Triumph SPECT/CT scanner for small rodents. **Results**. The conjugate was stable under cysteine challenge. In vitro-binding of ^{99m}Tc-ZEGFR:2377 to EGFR-expressing cells was receptor-specific and strong (KD=280 pM). Internalization of ^{99m}Tc-ZEGFR:2377 was relatively slow, and less than 35% of cell-associated radioactivity was internalized after 24h incubation at 37°C. In vivo, accumulation of ^{99m}Tc-ZEGFR:2377 in A431 xenografts was EGFR-specific. The tumour uptake was 3.6±0.9 and 2.5±0.9 % ID/g at 3 and 24 h after injection, respectively. Clearance of radioactivity from normal tissues was rapider than clearance from tumours, which resulted in significant increase of tumour-to-organ ratios at later time point. The tumour-to-blood and tumour-to-muscle ratios at 24h after injection were 8±3 and 18±4, respectively. Tumours were clearly visualized at both time points. **Conclusion.** The use of C-terminal amino acid KVDC sequence as a chelator provides stable labelling of ZEGFR:2377 with ^{99m}Tc. ^{99m}Tc-ZEGFR:2377 has high affinity to EGFR-expressing cells. Imaging of EGFR-expressing tumours using ^{99m}Tc-ZEGFR:2377 is feasible.

New ^{68}Ga-HBED-CC conjugated GRPr targeted ligands for cancer imaging: a comparative study

C. Liolios[1], B. Buchmuller[1], A. Wacker[1], M. Schäfer[1], U. Bauder-Wüst[1], U. Haberkorn[2,3], M. Eder[3], K. Kopka[1]; [1]Department of Radiopharmaceutical chemistry, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [2]Department of Nuclear Medicine, University Hospital, Heidelberg, GERMANY, [3]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), Heidelberg, GERMANY.

Aim: Overexpression of the gastrin-releasing peptide receptor (GRPr) in many types of cancer (i.e. pancreatic, prostate and breast) renders GRP and its analogues attractive for peptide-mediated radionuclide imaging and therapy[1]. In this study, three bombesin (BN) analogues, two agonists: H_2N-BN(2-14) (**1**), H_2N-PEG_2-[(R)-Tyr^6,β-Ala^{11}, Thi^{13}, Nle^{14}]BN(6-14) (**2**) and one antagonist, 4-amino-1-carboxymethyl piperidine-[(R)-Phe^6,Sta^{13}]BN(6-14) (**3**) were conjugated to the acyclic chelator N,N'-bis[2-hydroxy-5-(carboxyethyl)benzyl]ethylenediamine-N,N'-diacetic acid (HBED-CC), which allows fast and stable chelation of the short-lived positron emitter ^{68}Ga. Compounds (**1**), (**2**), (**3**) were labeled with ^{68}Ga and evaluated in vitro on PC-3 cells (GRPr +) and in vivo in PC-3 tumor-bearing mice. Methods: Syntheses were according to published solid-phase peptide chemistry methods[2,3]. Radiolabeling with [^{68}Ga]Ga^{3+} eluate was accomplished within 10 min[3]. **^{68}Ga-1-3** were then investigated in vitro for their lipophilicity, GRPr-affinity, specific binding on and internalization in PC-3 cells, according to known methods[3]. The biodistribution was evaluated in PC-3 xenografted mice along with μPET imaging. Results: All peptides were labeled with RCY > 98 %. **^{68}Ga-2** presented the highest lipophilicity followed by **^{68}Ga-3** and **^{68}Ga-1** (logD = -1.13 ± 0.04; -1.54 ± 0.07; -1.91 ± 0.06, pH 7.4, respectively). All tracers showed specific binding on GRPr with binding affinities in the nanomolar range (**1**) 4.09, (**2**) 3.65, (**3**) 3.51 nM. Maximal cell uptake was achieved after 40-50 min of incubation. **^{68}Ga-2** and **^{68}Ga-3** presented higher cell binding than **^{68}Ga-1**. The majority of the cell-bound radioactivity was internalized for **^{68}Ga-1** and **-2** (60-70 %), while for **^{68}Ga-3** the radioactivity mainly remained on the cell surface (~80 %). Biodistribution experiments at 30 min p.i. showed the lowest tumor uptake for **^{68}Ga-2**, 3.06 ± 0.28 % injected dose (ID)/g, while **^{68}Ga-1** reached 4.36 ± 0.90 % ID/g and **^{68}Ga-3**, 4.32 ± 0.25 % ID/g. The uptake of the agonists significantly decreased at 60 min p. i., while for **^{68}Ga-3** it remained higher (4.74 ± 1.43 % ID/g). Also, antagonist **^{68}Ga-3** showed lowest off-target accumulation in muscle, intestines, kidneys and the pancreas. The μPET image of **^{68}Ga-3** was in accordance with these results, so that the tumor clearly was visualized. Conclusion: Of the three new tracers that were synthesized and evaluated, the antagonist **^{68}Ga-3** presented optimal pharmacokinetic characteristics, i.e. the highest tumor uptake and the lowest non-target organ accumulation. EPW85

Does the use of protease inhibitors outperform the chemical stabilization approach on targeting the cholecystokinin 2 receptor in vivo with radiolabelled gastrin analogues?

A. W. Sauter[1], R. Mansi[1], I. Valverde[1], L. Del Pozzo[1], M. Béhé[2], D. Wild[1], M. Fani[1]; [1]University Hospital Basel, Basel, SWITZERLAND, [2]Paul Scherrer Institute, Villigen, SWITZERLAND.

Purpose: Systemic treatment options are limited in patients with metastatic medullary thyroid cancer (MTC). The cholecystokinin 2 receptor (CCK2) is a favoured target for imaging and therapy of MTC using radiolabelled gastrin analogues. These analogues are cleaved rapidly by proteases in vivo and therefore their potential therapeutic efficacy decrease. We aimed to evaluate the effect of protease inhibitors on the biodistribution and tumour uptake of different minigastrin analogues with varying in vivo stability in 2 xenograft models, to conclude on the preferable stabilization approach. **Materials and Methods:** The effect of the two protease inhibitors phosphoramidon (PA) and thiorphan (TH) on the stability of the radiotracers ^{177}Lu-MG11 (^{177}Lu-DOTA-D-Glu-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH_2), ^{177}Lu-PP-F11 (^{177}Lu-DOTA-$(D\text{-}Glu)_6$-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH_2) and ^{177}Lu-PP-F11N (^{177}Lu-DOTA-$(D\text{-}Glu)_6$-Ala-Tyr-Gly-Trp-Nle-Asp-Phe-NH_2) was assessed in non-tumour-bearing mice. Biodistribution studies were performed for first time in human medullary thyroid cancer MZ-CRC-1 xenografts and in the A431-CCK2 xenografts. All three radiotracers were evaluated alone (w/o) or in combination with the Inhibitors 4h post injection (p.i.). The results were expressed as injected activity per gram (%IA/g). **Results:** ^{177}Lu-MG11 is highly unstable in vivo (<4% intact peptide, 5 min p.i.) and is tremendously stabilized when co-injected with PA or TH (>70% and >90%, respectively). Diminished stabilization was found for the highest stable analogue in the series ^{177}Lu-

PP-F11N (intact peptide 39%, 5 min p.i.) after co-injection of PA or TH (60% and 66%, respectively). Due to improved stability the tumour uptake (%IA/g) of ^{177}Lu-MG11 increased from 1.2±0.5 to 7.8±0.8 by co-injection of PA and to 5.4±1.4 with TH in A431-CCK2R tumours, and in MZ-CRC-1 from 3.2±1.5 to 17.2±4.8 and to 12.4±4.2 co-injecting PA and TH, respectively. Less profound effect was found in the tumour uptake of ^{177}Lu-PP-F11 that increased as follows: A431-CCK2R: 6.7±0.6 (w/o), 9.3±1.1 (PA), 8.7 ±1.2 (TH); MZ-CRC-1: 11.2±0.6 (w/o), 19.7±4.7 (PA), 11.8±8.6 (TH). For ^{177}Lu-PP-F11N the effect is also small in A431-CCK2R tumours: 6.9±0.8 (w/o), 8.5±2.2 (PA), 10.0±2.8 (TH) while no increase was found in the MZ-CRC-1 tumours: 18.8±4.8 (w/o), 15.6±3.8 (PA), 19.3±7.1 (TH). **Conclusion:** The use of protease inhibitors impacts significantly on the in vivo stability and tumour uptake of highly unstable gastrin-based radiotracers (i.e. ^{177}Lu-MG11). However, this effect cannot be documented for "stabilized" analogues, such as ^{177}Lu-PP-F11N. The performance of ^{177}Lu-PP-F11N w/o inhibitors is as good as the performance of ^{177}Lu-MG11 in the presence of inhibitors. The human application of single compounds without additives is preferable, as it will facilitate licensing. A clinical phase 0/I study with ^{177}Lu-PP-F11N is already planned.

EPW86

Novel SPECT hypoxia imaging probes with unique retention mechanism

I. O. Umeda, S. Kimura, H. Fujii; National Cancer Center, Kashiwa, JAPAN.

Aim: Hypoxia is a characteristic feature of most solid tumor and closely related to tumor malignancy and treatment-resistance; therefore, *in vivo* visualization of tumor hypoxia promises to greatly contribute for optimization of cancer therapy. However, there is no general clinical probe for hypoxia imaging at present. Most available probes are nitroimidazole derivatives that are labeled with positron-emitters and unsuitable for general use. We herein developed new SPECT probes with a unique retention mechanism, differing from conventional nitroimidazole derivatives. **Strategy and Methods:** We designed new probes as compact compounds that consisted of ^{99m}Tc-binding ligand components and 4-nitrobenzyl ester or 4-nitrobenzyl sulfide groups. We postulated that, under excessive reductive conditions after the uptake in hypoxic cells, 4-nitrobenzyl ester or sulfide groups would be reduced and released from the original structure, resulting in production of hydrophilic and negatively charged ^{99m}Tc-complexes. These ^{99m}Tc-complexes will not be able to penetrate the cell membrane, consequently remaining inside hypoxic cells. To test this hypothesis, we synthetized some candidate compounds and evaluated them by using FM3A and EMT-6 tumor cells and tumor-bearing mice. Their biodistribution patterns were confirmed by *in vivo* SPECT/CT imaging. **Results:** We successfully synthetized some candidate compounds that consisted of ^{99m}Tc-binding ligand components [triamide mercaptide (N3S) or diamide dithiolate (N2S2)] and 4-nitrobenzyl ester or 4-nitrobenzyl sulfide groups, and labeled them with ^{99m}Tc. In cell-based assay, they demonstrated significantly higher uptake in hypoxic cells than in normoxic cells, indicating the validity of our strategy. Animal studies revealed that their tissue distribution pattern including tumor accumulation after intravenous injection were greatly different depending on the structure of ligand components. By modifying them, the tumor uptake was improved as high as 1-2 % administered dose/g at 1 h after injection, yielding good tumor-to-background ratios. *In vivo* SPECT/CT images clearly depicted their accumulation in tumors. Additionally, intratumoral localization of our probes shown by autoradiography correlated well with positive areas stained with pimonidazole, a marker of hypoxia. **Conclusion:** Newly developed ^{99m}Tc-labeled probes successfully accumulated in the hypoxic region in the tumor according to our unique retention mechanism. ^{99m}Tc is the most common nuclide for nuclear medicine probes, therefore they are quite promising as general clinical probes for hypoxia imaging.

Automated copper-mediated synthesis of ^{18}F-Flumazenil using the Ora Neptis® and the GE TRACERlab® MX Synthesizers

A. Hienzsch[1], R. Martin[1], A. Zerges[1], S. Preshlock[2], S. Verhoog[2], M. Tredwell[2], V. Gouverneur[2], R. Smits[1], A. Hoepping[1], M. Müller[1]; [1]ABX advanced biochemical compounds GmbH, Radeberg, GERMANY, [2]University of Oxford, Chemistry Research Laboratory, Oxford, UNITED KINGDOM.

Aim: ^{18}F-Flumazenil (**[^{18}F]-FMZ**) is a ligand for the benzodiazepine binding site of the central GABA-A receptor. As a marker for neuronal density [^{18}F]-**FMZ** is a promising PET radiotracer for the localisation of the epileptogenic zone in drug-resistant epilepsy[1] and the detection of neuronal loss in the hippocampus of patients with temporal lobe epilepsy. [2] Until now, main approach for the synthesis of [^{18}F]-**FMZ** is the nucleophilic introduction of ^{18}F-fluoride into a mazenil precursor bearing a nitro leaving group.[3] However, the synthesis requires high temperatures, is giving numerous side products and low yields. This makes the synthesis and purification a challenge to any radio chemist. Recently, V. Gouverneur and her co-workers reported a method for the nucleophilic introduction of fluorine into electron rich, neutral and poor aromatic systems. They used boronic acid esters as precursors and replaced them via a copper-mediated coupling with ^{18}F-fluoride.[4] Based on these findings we aimed to develop an automated, feasable and high-yielding synthesis of [^{18}F]-**FMZ** using a pinacol boronate precursor on the Ora Neptis® and GE TRACERlab® MX synthesizers. **Methods:** ^{18}F-Fluoride labelling of ^{18}F-Flumazenil has been fully automated on the Ora Neptis® and GE TRACERlab® MX synthesizers including the following steps: (a) ^{18}F-fluoride fixation on a Sep-Pak® QMA Light cartridge and elution with a mild cryptofix solution, (b) azeotropic drying, (c) copper-mediated introduction of ^{18}F-fluoride into the precursor, (d) isolation of the labelled product on a tC18 cartridge, and (e) for the Ora Neptis® synthesizer: HPLC purification and final formulation of the product. For the GE TRACERlab® MX synthesizer, the crude product is easily obtained in order to proceed with a custom-made HPLC purification. **Results:** We established an automated and remotely controlled synthesis of ^{18}F-Flumazenil on Ora Neptis® and GE TRACERlab® MX synthesizers using a disposable kit system. For the Ora Neptis® synthesizer ^{18}F-Flumazenil was typically obtained in 15-20% non-decay-corrected yield. The chemical and radiochemical purities were >95% and >99% respectively (evaluated by HPLC). For the GE TRACERlab® MX synthesizer ^{18}F-Flumazenil was obtained as a raw product in 25-30% non-decay-corrected yield. **References:** [1] A. Hammers *et al*., *Neurology* **2001**, *56*, 897-906. Bissultones as attractive tools for the radiolabeling with fluorine-18 of native biopolymers for PET imaging under biocompatible conditions

A. Lafargue, **C. Perrio**; UMR 6301 ISTCT, LDM-TEP, CNRS, CEA, Univeristy Caen Normandie, CAEN, FRANCE.

Aim: Biopolymer-based radiopharmaceuticals are very attractive for PET imaging due to high affinity and specificity toward their biological molecular targets. However, the incorporation of fluorine-18 into biopolymers remains problematic. Recent advances in direct radiofluorination by formation of ^{18}F-Si, ^{18}F-Al or ^{18}F-B bonds involve functionalization of the macromolecular

object which is not always straightforward.[1] Radiolabeling strategies encompassing ^{18}F–C bond formation, require radiofluorination of prosthetic groups followed by multiple steps of functional group transformations and purifications before conjugation to the native or modified biopolymer. Previously, we developed a new radiofluorination reaction based on the sultone ring opening with [^{18}F]fluoride to afford easily purified ^{18}F-labelled hydrophilic sulfonated products in high yields.[2] We extended this methodology to a two-step radiofluorination / conjgation sequence from a bissultone precursor as an original "double click" strategy for the radiolabeling of lysine, glucose and glucosamine residues as model substrates under biocompatible conditions. Method: Fluorination and radiofluorination of bispropanesultone and bisbutanesultone were performed using [$^{19/18}$F]fluoride in acetonitrile at room temperature, 50 or 75°C, and followed up by ^{19}F NMR and HLPC respectively. Conjugation reactions to lysine, glucose and glucosamine were studied in buffer at pH ranging from 8 to 13. Finally, the overall radiofluorination / conjugation sequence was carried out using microfluidics based on staggered herringbone technology. Results: Bispropanesultone was found to be highly reactive for fluorination (quantitative yield after 1h at room temperature) and radiofluorination (about 60% radiochemical yield after 15 min at 50°C) leading to the corresponding [$^{19/18}$F]fluorosulfonatesultone. Conversion of bisbutanesultone was much more slower (quantitative fluorination after 30h at room temperature, no radiofluorination at 75°C after 15 min). Under non-radioactive condition, conjugation of monofluorosulfonatesultone was quantitative for lysine after 24h for all pH conditions, and for glucosamine after 24h at only pH 13. No conjugation to glucose was observed whatever the conditions. Under radioactive conditions, conjugation was successful only for lysine with optimum radiochemical yields (60%) obtained at pH 8 after 30 min at 50°C. The overall radiofluorination / lysine conjugation process in micromixers led to lysine ^{18}F-conjugate in around 50% radiochemical yield from [^{18}F]fluoride in less than 1 min at room temperature. Conclusion: The bissultone double ring-opening approach has been validated for 18F-radiolabeling of lysine containing biopolymers under biocompatible conditions. (1) K. Chansaenpak, B. Vabre, F. P. Evaluation of high polar ^{18}F-Alanine for the labeling of a folate derivative

K. Kettenbach[1], H. Schieferstein[1], S. Pektor[2], G. Otto[2], L. M. Reffert[3], R. Eckert[1], M. Miederer[2], F. Rösch[1], T. L. Ross[3]; [1]Johannes Gutenberg University Mainz, Mainz, GERMANY, [2]Universitätsmedizin Mainz, Mainz, GERMANY, [3]Hannover Medical School, Hannover, GERMANY.

Objectives: Many relevant biomolecules are based on amino acids what encouraged us to develop a novel ^{18}F-labeled prosthetic group based on Alanine [1]. This highly polar ^{18}F-Alanine derivative was used for ^{18}F-labeling of azide-functionalized molecules, in particularly a azido-folate to improve its pharmacokinetic profile. **Methods:** The labeling precursor was obtained by alkyne-functionalization of *L*-serine using 3-bromo-1-(trimethylsilyl)-1-propyne. This enables the Alanine derivative to participate in CuAAC (copper-catalyzed azide-alkyne cycloaddition).. For the ^{18}F-radiolabeling we used the kryptofix/carbonate system and a chloro-precursor. The ^{18}F-prosthetic group was isolated via HPLC and subsequently used for the reaction with an azido-functionalized folate derivative. The coupling was performed in PBS at 40 C using $CuSO_4$ as catalyst. The ^{18}F-Ala-folate was isolated via semi preparative HPLC and further evaluated in terms of lipophilicity and human serum stability as well as its binding and pharmacokinetic behavior. For *in vitro* and *in vivo* evaluation KB cells and xenografts in mice will be used for dynamic μPET and biodistribution studies. **Results:** The prosthetic group precursor was synthesized in good overall yields of 17% over 5 steps. The ^{18}F-labeling was optimized using different bases and reaction conditions, leading to very good conversion rates of 77±6% after 5 min using a microwave-supported synthesis route. Complete deprotection of the ^{18}F-prosthtic group was performed using 3.3 M HCl at 100 °C for 15 min followed by a semi preparative HPLC giving the final ^{18}F-prosthetic group. The lipophilicity of the radiolabeled ^{18}F-prosthetic group was determined as octanol-water-partition by shake flask. A logD value of -1.18±0.03 was calculated. The azido-functionalized folate was labeled via this novel ^{18}F-prosthetic group using $CuSO_4$ and sodium ascorbate at 40 °C for 15 min followed by HPLC and SPE purification. **Conclusions:** This novel ^{18}F-Alanine derivative promises an improved pharmacokineticprofile when coupled to biomolecules because of its amino acid structure having a high polarity. Especially, for peptide structures or very polar biomolecules this new ^{18}F-radiolabeling method implies a very low influence on the biochemical properties. In summary, this approach offers the introduction of a hydrophilic ^{18}F-prosthetic group with a minor effect on the physiological behavior of the ^{18}F-labeled molecule since alanine is a biogenic amine of the amino acid aspartic acid. **Acknowledgements:** The authors thank the Max Planck Graduate Centre Mainz and the Ci3 cluster of excellence for financial support. **References:** [1] H. Schieferstein *et al.*, Eur J Org Chem, 2014, 3546

EPW90

Integrated microfluidic lab-on-a-chip systems for synthesis and purification of fluorine-18 radiotracers

P. He, M. D. Tarn, M. M. N. Esfahani, N. J. Brown, N. Pamme, **S. J. Archibald**; University of Hull, Hull, UNITED KINGDOM.

Aims: Dose-on-demand production of radiopharmaceuticals has the potential to revolutionise positron emission tomography (PET) medical imaging. Producing a single dose of a desired radiotracer on-site will allow facile adoption of a stratified approach to patient treatment with rapid access to an increased range of radiotracers. We aim to produce modules for lab-on-a-chip device design that can be used for isotope processing, synthesis and quality control tests on a microfluidic scale. Materials and methods: Modules for electrode trapping and release of [18F]fluoride, synthesis of [18F]FDG and [18F]FLT and purification were produced as prototypes using bespoke manufactured microfluidic glass chips with etched channels. [^{18}F]fluoride was separated from [^{18}O]water by means of a microfluidic electrochemical cell into dry MeCN solution (0.3 mL) containing $KHCO_3$ and K222. [^{18}F]FLT was synthesized from 3'-N-Boc-5'-dimethoxytrityl-3'-O-nosyl-thymidine (10-15 mg) in capillary at 100 °C for 5 min followed acidic hydrolysis at room temperature for 2 min. Monolithic separation columns were produced in-house using a sol-gel process and chemically modified. Results: A process for highly efficient trap and release of [18F]fluoride from a low volume (< 200 μl) of aqueous solution allows trap and release into acetonitrile with an efficiency of up to 95% in both steps. [^{18}F]fluoride activity of 95-99% (initial activity 10 mCi) can be efficiently trapped and 75-78% of trapped [^{18}F]fluoride can be released into 0.3 mL of dry MeCN solution within 5 min, which is subsequently used for fluorination of FLT precursors at 100°C for 5 min and hydrolysis for 2 min at room temperature. Over 75% labelling yield and 100% hydrolysis yield can be obtained. Conclusions: Modules have been designed and tested for the synthesis of [18F]FDG and [18F]FLT. An efficient process for transfer of the [18F]fluoride into acetonitrile via electrode trapping allows synthesis of fluorine-18 containing radiotracers with high efficiency at low volumes. Separation modules using short in-house produced silica monolith columns were effective in providing sufficiently pure tracer samples for in vivo studies. Research Support: The authors thank the Daisy Appeal (grant no. DAhul0211) and the University of Hull (HEIF) for financial support. We would like to thank Dr Assem Allam for his generous support of this project.

EPW91

Rapid and cost effective SPE purification screening utilising 96 well plate technology

A. K. Kirjavainen[1], I. Khan[2], G. McRobbie[2], R. Fortt[1], J. Grigg[2], W. Trigg[2], S. K. Luthra[2], A. Gee[1]; [1]King's College London, London, UNITED KINGDOM, [2]GE Healthcare, Amersham, UNITED KINGDOM.

Aim: The aim of the study was to develop a solid-phase extraction (SPE) purification method as an alternative to the time-consuming HPLC purification of [^{18}F]GE-179. Several stationary and mobile phases were screened using a 96-well plate manifold. This enabled a SPE method to be rapidly developed. **Materials & Methods:** Decayed crude reaction mixture was diluted and spiked with GE-179 reference standard. This sample solution was loaded onto the conditioned plates. The plate manifold was connected to a vacuum pump and eluted dropwise. 96-well plates loaded with either ion exchange or tC18 (Waters) stationary phases were used to determine if GE-179 could be separated from the crude reaction mixture. Ion exchange well plates containing mixed cation (MCX), weak cation (WCX), weak anion (WAX) and mixed anion (MAX) ion exchange resins (24 wells each) were loaded with the crude solution. The loading was performed under acidic (pH 1), neutral (pH 7) and alkaline (pH 10) conditions. The existing published Waters 2x4 Method was employed to screen the ion exchange resins. For the tC18 well plate, the following variables were screened: organic mobile phase (MeCN or EtOH); pH (adjusted with TEA/H_3PO_4 to pH 4, 7 or 10) and wash volume. All loading, wash and elution samples were collected and analysed by HPLC (ca. 300 samples analysed). **Results:** MCX and WCX matrices trapped crude GE-179 but could not selectively elute the desired product from other guanidine-containing species. However, using tC18 cartridges, the crude reaction mixture could be trapped and purified using 40% MeCN at pH 7, where MeCN was found to be more effective than EtOH in washing away the less lipophilic impurities. GE-179 was then eluted into the product vial with acidified EtOH. **Conclusion:** The 96-well plate manifold was successfully used for screening of SPE purification of GE-179 in a rapid and cost effective way. Up to 96 different SPE purification conditions were tested in a single experiment. In 2-3 weeks, up to 300 samples were analysed by HPLC in order to determine the initial purification procedure. This technology provides an efficient means of screening SPE purification conditions for radiopharmaceutical products as an alternative to HPLC purification. **Acknowledgements:** This work was supported by European Commission, Marie Curie Fellowship FP7-PEOPLE-2012-ITN (316882, RADIOMI) and the National Institute for Health Research (NIHR) Biomedical Research Centre based at Guy's and St Thomas' NHS Foundation Trust and King's College London.

EPW92

Development of a simple kit-based method for the preparation of pharmaceutical grade ^{68}Ga-labelled radiopharmaceuticals

M. Asti, M. Iori, P. C. Capponi, S. Rubagotti, A. Fraternali, A. Versari; Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, ITALY.

Background: The use of the ^{68}Ge/^{68}Ga generators is still limited if compared to the ^{99}Mo/^{99m}Tc counterpart, mainly because of the absence of commercial kits and of a kit-based method for preparing ^{68}Ga-radiopharmaceuticals in a reliable way. The present study aim to develop and optimize a reliable direct preparation of gallium-68 labelled radiopharmaceuticals through a kit-based approach. **Methods:** A fraction of the eluate of two different 1110 MBq commercial ^{68}Ge/^{68}Ga generators (EZAG, ITG) or the whole eluate of a 370 MBq of a IRE-Elit generator, were directly directed into a vial prefilled with precursors (DOTATOC, DOTATATE, PSMA-11, PSMA-617) buffer and scavenger (the prototype of a potential lyophilized kit). The vial was directly warmed at 100 °C, or simply shaken a RT for HBED-CC-PSMA precursors, and then buffered with a 1.5 sodium ascorbate solution. Parameters influencing the reactions (reaction time, heating source, reaction pH, state of the reagents) were studied and optimized. The efficacy of the method in terms of incorporation yield and quality of the final radiotracers was compared to preparations performed with two commercial automatic synthesizers. For ^{68}Ga-DOTATOC the comparison was performed in terms of compliance to the Ph. Eur. Monograph. **Results:** In the optimal conditions, the incorporation yields were close to 98 % giving an overall radiochemical yield of the kit-based process between 75±4 % and 90±2 % not decay corrected (depending on the generator used). The radiochemical purities were all > 95 %. The ^{68}Ga-DOTATOC preparations were compliant with all specifications reported in the pharmacopoeia monograph. **Conclusions:** RCY and RCP of the proposed gallium-68 labelled radiopharmaceuticals performed by a kit-based approach are comparable to those obtained by automatic synthesizers. The feasibility of a kit-based approach for the preparation of ^{68}Ga-DOTATOC / DOTATATE / PSMA-11 / PSMA-617 was proved and a first home-made version of a putative lyophilized kit was proposed.

EPW93

Chemoselective ligation of 2-cyanobenzothiazole with 1,2-aminothiol: a novel approach to label biomolecules

C. Ieritano, **Y. Seimbille**; TRIUMF, Vancouver, BC, CANADA.

Aim: Development of molecular imaging probes has not kept pace with the discoveries in biology, and the labeling of biomolecules (peptides, antibodies, oligonucleotides, etc.) is one of the major limitations hampering further development and deployment of functional imaging as experimental and clinical tool. Novel bioorthogonal chemistry, including Huisgen's cycloaddition (CuAAC) or inverse electron-demand Diels-Alder cycloaddition (IEDDA), have been recently explored and demonstrated that they are promising avenues to label biomolecules. Considering the biocompatibility and the fast kinetics of the naturally occurring chemoselective ligation between 2-cyanobenzothiazole (CBT) and 1,2-aminothiol to produce firefly luciferin, we have investigated if this specific chemical reaction could be an attractive alternative. Materials and methods: CBT reacts rapidly and specifically with 1,2-aminothiol. This chemical reaction adheres perfectly to 'click' criteria. We have envisioned a series of CBT-based chelating agents and a fluorescein-CBT derivative, and subsequently labeled a peptide containing a N-terminal cysteine residue with various radioisotopes to demonstrate the efficiency and versatility of our ligation approach. Results: We have synthesized a fluorescein, DOTA, NOTA and deferoxamine (DFO) derivatives containing a 2-cyanobenzothiazole moiety. Synthesis of fluorescein-CBT was accomplished in three steps from 6-hydoxy-2-cyanobenzothiazole, while DFO-CBT and the two macrocyclic chelating agents - DOTA-CBT and NOTA-CBT - were obtained in four and five steps from the same starting material, respectively. To test our labeling strategy, a cyclic RGD peptide has been functionalized with a polyethylene glycol spacer bearing the 1,2-aminothiol bioorthogonal click handle. Chemoselective ligation of the RGD peptide with fluorescein-CBT, and subsequently with Al18F-NOTA-CBT, 68Ga-DOTA-CBT and 89Zr-DFO-CBT have been successfully achieved under mild aqueous conditions. Conclusions: Our work is demonstrating the potential of the condensation reaction between CBT and 1,2-aminothiol to label sensitive biomolecules. As a proof of concept, it has been illustrated with a RGD peptide containing a N-terminal cysteine residue, but we anticipate that it could be applied to a large spectrum of biomolecules with wide imaging applications in Life Sciences.

EPW94

Metal Ion Selectivity of Novel Chelates with Application to PSMA Targeted Theranostics

J. M. Kelly, A. Amor-Coarasa, A. Nikolopoulou, D. Kim, C. Williams, Jr., S. Vallabhajosula, J. W. Babich; Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, USA, New York, NY, UNITED STATES.

Aim: Theranostic probes for prostate cancer are of potential value due to their ability to detect and treat lesions using a single ligand. DOTA is commonly the chosen chelator for such use. Quantitative labeling with DOTA requires the use of high temperatures and/or long labeling times. We compared three cyclen-based chelators: the octadentate, DOTA, and the decadendate (**107**) and dodecadentate (**106**) macrocycles, originally

described by Chong, conjugated to the PSMA-targeting Glu-urea-Lys (EuK) moiety via a thiourea bond to the lysine ε-NH_2. *Methods:* Labeling kinetics were assessed for a series of M^{3+} radiometals, including ^{68}Ga, ^{111}In, ^{177}Lu and ^{225}Ac. Labeling was performed at pH 4.5-5.5 in NaOAc or NH_4OAc buffer using 5, 12.5 or 25 μg of ligand. Complex formation was studied at 25°C, 50°C and 95°C at 1, 5, 10, 15 and 30 min incubation using radioTLC. In addition, each ligand was labeled with ^{68}Ga for μPET/CT imaging studies in nude mice bearing LNCaP xenografts at 1hr p.i. *Results*: EuK-**107** chelated each of the four metals with >90% efficiency after 1 min at 95°C. Near-quantitative chelation was observed for ^{111}In at 25°C. EuK-DOTA performed similarly to **107**, although chelation of ^{111}In, ^{177}Lu and ^{225}Ac was slower. EuK-**106** achieved >90% chelation of ^{111}In at both 25°C and 95°C. In contrast, the maximum chelation of ^{68}Ga was >93% (95°C), chelation of ^{177}Lu was <40% after 30 min at 95°C and chelation of ^{225}Ac never exceeded 10%. Chelation at 50°C showed considerable variability for all of the complexes with each metal ion studied. The ^{68}Ga-labeled complexes accumulated in LNCaP tumors in the order EuK-**107**> -**106**> -DOTA (5, 4 and 3 %ID/g respectively) displaying good contrast to surrounding tissue. *Conclusions:* Decadentate **107** chelates a range of radiometals of diagnostic and therapeutic interest in near quantitative yields at 95°C. A PSMA-targeting ^{68}Ga-labeled construct incorporating **107** showed good tumor uptake (comparable to ^{68}Ga-HBED-CC). Some residual blood pool activity was observed, suggesting that tumor uptake may continue to increase over time, which is potentially valuable when therapeutic radionuclides such as ^{177}Lu or ^{225}Ac are coordinated. This property was not as evident for EuK-DOTA. On this basis, **107** merits further investigation as a potential chelating moiety for theranostics.

EPW95

68Ga vacuum elution approach for direct labelling of DOTA and NODAGA-conjugated peptides

R. BEN AZZOUNA[1,2,3], S. Leygnac[1,2,3], F. Al-Shoukr[1], F. Rouzet[1,2,3], D. Guilloteau[4], D. Le Guludec[1,2,3]; [1]Nuclear Medicine Department and DHU FIRE, Bichat-Claude Bernard University Hospital, AP-HP, Paris, FRANCE, [2]UMR 1148 Inserm, Paris, FRANCE, [3]Federation de Recherche en Imagerie Multimodale, Paris 7 University, Paris, FRANCE, [4]Inserm, U930, Université de Tours, CHRU, Tours, FRANCE.

Background and objective: In the last few years ^{68}Ga-labelling have gained increased interest for clinical PET. With chemical ^{68}Ge/^{68}Ga generators, a costly synthesizer was necessary to concentrate and pre-purify the eluate from its metallic impurities. A European pharmaceutical-grade generator has recently received marketing authorisation. The compliance of its eluate with the Eur. Pharmacopeia specifications makes possible the direct labelling of vectors. With the recent advent of single vial formulations, production of ^{68}Ga-radiopharmaceuticals becomes readily accessible to all PET centres. However, manual handling of ^{68}Ga results in a high radiation dose to the hand. Moreover, the elution of ^{68}Ga/^{68}Ge generator with the recommended HCl volume leads to a low ^{68}Ga concentration which can disturb the labelling. Our approach aimed to circumvent these disadvantages by the use of a concentrated vacuum elution which avoids the radiation exposure and allows the production of ^{68}Ga-labelled peptides with high radiochemical (RCP) and radionuclidic purities (RNP), ready for injection without further purifications. **Methods:** Labelling was performed using "vacuum elution and concentration approach". A vial containing 2.5 mL of 0.1M HCl and filled under nitrogen was connected to the inlet line of generator. A mixture of sodium acetate solution and DOTA or NODAGA-conjugated peptide was first transferred to an evacuated collection vial. The elution was then performed by the action of vacuum. The labelling of NODAGA-c(RGDyK) occurred instantly at room temperature (RT). DOTATOC labelling solution was incubated 7 minutes at 95°C. An evaluation of the radiation exposure using the manual elution with syringe vs the vacuum approach was done. **Results:** The "vacuum elution and concentration approach" makes possible the elution of 95% of the available generator activity with 2.5mL of eluent (vs. the 5 recommended mL). The radiochemical purities exceed 99% for ^{68}Ga-NODAGA-c(RGDyK) and 97% for ^{68}Ga-DOTATOC (n=3). ^{68}Ge breakthrough ranged from 1.62.E-06 to 2.19E-06 % (Eur. Pharmacopeia specification <1.E-03%). When elution was performed manually, the estimated dose to the hand Hp(0.07) at the calibration date of a 50mCi generator was 39μSv for RT preparation when collection vial is placed into a shielding and >117μSv when heating is required and therefore the collection vial is placed into a dry-heater without further shielding. Hp(0.07)= 0μSv with vacuum approach. **Conclusion:** The 68Ga vacuum elution and concentration approach allows production of 68Ga-radiopharmaceuticals with high RCP and RNP and marked reduction in radiation dose comparatively to the manual approach, making the 68Ge/68Ga generator the "PET equivalent" of the 99Mo/99mTc generator.

Copper-mediated nucleophilic [^{18}F]fluorination for [^{18}F]FMTEB and [^{18}F]flumazenil

A. Krzyczmonik[1], K. Grafinger[1,2], T. Keller[1], L. Pfeifer[3], S. Forsback[1], F. R. Lopez-Picon[1,2], M. Haaparanta-Solin[1,2], V. Gouverneur[3], O. Solin[1,4,5]; [1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]MediCity Research Laboratory, University of Turku, Turku, FINLAND, [3]Chemistry Research Laboratory, University of Oxford, Oxford, UNITED KINGDOM, [4]Accelerator Laboratory, Åbo Akademi University, Turku, FINLAND, [5]Department of Chemistry, University of Turku, Turku, FINLAND.

Aim: Copper-mediated nucleophilic [^{18}F]fluorination of boronic esters is a new method of preparation of PET tracers [1,2]. [^{18}F]Flumazenil [3] and [^{18}F]FMTEB [4] are examples of such tracers which can be synthetized by this method. The aim of this project was to test the quality of the final products and evaluate both tracers in rats. **Materials and methods:** [^{18}F]FMTEB and [^{18}F]flumazenil were synthesized from boronic ester precursors by nucleophilic fluorination using tetrakis(pyridine)copper(II) triflate as a catalyst. The products were purified by preparative HPLC methods and formulated in saline solution containing 10% ethanol. The quality control of the final products were done by analytical radioHPLC and radioTLC. Sprague Dawley rats were injected with [^{18}F]flumazenil (n=2; 21.5 and 15.6 MBq; 11.3 and 11.9 ng/kg, respectively) and with [^{18}F]FMTEB (n=3; 14.7±6.9 MBq, 0.9±0.5 ng/kg). The dynamic PET/CT scan was carried out for 60 min. The specific uptake of [^{18}F]flumazenil and [^{18}F]FMTEB in brain was demonstrated by pre-treatment studies. Midazolam, that acts at the $GABA_A$ receptor benzodiazepine modulatory site, and ABP688, a high affinity mGlu5 receptor antagonist, were injected 30 min before [^{18}F]flumazenil and [^{18}F]FMTEB injection. **Results:** [^{18}F]Flumazenil and [^{18}F]FMTEB were successfully synthetized using copper-mediated nucleophilic [^{18}F]fluorination. [^{18}F]Flumazenil syntheses (n=4; 498 ± 84 MBq) resulted in a final product with radiochemical purity (RCP) of 98±2 % and specific activity (SA) of 15±4 GBq/μmol. [^{18}F]FMTEB (n=4; 251±195 MBq) was produced with a RCP of 99±2 % and SA of 153±63 GBq/μmol. In both cases the SA was high enough to provide high quality PET images and the pre-treatment studies in rats confirmed specific uptake in brain. **Conclusion:** Copper-mediated nucleophilic fluorination provides high quality tracers suitable for in vivo PET imaging. **Acknowledgement:** Funding was received from the European Union's 7th Framework Programme for Research, grant number 316882 and from the Academy of Finland, grant number 266891. **References:** [1] Tredwell M et al. *Angew. Lymphatic system involvement in Klippel-Trénaunay syndrome detected by lower limbs lymphoscintigraphy with 99mTc-albumin nanocolloid

S. Capitanio[1], R. Dentici[2], C. Popescu[1], C. Coppola[3], R. Mattassi[4], C. Rossetti[1]; [1]Nuclear Medicine Department, ASST Niguarda Hospital, Milan, ITALY, [2]Nuclear Medicine Department, ASST Rhodense, Bollate Hospital, Bollate, (MI), ITALY, [3]Nuclear Medicine Department, University of Milano-Bicocca, Milan, ITALY, [4]Vascular Surgery Department, Humanitas Mater Domini Hospital, Castellanza (VA), ITALY.

AIM: Klippel-Trénaunay syndrome (KTS) is a rare congenital disease classically defined as the triad of vascular stain, soft tissue and/or bony hypertrophy, and venous varicosities more commonly affecting the lower limbs and usually isolated to one extremity. Lymphatic malformations are often associated to KTS but surprisingly difficult to diagnose with conventional imaging. Lymphoscintigraphy with 99mTc-albumin nanocolloid (LS) could represent a valid tool to easily detect lymphatic abnormalities in these patients improving their clinical management. The aim of our study was to determine the role of LS in the identification of lymphatic involvement in KTS patients. MATERIALS AND METHODS: we retrospectively analyzed 28 KTS patients (16 males and 12 females, age 30±16) who underwent a lower extremities LS between 2011 and 2015 at Nuclear Medicine Department of ASST Rhodense Hospital (Bollate, Milan). We performed a two-compartment LS in order to evaluate both deep and superficial lymphatic drainages. Firstly, we studied deep lymphatic circulation injecting about 15 MBq in a 0.3 mL dose using a 26-gauge needle in aponeurotic site of the soles of both feet. Images were recorded with a dual-detector instrument, using high-resolution parallel-hole collimators, in the whole-body scanning mode from the feet to the abdomen, at 5 and 30 minutes after plantar injections. Then, for the evaluation of the superficial lymphatic drainage, we performed 4 subcutaneous injections (about 9 MBq each) in the web space between the first and second and the fourth and fifth digits of the feet and in the medial and lateral retromalleolar regions of both limbs. Other series of images were subsequently acquired at 5 and 30 minutes after injections. Criteria for lymphatic dysfunction included delay, asymmetric or absent visualization of regional lymph nodes and/or lymphatic channels, the presence of "dermal flow", collateral lymphatic channels, hyperplasic or irregolar lymphatic channels. RESULTS: 23 of 28 patients (82%) showed lymphatic system anomalies. In 11 patients (39%) lymphatic abnormalities were bilateral involving also the limb without edema or other pathological features. In 13 of 28 patients (46%) the two-compartment technique allowed the identification of an altered deep circulation despite a normal superficial flow. CONCLUSION: Two-compartment LS showed that lymphatic abnormalities of the lower limbs are a common finding in KTS patients contributing to the limb swelling. This imaging technique could offer a reliable approach to diagnose and characterize the severity of lymphatic disease in these patients, leading to a more appropriate and effective treatment and preventing secondary effects.

PW02

Imaging of chronic recurrent multifocal osteomyelitis using ^{18}F-NaF PET/MRI

M. Ø. Fosbøl[1], H. H. Johannesen[1], C. Myrup[1], T. Bjarnsholt[1], V. A. Kristensen[2], L. Borgwardt[1]; [1]Rigshospitalet, Copenhagen, DENMARK, [2]Næstved Hospital, Næstved, DENMARK.

Introduction: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare inflammatory disorder in children and adolescents. Reliable imaging modalities are important to support diagnosis of CRMO and detect subclinical lesions. Aim of this study was to investigate the value of ^{18}F-NaF PET/MRI in detecting CRMO lesions compared to standard ^{99m}Tc-diphosphonate bone scintigraphy with supplemental SPECT/low dose CT. **Methods:** ^{18}F-NaF PET/MRI was performed in four patients (all females, age range 9-12 years) with CRMO verified by histopathology. PET/MRI was performed using a Siemens Biograph mMR 3 Tesla scanner 45 minutes after administration of ^{18}F-NaF (2.2 MBq/kg, max 100 MBq). MR imaging: DIXON sequences for attenuation correction, coronal STIR and coronal T1 weighted sequences from scull base to toes for diagnostic imaging. Images were interpreted by experienced pediatric nuclear medicine physician and -radiologist. Lesions with increased tracer uptake and/or pathology identified on MRI were classified as symptomatic CRMO foci, subclinical CRMO foci, equivocal foci or classified as pathology not related to CRMO. PET/MRI results were compared to planar whole-body bone scintigraphy with supplemental SPECT/ldCT. Study was approved by the local ethical committee. **Results:** 21 lesions were identified (9 symptomatic CRMO foci, 8 subclinical CRMO foci, 1 equivocal focus and 3 foci not related to CRMO). The CRMO lesions were localized in the long bones (n=11), pelvis (n=3), calcaneus (n=2) and talus (n=1). All CRMO lesions had increased uptake of ^{18}F-NaF, although one histopathological verified lesion presented as lower uptake in an epiphyseal plate with adjacent diffuse increased uptake. One symptomatic CRMO focus had no corresponding pathology on MRI. Bone scintigraphy identified 8 (89%) of the symptomatic foci and two (25 %) subclinical foci. **Conclusion:** Preliminary results suggest that ^{18}F-NaF PET/MRI can be valuable in CRMO patients by increasing detection rate of foci compared to MRI and bone scintigraphy with supplemental SPECT/ldCT.

PW03

Differential diagnostic value of bone SPECT/CT versus SPECT alone in patients presenting with newly diagnosed cervical neck pain

L. D'hulst[1], D. Nicolaij[2], L. Nouwynck[3], O. Gheysens[1,4], I. Malfait[3], A. Maes[2,4], C. Van de Wiele[2]; [1]Nuclear Medicine, AZ Groeninge Kortrijk and Nuclear Medicine and Molecular Imaging, University Hospital Leuven, Kortrijk, BELGIUM, [2]AZ Groeninge, Kortrijk, BELGIUM, [3]Catholic University Leuven, Kortrijk, BELGIUM, [4]Department of Imaging and Pathology, Catholic University Leuven, Leuven, BELGIUM.

Aim of the study: To assess differences in diagnostic value between bone single photon emission computed tomography (SPECT) / computed tomography and SPECT alone in patients referred for newly diagnosed cervical neck pain. **Patients and methods:** All consecutive patients that were referred to our department between 04-2014 and 02-2015 with new onset of cervical neck pain and without history of cervical interventions, were retrospectively included in the study. All patients underwent diagnostic bone SPECT/CT imaging of the cervical spine 4h after injection of a weight-adjusted activity of ^{99m}Tc-HDP according the EANM recommendations. SPECT and SPECT/CT images were independently interpreted by two experienced nuclear medicine physicians blinded to the clinical findings and other imaging results. Differences in image interpretation were resolved by consensus. Images were analyzed for the presence of abnormal findings and in case of a positive scan, the exact location was determined on SPECT and SPECT/CT. SPECT/CT imaging was used as gold standard for identifying the exact location of abnormal uptake. **Results:** Fifty-eight patients (13 men and 45 women) with a mean age of 49 years (range: 19 - 79 yrs) were included. In 21 patients (36%), both SPECT and SPECT/CT proved negative. In 11 patients (19%) both SPECT and SPECT/CT imaging showed facet joint arthropathy and/or discarthrosis that were concordant in terms of their exact level localization. In an additional 23 patients (40%) SPECT and SPECT/CT showed concordant pathological uptake in either disc or

facet joint but were discordant with regards to their location. Finally, in the remaining 3 patients (5%), SPECT findings were judged negative whereas SPECT/CT findings were considered positive. **Conclusion:** SPECT/CT imaging improves the accuracy for detection and localization of pathological bone uptake in patients presenting with newly diagnosed cervical neck pain. In our study, the location of active disease was changed in 40% of the patients when using SPECT/CT. Additionally, in three patients, SPECT/CT demonstrated pathology which was not detected on SPECT alone.

PW04

Canine NaF-18 PET/CT: Knee Assessment Using an Old Skeletal Radiotracer

M. I. Menendez, B. Hettlich, L. Wei, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

Osteoarthritis (OA) is a complex degenerative disease affecting the entire joint including synovium, menisci, ligaments and subchondral bone. It has been suggested that these subchondral bone changes are related to the severity of the cartilage lesions. Surgically-induced animal models of OA, such as an anterior cruciate ligament transection (ACLT) mainly involve inducing a mechanical instability within the joint, leading to pathological changes analogous to those observed in post-traumatic human OA. Sodium 18F-fluoride (18F-NaF) as a radiotracer per se in noninvasive in vivo imaging has been used to investigate musculoskeletal diseases. In clinical oncology, primary bone tumors, skeletal metastasis, benign bone diseases, and patellofemoral pain can reliably be detected by 18F-NaF PET. The aim of this study was to examine the use of 18F-NaF PET for the qualitative serially *in vivo* assessment of pathophysiological bone metabolism of induced OA in a canine model.Five skeletally mature Beagles underwent ACLT in one knee via arthroscopy, the contralateral knee served as control. Prior, 3 and 12 weeks after ACLT, under general anesthesia, the dogs underwent Na-F-18 PET-CT. Na-F-18 was injected (111 MBq) and PET/CT was performed using a Philips Gemini TF 64 PET-CT system (Cleveland, Ohio). Combined dynamic and whole-body imaging over 50 min were acquired. PET/CT parameters included 120KVp, 163mAs and 4 mm slice thickness, 90 seconds per bed position. Images were qualitatively analyzed by experienced blinded reader review and quantitatively by 3D ROI placement on the knee. The qualitative assessment of the scans performed prior to ACLT and post-arthroscopy, demonstrated significant differences in imaging characteristics. The knees that underwent ACLT showed a significantly higher Na-F-18 uptake than the contralateral uninjured knees at 3, 6 and 12 weeks. The higher Na-F-18 uptake found sequentially in the canine knees after ACLT is indicative of active bone turnover and altered bone metabolism. Thus, Na-F-18 PET/CT demonstrated to be a capable and reliable bone imaging marker detecting bone remodeling changes in the knee after a post-traumatic ACL transection in an *in vivo* canine model of OA. Na-F-18 PET provides insight into OA pathophysiology and appears to enable early diagnostic OA surveillance and therapy monitoring n pre-clinical studies.

PW05

The role of the scintigraphy using ^{99m}Tc-HMPAO labelled leucocytes in the diagnosis of inflammatory bowel disease in children with abdominal pain

D. Chroustova[1], N. El-Lababidi[2], J. Trnka[3], V. Ptacnik[1], J. Kubinyi[1]; [1]Department of Nuclear Medicine General University Hospital and 1st Faculty of Medicine, Charles University, Prague, CZECH REPUBLIC, [2]Clinic of Paediatrics and Adolescent Medicine, General University Hospital and 1st Faculty of Medicine, Charles University, Prague, CZECH REPUBLIC, [3]Department of Radiation Protection General University Hospital and 1st Faculty of Medicine, Charles University, Prague, CZECH REPUBLIC.

Introduction: Abdominal pain is one of the leading complaints in childhood. Its differential diagnosis is very broad. The possibility of inflammatory bowel disease (IBD) should be taken in mind. The clinical and laboratory findings are often unspecific. Imaging techniques can be helpful in setting the diagnosis. The first imaging method of choice is abdominal ultrasound and scintigraphy, due to their availability and non-invasive nature. The aim of this study was comparison of the results of scintigraphy using ^{99m}Tc-HMPAO (HexaMethylPropylenAmine Oxime) labelled leucocytes (LLE) and the final diagnosis in 69 children with suspected IBD and the evaluation of this method in the diagnostic scheme. Patients and methods: 69 children (30 boys and 39 girls, aged 4 to 18 years, average age 13.4 years) complaining of abdominal pain, examined between years 2010 and 2015 were included. After a detailed clinical and laboratory examination (in the majority of cases ASCA and fecal calprotectin levels were evaluated), scintigraphy using INFINIA Hawkeye 4 camera was performed after the administration of LLE. Early abdominal scintigrams were taken 40 minutes, abdominal SPECT 90 minutes and WB scans 180 minutes post LLE injection. The results were compared with the children's final diagnosis, which was established using other paediatric investigations and follow-up. Results: Corresponding scintigraphic findings and the final cause of abdominal pain were found in 92%. Using scintigraphy, 15 children were identified with IBD (in 14 cases Crohn's disease and in 1case ulcerative colitis). IBD was verified in these children using MR enterography and endoscopies including biopsies. 48 children had a negative scintigraphic result. Their final diagnoses were mostly a different chronic GIT illness or another systemic diseases. 6 children (8%) had a disagreement between the scintigraphy outcome and the MR enterography and/or biopsy findings. 4 children had a positive scintigraphy finding but IBD was not confirmed on a histological level. 2 children had a negative scintigraphy outcome but enterography and histological findings admitted the presence of IBD. Conclusion: The corresponding findings using scintigraphy using LLE and the final cause of the abdominal pain in children confirm the importance of this method as a non-invasive screening tool for verifying the presence and the degree of inflammation with a high sensitivity. In many cases, when this examination's result marks the probability of IBD as unlikely, it saves the child from undertaking more invasive procedures.

PW06

Diagnostic performance of (18F)-Fluorocholine PET/CT in comparison to conventional scintigraphic imaging in primary hyperparathyroidism

A. Cuderman[1], S. Rep[1], M. Hocevar[2], K. Zaletel[1], M. Jensterle Sever[3], T. Kocjan[3], L. Lezaic[1]; [1]Department for Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA, [2]Department for oncological surgery, Oncology Institute, Ljubljana, SLOVENIA, [3]Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Background: Primary hyperparathyroidism (PHPT) is a common endocrine disorder characterized by parathyroid PTH overproduction with surgical removal of overactive gland(s) being its definitive treatment. Conventional nuclear medicine imaging currently remains the method of choice in preoperative localization of the causative gland(s), however sensitivity in cases of multiple gland disease (multiple adenoma or hyperplasia) is suboptimal. In several pilot series, (18F)-Fluorocholine PET/CT was suggested as superior imaging modality in comparison to conventional scintigraphic imaging. **Objective:** evaluation of (18F)-Fluorocholine PET/CT as the possible superior modality in preoperative hyperfunctioning gland localization in a larger patient series. **Methods:** 88 patients with PHPT were imaged preoperatively with (18F)-Fluorocholine PET/CT and conventional parathyroid scintigraphic methods consisting of 99mTc-sestaMIBI SPECT/CT, 99mTc-sestaMIBI/pertechnetate subtraction imaging and 99mTc-sestaMIBI dual-phase imaging. Imaging results were compared against histology as the

gold standard and postoperative Ca2+ and iPTH to calculate sensitivity and specificity; McNemar's test was used for comparison of imaging methods. **Results:** The sensitivity of (18F)- Fluorocholine PET/CT was significantly higher at 95% than conventional scintigraphic methods combined at 65% (53%, 43% and 37% for 99mTc-sestaMIBI SPECT/CT, 99mTc-sestaMIBI/pertechnetate subtraction imaging and 99mTc-sestaMIBI dual-phase imaging, respectively; McNemar < 0,05 for all comparisons). The diagnostic superiority of (18F)-Fluorocholine PET/CT was particularly evident in patients with multiple gland disease. Specificity was 100% in all modalities. **Conclusion:** (18F)-Fluorocholine PET/CT is a significantly superior imaging modality than currently widely used conventional scintigraphic imaging.

PW07

The value of FDG-PET/CT in diagnosis and during follow-up of 273 patients with chronic Q fever

I. Kouijzer[1], **E.Aarntzen**[1], L. Kampschreur[2], P. Wever[3], C. Hoekstra[3], M. van Kasteren[4], M. de Jager-Leclerque[5], M. Nabuurs-Franssen[6], M. Wegdam-Blans[7], L. de Geus-Oei[8], W. Oyen[1], C. Bleeker-Rovers[1]; [1]Radboudumc, Nijmegen, NETHERLANDS, [2]University Medical Center Utrecht, Utrecht, NETHERLANDS, [3]Jeroen Bosch Hospital, Den Bosch, NETHERLANDS, [4]Elisabeth Hospital, Tilburg, NETHERLANDS, [5]Bernhoven Hospital, Uden, NETHERLANDS, [6]Canisius Wilhelmina Hospital, Nijmegen, NETHERLANDS, [7]Laboratory for Pathology and Medical Microbiology (PAMM), Veldhoven, NETHERLANDS, [8]Leiden University Medical Center, Leiden, NETHERLANDS.

Aim: Between 2007 and 2010, a large Q fever outbreak was observed in the Netherlands with over 4000 notified cases. In one to five percent of all acute Q fever infections, chronic Q fever develops, mostly manifesting as endocarditis, infected aneurysms, or infected vascular prostheses. Diagnosis is often difficult, because symptoms may be aspecific and infectious foci are often not visible with conventional imaging techniques. In this study, we investigated the diagnostic value of 18F-fluorodeoxyglucose positron emission tomography with combined computed tomography (FDG-PET/CT) in chronic Q fever at the time of diagnosis and during follow-up. **Materials and methods:** All Dutch adult patients suspected of chronic Q fever who were detected since the start of the Dutch Q fever epidemic in 2007 were retrospectively included until March 2015 when at least one FDG-PET/CT was performed. Clinical data and results from FDG-PET/CT scans at diagnosis and during follow-up were collected. **Results:** 273 patients suspected of chronic Q fever were included. Eventually, of 147 patients with proven chronic Q fever, 63 patients were diagnosed with infected vascular prostheses, 34 patients had an infected aneurysm, and 9 patients had definite endocarditis according to the revised Duke criteria. Of all 273 FDG-PET/CT scans performed at diagnosis, 31 scans (11.4%) led to a change in diagnosis (switch from probable to proven chronic Q fever). At diagnosis, 42 scans (15.4%), performed after blood and sometimes tissue PCR, led to treatment adjustment (start of antibiotic treatment in 37 patients, stop of antibiotic treatment in 2 patients, change of antibiotic treatment in 3 patients). Of all 175 scans performed during follow-up in 100 patients (median 2 scans per patient), 2 scans (1.4%) led to a change in diagnosis (switch from probable to proven chronic Q fever). Of 144 follow-up scans in patients with proven chronic Q fever, FDG-PET/CT led to a stop of antibiotic treatment in 12 (8.3%) of cases and 78 (54.2%) of FDG-PET/CT scans led to the decision of continuing antibiotic treatment. When adding FDG-PET/CT to the Duke criteria as major criterion, 15 more definite endocarditis were diagnosed. **Conclusions:** FDG-PET/CT is a valuable diagnostic technique in localizing chronic Q fever and during follow-up often leading to a change in diagnosis and/or adjustment of treatment.

PW08

Diabetic Patients With Suspected Foot Osteomyelitis: SPECT-WBC/MRI Versus SPECT-WBC/CT

M. Zorkaltsev, A. Kurazhov, V. Zavadovskaia, M. Zamyshevkaia, V. Udodov, E. Grigoriev; Siberian State Medical University, TOMSK, RUSSIAN FEDERATION.

Aim. To evaluate the diagnostic value of SPECT-WBC/MRI and SPECT-WBC/CT in detection of osteomyelitis in patients with various forms of diabetic foot (including Charcot foot). **Material and methods.** 80 patients (38 males and 42 females, aged 57.4 ± 12.1 years) with suspected diabetic foot bone infections were studied. Patients underwent 99mTc-HMPAO-labeled leukocytes scintigraphy (n=80, 370 MBq, SPECT Philips BrightView), MRI (n=54, Siemens Magnetom Essenza 1.5T), CT (n=26, GE Optima CT660 M40). Fusions of SPECT and MRI or CT were performed in program RView 9.06 (Colin Studholme). Diagnosis of osteomyelitis was established by pathologic specimen (n=31) and successful response to medical management (n=14). **Results**. When using SPECT-WBC/MRI (diagnostic criterion was a maximum accumulation of radiopharmaceutical in bone determined by MRI) were obtained 28 TP, 24 TN, 1 FP, and 1 FN results. SPECT-WBC/CT was demonstrated 15 TP, 9 TN, 1 FP, and 1 FN results. FP results in both methods were acquired in the case of neuroarthropathy (Charcot foot). Identified both FN results were due to the complexities of toes fusion. Summary, for SPECT-WBC/MRI in detections of osteomyelitis sensitivity, specificity, positive, negative predictive value and accuracy were 96.6%, 96.0%, 96.3%, 96.6%, and 96.0%, respectively, and for SPECT-WBC/CT 93.8%, 90.0%, 92.3%, 93.8%, and 90.0%, respectively. **Conclusion.** SPECT-WBC/MRI and SPECT-WBC/CT both demonstrated high sensitivity and specificity, and were comparable in detection of osteomyelitis in diabetic foot patients. FN results of SPECT-WBC/CT should be avoided if hybrid technic were used directly. But SPECT-WBC/MRI has potentially advantage in the indication of soft tissue infections.

PW09

Can we avoid early image at 30min on labelled leukocytes scintigraphy in the diagnosis of osteoarticular infection?

E. Noriega Álvarez[1], J. Rodríguez-Rubio Corona[1], I. Romero Zayas[2], M. T. Bajén Lázaro[1], A. M. Benítez Segura[1], M. P. Boya Román[1], A. Rodríguez-Gasén[1], G. A. Martínez-Pimienta[1], R. Jaller Vanegas[1], J. Suils Ramón[1], J. Mora Salvadó[1]; [1]Nuclear Medicine Department. Hospital Universitari de Bellvitge-IDIBELL., Barcelona, SPAIN, [2]Radiopharmacy and PET Units. Nuclear Medicine. IDI. Hospital U. de Bellvitge-IDIBELL, Barcelona, SPAIN.

Introduction and aim: Except for spine, white blood cell scintigraphy images (WBCS) is consider the first choice in Nuclear Medicine for bone infection diagnosis and the recommended protocol in literature includes images acquisition at 30min, 4h and 24h. The objective of this study is to demonstrate that it is possible to avoid early image at 30min in osteoarticular infection diagnosis in order to substantially shorten and simplify the exploratory protocol. ***Material and methods:*** 100 patients were studied (61 women, age 22-83 years) with suspected osteoarticular infection (e.g. axial osteomyelitis, peripheral osteomyelitis, joint prostheses, diabetic foot, etc.). Autologous leukocytes were radiolabelled with 740MBq of 99mTc-HMPAO following the EANM "Guidelines for the labelling of leucocytes with 99mTc-HMPAO." Acquisition of spot images at 30min, 4 and 24h p.i. with acquisition times of 5, 8 and 20 minutes respectively (based on the time correction acquisition decay). Two set of images were used: a) Group1: at 30 min, 4 and 24h b) Group2: only at 4 and 24h. The images were interpreted visually without any manipulations by two experienced nuclear medicine physicians. They classified WBCS

as: *Positive*: when there was an increase in intensity or extension of activity at 24h in comparison with earlier images. *Negative*: when there was no activity or there was a decrease in activity at 24h in comparison with earlier images. The clinical diagnosis was established by culture and/or biopsy in 52 cases and 6 months of clinical follow-up in the 48 remaining cases. Sensitivity, specificity, positive predictive value, negative predictive value and accuracy were analyzed in the two set of images. **Results:** Infection was confirmed by cultures/biopsy in 23 cases and infection was discarded in 77 cases (48 through follow-up and 29 by cultures). In Group1 WBCS were positive in 19 cases and negative for infection in 75 cases. In Group2 comparing with the Group1 there was not changes in visual analysis and the statistical data results are the same than Group1. ***Conclusion*:** Despite the small sample size in this preliminary study, the results both groups are the same, so it is possible to avoid 30min WBCS image without any changes in the scintigraphic diagnosis, in order to obtain a shorter acquisition protocol.

PW10

Usefulness of SPECT/CT in the diagnosis of posttraumatic and postsurgical peripheral bone osteomyelitis by Tc-99m-HMPAO-labeled leucocyte scan

S. Georga[1], V. Athanasiou[1], V. Vraggalas[2], G. Gkouvas[3], D. Karapiperis[4], D. Katsaboukas[1], I. Iakovou[1], V. Mpalaris[1], D. Lo-Presti[1]; [1]3rd Dept of Nuclear Medicine, Aristotle University Medical School, Papageorgiou Hospital, THESSALONIKI, GREECE, [2]2nd Orthopedic Dept of 424 General Military Hospital, THESSALONIKI, GREECE, [3]1st Orthopedic Dept of 424 General Military Hospital, THESSALONIKI, GREECE, [4]Infectious Diseases Dept of 424 General Military Hospital, THESSALONIKI, GREECE.

Introduction-Aim: Scintigraphy with in vitro labeled leucocytes has proven useful method for diagnosing complicated peripheral bone osteomyelitis. The aim of the study was to evaluate the contribution of SPECT/CT as an adjunct to planar images of ^{99m}Tc-HMPAO-labeled leucocyte scan (LS) for diagnosing posttraumatic and postsurgical peripheral bone osteomyelitis (OM). Patients and methods: Thirty two adult patients with clinical suspicion of peripheral bone OM in 36 sites, after trauma or fracture with or without metallic implants (n=24 sites), or after surgery (n=12) were enrolled in the study. Sites of suspected infection included: tibia (n=14), fibula (n=5), femur (n=4), calcaneous (n=5), other tarsal bones (n=3), metatarsus (n=3) and humerus (n=2). All patients underwent LS. Planar images were acquired 1 and 4 hours p.i. followed by a SPECT/CT scan. Bone marrow scan with ^{99m}Tc-tin-colloid (BMS) was additionally performed in 23 pts (26 sites). LS planar images were interpreted alone, in conjunction with SPECT/CT scans, and with BMS images. Persistent increased leucocyte bone uptake was compatible with OM. Incongruent LS/BMS images indicated OM. Final diagnosis was based on clinical follow-up or surgical results. Results: Final diagnosis was OM in 13/36 sites, soft tissue infection (STI) in 10/36 sites and no evidence of active infection in 13/36 sites. LS planar imaging results were: TP 11, TN 16, FP 7 and FN 2. The addition of SPECT/CT correctly localized infection to bone in 13/13 sites with OM and to soft tissues in 10/10 sites with STI, changing the interpretation of planar images in 6/36 sites (16.7%) and allowed better definition of the extent of infection in 17 more sites. SPECT/CT results were: TP 13, TN 19, FP 4 and FN 0. Sensitivity, specificity and accuracy of LS planar images for diagnosing posttraumatic and postsurgical OM were 84.6%, 69.6% and 75%, respectively, improved to 100%, 82.6% and 88.9%, respectively with the addition of SPECT/CT. The addition of BMS further improved specificity and accuracy of LS from 82.6% to 100% and from 88.9% to 96.1%, respectively, by reducing false positive results due to active bone marrow. Conclusion: SPECT/CT increases the diagnostic accuracy of LS for diagnosing posttraumatic and postsurgical peripheral bone OM, allowing accurate discrimination of bone from soft tissue infection and better definition of the extent of infection. Combination with bone marrow scan, in cases of equivocal LS results, further improves accuracy of LS by enabling differentiation of active bone marrow due to healing processes from infection.

PET Imaging In The Diagnosis Of Prosthetic Valve Endocarditis: Contribution Of The Standardized Uptake Value

A. Jiménez-Ballvé, C. Sánchez-Enrique, M. J. Pérez-Castejón, A. Ortega-Candil, M. Pedrera-Canal, I. Vilacosta, C. Olmos, I. Serrano García, J. L. Carreras-Delgado; Hospital Clinico San Carlos, Madrid, SPAIN.

Aim: The aim of this study was to assess the usefulness of the maximum Standardized Uptake Value (SUVmax) in ^{18}F-FDG PET/CT scans for the diagnosis of prosthetic valve endocarditis (PVE). Materials and methods: We performed a prospective study including 45 patients (30 male and 15 female), with suspiction of PVE according to the Duke criteria from February 2013 to August 2015. SUVmax was measured in the suspicious foci (prosthetic material) and in two regions with physiological FDG uptake (mediastinal blood pool in ascending aorta and liver parenchyma in right hepatic lobe). We calculated two SUV ratios by dividing SUVmax prosthesis/SUVmax aorta and SUVmax prosthesis/SUVmax liver. The gold standard was the Duke pathological criteria (when tissue available) and in cases without surgery the final diagnosis was established by the endocarditis team decision after ≥ 4 month follow-up. Results: In the 45 PET/CT scans, we analyzed 62 prosthesis (35 mechanical and 27 biological); 64% localized in aortic valve, 31% in mitral valve and 5% in tricuspid valve. The abnormal uptake distribution on the prosthesis was 58% diffuse, 29% focal and in 13% non increased uptake was detected. The mean of SUVmax in the prosthesis, aorta and liver were 5.0, 2.0 and 3.5, respectively. Final diagnosis was PVE in 31 foci (50%). Mean values of SUVmax showed significant differences (p<0,001) between the group with final diagnosis of definitive and rejected infective endocarditis (6.7 vs 3.4 for SUVmax prosthesis; 3.6 vs 1.6 for SUV ratio aorta and 2.1 vs 0.64 for SUV ratio liver). The ROC curves showed an area under the curve of 0.85 for SUVmax prosthesis, 0.89 for SUV ratio aorta and 0.91 for SUV ratio liver. Semiquantitative parameters identified positives cases of infective endocarditis with a SUVmax prosthesis cutoff value of ≥4.5 (81% sensitivity and 65% specificity), SUV ratio aorta cutoff value of ≥2.3 (84% sensitivity and 74% specificity) and SUV ratio liver cutoff value of ≥1.3 (87% sensitivity and 74% specificity). Cutoff value ≥6.3 SUVmax prosthesis, ≥3.0 SUV ratio aorta and ≥1.8 SUV ratio liver, achieved a specificity of 97% to confirm infection. We did not found differences in the mean of SUVmax between mechanical and biological prosthesis (4.7 vs 5.5; p=0.273). Conclusion: Semiquantitative analysis of FDG uptake seems to be useful in distinguish presence from absence of infection in patients with suspicion of prosthetic valve endocarditis, not finding differences in the prosthetic material.

PW22

Doxorubicin Effect on Myocardial Metabolism: a ^{18}F-FDG PET/CT and Echocardiographic Approach

M. Bauckneht[1], F. Fiz[1,2], G. Ferrarazzo[1], A. Ghidella[3], P. Ameri[3], P. Spallarossa[3], S. Fiordoro[1], A. Bellodi[4], L. Picori[1], G. Siclari[1], M. Miglino[5], S. Morbelli[1], C. Marini[6], G. Sambuceti[1]; [1]Nuclear Medicine Unit, IRCCS AUO San Martino IST, Genova, ITALY, [2]Nuclear Medicine Unit, Department of Radiology, Uni-Klinikum, Tübingen, GERMANY, [3]Cardiology Unit, IRCCS AUO San Martino

IST and Department of Internal Medicine, University of Genova, Genova, ITALY, [4]Department of Hematology and Oncology, IRCCS AOU San Martino – IST, Genova, ITALY, [5]Haematology Clinic, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOU S, Martino-IST, Genova, ITALY, [6]Institute of Bioimaging and Molecular Physiology, CNR, Milan, Genoa Section, Genova, ITALY.

Aim. Doxorubicin (DXR) induced cardiotoxicity is related to several mechanisms, including interference of mitochondrial respiratory chain and acceleration of glycolysis. We previously reported that this treatment may enhance myocardial FDG uptake. The present study aimed to verify whether this metabolic response on serial PET/CT imaging can predict myocardial function, non-invasively evaluated by follow-up echocardiography (ECHO). **Materials and Methods.** ^{18}F-FDG PET/CT of 25 patients affected by Hodgkin Disease (HD), treated following ABVD scheme were analyzed. Inclusion criteria were: 1) availability of 4 consecutive PET/CT scan for staging (PET1), interim (PET2), post-therapy (PET3) and six months follow-up evaluation (PET4); 2) full remission after two ABVD cycles; 3) normal baseline EKG and ECHO findings and 4) no concurrent treatment with external thoracic radiotherapy. A volume of interest was manually drawn on the left ventricular myocardium. Average standardized uptake value within this region was normalized for the corresponding blood pool index measured in the inferior vena cava to obtain LV-SUV. All patients underwent a 12 months cardiological follow-up assessment encompassing clinical evaluation, EKG and ECHO. A cardiologist unaware of PET findings performed this procedure. **Results.** LV-SUV progressively increased from PET1 to PET4 in 6 patients (24%, 2 females, mean age 39±17, termed "increasers") being 1.34±0.9, 3.34±2.6, 4.32±2.8 and 4.43±1.5 respectively. In the remaining 19 patients (76%, 7 females, 36±14), FDG uptake showed a largely variable response without any progressive increase. Accordingly, the ratio between PET4 and PET1 LV-SUV in the two subgroups was 3.85±0.8 and 1.06±0.4, respectively ($p<0.001$). Up to six months after therapy discontinuation, none of the 25 patients showed signs or symptoms potentially related to DXR cardiotoxicity. However, late follow-up ECHO detected the appearance of first-degree diastolic impairment with respect to baseline in 9 of the 25 examined patients (36%, 4 females, mean age 36 ±18). This finding occurred in 5/6 "increasers" (83%) and in only 4/19 non-increasers (21%) ($p<0.001$). **Conclusions**. The present data indicate that DXR related myocardial damage can be preceded by an enhanced glucose uptake. ^{18}F-FDG PET/CT imaging might represent a useful tool to identify high-risk patients and to implement personalized program to monitor and prevent DXR-induced cardiotoxicity.

PW23

Quantitative and qualitative analysis to decide if perform only stress MPI protocol

A. Di Palo, **A. Niccoli Asabella**, C. Altini, F. Iuele, A. Cimino, G. Rubini; Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, Bari, ITALY.

Aim: Myocardial perfusion imaging (MPI) is often employed to diagnose coronary artery disease (CAD) in patient with suspected angina. It is possible perform only stress MPI protocol (S-MPI) to saving time, costs and radiation exposure of patients and staff. We performed this study to establish a line of behavior to reduce significantly the radiation exposure but able to perform a reliable diagnosis of CAD. The aim of this study is evaluate if the choice to performing also the R-MPI is influenced by the qualitative or the quantitative analysis results in patients with the S-MPI. Material and Methods: We retrospectively analyzed S-MPI in 152 patients (57 female, 95 male), mean age 62,4 (range 12-84 years) who performed MPI according the standard protocol. We select patients with cardiac symptoms and without myocardial scar; among these 48/152 (31.5%) had a history for cardiovascular events, 31/152 (20%) had a doubt echocardiography, 42/152 (48%) had a pre-test doubt (ECG-stress or coronarography), 27/152 (17%) both the events and 4/152 (2.6%) none. 82/152 (53%) had a maximal stress test during the S-MPI. Images were analyzed with qualitative perfusion and quantitative gated single-photon emission computed tomography (SPECT) (QPS/QGS) software. We performed a qualitative analysis of stress imaging (QA-SI) and considered the Summed Stress Score (SSS) for the quantitative assessment. The agreement between the QA-SI and the SSS analysis was calculated with Cohen's Kappa. Results: Considering the qualitative analysis, the exam resulted positive in 81/152 (53%) and negative in 71/152 (47%); considering the SSS analysis 39/152 (26%) patients were positive while 113/152 (74%) were negative. Both the QA-SI and SSS analysis was positive in 28/152 (18%) patients; in 11/152 (7%) SSS analysis was positive and QA-SI was negative. SSS analysis was negative and the QA-SI was positive in 53/152 (35%) while SSS analysis and QA-SI were both negative in 60/152 (39%). The agreement between the qualitative analysis and the SSS analysis was considered to be poor (K=0.184;95%IC: from 0.054 to 0.314). Conclusion: The SSS analysis could be influenced by the presence of myocardial hypertrophy or dilatation or by no maximal ECG-stress-test; this explained the poor concordance. To avoid R-MPI is necessary know patients clinical history, pre-MPI test results but SSS analysis and especially QA-SI and a negative concordance of both evaluation permit to save about 50% of radiation exposure.

PW24

Implications of Residual Regional Myocardial Blood Flow and Perfusion/Metabolism Mismatch in Patients with Myocardial Infarction (MI)

E. Milan[1], L. Gallo[1], A. Pacchioni[2], L. Camoni[3], R. Giubbini[3]; [1]S. Giacomo Hospital, Castelfranco Veneto - Treviso, ITALY, [2]ULSS 13, Mirano - VE, ITALY, [3]University of Brescia, Brescia, ITALY.

Perfusion and glucose metabolism mismatch as detected by PET is an accurate parameter for assessment of myocardial viability and it is used to evaluate the amount of viable recoverable myocardium. Absolute myocardial blood flow (MBF) provide additional diagnostic and prognostic information for coronary disease. Aim of our study was to investigate the role of residual MBF as compared to extension of mismatch in patients with previous MI. METHODS 16 pts (63±9 y; 14M) with previous MI (3 anterior, 12 inferior, 1 lateral) and multivesses coronary artery disease were evaluate. All Pts underwent rest dynamic 13N-NH3 gated-PET and 18F-FDG gated-PET. Quantitative MBF evaluation was performed by using PMOD software, using 1-compartiment model developed by DeGrado. Extension of perfusion/metabolism mismatch was quantify by using 4D-M PET software: both 13N-NH3 summed rest score (SRS) and 18F-FDG SRS were calculated. RESULTS : 12/16 (75%) Pts received coronary revascularization (10 underwent PCI and 2 CABG). 14 vessel were revascularized by PCI and 5 by CABG. The median time from PET to revascularization was 10 (1, 28) days. 13N-NH3 SRS was 13.42 ± 10.3 and 18F-FDG SRS was 9.58 ±9.28 ($p<0.05$). In territories referred to vessel which were or were not revascularized 13N-NH3 SRS was 5.06 ±6.53 and 4.05±7.09, respectively (p= N.S.). 18F-FDG SRS was 3.65 ± 5.98 and 2.61 ±5.27 (p=N.S) in territories referred to vessel which were or were not revascularized. Rest MBF was reduced in 152/272 (56%) analyzed segments. Rest MBF was reduced in 11/14 (78%) vessels revascularized by PCI and in 4/5(80%) vessels revascularized by CABG. Rest MBF in segments attributed to LAD was 0.65 ± 0.17 in vessel revascularized vs 0.82 ± 0.23 in non revascularized ($p<0.05$). Rest MBF was 0.68 ± 0.14 vs 0.79 ± 0.18 (P= NS) in revascularized LCX and in non revascularized LCX, respectively. Rest MBF was 0.65 ± 0.12 vs 0.62 ± 0.23 (P= NS) in revascularized RCA and in non revascularized RCA, respectively. Analyzing the 4 pts whom didn't received revascularization a reduced rest MBF was found in only one coronary territory. CONCLUSION: neither FDG nor NH3 PET seem to influence the intention to treat in this group of pts. However the results of

PET scan can help Cardiologist in deciding which vessel need to be revascularized in multivessel diseased patients when partial revascularization is the therapy option

PW25

Rubidium-82 tracer activity optimisation for PET myocardial perfusion imaging

E. D. Huizing[1,2], J. D. van Dijk[1], J. A. van Dalen[3], J. R. Timmer[4], H. Arkies[1], C. H. Slump[2], P. L. Jager[1]; [1]Isala Hospital, Department of Nuclear Medicine, Zwolle, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS, [3]Isala Hospital, Department of Medical Physics, Zwolle, NETHERLANDS, [4]Isala Hospital, Department of Cardiology, Zwolle, NETHERLANDS.

Introduction: Rubidium-82 PET/CT is increasingly being used for relative and quantitative myocardial perfusion imaging (MPI). However, recommended administered activities may be unnecessarily high for the present generation PET scanners. These high activities expose patients to higher doses and may interfere with blood flow quantification because of dead time effects. Our aim was to derive the minimum administered activity that allows reliable relative MPI assessment, using a present generation PET/CT scanner. **Method**: We included twenty-eight consecutive patients who underwent clinically indicated rest-stress MPI PET (Ingenuity TF, Philips) using an activity of 1110MBq Rb-82 per scan. List-mode data was reconstructed to create a reference scan, and was used to simulate scans with administered activities of 925, 740, 555 and 370MBq. The reference rest scan was compared to each simulated rest scan and differences in summed rest score (SRS) and total perfusion deficit (TPD) were derived. Differences in SRS≥3 or TPD>7% were considered to potentially influence diagnostic outcome. Experts scored the image quality of all simulation and reference scans as sufficient or insufficient for diagnostic interpretation. Next, the two simulated activities which showed the most potential for clinical adoption were selected. Stress-rest PET scans of these two simulations were interpreted by experts as being normal, containing reversible and/or irreversible defects, and were compared to the interpretation of the reference scan using 1110MBq Rb-82. **Results**: Differences in SRS≥3 between simulations of 925, 740, 555 and 370MBq and the reference scan occurred in zero (0%), two (7%), four (14%) and five (18%) patients, respectively. TPD changes >7% were found only in the 370MBq simulation in one patient. Image quality was the same between the reference scan and the 925MBq and 740MBq simulations but differed between the reference and 555MBq ($p=0.046$) or 370MBq ($p<0.001$) simulations. The two simulated activities with the most potential for clinical adoption were 740MBq and 555MBq. Interpreted diagnostic outcome only changed in one patient at 740MBq as well as at 555MBq. However, for this patient SRS and TPD did not change. **Conclusion**: For PET MPI an administered activity of 740MBq Rubidium-82 can safely be adopted in clinical practice without affecting image quality. Lowering the activity to 555MBq could be considered, as this does not affect diagnostic outcome, although image quality decreases.

PW26

Single Stress Dual-Isotope Myocardial Perfusion Imaging using ^{99m}Tc SPECT and ^{82}Rb PET: A Phantom Study

N. L. Christensen, L. C. Gormsen, L. P. Tolbod; Dept. of Nuclear Medicine and PET-Centre, Aarhus University Hospital, Aarhus N, DENMARK.

Aim: Technetium-99m SPECT and rubidium-82 PET are two well established MPI modalities that have been used for decades in the diagnosis of cardiovascular diseases. In previous comparison studies, the patients underwent pharmacological stress imaging in different days, thereby complicating the evaluation of the methods. A way to directly compare the two modalities could be to use the same infusion of pharmacological stress agent for both exams, injecting ^{99m}Tc-sestamibi during the ^{82}Rb PET scan immediately after injection of ^{82}Rb. Our aim was to evaluate the technical aspect of having same-day PET and SPECT with a single episode of pharmacological stress. With this approach, we will be able to directly compare the diagnostic power of ^{82}Rb PET and ^{99m}Tc-sestamibi SPECT in patients with varying degrees of coronary artery disease. **Methods:** A thorax-cardiac phantom underwent five 10 minute dynamic PET scans in the following setups; 1) injection of 1110 MBq ^{82}Rb in the left ventricle, 2) injection of 50 MBq ^{99m}Tc-sestamibi in the phantom background and injection of 1110 MBq ^{82}Rb in the left ventricle, 3) 50 MBq ^{99m}Tc-sestamibi in the phantom background and injection of 1110 MBq ^{82}Rb in the left ventricle, followed by a bolus injection of 500 MBq ^{99m}Tc-sestamibi in a tube across the phantom, 4) 50 MBq ^{99m}Tc-sestamibi in the phantom background, followed by an injection of 40 MBq ^{99m}Tc-sestamibi in the left ventricle and 5) 50 MBq ^{99m}Tc-sestamibi in the phantom background and 40 MBq ^{99m}Tc-sestamibi in the left ventricle followed by an injection of 1110 MBq ^{82}Rb in the left ventricle. CT scans were made for attenuation correction. Furthermore, a 15 minute SPECT scan was made to ensure, that the ^{99m}Tc-sestamibi was correctly injected into the left ventricle. PET scans were analyzed by evaluating true coincidences, scatter fraction factor and deadtime factor. Furthermore, visual inspection of the images was made.**Results:** The injection and presence of ^{99m}Tc-sestamibi in the phantom does not influence the image quality of ^{82}Rb PET, as no significant changes was seen in either deadtime or scatter fraction corrections. Furthermore, visual inspection of the images showed no influence from the ^{99m}Tc-sestamibi tracer in the PET images either. **Conclusion:** The ^{82}Rb PET images are not affected by the presence of ^{99m}Tc-sestamibi, allowing for single stress same-day protocols of dual-isotope/dual-modality MPI studies in both patients with coronary artery disease as well as in healthy volunteers.

PW27

New analysis tool for automatic and unsupervised analysis of dynamic cardiac PET studies

C. Velasco Jimeno, J. Mateo, J. Ruiz-Cabello, S. España; Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, SPAIN.

Introduction: Dynamic cardiac PET imaging provides valuable information of myocardium physiological state. Analysis of dynamic cardiac PET scans requires volumetric delineation (left ventricle, right ventricle, and myocardium), determination of the left ventricular long- and short-axis, kinetic modeling analysis, and generation of polar plots. This process is very time consuming and the results are user-dependent leading to an intra- and inter-observer variability, which prevent its implementation in the clinical routine[1]. Thus, a tool for fully automatic analysis of dynamic cardiac PET studies has been developed in order to provide fast, robust and reproducible results. Methods: The analysis tool has been implemented in Python language using open source libraries for numerical and image processing. A series of dynamic PET images and a low-dose CT are loaded in order to perform the analysis. Left and right ventricles are automatically delineated applying k-means clustering to the early dynamic PET frames after tracer injection. Arterial input function is derived within the left ventricle. Myocardium is later segmented combining full dynamic PET and CT information including some anatomical constrains. According to the employed tracer a particular pharmacokinetic model is applied to derive the kinetic constants and to obtain parametric images. Short- and long-axis of the left ventricle are also obtained and images are resampled. In addition, myocardium delineation is used to generate polar plots of the results. The tool was tested on ^{68}Ga-DOTA PET/CT studies performed on a pig model of myocardial infarction. Results: Automatic delineation of left ventricle, right ventricle and myocardium as well as determination of short- and long-axis of left ventricle were validated against manually segmented and oriented contrast-CT images. Figure 1 shows the short- and long-axis views of perfusion of extracellular

volume fraction images obtained from the kinetic model as well as their polar plot representation Conclusions: We have developed and validated a fully automatic tool for analysis of dynamic cardiac PET studies. Obtained results show the ability of this tool to obtain parametric images of myocardium without user intervention.

Response to Hemorheological Parameters and Relative to Oxidative Stress in Patients with Cardiac Syndrome X diagnosed by Myocard Perfusion Scintigraphy

O. Yaylali, E. K. Toprak, T. Sengoz, Y. T. Yaylali, Y. Özdemir, Y. Ekbic, D. Yuksel, H. Senol, M. B. Kucukatay, V. Kucukatay; Pamukkale University Medical Faculty, DENIZLI, TURKEY.

Introduction: Cardiac syndrome X (CSX) is a clinical interest, yet the underlying pathophysiological mechanisms have not been fully elucidated. The most current pathomechanisms suggested for CSX tend to emphasize endothelial dysfunction and chronic, low grade inflammation. Although abnormal hemorheologic parameters and increased oxidative stress play a pivotal role in different cardiovascular pathologies have been well-defined, no clear information is available about the effects of CSX. The aim of the current study was to determine alterations in blood rheology (erythrocyte aggregation and deformability) and relative to oxidative stress parameters [total oxidant/antioxidant status and oxidative stress index (OSI)] in CSX patients with abnormal myocardial perfusion scintigraphy (MPS) and normal coronary angiography. **Materials and methods:** The study comprised 26 CSX patients (55.77±12.33 years) with angina pectoris, positive exercise test, abnormal MPS (Philips Brightview XCT; Ohio, Cleveland, USA), normal coronary angiography and 37 age and sex matched (56.32±11.98 years) healthy controls. Elongation index (EI) which is the indicator of erythrocyte deformability and erythrocyte aggregation were measured by an ektacytometer. Total oxidant/antioxidant status (TOS, TAS) were measured using a commercial kit and oxidative stress index (OSI) was calculated. **Results:** Erythrocyte deformability measured at 1.69, 3.00 and 30.00 Pa were lower in CSX patients compared to control (p=0.001, 0.017 and 0.006 respectively). On the other hand, erythrocyte aggregation index (AI) (72.75±7.65 vs. 66.48±6.63, p=0.002); TOS (24.058±7.833 vs. 16.398 ±7.963, p=0.001); TAS (1.998±0.327 vs. 1.595±0.549, p=0.0001) were significantly higher in the CSX group compared to control group. **Conclusion:** In CSX, higher oxidative stress values appear to be related with lower erythrocyte deformability and higher erythrocyte aggregation. Abnormal hemorheological parameters and increased oxidative stress might be involved in the pathophysiology of CSX. Treatment modalities that decrease oxidative stress and modify rheological parameters might be beneficial for the management of CSX.

PW29

Real-World Evidence of the Safety of Pharmacologic Stress in Myocardial Perfusion Imaging

A. Sabra[1,2], M. Heatley[1], M. Martins[3], R. Bidder[3]; [1]Cardiology Department, Singleton Hospital, Swansea, UNITED KINGDOM, [2]Swansea University School of Medicine, Swansea, UNITED KINGDOM, [3]Nuclear Medicine Department, Singleton Hospital, Swansea, UNITED KINGDOM.

Background: Myocardial perfusion imaging (MPI) is increasingly used as recommended by the National Institute for Health and Care Excellence (NICE) for patients with a 30-60% estimated likelihood of coronary artery disease. We aimed to investigate the safety of drugs used in patients undergoing pharmacologic stress MPI in our nuclear cardiology department. **Methods:** An 18-month (July 2014 - Feb 2016) retrospective study to investigate the incidence of adverse effects (AE) in patients undergoing pharmacologic stress MPI. We employ standardized protocols (Tc-99m) using 4 agents: dipyridamole, regadenoson, adenosine and dobutamine. Clinical data including AEs were collected from cardiobase. Descriptive analysis and frequencies were calculated. AE in MPI were compared to those occurring in 165 patients who underwent conventional exercise tolerance testing (ETT) using chi-squared test. **Results:** Seven hundred fifty-one patients were included in this analysis. Of the 586 patients (mean age 67 years [SD 11]; 310 men, 276 women), who had pharmacologic stress agent administered, 268 (45.7%) became symptomatic: dyspnoea (21.8%), flushing (15.4%), chest discomfort (11.4%), cough (3.2%), chest pain (2.6%), headache (2.6%), pain elsewhere (2.6%), nausea (2.4%), wheeze (2.2%), dizziness (2%), vasovagal reaction (1.9%), vomiting (1%), abdominal discomfort (0.5%). The commonest symptoms were chest discomfort and dyspnoea for dobutamine, flushing and dyspnoea for adenosine and regadenoson, and mainly dyspnoea for dipyridamole. Adenosine had the highest incidence of AE (69%). No significant complications were recorded that required hospital admission. Interestingly, patients who underwent ETT were reported to have a significantly higher incidence of AE than MPI patients did (MPI 268/586 [45.7%], ETT 104/164 [63.4%]; p <.0001). **Conclusions:** This real-world data show that pharmacologic stress MPI is safe when performed within agreed clinical protocols. Given that technicians routinely perform ETT, well trained physicists who are confident in managing the side effects and reassuring patients can lead the MPI testing particularly in busy cardiac units as long as support is available from medical staff.

PW30

F-18-FDG-PET/CT does not detect atrial inflammatory activity in patients with atrial fibrillation under routine conditions

N. Avramovic[1], P. Lange[2], M. Schäfers[1], G. Frommeyer[2], K. Wasmer[2], C. Pott[2], L. Eckardt[2], C. Wenning[1]; [1]Clinic for Nuclear Medicine, University Hospital Münster, Münster, GERMANY, [2]Section Rhythmology, Department of Cardiology and Angiology, University Hospital Münster, Münster, GERMANY.

INTRODUCTION: Atrial fibrillation (AF) is the most common cardiac arrhythmia in developed countries. Increasing evidence both from preclinical and clinical studies support a role for inflammation in the development, maintenance and progression of AF. However, direct evidence of persistent inflammatory activity in the atria of AF patients is scarce. On the basis on previous case reports, F-18-FDG-PET/CT was assumed to detect inflammatory activity in the atrial walls. In this study we wanted to test this hypothesis in a larger cohort. METHODS: Routine 18-FDG-PET/CT scans of patients referred for various clinical indications were retrospectively analyzed. Patients with a history of AF (n=37, 25 men; mean age 70±7 years) were compared to a control group without AF (n=37, 24 men; mean age 71±7 years). Standardized uptake values (SUV) were obtained in the left and right atrial wall, as well as in the lateral wall of the left ventricular myocardium, by placing 5 regions of interest (ROI) of equal size. Background activity was measured by one ROI in the right ventricular blood pool. Target to background ratios (TBR) were determined by calculating the ratio of SUVmax in the atrial wall and the SUVmean in the right ventricular blood pool. RESULTS: TBR of the left atrial wall did not display significant differences between patients with and without AF (1,14 ±0,29 vs. 1,21±0,27; p=0,338). A weak, albeit significant difference was observed in signal intensities in the right atrial wall compared to control (0,96 ±0,20 vs. 1,14±0,45; p=0,028). However, the absolute SUV of the right atrial wall did not differ markedly. In addition, this difference could not be recapitulated visually. Moreover, SUVmax of the atrial myocardium correlated with SUVmax of the left ventricular myocardium (r=0,35; p<0,01) thereby pointing towards a metabolic correlation. CONCLUSION: PET/CT imaging did not detect a difference in inflammatory atrial activity in patients with AF. Contrary to previous reports, these results do not support a role for FDG-PET/CT imaging of inflammatory activity in the atrial wall under routine imaging conditions. Prospective clinical studies would be helpful to clarify if metabolic myocardial suppression techniques may unmask inflammation.

PET imaging with [^{11}C]ITDM, a selective radioligand for metabotropic glutamate receptor subtype 1 (mGluR1), in pilocarpine-induced epileptic rat brain

T. Yamasaki, III[1], J. Yui[1], M. Fujinaga[1], Y. Shimoda[1], W. Mori[1], Y. Kurihara[1,2], H. Wakizaka[1], M. Zhang[1]; [1]National Institutes for Quantum and Radiological Science and Technology, Chiba, JAPAN, [2]SHI Accelerator Service Co. Ltd., Tokyo, JAPAN.

Aim: Epilepsy is known as one of neurological diseases characterized by epileptic seizures induced via overstimulation of glutamatergic neurons. The metabotropic glutamate receptors (mGluRs) moderate in excitatory neurotransmission upon the central nerves system (CNS). Among mGluRs, mGluR1 is known as a trigger of neurotoxic cascades. In this study, we aimed to in vivo monitor regional changes of mGluR1 in pilocarpine-induced status epilepticus (PISE) model rat brains via longitude PET assessments. **Methods:** PISE model rats were induced by repeated pilocarpine hydrochloride treatments (10 mg/kg) after administration with lithium chloride (127 mg/kg). PET assessments with *N*-[4-[6-(isopropylamino)-pyrimidin-4-yl]-1,3-thiazol-2-yl]-N-methyl-4-[^{11}C]-methylbezamide ([^{11}C]ITDM), a selective radioligand for mGluR1, were scheduled in acute (1 day), subacute (1 week), and chronic (3 weeks) periods after status epilepticus (SE). Acquired PET data were analysed with reference tissue models by PMOD software. To validate results of PET assessments, in vitro autoradiography with [^{11}C]ITDM was performed using PISE rat brain sections prepared in same experimental period used in PET experiments. **Results:** In PET assessments with [^{11}C]ITDM, binding potential (BP_{ND}) in the 1-3 cerebellar lobes significantly decreased ($P < 0.001$) in acute period ($BP_{ND} = 3.2$), subsequently recovering to normal level over subacute period ($BP_{ND} = 4.6$). Additionally, thalamic and hippocampal BP_{ND}s showed gradual declines with time after SE over chronic period. However, in vitro autoradiography showed no change of specifically bindings of [^{11}C]ITDM in the cerebellum in acute period, whereas bindings of [^{11}C]ITDM in the thalamus and hippocampus indicated a tendency of decrease with time after SE. **Conclusion:** Our study indicates that gradual declines of mGluR1 expressions in the thalamus and hippocampus of PISE model rat brain via longitude PET imaging. In vivo monitoring of mGluR1 using PET with [^{11}C]ITDM may enable to further understand mechanism involved in dysfunction of CNS.

PW32

Combined [^{18}F]DPA-714 and [^{18}F]FDG PET and autoradiography imaging of microglia activation in traumatic brain injury in mice

I. Israel[1], A. Ohsiek[2], E. Al-Momani[1], C. Stetter[2], C. Albert-Weißenberger[2], A. Buck[1], A. Sirén[2], **S. Samnick**[1]; [1]University of Wuerzburg, Wuerzburg, GERMANY, [2]Department of Neurosurgery, University of Wuerzburg, Wuerzburg, GERMANY.

Background: Traumatic brain injury (TBI) is a major cause of death and disability. Activated microglia contribute to acute damage after TBI and modulate long-term evolution of degenerative and regenerative responses to injury. In the present study, we correlated microglia activation to lesion severity and cellular identity of inflammatory cells in a murine closed head injury model using a combined approach of intra-individual *in vivo* μPET imaging and *ex vivo* autoradiography with the specific 18-kDa translocator protein (TSPO) radioligand [^{18}F]DPA-714. In parallel, [^{18}F]FDG-PET was also performed in the same animals to evaluate the cerebral glucose metabolism. Imaging data with [^{18}F]DPA-714 were correlated with immunohistochemical analysis. ***Methods:*** A closed head TBI on C57BL/6N mice was induced by a falling weight onto the skull of mice. According to the height of the weight a diffuse or focal TBI was induced. The functional outcome was evaluated 1 h, 3 and 7 days after injury induction using a standardized neuroscore (NSS). [^{18}F]DPA-714-μPET imaging was performed on day 1, 7 and 16 and [^{18}F]FDG-μPET on days 2-5 after trauma using freshly synthesized radiotracers. On days 7 and 16, [^{18}F]DPA-714-autoradiography was performed on brain cryosections prepared immediately after μPET imaging. The sections used for autoradiography were subsequently exposed to antibodies against the activated microglia marker IBA-1. ***Results:*** Functional outcome in mice with a focal TBI was significantly worse than in sham operated mice or mice with diffuse TBI. [^{18}F]FDG uptake was acutely reduced in the brains with focal lesions. Mice with diffuse TBI and less severe neurological deficits showed no significant reduction in [^{18}F]FDG accumulation. Repeated μPET imaging with [^{18}F]DPA-714 showed increased radiotracer uptake in focal brain lesions on days 7 and 16 after TBI. In autoradiography [^{18}F]DPA-714 uptake in focal trauma lesions correlated strongly with both NSS and the number of IBA1-positive microglia. After diffuse TBI microglia activation was detected in both hemispheres by immunohistochemical staining; however, it was not clearly observable by autoradiography or in μPET imaging. ***Conclusion:*** [^{18}F]DPA-714 uptake correlates with functional outcome and number of activated microglia after closed head TBI and can be used for repeated monitoring of neuroinflammation after TBI.

PW33

Biodistribution and metabolism of [^{18}F]FMTEB in rats

F. R. Lopez-Picon[1,2], A. Krzyczmonik[1], K. Grafinger[1,2], T. Keller[1], L. Pfeifer[3], S. Forsback[1], O. Solin[1,4,5], V. Gouverneur[3], M. Haaparanta-Solin[1,2]; [1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]Medicity Research Laboratory, University of Turku, Turku, FINLAND, [3]Chemistry Research Laboratory, University of Oxford, Oxford, UNITED KINGDOM, [4]Accelerator Laboratory, Åbo Akademi University, Turku, FINLAND, [5]Department of Chemistry, University of Turku, Turku, FINLAND.

Aim In this study we aimed to study in rats the biodistribution and metabolism of [^{18}F]FMTEB, a tracer for metabotropic glutamate subtype-5 receptors (mGluR5s), prepared via copper-mediated nucleophilic [^{18}F]fluorination of boronic ester [1,2]. **Materials and methods** To study pharmacokinetics *ex vivo,* we injected 18 healthy adult Sprague Dawley rats (289±17 g) with [^{18}F]FMTEB (injected dose, 15.9±5.1 MBq; injected mass, 0.7±0.3 ng/kg; SA, 153±64 GBq/μmol at the time of injection). The rats were sacrificed 5, 15, 30, 60 or 90 min post injection. Organs of interest were dissected, weighted, and measured for radioactivity. Retention and distribution of [^{18}F]FMTEB in the rat brain was evaluated with *ex vivo* autoradiography. For three animals dynamic PET/CT scan was carried out for 60 min. The amount of intact tracer and its radioactive metabolites were analysed from blood and brain homogenates. The specificity of the synthetized [^{18}F]FMTEB for mGluR5s, was tested blocking with ABP688, a high affinity mGluR5s antagonist. **Results** [^{18}F]FMTEB was cleared rapidly from the blood, and in most tissues and organs the radioactivity uptake peaked at 5 min. The highest radioactivity was detected in the liver at 5 min, and later in the small intestine and urinary bladder. High levels of radioactivity were also recorded in the Harderian glands, brown adipose tissue and adrenals. Plasma metabolite analyses demonstrated that [^{18}F]FMTEB was metabolized rapidly into three polar metabolites. One polar radioactive metabolite was found in brain, however its concentration at all analysed time points did not exceeded 10%. Both PET/CT scans and *ex vivo* brain autoradiography showed high uptake in the striatum, hippocampus and cortex. Using the cerebellum as a reference region, the uptake ratios of 22.6±3.2 and 16.5±2.4 (n=3) were obtained at 60 min for the striatum and hippocampus, respectively. Pre-treatment with ABP688 reduced the radioactivity uptake in striatum and hippocampus up to 85%. **Conclusion** PET/CT and ex vivo brain autoradiography studies demonstrated that [^{18}F]FMTEB rapidly entered the rat brain, and specifically bound

to mGluR5s rich regions such as striatum, hippocampus and cortex. **Acknowledgement** Funding was received from the European Union's 7th Framework Programme for Research, grant number 316882 and from the Academy of Finland, grant number 266891. Investigating the co-grafted effects of rat Sertoli cells and porcine VM tissue in a rat model of Parkinson's disease using [^{18}F]-DOPA/PET

K. Ma[1], Y. Jhao[1], T. Liu[1], S. Weng[1], R. Yen[2], K. Tzen[3]; [1]Department of Biology and Anatomy, National Defense Medical Center, Taipei, TAIWAN, [2]Department of Nuclear Medicine, National Taiwan University Hospital, Taipei, Taiwan., TAIPEI, TAIWAN, [3]Department of Nuclear Medicine, National Taiwan University Hospital, Taipei, Taiwan, TAIPEI, TAIWAN.

Aim: Parkinson's disease (PD) is a neurodegenerative disease characterized by a loss of dopaminergic neurons in the nigrostriatal pathway, leading to the progressive movement disorder. The cell therapy has been demonstrated a viable treatment in the late stages of PD. However, the usage of human fetal ventral mesencephalic (hfVM) tissue raises ethnic issues that remain unresolved. The xenograft strategy using porcine VM (pVM) tissue may be an alternative source for cell replacement, but the transplant rejection induced by pVM needs to be resolved. The Sertoli cells (SCs), also called nurse cells, may provide immunomodulatory effects for both allografts and xenografts and increase the survival rate of the grafted neurons. In this study, the rat SCs and pVM were co-grafted in the striatum of the PD rat, and the beneficial effects contributed by the SCs for xenograft were evaluated using apomorphine-induced behavioral test, immunohistochemistry, and [^{18}F]-DOPA/animal-PET. **Materials and methods:** The PD rat model were created by injecting 6-hydroxydopamine (6-OHDA) into right median forebrain bundle of the rats. The SCs were isolated from SD rats at postnatal 21 days and the pVM tissues were dissected from swine at 27 embryonic days. The rat SCs and pVM tissues were co-grafted into the striatum of the PD rat and the Apomorphine-induced rotational behavior was tested at 1 and 2 months after the transplantation. The [^{18}F]-DOPA/animal-PET was employed to evaluate the survival status of the dopaminergic neurons. Two months after transplantation, immunohistochemistry studies were performed to investigate the immunomodulatory effects of SCs in the grafted striatum. **Results:** In the test of drug-induced rotational behavior, the numbers of rotation were significantly reduced at 2 months after the co-grafted surgery. The images of PET showed that [^{18}F]-DOPA uptakes in the co-grafted area were increased at 2 months after the surgery of the PD rats. The immunohistochemistry data demonstrated that microglia (OX42 positive cells) in the striatum of co-grafted group were obviously less than that of pVM-grafted group. **Conclusion:** Our results suggested that the SCs may provide immunomodulatory effects on the grafted porcine dopaminergic neurons in the striatum of the rat brain.

PW35

Influence of reference regions in the performance to quantify 18F-Florbetapir studies

A. Fernandez-Leon[1,2], F. Sampedro[3], E. Vilapalana[4,5], J. Fortea[5,4], M. Carmona[4,5], D. Lopez Mora[1], D. Alcolea[4,5], A. Lleo[4,5], R. Blesa[4,5], I. Carrio[1], V. Camacho[1]; [1]Nuclear Medicine Department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [2]Departament de Ciencies Morfologiques. Universitat Autonoma de Barcelona, Barcelona, SPAIN, [3]Faculty of Medicine. Universitat Autonoma de Barcelona, Barcelona, SPAIN, [4]Memory Unit, Neurology Department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [5]Centre of Biomedical Investigation Network for neurodegenerative Diseases (CIBERNED), Barcelona, SPAIN.

The objective of this study was to evaluate different reference regions to quantify amyloid PET studies and correlate them with cerebrospinal fluid (CSF) measurements in 18F-Florbetapir studies. **Material and methods:** we included 50 consecutive patients (27 health control (HC), 12 with mild cognitively impairment and 10 with Alzheimer's disease AD)) who underwent 18F-Florbetapir PET-CT. Studies were performed 50 minutes after injection of 370mBq of tracer. After transmission data was obtained, brain PET dynamic acquisition was performed (2x5min frames). The reconstruction method was iterative (LOR RAMBLA, 3 iterations and 33 subsets) with a 128x128 image size, 2mm pixel size and 2mm pixel slice thickness. Florbetapir PET images were visually assessed as positive and negative. For the quantitative analysis, Freesurfer segmented T1 MRI were coregistered to PET studies, which were subsequently used to extract weighted cortical retention means (SUVRs) using five different reference regions (whole cerebellum (WhCer), cerebellar gray matter (CGM), brainstem (B), eroded subcortical white matter (ESWM) and composite reference region (C). Also we determined the CSF measurements: Aβ42, Tau, pTau and Aβ42/Tau ratio. **Results:** To differentiate between HC and AD patients, the best SUVr cut-off points for each reference region: 1.102 using WhCer (AUC 0.95; S:90%, E:89%), 1.216 CGM (AUC 0.937; S:90%; E:89%), 0.947 B (AUC 0.948; S: 90%, E:96%), 0.74 ESWM (AUC 0.885; S:90%, E:96%) and 0. 931 C (AUC 0.930; S:90, E:96%). No significant performance differences were obtained between the reference regions. Significant correlation between CSF measurements and SUVr values using different reference regions were observed. The Aβ/Tau ratio presented the highest correlation with the SUVr values in all reference regions (WhCer: -0.785;CGM:-0.776,B: -0.787; ESWM:-0.745; C: -0.789; $p<0.01$). **Conclusion:** Several reference regions may be used to quantify Florbetapir studies. Significant correlation between SUVr values using different reference regions and CSF measurements were observed; the highest correlation was observed between the Aβ/tau ratio and SUVr values obtained from all reference regions studied.

PW36

Optimal reference region to measure longitudinal amyloid-beta change with 18F-florbetaben PET

S. Bullich[1], A. M. Catafau[1], V. L. Villemagne[2], C. C. Rowe[2], S. De Santi[3]; [1]Piramal Imaging GmbH, Berlin, GERMANY, [2]Department of Nuclear Medicine and Centre for PET, Austin Hospital, Melbourne, AUSTRALIA, [3]Piramal Pharma Inc, Boston, MA, UNITED STATES.

Background: Accurate measurement of longitudinal changes of amyloid-beta (Aβ) deposition in the brain is important in anti-Aβ therapeutic trials. Optimal reference region (RR) selection is essential to reduce the variance of PET measurements, allowing early detection of treatment efficacy. The aim of this study was to determine the RR that allows earlier detection of subtle Aβ changes using 18F-florbetaben (FBB) PET. **Methods:** 18F-FBB PET scans from 45 mild cognitively impaired (MCI) patients (72.69 ± 6.54 yrs., 29 male/16 female) who underwent three FBB scans were included (baseline (n=45), one-year (n=41) and two-years (n=36)). FBB scans were visually assessed as positive and negative. Cortical regions (frontal, lateral temporal, occipital, parietal, anterior cingulate and posterior cingulate) were quantified using the standardized AAL region-of-interest (ROI) atlas applied to the spatially normalized gray matter PET image obtained from the segmentation of the participant's baseline T1-weighted volumetric MRI. Four regions of reference (gray matter cerebellum (CGM), whole cerebellum (WCER), pons (PONS) and subcortical white matter (WM)) were studied. Cortical standardized uptake value ratio (SUVR) for each RR was calculated dividing cortex activity by the RR activity. A composite SUVR was calculated by averaging SUVRs from all cortical regions. SUVR at baseline to the SUVR from one- and two-years follow-up scans were compared using a T-test grouped

according the anticipated pattern of change for the MCI patients. **Results:** Both CGM and WCER RRs enabled early detection of cortical SUVR changes in those scans that were positive at baseline. Average percent of Aβ accumulation per year (mean±SD) derived from composite SUVR in negative (-) and positive (+) scans was 0.13±1.68(-)/1.39±2.02(+) for CGM, 0.16 ± 1.43(-)/1.36±1.79(+) for the WCER. Composite SUVR increase in positive scans was significantly larger than those in negative scans between baseline and 1-year follow-up (p(CGM)=0.04, p(WCER)=0.02) and between baseline and 2-years follow-up scans (p(CGM)=0.04, p(WCER)=0.02). PONS detected significant changes only at 2-years follow-up (p(1-yr)=0.71, p(2-yrs)=0.001) while SWM did not show significant difference either follow-up (p(1-yr)=0.50, p(2-yrs)=0.04). **Conclusions:** Reference region selection is essential to obtain reliable and early measurement of amyloid-beta changes. Cerebellar reference regions (CGM and WCER) are recommended as RR for 18F-FBB PET since they allow earlier detection of amyloid-beta change.

PW37

Brodmann ´s areas agreement between the early acquisition of FLORBETABEN-PET and FDG-PET. Multicenter study

P. SOPENA-NOVALES; HOSPITAL 9 DE OCTUBRE, valencia, SPAIN.

Aim: The aim of this work, is to compare the uptake brain pattern between the early vascular phase of florbetapen-PET (eFBB) and FDG-PET based on the hypothesis that the eFBB represents regional brain perfusion and could be a surrogate of glucose brain metabolism measured by FDG-PET. **Materials and Methods:** Thirty-two patients with early and/or atypical onset of cognitive impairment from two different PET-CT centers were enrolled, 20 men; mean age 66.5 ± 7.2 years. All patients were explored by FDG-PET (acquisition according to EANM procedure guidelines) and two acquisitions of FBB-PET: the early FBB-PET scan (eFFB), 0-10' p.i 3D, and a standard FBB-PET scan (sFBB), 90' p.i 3D. Performed by specific protocol and the following Manufacturer recommendations Data from FDG and eFBB were processed using a extraction algorithm that computes the mean intensity of 116 Brodmann´s areas (BAs). Afterwards data were analyzed for independent BAs, based on correlation analysis and two-sample t-test (α=0.05) between both modalities. **Results:** Correlation analysis in 14 regions (including Rectus, Cingulum, Parietal, Angular, Precuneus, Caudate, Heschl, Temporal and Vermis regions) were found to be significant ($p<0.05$) between both uptakes. The p-value was computed by transforming the correlation to create a ¨t¨ statistic having N-2 degrees of freedom, where N is the number of samples. The complementary analysis based on two sample t-test for α =0.05 (the type II error may be negligible due to the sample size), enabled to discard the BAs that are not statistically similar in both modalities. A total of 68 out of 116 regions couldn't be rejected under the test including Frontal, Insula, Cingulum, Hippocampus, Temporal, Cerebellum, etc. subregions. Moreover, when the image patterns were considered as inputs into a supervised learning system (i.e. PCA-based PETRA method), the classification accuracy, sensitivity and specificity were extremely low (<5%) and the system failed to predict the underlying classes (i.e. modalities). **Conclusion:** The eFBB uptake showed a significant correlation in the most of BAs and only different in a small fraction of BAs to FDG acquisition which prompted to supervised learning computed system to not tell if the study corresponded to eFBB or FDG.

PW38

FDG-PET and MRI study of default-mode network integrity in disorders of consciousness

G. Marotta[1], C. Rosazza[2], A. Andronache[2], D. Sattin[2], M. Bruzzone[2], A. Nigri[2], S. Ferraro[2], R. Benti[1], M. Leonardi[2], L. D'Incerti[2], L. Minati[2]; [1]Department of Nuclear Medicine, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY, [2]Neuroradiology Dept, Istituto Neurologico Besta, Milano, ITALY.

Introduction. Disorders of consciousness (DOC) encompass a spectrum of conditions ranging from coma, vegetative state/unresponsive wakefulness state (VS/UWS), minimally conscious state (MCS) to severe disability (SD). The default-mode network (DMN) is known to be dysfunctional, although correlation with level of consciousness remains controversial. We investigated DMN activity with resting-state functional MRI (rs-fMRI) and conducted separate analyses for independent component analysis (ICA), seed-based analysis (SBA), and FDG-PET. **Methods.** We enrolled 119 consecutive patients: 72 in VS/UWS, 36 in MCS, and 11 with SD. All underwent structural MRI and rs-fMRI, and a subset of 85 patients also underwent FDG-PET. Data were analyzed with manual and automatic approaches. DMN integrity was assessed multimodally: (1) functionally, based on ICA and SBA of rs-fMRI; (2) anatomically, based on visual ratings of anatomical damage in the DMN regions, as visualized by conventional MRI scans; and (3) metabolically, based on average SUV values in the DMN regions by FDG-PET scans. FDG-PET images were coregistered using SPM12 to individual volumetric T1-MRI series, which were segmented to generate the normalization deformation field to be applied to coregistered FDG-PET scan. Using the DMN mask, the average SUV values for PCC, LPC and MFC were computed. **Results.** DMN activity was decreased in VS/UWS compared to MCS ($p<0.001$), and correlated with clinical score. Independent-component and seed-based analyses provided similar results, although the latter and their combination were most informative. Structural MRI and FDG-PET were less sensitive to head movement and had better diagnostic accuracy than rs-fMRI when all cases were included. Excluding the quartile with largest head movement and considering only the subsample of patients who underwent FDG-PET, sMRI (AUC 0.72) and rs-fMRI (AUC 0.65) provided similar performance, and FDG-PET was slightly superior to both (AUC 0.75). Voxelwise analyses of SUV maps delineated a broader set of regions, which encompass the posterior DMN nodes; whereas correlation with the CRS-R yielded a clear and broader effect, comparison of MCS versus VS/UWS led to a more constrained difference than rs-fMRI. **Conclusion.** We investigated the integrity of DMN in relation to consciousness with rs-fMRI in the largest group of DOC patients, directly comparing rs-fMRI with sMRI and FDG-PET. We confirm a significant relationship between functional, anatomical, and metabolic integrity of the DMN and clinical status, and provide additional insight on the potential clinical contribution of each technique. Structural integrity across DMN regions also correlates with consciousness level, and FDG-PET yields the highest accuracy scores.

PW39

Evaluation of Parkinson's disease by neuromelanin-sensitive MR imaging and ^{123}I-FP-CIT SPECT

T. Ogawa, K. Kuya, Y. Shinohara, F. Miyoshi, S. Fujii, Y. Tanabe; Tottori University, Yonago, JAPAN.

Introduction: Neuromelanin-sensitive MRI can visualize the neuromelanin-containing neurons in the substantia nigra pars compacta (SNc), and its utility has been reported in the evaluation of parkinsonism. On the other hand, dopamine transporter imaging by ^{123}I-FP-CIT SPECT (DaTSCAN) is now an established method for evaluating parkinsonism, detecting presynaptic dopamine neuronal dysfunction. Both methods can assist the differentiation between the neurodegenerative parkinsonism and the other parkinsonisms. However, to our knowledge, there have been a few studies concerning a correlation between two methods. The aim of this study is to correlate the utility of neuromelanin-sensitive MRI and DaTSCAN for the diagnosis and management of Parkinson's disease. **MATERIALS AND METHODS**: Seventeen patients with Parkinson's disease who underwent both neuromelanin-sensitive MRI and DaTSCAN were included. We measured the volume of the neuromelanin-positive SNc region by manually contouring the high signal intensity region of the SNc on neuromelanin-sensitive MRI, and measured the specific binding ratio (SBR) on DaTSCAN. The asymmetry index of neuromelanin-positive SNc volume

(AI_{vol}) and the asymmetry index of the SBR (AI_{SBR}) were also calculated. We also evaluated the relationship between the Unified Parkinson's disease rating scale part III (UPDRSIII) score widely used for the clinical evaluation of Parkinson's disease and each of the volume of the neuromelanin-positive SNc region and SBR. **RESULTS:** The volume of the neuromelanin-positive SNc region showed significant correlation with the SBR (right: $p<0.001$, $\rho=0.77$, left: $p<0.001$, $\rho=0.86$). The AI_{vol} and the AI_{SBR} also showed a significant correlation ($p<0.001$, $\rho=0.64$). A significant negative correlation was found between the UPDRSIII score and mean of bilateral SBR ($p<0.01$, $\rho=-0.56$), but there was no significant correlation between the UPDRSIII score and mean of bilateral volume of the neuromelanin-positive SNc region ($p=0.27$, $\rho=-0.28$). **CONCLUSION:** Decrease of the high signal intensity region of the SNc on neuromelanin-sensitive MRI would indicate the damage of the nigrostriatal dopaminergic system as well as loss of the dopaminergic neurons itself. However, we conclude that DaTSCAN is more suitable for the evaluation of clinical severity of Parkinson's disease than neuromelanin-sensitive MRI.

PW40

^{18}F-FDG Uptake in the Healthy Brain as a Function of Age and Start of Acquisition

E. Pauwels[1], S. Bonte[1,2], **A. Dobbeleir**[1], S. Verleden[3], K. Audenaert[3], R. Van Holen[2], I. Goethals[1]; [1]Department of Radiology and Nuclear Medicine, Ghent University Hospital, Ghent, BELGIUM, [2]Medical Imaging and Signal Processing (MEDISIP) - IBiTech - Department of Electronics and Information Systems (ELIS), Ghent University, Ghent, BELGIUM, [3]Department of Psychiatry, Ghent University Hospital, Ghent, BELGIUM.

Aim: ^{18}F-FDG positron emission tomography (PET) is a well-established tool in clinical practice for the diagnosis and evaluation of neuropsychiatric disorders. A thorough understanding of the healthy brain glucose metabolism - and thus ^{18}F-FDG uptake - including changes due to physiological processes and individual variations is essential for a correct interpretation of PET images. Healthy ageing for instance not only results in a global decrease of the cerebral glucose metabolism but also in significant regional brain metabolism decrease. Furthermore, time after injection will exert a probable influence on the distribution pattern of ^{18}F-FDG uptake. The aim of this study was to present regional normal values for ^{18}F-FDG uptake as a function of age and time after injection which can be used in clinical practice to detect abnormal brain metabolism. *Materials and methods:* 82 healthy subjects were carefully selected according to strict inclusion criteria. Each subject underwent an MRI and a dynamic brain FDG PET scan for a total acquisition time of 75 minutes. PET images were normalised to minimise inter-individual variation using three different reference regions: global mean, central white matter (WM) and cerebellum. Fifteen brain regions were defined using the Hammers Adult Brain Atlas 30 (30 subjects, 83 regions; http://brain-development.org). First, sex-related differences were studied. Subsequently, for each time frame a linear regression analysis of the uptake for each brain region as a function of age was performed. These data can be used to calculate the normal values for ^{18}F-FDG uptake. *Results:* In females, a significantly higher ^{18}F-FDG uptake is observed in the thalamus and striatum in a limited number of time frames. Since relative differences are small, the application of a mixed age-matched normative database is valid. The most prominent age-related decrease in ^{18}F-FDG uptake is observed in the frontal brain regions and the anterior cingulate. Global mean normalisation shows an increased uptake with age in the cerebellum, brainstem and thalamus. However, this is probably an artefact due to the use of the global mean as reference region. Indeed, using central WM and cerebellum as the reference region for normalisation no significant age-related differences are found in these regions. *Conclusion:* A mixed age-matched normative database of 82 carefully selected subjects is presented from which normal values of ^{18}F-FDG uptake as a function of age and time after injection (up to 75 minutes post injection) can be calculated and readily applied in clinical practice to detect abnormal uptake.

Frequency of skeletal metastasis in patients with germ cell tumors on bone scintigraphy as part of staging work up

M. Siddique, A. Hassan, H. Bashir, M. Nawaz; Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore.Pakistan., Lahore, PAKISTAN.

Background: Germ cell tumors (GCT) are the most common malignant solid tumors in young male adults. Osseous metastases are rare at initial diagnosis and usually presents as a late event combined with synchronous nodal, pulmonary or hepatic metastases. Our aim is to determine the frequency of skeletal metastasis in patients with newly diagnosed germ cell tumors (GCT) on bone scintigraphy done as part of baseline staging work up. **Method:** Electronic medical records of 126 patients treated for histologically proven GCT of gonadal or extragonadal origin between October 2010 and September 2015 were retrospectively analyzed. Data was collected for histopathology, presence of bone metastasis on ^{99m}Tc-MDP bone scintigraphy at diagnosis, frequent sites of metastasis, association of osseous metastases with histologic subtypes and concurrent nodal/systemic metastasis. Bone metastases were further confirmed on the basis of clinical symptoms and correlative radiological imaging or histologic confirmation where available. **Results:** A total of 126 patients, 59(47%) females and 67(53%) males, who underwent bone scans were reviewed. Age range: 1 month-72 years ;(mean age=18 years). 105(83%) cases were of pediatric age group(<18 years) at the time of initial diagnosis. Of the total; 41(32.5%) had yolk sac tumor (27 of gonadal origin, 13 abdomino-pelvic masses and 1 mediastinal mass), 34(27%) had mixed germ cell tumors (24 of gonadal origin, 9 sacrococcygeal and 1 on femur biopsy), 16(13%) mature cystic teratoma, 14(11%) dysgerminoma of ovaries, 9(7%) seminoma of testis, 7(5.5%) immature teratoma of abdominopelvic masses, 3(2.4%) non seminomatous GCT of mediastinum and 2(1.6%) embryonal carcinoma. Osseous metastasis was detected in 12(9.5%) cases. 2 (17%) had solitary, and 10 (83%) multifocal skeletal metastases. Most frequent site of bone metastases was thoracolumbar spine (7,58%) with cord compression in 4 patients. Other sites included pelvis (6,50%), ribs (5,42%) and long bones (5,42%). Clinically, all patients had localized bone pain. Histologically bone metastases were more frequently associated with yolk sac tumor and primary mediastinal GCT. In patients with osseous metastases; additional sites of metastases included; lymph nodes (5,42%), lung (4,33%) and 42% had no other site of metastasis. None had concomitant hepatic metastases. 5/12, 42% died over a period range of 4-18 months. **Conclusion:** Distant osseous involvement was found in 9.5% of the GCT patients undergoing diagnostic skeletal scintigraphy. Based on our findings, baseline skeletal evaluation for metastases; especially in cases with bone pains or known systemic metastases should be done.

EP002

Assertiveness in Bone Scintigraphy: Is It a Matter of Faith?

A. S. Pinto, A. R. Fernandes, V. Alves, T. Vieira, T. Faria, A. Oliveira, M. Pérez, J. Pereira; Centro Hospitalar de São João, Porto, PORTUGAL.

Introduction: Bone Scintigraphy is a frequently performed Nuclear Medicine (NM) exam to evaluate bone metastasis (BM). Its specificity is relatively low, which leads to less assertive diagnostic answers by the NM doctors. **Aim:** To evaluate the diagnostic assertiveness of BM in Bone Scintigraphy, to study the correlation between assertiveness and specificity and to compare the assertiveness between specialists and interns of specialization at our NM Department. **Materials and Methods:** Bone Scintigraphies of 50 consecutive patients with oncological pathology, performed in January 2014, were included. Besides the whole body images, SPECT of regions of interest were also performed in 24 patients. Five NM specialists and three interns (1st, 2nd and 4th years), without knowledge of the patients' clinical information, classified each bone scintigraphy as "positive - P", "probably positive - PP", "probably negative - PN" and "negative - N" for BM. To ascertain the existence of BM, the patients' clinical processes were later consulted. Two were excluded due to the impossibility of confirming BM. To calculate the sensitivity and specificity, the exams were considered "positive" when the bone scintigraphy was classified as "P" or "PP" and "negative" when the bone scintigraphy was "N" or "PN". The global assertiveness (GA) was studied calculating the proportion of "P" and "N" answers [GA=(P+N)/(P+PP+N+PN)*100]. The positive assertiveness (PA) [PA=P/(P+PP)] and negative assertiveness (NA) [NA=N/(N+PN)] were also calculated. The statistical analysis was performed with IBM-SPSS 22 [comparative test of Mann-Whitney U ($p<0.05$) and Spearman's correlation coefficient - r]. **Results:** The mean specificity was 78.96±11.94%. The sensitivity was 100%. The mean GA was 64.85±9.78%. Specialists and interns did not had values of GA significantly different ($p=0.250$) [specialists: mean=67.9±10.89%; interns: mean=59.77±6.00%].The mean PA was 55.83±21.07% and the mean NA was 62.25±10.76%. There was no statistically significant differences between PA and NA, neither between specialists and interns. The correlation between GA and specificity was not statistically significant in the entire group ($r=0.554$;$p=0.154$), neither in the subgroups of specialists ($r=0.100$; $p=0.873$) or interns ($r=0.866$;$p=0.333$). There was a significant difference ($p=0.036$) between specialists and interns at the probability of hitting the diagnosis when the answer was globally non-assertive (specialists: mean=80.54±8.92%; interns: mean=59.43±10.64%). **Conclusion:** Non-assertiveness, even being associated with a high specificity, may imply a treatment delay, a greater anxiety in the patient and an increase in diagnosis costs, whereby it is crucial and potentially feasible to give a confident result.

EP003

Prospective study regarding the reliability of the detection of bone metastases using planar scintigraphy, whole-body SPECT, and a computer-assisted analysis software

M. Schubring, M. Zuhayra, M. Marx, Y. Zhao, M. Jüptner, U. Lützen; Universitätsklinikum Schleswig-Holstein, KIEL, GERMANY.

Aim Bone scintigraphy is a well-known method for detection of bone metastases. This study evaluates the sensitivity and specificity of planar whole-body scintigraphy (WBS), whole-body SPECT (WB SPECT) and a computer assisted evaluation program for detection of bone metastases. **Methods** In 64 patients (58 women and 6 men, mean age 61.7 (34 - 86) years) with malignant tumor disease (breast cancer n=46, malignant melanoma n=11, breast cancer and malignant melanoma n=3, prostate cancer n=2, malignant melanoma and lung cancer n=1, breast cancer and renal cancer n=1) prospectively a bone scintigraphy was performed, consisting of a planar whole-body scintigraphy (WBS) and a 5-position whole-body SPECT (WB SPECT) of each patient. The images were randomized and anonymized. Both the planar and SPECT data were analyzed by two nuclear medicine specialists (A and B) concerning the existence of bone metastases (classification 1 - 4, 1= certainly yes, 2 = rather yes, 3 = rather no, 4 = certainly no). The WBS were additionally analyzed by the EXINI bone program. The evidence of bone metastases was verified by all available clinical information including diagnostic tools such as MRI, PET/CT and CT and was used as reference for each patient. **Results** Regarding the references 23 of the 64 patients (35.9 %) suffered from bone metastases. The evalution showed a sensitivity of 78.3 % (A 82.6 %, B 73.9%) for

WBS, 84.8 % (A 82.6 %, B 87.0 %) for WB SPECT, and 78.3 % for EXINI bone software. The specificity of WBS was 87.8 % (A 90.2 %, B 85.4 %), of WB SPECT 73.2 % (A 75.6 %, B 70.7 %), and of EXINI-bone 90.2 %. Moreover the interobserver variability of the detection of bone metastases was significantly lower in the analysis of planar WBS compared to WB SPECT (p=0.02). **Conclusions** This study shows a higher sensitivity and a lower specificity for WB SPECT in comparison to planar WBS. Consequently it is not meaningful to perform only a WB SPECT without a planar WBS. The computer assisted evaluation offers a comparable sensitivity and specificity. The solely use of the program cannot be recommended but it is very helpful especially in training of students and young physicians.

EP004

Fluorocholine PET/CT Predicts Skeletal Progression, Skeletal Event and Cancer Specific Survival in Patients with Biochemical Relapse for Prostate Cancer

L. Evangelista[1], M. Hodolic[2], F. Zattoni[3], A. Guttilla[4], E. Pizzirani[5], F. Zattoni[3], G. Saladini[1]; [1]Nuclear Medicine and Molecular Imaging Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY, [2]Nuclear Medicine Research Department, IASON, Graz, AUSTRIA, [3]Department of Oncological and Surgical Sciences, Urology Clinic, University of Padua, Padua, ITALY, [4]Urology Unit, Hospital of Camposampiero, Padua, ITALY, [5]Radiology Oncology Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY.

Objectives: the aim of our study is to evaluate the prognostic impact of 18F-Choline (FCH) positron emission tomography (PET)/computed tomography (CT), CT alone and bone scan (BS) in PCa patients with skeletal recurrences. **Methods:** we retrospectively selected 62 patients who underwent, between June 2010 and February 2013, both FCH PET/CT and BS within a span of six months. All patients had a biochemical PCa recurrence after radical prostatectomy and/or radiation therapy. Two independent observers reviewed PET/CT and BS images. The bone window of CT portion from PET/CT was separately assessed. Time to progression (TTP), skeletal event free survival (SES) and OS were defined as the length of time between imaging and progression of disease, skeletal related events and all-cause mortality, respectively. A patient based and a K agreement analysis were used to compare the findings of all three imaging modalities. Kaplan-Meier and log-rank analysis were computed for survival assessment. A multivariate Cox regression analysis was used to identify the independent predictors for OS and TTP. **Results:** bone metastases were detected in 25 (40%) patients at FCH PET/CT, in 30 (48%) at BS and in 27 (44%) at CT. The agreement between PET/CT and BS, CT and BS, and PET/CT and CT were fair/moderate (respectively, k: 0.513, 0.32 and 0.47; all p<0.05). After 36 months (IQR: 26-52 months) of follow-up, 36 (61%) patients had a new recurrence of disease, 13 (21%) had skeletal related events and 22 (35.5%) died. Three subjects (5%) were lost during the observational period. At survival analyses, a worse TTP, SES and OS were found in patients with a positive PET/CT at bone level than those with a negative scan (all p= <0.05). Conversely, any significant difference in TTP, SES and OS was found for patients with both a positive BS and CT scan. At univariate analysis, a positive PET/CT at skeletal level was associated with all events (all p<0.05). However, only a negative PET/CT at any site was an independent prognostic variable of TTP (HR: 0.29; CI 95%: 0.10-0.82; p=0.02). **Conclusions:** PET/CT should be preferred to CT and BS in the evaluation of bone metastatic PCa because it allows a better stratification of TTP, SES and OS compared to CT and BS. Additional studies are needed to compare the prognostic impact of FCH PET/CT with either magnetic resonance imaging or new radioactive tracers, such as radiolabeled prostate specific antigen membrane.

EP005

Multicenter prognostic registry for prostate cancer using bone scintigraphy and bone scan index: PROSTAT-BSI study design

K. Nakajima[1], A. Mizokami[1], M. Ueno[2], H. Horikoshi[3], T. Ichikawa[4], S. Takahashi[5], H. Matsuyama[6], H. Shiina[7]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]Saitama Uro-Dermatol Clinic, Saitama, JAPAN, [3]Gunma Prefectural Cancer Center, Ohta, JAPAN, [4]Chiba University Hospital, Chiba, JAPAN, [5]Nihon University Itabashi Hospital, Tokyo, JAPAN, [6]Yamaguchi University Hospital, Ube, JAPAN, [7]Shimane University Hospital, Izumo, JAPAN.

Purpose: In patients with prostate cancer, amount of bone metastasis has been considered to be an important prognostic factor to evaluate therapeutic effect, skeletal-related events, and mortality. While bone scan index (BSI) has been proposed as a quantitative measure of bone metastasis, few studies have validated the role of BSI in a prospective manner during standard hormonal therapy and chemotherapy. The objective of this study was to create a multicenter cohort registry and to evaluate the utility of BSI in the management of prostate cancer. Methods: The patient inclusion criteria included newly diagnosed prostate cancer with definite bone metastasis as evidenced by imaging modalities, such as bone scan, X-ray computed tomography and/or magnetic resonance imaging. Patients were classified into groups of hormonal therapy (Group H) and chemotherapy with Docetaxel due to resistance to hormonal therapy (Group C). Bone scintigraphy was performed using whole-body anterior and posterior imaging in each hospital before and after treatment every 3 months. The software BONENAVI (FUJIFILM RI Pharma/EXINI bone, EIXINI Diagnostics) used artificial neural network to determine locations and extent of bone metastasis. Using a Japanese multicenter database (n=1,532), the software was upgraded to provide the diagnostic sensitivity and specificity of 90% as validated previously. BSI was calculated to express percentage of bone metastasis divided by whole bone mass. The primary target of this study was to investigate the relationship between BSI and relapse-free survival and prostate specific antigen (PSA)-progression-free survival, as well as overall survival. Changes in BSI from the baseline condition to after treatment will be compared to those in PSA and other bone metabolic markers. Results: A total of 237 patients were registered from 30 hospitals in Japan, including 157 patients with hormonal therapy and 80 with chemotherapy. Based on the clinical data as of March 2016 (n=174), mean BSI calculated on-site was 3.1±3.0 ranged from 0.02 to 13, and number of hot spots 29±31, ranged from 1 to 119. Lymph node metastasis was observed in approximately 70% at the time of entry. Median PSA was 285 and 30 ng/ml for Groups H and C, respectively. While incidence of lung metastasis did not differ between groups (12%), that of liver metastasis was higher in Group C (7%) than Group H (1%). Conclusion: Multicenter registry involving patients with prostate cancer with bone metastasis was designed, and the role of BSI in prostate cancer treatment would be clarified in this cohort study.

EP006

Whole body (WB) vs. Limited Field of View (LFOV) Sodium Fluoride (NaF) Positron Emission Tomography/Computed Tomography (PET/CT) Imaging; comparison of both techniques

S. Alratroot[1], A. Al-Dhafiri[2], A. Al-Tuwaijri[2], R. Al-Muslem[3], A. Moin[2]; [1]King Fahad University Hospital, Dammam, SAUDI ARABIA, [2]King Fahad Specialist Hospital Dammam, Dammam, SAUDI ARABIA, [3]University of Dammam, Dammam, SAUDI ARABIA.

Purpose: NaF PET CT imaging is commonly used for osseous evaluation. Routinely the FOV for NaF follows the same technique as planar bone scintigraphy (BS) i.e. whole body imaging from vertex to toes with arms down. Here we evaluate the comparison of WB vs. LFOV from base of skull till proximal thighs with arms down. **Methods:** The study was approved by

institutional review board. We did retrospective review of NaF PET CT scans that were performed during three weeks. **Results:** 47 scans were performed. There were 41 females and 6 males, aged 26-84 years. Most of the scans were performed for breast cancer staging followed by prostate and thyroid cancers workup. 15 scans were positive for metastatic lesions. 4/15 patients had super scans. Remaining 11 scans showed lesions in the ribs, spine, base of skull, proximal humeri, scapulae, sternum and proximal femurs. Only one patient showed additional lesion in left distal femur (along with multiple others in axial and proximal appendicular skeleton) that was suspicious for metastatic disease. Out of 32 negative scans, 1 scan had CT lytic changes but did not show any NaF uptake and it was considered false negative. Remaining 31 scans showed mostly degenerative changes and traumatic lesions which could have been mostly visualized in LFOV imaging. **Conclusion:** We conclude that NaF PET CT can be used with limited FOV instead of WB imaging for tumor staging work up. This can avoid unnecessary radiation exposure to the patient, especially to the extremities and brain.

EP007

The Screening Potential of Bone Scintigraphy and Serum Bone Metabolic Markers for Early-stage Medication-related Osteonecrosis of the Jaw

S. Watanabe, K. Nakajima, A. Mizokami, N. Noguchi, S. Kawashiri, M. Inokuchi, S. Kinuya; Kanazawa University, Kanazawa, JAPAN.

Aim: Medication-related osteonecrosis of the jaw (MRONJ) is an important side effect of antiresorptive and antiangiogenic drugs. Early detection of MRONJ has been attempted by various methods. The aim of this study was to quantitatively evaluate the screening potential of bone scintigraphy and serum bone metabolic markers for early-stage MRONJ. Methods: A total of 68 cancer patients treated with antiresorptive drugs were evaluated retrospectively. All patients underwent bone scintigraphy, and tracer uptakes in the jaw were analyzed semiquantitatively by bone scan index (BSI) of the jaw related to MRONJ ($BSIJ_{MRONJ}$). The software BONENAVI (FUJIFILM RI Pharma, Japan; EXINIbone, EXINI Diagnostics, Sweden) could detect abnormal intensities and calculate each regional BSI (rBSI), which was defined by the fraction of abnormality to the entire skeleton (%). Using the regions detected by the software, we selected MRONJ-related regions manually. The largest rBSI in the jaw (BSIJmax) and the BSI of the whole body were also calculated. The serum levels of bone alkaline phosphatase (BAP) and pyridinoline cross-linked carboxy-terminal telopeptide of type I collagen (1-CTP) were examined. Results: In 22 patients who developed stage 2 MRONJ, $BSIJ_{MRONJ}$ and BSIJmax showed significant correlation ($p<0.05$). The BSIJmax was significantly higher in patients who developed MRONJ than in those who did not, even 6 months before the diagnosis of stage 2 MRONJ ($p<0.002$). The BSIJmax was significantly higher in the maxilla than in the mandible in patients who did not develop MRONJ ($p=0.02$) and in those who developed stage 2 MRONJ at 6 months before the diagnosis ($p=0.03$). Using the cutoff value of 0.06%/0.10% in the mandible/maxilla, BSIJmax for predicting stage 2 MRONJ showed sensitivity and specificity of 57%/71% and 80%/93%, respectively, at 6 months before the diagnosis. The BSIJmax≥0.06%/0.10% in the mandible/maxilla was much more frequently observed in patients who subsequently developed stage 2 MRONJ 6 months after bone scintigraphy than in those who did not ($p=0.003/0.0004$, odds ratio=7.6/35.8). In contrast, the serum bone metabolic markers (BAP and 1-CTP) did not correlate significantly with the incidence of MRONJ. The serum bone metabolic markers and the BSI of the whole body showed significant correlation ($p<0.005$). Conclusion: The BSIJ provided a new index for evaluating MRONJ. For predicting occurrence of MRONJ, the threshold of BSIJmax=0.06%/0.10% in the mandible/maxilla may be used in patients treated with antiresorptive drugs, and a differential diagnosis of MRONJ is recommended. In contrast, serum bone metabolic markers reflect systemic bone metastasis rather than MRONJ.

EP008

Performance of SPECT/low dose CT imaging in the diagnosis of metastatic bone disease

T. Pipikos[1], F. Vlachou[1], A. Nikaki[1], K. Dalianis[2], D. Papoutsani[1], S. Merisoglou[1], V. Papoutsis[1]; [1]Nuclear Mecine & PET/CT Department, Hygeia SA, Athens, Marousi, GREECE, [2]Medical Physics Department, Hygeia SA, Athens, Marousi, GREECE.

AIM: Bone scintigraphy is a very sensitive imaging modality for whole body bone staging of cancer patients. Although the sensitivity of the method is high, specificity is rather low. Modern hybrid SPECT/low dose CT devices, give anatomic localization and further characterization of abnormal tracer uptake foci. In this study we evaluated the performance of SPECT/low dose CT in the diagnosis of metastatic bone disease. **MATERIAL AND METHODS:** We reviewed the SPECT/low dose CT images of 43 patients, that underwent a bone scan for malignancy staging and had limited findings (solitary lesions) suggestive or highly suspicious of metastasic bone disease. We evaluated the findings of low dose CT in the site of abnormal tracer uptake. All patients were followed up with diagnostic CT/MRI, were re-evaluated in a period of 1 year and in some cases a bone biopsy was performed. **RESULTS:** From the total of 48 patients, 19 had a lytic corresponding lesion in low dose CT images, 15 of them had a sclerotic or mainly sclerotic lesion, 5 patients had lesions with mixed lytic-sclerotic characteristics, while 9 patients showed no corresponding abnormality. In the group of patients with lytic findings, one patient was proven to show uptake in an aneurysmal bone cyst. One sclerotic lesion was proven to be fibrous dysplasia and one patient had an osteoma. One lesion with mixed sclerotic- lytic appearance was finally attributed to an enchondroma. Two patients with no findings in low dose CT were proven to have benign lesions, a bone infract and a femoral shaft stress fracture. Overall SPECT/CT correctly identified 42/48 (88%) patients with metastatic bone disease. **CONCLUSION:** SPECT/low dose CT imaging increases the specificity of bone scan, but abnormal uptake does not always correspond to a metastatic deposit. In our small group of patients, lytic appearance is the most specific pattern of a metastasic lesion. SPECT/CT imaging systems with a diagnostic CT component, are expected to further improve diagnostic performance.

EP009

Value of the EXINI Bone Scan Index as a Biomarker During Xofigo Therapy in Patients with high Tumor Load

M. Miederer[1], C. Thomas[1], V. Weyer[1], H. Buchholz[1], F. Luttropp[2], M. Schreckenberger[1]; [1]University Medical Centre Mainz, Mainz, GERMANY, [2]EXINI Diagnostics, Lund, SWEDEN.

Objectives: Several promising drugs have been approved for treatment of mCRPC within the last years. One of them is Radium-223, an osteotrophic radiopharmaceutical. Due to heterogeneity of disease, limited validity of blood based biomarkers and difficulties in quantification of tumour load on imaging, monitoring the therapeutic effect of Radium-223 remains challenging. Imaging with osteotrophic tracers might be a viable option to visualize treatment induced reduction of osteoblastic activity. In the current study, we investigated the prognostic role of a new quantification technique for tumour load on bone scans in mCRPC patients undergoing Radium-223 treatment. Methods: In 15 consecutive mCRPC patients with multifocal/disseminated bone metastases baseline and interim bone scans were obtained and analyzed for tumor load using the commercial software EXINI bone scan. Changes in bone scan quantification were compared to Serum-PSA response and overall survival. The EXINI software was recently updated to ensure validity in particular in patients with high tumor burden up to a value of 13 (BSI 2.1). Based on the

validation of the software, statistical analysis as a biomarker for outcome was restricted to 12 patients displaying initial BSI between 3 and 13. Three additional patients with higher tumor loads were analyzed separately. Results: Manual corrections were necessary in one patient due to obstruction induced urine uptake in the upper urinary tract and in two patients due to incontinence induced urine contamination (3/30 scans). In one patient pelvic metastasis could not be discriminated from bladder activity. Comparison of BSI Version 1.8 and 2.1 for 15 patients revealed higher values in particular at higher tumor burden both for baseline (mean 6.3 vs 8.7) and for follow up (mean 7.1 vs 9.4). However, difference between baseline and interim-staging was not significant between both versions (p=0.83). 5/15 patients showed a decrease of bone scan index after the first two cycles of radium-223. In contrast, only two patients with initial low levels of serum PSA (<100 ng/ml) presented a PSA decline at this time point. Cox regression analysis showed a trend towards validity for bone scan index to serve a predictive marker similar to serum PSA (p=0.035 and p= 0.18 for BSI version 1.8 and 2.1; p=0.034 for PSA) Conclusion: The bone scan index is a valuable and easily applicable tool to quantify tumor load and treatment response on bone scans in mCRPC patients undergoing Radium-223 treatment.

EP010

Multiple Non Ossifying Fibromas in 20 year old patient with Speckled Lentiginous Nevus syndrome; Jaffe-Campanacci syndrome?

I. Sisko Markos, M. Romić, P. Petranovic Ovcaricek, V. Gladic Nenadic, M. Franceschi, Z. Kusic; UHT Sestre Milosrdnice, Zagreb, CROATIA.

INTRODUCTION: Speckled lentiginous nevus syndrome is a recently described syndrome with male to female ratio of 4:3; usually present at birth but may appear during first years of life. Cafe au lait macules can be topped by either browns or black macules or papules. Patients usually present with musculosceletal and neurological anomaly at ipsilateral site. Nonossifying fibromas (NOFs) are the most common benign bone tumor in children. The tumors affected long bones as the humerus, the tibia, the femur, the fibula. Approximately 8 % of people with NOF will have more than one tumor. It is uncommon to have more than two or three tumors except in certain very rare conditions like Jaffe - Campanacci 's syndrome. This syndrome can present only with skin patches and NOFs, but also as a part of more severe systemic presentation like cardiovascular, renal, ocular abnormalities and mental retardation. CASE PRESENTATION: a 20 year old female with a known diagnosis of Speckled lentiginous nevus Syndrome presented to our Department in 2012 for evaluation of prolonged discomfort in the right leg. Performed MRI showed atrophy in right leg and hyperintensive ovale zone (24x10 mm) in distal part of left femur. Three phase bone scan revealed decreased uptake in all 3 phases in right lower extremity, without focal lesions in the left and increased uptake in right humerus (initally evaluted as a bone infarct or eosinophilic granuloma). Bone scan performed in 2013 showed increased left - right asymmetry uptake between lower extremities. Since than she developed paresthesia in right arm. X-ray showed a 41x10 mm zone in proximal diaphysis of right humerus suspected for NOF. Bone scan performed in 2016 showed same changes in right humerus as 2012, but with new focal increased uptake in distal part of diaphysis of left femur with same scintigraphy pattern as in the right arm. Diagnosis of multiple non-ossifying fibromas was presumed. CONCLUSION: Regarding the clinical presentation and bone scan, diagnosis of Jaffe-Campanacci syndrome was presumed.

EP011

Volumetric FDG-PET indices for the assessment of histological response to neoadjuvant chemotherapy and outcome in paediatric patients with Ewing sarcoma and osteosarcoma

C. Bailly[1], L. Campion[2], E. Thebaud[1], N. Corradini[1], A. Moreau[1], D. Dansette[1], F. Kraeber Bodere[1], T. Carlier[1], C. Bodet Milin[1]; [1]University Hospital, Nantes, FRANCE, [2]Cancer Center ICO René Gauducheau, Nantes, FRANCE.

Aim: Response to chemotherapy is a prognostic factor in patients with Ewing sarcoma (EWS) and Osteosarcoma (OST). Several studies showed high diagnostic accuracy of positron emission tomography using 18F-fluoro-2-deoxy-glucose (FDG-PET) for response to initial chemotherapy (CHT) in these patients and a correlation with outcome. Despite a potential impact of age on the prognosis of bone sarcoma patients, most of these studies mixed adult and paediatric populations. The objective of this retrospective work was to evaluate the prognostic value of quantitative indices derived from FDG-PET in an homogeneous paediatric bone sarcoma population including EWS and OST. Methods: 31 paediatric patients with EWS (median age 14.7 years) and 31 with OST (median age 12.8 years) were included. All patients were treated with CHT, and underwent surgery for local control. All patients had FDG PET at diagnosis and after induction CHT, prior to surgery. Several parameters for assessment of response of the primary tumour to therapy by FDG PET were evaluated: SUV_{max}, SUV_{peak}, SUV_{mean}, metabolic tumor volume (MTV), total lesion glycolysis (TLG), Tumor to contralateral Background Ratio (TBR), 7 textural features (TF) and 3 shape features (SF). For each metric requiring a segmentation step, 3 delineation methods were compared including an adaptative approach, 40% of SUVmax and SUV>2.5. Each pair of FDG-PET scan were also classified as responding (R) and non-responding (NR) according to PERCIST criteria. Results were then compared to histopathological regression of the resected tumour as defined by Salzer-Kuntschik and to the clinical follow-up for survival evaluation (median of follow-up: 5 years). Results: After CHT, the absolute SUVs, MTV, TLG, TF, SF or TBR, the reductions of SUVs, TF or SF, TBR and PERCIST criteria were neither significantly associated with histologic response nor overall survival or progression free survival for either EWS or OST. The MTV and TLG reduction (segmentation SUV > 2.5) were the only quantitative indices that significantly discriminated histopathological responders from non-responders using the entire patient population ($\Delta MTV_{2.5}$, p=0.0109; $\Delta TLG_{2.5}$, p=0.0076) as well as in the subgroup of OST patients ($\Delta MTV_{2.5}$, p=0.0032; $\Delta TLG_{2.5}$, p=0.0040), but not in the EWS subgroup. Conclusion: Only MTV and TLG reduction seem to enable accurate non-invasive assessment of histopathological reduction after CHT in the OST paediatric population but reveal limited additional prognostic value in paediatric patients with EWS.

EP012

Prognosis value of SUV-based metrics, textural and shape features derived from initial FDG-PET in paediatric patients with Ewing sarcoma and osteosarcoma

C. Bailly[1], L. Campion[2], E. Thebaud[1], N. Corradini[1], A. Moreau[1], D. Dansette[1], F. Kraeber Bodere[1], C. Bodet Milin[1], T. Carlier[1]; [1]University Hospital, Nantes, FRANCE, [2]Cancer Center ICO Rene Gauducheau, Nantes, FRANCE.

Purpose: Histologic response, measured by the percentage of tumor cells remaining after neoadjuvant chemotherapy (CHT) is the main prognostic factor in Osteosarcoma (OST) and Ewing sarcoma (EWS). Previous positron emission tomography using 18F-fluoro-2-deoxy-glucose (FDG-PET) studies tried to determine the value of FDG uptake as an accurate and non-invasive preoperative marker of response. Yet most of them explored heterogeneous populations mixing different histological

subtypes, CHT regimens or age groups. Our objective was to evaluate, retrospectively, the accuracy of FDG-PET for OST and EWS staging and to determine the prognosis values of quantitative parameters in a homogeneous paediatric bone sarcoma population. Methods: 31 patients with EWS (median age 14.7 years) and 31 with OST (median age 12.8 years) were included. All patients were treated with neoadjuvant CHT, and underwent surgery for local control. All patients were examined with conventional imaging (CI) modalities (CT, MRI, bone scintigraphy) and with FDG-PET at diagnosis. Several parameters were extracted from the main lesion: SUVmax, SUVpeak, metabolic tumor volume (MTV), total lesion glycolysis (TLG), 7 textural features (TF) using two different normalization and 3 shape features (SF). The segmentation was performed using an adaptative approach. Results were compared to histopathological regression of the resected tumour as defined by Salzer-Kuntschik using Spearman analysis and to the clinical follow-up and CI for survival evaluation (median of follow-up: 5 years) using univariate and multivariate Cox analysis. Results: FDG-PET and CI were equally effective in the detection of primary tumors (accuracy, 100%). FDG-PET was superior to CI for detection of bone metastases in both EWS (sensitivity, 80% vs. 60%) and OST (sensitivity, 100 vs. 20%), whereas CI was more reliable than FDG-PET in depicting lung metastases (sensitivity, 100% v 50%, respectively). For EWS, univariate analysis did not highlight any prognostic value on histological response, PFS and OS regardless of all the considered metrics and known pronostic factors such as anatomic primary site or presence of metastatic disease. For OST univariate analysis showed that presence of metastatic disease and one of the SF, namely elongation, were significantly associated with PFS and OS. Multivariate analysis confirmed that the presence of metastatic disease was an independent factor for OS whereas elongation was the only significant factor for PFS. Conclusion: Only a SF called elongation determined on initial FDG-PET has a potential interest as a prognostic factor of PFS in paediatric OST patients. All the metrics reveal limited additional prognostic value in paediatric EWS patients.

EP013

The physiological accumulation of FDG in the muscles in relation to the side of intravenous administration

Y. Otomi[1], T. Shinya[1], Y. Arai[1], K. Miyamoto[1], K. Takechi[2], N. Uyama[1], M. Harada[1]; [1]Tokushima University Hospital, Tokushima, JAPAN, [2]Tokushima Red Cross Hospital, Tokushima, JAPAN.

Purpose: The purpose of the present study was to evaluate the physiological accumulation of FDG in the muscles in relation to the side of intravenous administration. Methods: We retrospectively reviewed 1,423 FDG-PET/CT exams that were performed in our institution in 2015. Cases that involved hyperglycemia (over 140mg/dl), metastases to the muscles or subcutaneous tissues in the shoulder and arm, diffuse FDG accumulation in the arm muscles, cases of neurofibromatosis, cases in which the patients had arteriovenous fistulas for hemodialysis, the intravenous administration of FDG to the lower limbs, subcutaneous extravascular leakage of FDG, and cases in which the patients were not imaged in the supine position were excluded from the analysis. Thus, a total of 1,310 exams were included in the present study. We evaluated the physiological accumulation of FDG in the muscles of the shoulder and arm related to the side of intravenous administration. We investigated the association of the accumulation in the teres minor muscles and the side of administration. We also investigated the association of the accumulation in the muscles between the radioulna near the elbow and the side of administration. Results: Two hundred eighty-four of the 1310 (21.7%) exams showed the physiological accumulation of FDG in the teres minor muscle. Accumulation was seen on the side of administration in 223/284 (78.5%) exams. Accumulation was observed contralateral to the side of administration in 26/284 (9.2%) exams. Accumulation in the bilateral teres minor muscles was seen in 35/284 (12.3%) exams. Accumulation in the muscles between the radioulna near the elbow was observed on the side of administration in 161/194 (83.0%) exams and contralateral to the side of the administration in 16/194 (8.2%) exams. Accumulation in the muscles between the radioulna near the elbow was observed bilaterally in 17/194 (8.8%) exams. The Cohen k coefficient was 0.791 when confined to cases with unilateral accumulation in the teres minor muscles. The Cohen k coefficient was 0.896 when confined to cases with unilateral accumulation in the muscles between the radioulna near the elbow. Conclusion: The present study reported that accumulation in the teres minor muscles and accumulation in the muscles between the radioulna near the elbow on the side of intravenous administration occurred significantly more frequent than accumulation on the contralateral side. Our results indicate that the accumulation in both the teres minor muscle and the muscles between the radioulna near the elbow was associated with the side of intravenous administration.

EP014

Role of ^{18}F-FDG PET/CT for initial staging and restaging of sarcomas

C. Bentancourt, A. Banchero, S. Rossi, O. Alonso, J. Gaudiano, H. Engler; Uruguayan Centre of Molecular Imaging, Montevideo, URUGUAY.

Introduction: Sarcomas are a heterogeneous group of malignancies that can arise either from soft tissue or bone. They represent 1% of all cancers. Soft tissue sarcomas have an incidence 3-4 times higher than osseous. The role of MRI in local characterization and thorax CT in the diagnosis of distant metastasis (mainly pulmonary) is well known. However, the utility ^{18}F-FDG PET/CT for both initial staging and restaging remains uncertain. **Objective:** The aim of our study was to investigate the clinical value of ^{18}F-FDG PET/CT for staging and restaging in patients with sarcomas. **Material and method:** We retrospectively analyzed 164 patients who underwent PET/CT scans in the Uruguayan Centre of Molecular Imaging from January 2011 to March 2016. Fifty-six % of patients were women (mean age 46 ± 19 yr). Mean age for men was 45 ± 22 yr. Fourteen patients were under 14 yr. Scans were performed 60 minutes after the injection of 4.07 MBq/Kg ^{18}F-FDG. Children were injected according the EANM pediatric dose chart. The study was performed for initial staging (n=17) or restaging (n=147) of a confirmed sarcoma. Forty-one patients (25%) were diagnosed with osteosarcoma and 123 (75%) with soft tissue sarcoma (11% initial staging in each group). **Results:** Overall, PET/CT shows a detection rate of 53% in patients for initial staging and 51% in patients for restaging. When performed as initial staging in osteosarcomas, PET/CT detected local lesions in 50% of patients, with no distant metastases. For initial staging of soft tissue sarcoma, PET/CT detected local lesions in 46% of patients, distant in 15% and both in 15%. The most important feature in defining local disease is surgical planning, allowing a better characterization of bone marrow involvement to define the surgical strategy. This is important due the existence of new conservative techniques such as hemicortical allograft reconstruction. In restaging of osteosarcomas, PET/CT was able to diagnose local recurrence in 11%, distant metastases in 24% and both in 13%, with 48% detection rate. In the case of soft tissue sarcomas PET/CT detected local recurrence in 7% of patients, distant in 30% and both in 9%, with a detection rate of 46%. **Conclusion:** Despite controversy, ^{18}F-FDG PET/CT is useful in initial staging and restaging of sarcomas. We could characterize bone marrow involvement allowing surgical planning with a lesion detection rate of 53%. The diagnosis of local and distant metastases led to a more accurate treatment in 51% of patients.

EP015

FDG PET-CT Findings In Different Locations Synovial Sarcomas

J. BENOUHOUD, S. CHOUKRY, S. TOUIL, A. GUENSI; CHU Ibn Rochd, Casablanca, MOROCCO.

INTRODUCTION: Synovial sarcomas are rare malignant tumors that encompass from 5 to 10% of soft tissue sarcomas. They affect mainly young adults and present as a painful slow growth mass located in deep soft tissues of extremities, near joints, even though their onset can be in any part of the body. We report FDG PET/CT findings in 5 patients with 5 different synovial sarcoma locations. **MATERIALS AND METHODS:** We collected all PET-CT examinations performed in the staging of a synovial sarcoma between September 2014 and March 2016 at the nuclear medicine department of the Ibn Rochd University Hospital, Casablanca, Morocco. We conducted our tests using a SIEMENS BIOGRAPH 6 engine starting in 2011. We achieved All body PET/CT scan examination 60 minutes after injection of 5 MBq / kg of 18-FDG. **RESULTS:** All patients were male, mean age was 30.4 years. Synovial sarcomas locations were: the forearm, elbow, thigh, popliteal and pleura. The mean SUVmax lesions were 4.8 with extremes of 2.5 and 6.4. A lymph node was found in 3 patients, she was axillary in 2 patients and in the other mediastinal. All patients had metastatic lung lesions, and 3 patients had secondary bone lesions. Pneumothorax was fortuitously discovered in one of the patients. Only two patients underwent resection surgery. **CONCLUSION:** In synovial sarcomas, a complete resection of the tumor is the best treatment. Tumors response to chemotherapy and radiation therapy is poor. The contribution of PET/CT to diagnosis and treatment sarcomas has not been identified properly yet. It seems show the involvement areas in whole body images. PET/CT may have a significant role managing synovial sarcoma. In fact, precociously diagnosis of lesion and metastasis may improve treatment strategy. Also, PET/CT scan may be an important tool in follow-up strategies in patient with synovial sarcomas by detecting the early metastatic disease.

EP016

Differential diagnose between hibernoma and liposarcoma, a case report

U. Jon, A. Perissinotti, A. Allende-Riera, C. Cardenas-Negro, E. Martinez-Gimeno, D. Cabello, O. Vilahomat, M. De Sequera-Rahola; Hospital Universitario Nuestra señora de la Candelaria, Santa Cruz de Tenerife, SPAIN.

Aim: Hibernomas are infrequent benign tumours that usually manifest in adults as a low growing painless mass located in the thigh, shoulder, back, neck, chest, arm or abdominal cavity/retroperitoneum. Hibernomas arise from fetal brown adipose tissue remnants and are highly 18F-FDG avid because of the elevated metabolic rate due to their high number of mitochondria for thermogenic purposes. Core needle biopsy is not recommended in cases of suspected hibernoma due to the tumor's hypervascularіy and, in opposition to liposarcomas, hibernoma treatment consists of complete surgical resection and postoperative prognosis is excellent. The aim of this report is to present a case of patient with an unknown hibernoma which was mistaken for malignant lesions at initial diagnosis. **Materials, methods and results:** A 23 year old female was admitted to our centre with a right thigh mass. She referred tightness in right groin and anterior thigh with presence of a rapidly increasing size tumour. She denied history of prior trauma. TC and MRI scans performed at our centre revealed a fat-density bilobulated 8.7 cm mass located in the right thigh in close contact with tensor fascia lata, sartorius, minor and medious gluteus and vastus lateral and anterior muscles. Presumptive diagnose was reported as liposarcoma. 18F-FDG PET/CT scan was performed using a PET/CT camera (Gemini TF-16, Philips) with an injected activity of 2.6 MBq/Kg. PET/CT showed a high focal uptake in the right tight mass with an homogeneous 14.2 SUVmax uptake value and no ametabolic necrotic areas. No other abnormal foci or FDG uptake was present on the rest of the study and PET/CT results put forward the differential diagnose of hibernoma. Surgical resection of the mass was performed and histopathological study revealed a well delineated adipose tumour with presence of mature adipocytes with no atipia or mitosis confirming the hibernoma diagnose. **Conclusion:** In the assessment of fatty tumours, usually low to intermediate glucose metabolism is associated to benign lipoma and low grade liposarcoma, while elevated 18F-FDG uptake suggest high grade liposarcoma. However, hibernoma should be considered in the differential diagnosis as PET/CT scan appearance can be worrying due to its high hypermetabolic rate and should not be confused with liposarcoma. Also, fluctuation in the SUVmax between PET/CT examinations has been described in hibernomas and is thought to be consequence of the influence of the external temperature.

EP017

Pathophysiology of Bone-Seeking Tracers in Patients with Disseminated Prostate Cancer: a SPECT/CT Study, Based on Computational Analysis

F. Fiz[1], S. Sahbai[1], C. Campi[2], M. Piana[2], G. Sambuceti[3], C. la Fougère[1]; [1]Nuclear Medicine Unit, Department of Radiology, University of Tübingen, Tübingen, GERMANY, [2]Department of Mathematics, University of Genoa, Genoa, ITALY, [3]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY.

Rationale: Whole body ^{99m}TC-DPD SPECT/CT is used for staging as well as response evaluation in patients with disseminated metastases from castration-resistant prostate cancer (CRPC) in which radionuclide therapy has become clinical standard recently. Understanding the interaction between bone density and tracer distribution might enable a personalized radionuclide therapy planning. In this study a computational approach was used, in order to analyze the relationship between bone density and tracer uptake. Material and Methods: Seventy-six ^{99m}TC-DPD SPECT/CT scans, from CRPC patients suffering from bone metastases, were analyzed with a dedicated software application. The output included the volumes of total (TBV), compact (CBV) and trabecular (IBV). Average Hounsfield density was computed for IBV and CBV (iHU and cHU, respectively). Also blood-pool normalized counts were computed separately: this value was labeled target-to-background ratio (iTBR and cTBR for trabecular and compact bone, respectively). In the analysis, whole-body, axial and appendicular skeleton were considered separately. Presence and extent of intraosseous metastases was quantified as the percentage of CBV on total skeleton (CBV%). Results: iTBR directly correlated with iHU in the whole-body, axial as well as appendicular skeleton IBV (R=0,62, 0,59, 0,65, respectively, p<0,001). In the axial skeleton, iTBR also correlated with cHU, albeit with a parabolic pattern, peaking at about 600 Hounsfield units and dwindling thereafter (R=0,59, p<0,01). Furthermore, a direct correlation between axial cHU and cTBR was found (R=0,64, p<0,001). Moreover, cTBR directly correlated with CBV% in the whole-body and in the axial bones (R=0,53 and 0,58, p<0,01). When stratifying the population according to CBV% quartiles, cTBR was higher than iTBR (p<0,05) in all groups; the difference was most notable in the highest CBV% quartile (45±12 vs. 28±10, p<0,01). Conclusion: Our data highlight a direct correlation between bone density and tracer uptake in both trabecular and compact bone, as well as a cross-correlation between compact bone density and activity in the trabecular bone. Moreover, a higher percentage of compact bone was linked with higher uptake values, particularly in the compact bone. These data could be of use in clarifying the mechanisms of bone marrow toxicity and therapy effectiveness in patients who might be candidate for radionuclide treatments. In particular, should these distribution patterns be mirrored by bone-seeking alpha- or beta-emitting radiopharmaceuticals, it would follow that a higher bone density could entail a higher dose to both the skeletal lesions as well as to hematopoietic bone marrow.

Diagnostic Accuracy for F18-FDG-PET/CT and C11-METHIONINE-PET/CT Co-registered with MRI For Differentiation of Recurrent Brain Tumor From Radiation Injury

L. RODRIGUEZ-BEL[1], C. GÁMEZ-CENZANO[1], J. GARCÍA-GARZÓN[2], A. SABATÉ-LLOBERA[1], J. VERCHER-CONEJERO[1], L. GRÀCIA-SÀNCHEZ[1], E. LLINARES-TELLO[1], C. MAJÓS-TORRO[3], A. LUCAS-CALDUCH[4], M. MACIÀ-GARAU[4], J. BRUNA-ESCUER[5]; [1]PET Unit. Department of Nuclear Medicine. IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona)., SPAIN, [2]PET ESPLUGUES Unit. CETIR-ERESA., Esplugues de Llobregat (Barcelona)., SPAIN, [3]RM Unit. Department of Radiology. IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona)., SPAIN, [4]Department of Radiation Oncology. ICO. Hospital Duran i Reynals-IDIBELL, L'Hospitalet de Llobregat (Barcelona)., SPAIN, [5]Department of Neurology. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona)., SPAIN.

Aim: Our purpose was to evaluate the ability of FDG-PET co-registered with MRI to differentiate recurrent tumor from radiation necrosis, in patients with inconclusive clinical and MRI findings. We also evaluated the additional role of ^{11}C-Methionine-PET (MET-PET) in the negative/equivocal FDG-PET scans. Materials and Methods: Retrospective study of 28 patients previously treated with radiotherapy after primary treatment for metastatic brain tumor (23) or glioma (5). A total of 33 FDG-PET scans were obtained (5 during follow-up). The mean interval between radiotherapy and FDG-PET was 15 months (range: 3-36). FDG-PET were co-registered with MRI and visually classified as: 1) negative when hypo or isoactivity was seen in the lesion, 2) positive when focal accumulation of FDG exceed any level of activity in the adjacent grey/white matter and 3) equivocal if an slightly increase homogeneous activity was seen at the margin around the irradiated lesion. FDG-PET images were also quantitatively assessed using T/N ratios (SUVmax tumor/SUVmax contralateral normal region). MET-PET was performed in 12 patients where FDG-PET was negative in 7, equivocal in 3 and positive in 2. MET-PET scans were visually assessed (evaluation of the grade of intensity and tracer uptake morphology) in PET/MRI co-registered images (Software-AGFA/SPM8) and quantitatively assessed using T/N ratios (SUVmax tumor/SUVmean contralateral region). The definitive diagnosis was based on clinical and radiological follow-up (median 17 months, range 4-51). Additional pathological confirmation was obtained in 6 patients. Results: FDG-PET sensitivity, specificity, positive predictive value and negative predictive value were 94%, 87%, 89% and 93% respectively. The results of MET-PET of the 12 patients were: true positive in 3 patients (with also FDG-positive scans), true negative in 9 patients (with also FDG-negative scans in 7 but 2 equivocal FDG-PET results). The interobserver agreement between FDG-PET and MET-PET was excellent (Kappa Coefficient: 1). The mean T/N ratios of positive FDG-PET scans was 1,28 (range, 0,86-2,06) and for the negative and equivocal ones was 0,91 (range, 0,71-1,2), and we found statistical differences in these two groups (t-Student test with a p less than 0,05). Conclusions: According to our results, MRI co-registration makes FDG-PET a more sensitive and useful test in differentiating brain tumor recurrence from radiation necrosis. The probability for disease detection is higher in patients with higher T/N ratios. In this scenario we considered MET-PET especially useful in equivocal and negative FDG-PET scans. These results must be confirmed by larger number of patients and biopsy-proven lesions.

EP019

Diagnostic Value of PET Using [^{11}C]Methionine in Suspected Glioma Recurrence

T. Skvortsova, Z. Savintseva, D. Zakhs, S. Medvedev; N. P. Bechtereva Institute of the Human Brain of Russian Academy of Sciences, Saint-Petersburg, RUSSIAN FEDERATION.

The purpose of the study was to assess the diagnostic accuracy of positron emission tomography with [^{11}C]methionine (PET-Met) in distinguishing brain tumor recurrence from posttreatment radiation effect (PTRE) and to analyze prognostic value of PET imaging. **Material and method.** PET-Met was performed in 308 patients (median age 35 years) with glioma (n=304) or other tumors (n=4) previously treated with multimodal therapy. Entry criteria included new or progressive enhancing lesions on MRI after treatment and final diagnosis on the basis of pathological examinations (n=84) or MRI and PET follow-up on an average 18 months (range 1-108). PET examinations were assessed by visual inspection and calculating [^{11}C]methionine uptake index (UI) as the ratio of the mean lesion uptake (ROI 10 mm in diameter) to normal cortex. Imaging results were also related to progressive free survival (PFS) in 262 patients. **Results.** 313 PET detected abnormalities in 308 patients were classified into three groups: pure PTRE (102 lesions), recurrent tumors (n=115) and mixture of radionecrosis with recurrent/residual tumor (n=96). Analysis of Met uptake showed that 96% of lesions with negative tracer uptake (UI<1,2) represented PTRE or complete metabolic response of glioma. But 4% of negative cases were recurrence with small size of glioma or large cyst component. Lesions with UI range from 1,2 to 1,6 represented residual irradiated tumor or radiation necrosis (85% of lesions). However low UI could be detected in initial recurrence (16%). UI between 1,6 and 2,0 was most typical for mixed pathology (55%) but one was observed in 12% of PTRE and 33% of progressive tumor. 89% of lesions with UI>2,0 were recurrence. Additional use of MR-perfusion allowed differentiating lesions with equivocal uptake. Using cutoff value of UI >1,87 ROC analysis showed a sensitivity of 74% and a specificity of 96% for differentiating recurrence from non-progressive disease (including PTRE and residual irradiated glioma). UI of the lesion had also significant independent influence on PFS (cut-off >1,9, PFS 12,5 vs 44 months, p<0,0001) **Conclusion.** PET-Met seems to be a method of choice in the evaluation recurrent brain tumor but sometimes diagnostic conclusion can be made with complimentary MR-perfusion or by comparing the serial studies.

EP020

Imaging of tumor-associated system xc- activity with 18F-fluoropropylglutamate (FSPG) PET/CT for intracranial malignancies

I. Sonni[1], R. Minamimoto[1], M. Jamali[1], N. Hatami[1], N. Koglin[2], M. Berndt[2], A. Stephens[2], F. Chin[1], N. Fischbein[1], G. Zaharchuk[1], S. S. Gambhir[1], E. Mittra[1]; [1]Stanford University, Stanford, CA, UNITED STATES, [2]Piramal, Berlin, GERMANY.

Introduction: The glutamate-cystine exchanger system x_C^- is an emerging target in oncology, balancing oxidative stress, providing a possible growth advantage for a variety of tumors, including those in the brain, and has been associated with higher-grade tumors. System x_C^- activity can be non-invasively visualized by means of the investigational PET radiopharmaceutical ^{18}F-FSPG. The aim of this study was to investigate the utility of ^{18}F-FSPG PET/CT in the evaluation of intracranial malignancies. Methods: Patients with primary brain tumors or brain metastases were recruited for this study. A single dose of ^{18}F-FSPG was injected intravenously (8.28 mCi ± 0.58). A dynamic PET/CT brain scan (0-30 min post-injection) was acquired, followed by a whole-body scan 60 min post-injection. Standard-of-care brain MRIs and, in some cases, ^{18}F-FDG PET/CT scans, were also acquired. The PET images were visually and quantitatively assessed, compared with MRI and, when available, standard-of-truth histopathology. The MRI scans were also independently read and lesions assessed for malignancy and growth (malignancy and growth score) by two neuroradiologists. Results: Twenty-six patients with primary brain tumors (17) or brain metastases (9) have been enrolled in the study (average age 54 ± 12 yrs). The dynamic images show increasing concentration of FSPG over the first 30 minutes in the brain lesions, and decreasing uptake in background tissues. At 60 minutes post-injection, FSPG uptake in

suspected lesions had an SUVmax of 7.47±7.15 in primary brain tumors, and 6.53±5.07 in brain metastases. FSPG uptake was nearly absent in healthy brain parenchyma (SUVmax 0.27±0.1 in patients with primary brain tumors, and 0.27±0.9 in patients with brain metastases). For primary brain tumors, SUVmax on FSPG scans correlated usually well to the independent MRI scores, whereas for brain metastases, the FSPG results were more equivocal. However, there were also some instances where non-specific MRI signals were not seen with FSPG, or suspected malignancy is seen with FSPG but not MRI. Clinical follow-up, pathology evaluation and kinetic analysis are still ongoing. Conclusions: ^{18}F-FSPG is a potentially useful PET imaging agent for the detection of residual/recurrent disease in the brain in settings where MRI alone is not definitive or discriminant, and can inform about system x_C- activity.

Contribution of 11C-Methionine PET/CT in the management of patients with brain tumors

J. L. López-Defilló, I. Martínez-Rodríguez, M. De Arcocha-Torres, J. Jiménez-Bonilla, R. Quirce, M. Jiménez-Alonso, F. Gómez-De La Fuente, C. Lavado-Pérez, N. Martínez-Amador, I. Banzo; Nuclear Medicine. Marqués de Valdecilla University Hospital. University of Cantabria, Santander, SPAIN.

Aim: Magnetic resonance imaging (MRI) is the current gold standard method for evaluation of brain tumors. However, MRI has known limitations in the differential diagnosis between brain tumor tissue and local post-therapy changes. The aim of this study was to evaluate the contribution of 11C-Methionine PET/CT (MET-PET) in the management of patients with suspected or known brain tumor in comparison with MRI findings. **Materials and methods:** This retrospective study included 47 MET-PET examinations (41 patients: 22 women, mean age: 46.3±17.5 y.). Eight examinations were requested for suspicion of brain tumor, 6 for evaluation of brain tumor extent and 33 for suspicion of persistent or recurrent disease on MRI. MET-PET scan was obtained 20' after intravenous injection of 740 MBq of 11C-Methionine. MET-PET images were assessed by visual analysis and the results were compared with MRI and Ki67 index at diagnosis (available in 25 examinations). Final diagnosis was established by histopathological sampling in 12 examinations and by clinical and radiological follow-up in 35. **Results:** MET-PET was positive in 29 examinations (61.7%) and negative in 18 (38.3%). Twenty-eight out of the 29 positive MET-PET scans were true positive and only 1 was a false positive result. Thirteen out of the 18 negative MET-PET scans were true negative and 6 were false negative results (sensitivity 82.4%, specificity 92.3%, positive predictive value 96.5%, negative predictive value 66.6% and accuracy 87.2%). Previous MRI was positive for malignancy in 33 examinations, negative in 7 and non-conclusive in 7. MET-PET was positive in 22 out of the 33 positive MRI (all MET-PET were true positive) and negative in 11 (5 true negative and 6 false negative). MET-PET was true positive in 3 out of the 7 negative MRI and true negative in 4. Finally, MET-PET was positive in 4 out of the 7 non-conclusive MRI (3 true positive and 1 false positive) and negative in 3 (all true negative). Mean Ki67 index was higher in true positive MET-PET scans (26±21.1) compared to false negative scans (13.7±7.5), although the difference was not statistically significant (p = 0.4959). All MET-PET scans with Ki-67 index >30% were true positives. **Conclusion:** MET-PET provided useful information in brain tumor patients with high specificity and positive predictive value. In a high percentage of non-conclusive MRI scans, MET-PET established a definitive diagnosis. Our results suggest a correlation between MET-PET scan and Ki-67 proliferation index although further investigation applying a semiquantitative analysis would be desirable.

EP022

Comparison of 11C-methionine PET and perfusion-weighted MRI in malignant gliomas

A. Mestre Fusco[1], L. Del Carpio[2], S. Gonzalez Ortiz[2], S. Medrano[2], J. Capellades[2], S. Mojal[3], G. Conesa[4], M. Suárez Piñera[1], Neuro-oncology PSMar Group; [1]Nuclear Medicine. Hospital del Mar., Barcelona, SPAIN, [2]Neuroradiology. Hospital del Mar., Barcelona, SPAIN, [3]Statistics department. IMIM., Barcelona, SPAIN, [4]Neurosurgery. Hospital del Mar., Barcelona, SPAIN.

Background: 11C-methionine PET (MET-PET) may help improve diagnostic procedures in malignance characterization of gliomas. In addition, perfusion-weighted MRI was used in gliomas to evaluate their vascularity. Recent studies suggest that perfusion-weighted MRI using regional cerebral blood volume (rCBV) may provide similar information to PET with amino-acid tracers. Aim: Compare methionine uptake ratio on MET-PET and rCBV perfusion on MRI in gliomas and evaluate their correlation. Methods: PET and MRI were performed in 22 patients diagnosed of glioma, who were consecutively included (12 male, mean:50.2, range:29-78). PET images were analyzed visually and quantitatively (ROI) and Ratio T/N was calculated of each lesion (SUVmax hot-spot-of-lesion/mean-cortical-uptake-in-healthy-brain). Gliomas were classified as low or high PET grade using a cut-off point of Ratio T/N=2.1. In case of Ratio T/N>2.1, glioma was classified as high PET grade. In addition rCBV perfusion score was calculated in the highest metabolic area on PET using MRWorkspace of Philips Healthcare software. In case of rCBV>2, glioma was classified as high rCBV grade. Gliomas were classified as low (II) or high (III-IV) grade depending on pathological criteria WHO classification. Association between PET grade and rCBV grade was analyzed (Chi-Square, Fisher test, $p<0.05$). Moreover correlation between Ratio T/N and rCBV scores was assessed (Pearson correlation coefficient, $p<0.05$). Results: Fifteen out of 22 gliomas were histopathologically classified as high grade: twelve glioblastomas, four anaplastic astrocytomas, and six grade II astrocytomas. Two grade II gliomas with negative perfusion showed Ratio T/N less than 1.4. Three astrocytomas were correctly classified as low grade according to Ratio T/N and rCBV. Thirteen glioblastomas were correctly classified as high grade according to Ratio T/N and rCBV. Nevertheless discordant grade classification between the two tests were found in 4 low grade gliomas: two of them were classified as high grade by PET and two of them were classified as high grade by perfusion. The rCBV value was higher in case of perfusion was evaluated on the point that PET has the highest uptake but rCBV was clearly lower in case of perfusion was measured on the borders of metabolic activity. An association between the two variables was found (Fisher test 2x2 table p=0.02). Moreover, a significant correlation between Ratio T/N and rCBV of gliomas was observed ($r=0.63$, $p=0.02$). Conclusion: 11C-methionine PET may provide grading information in gliomas, with a correlation between metabolic activity and perfusion on MRI. Our data suggests an association between Ratio T/N and rCBV in gliomas.

EP023

Diagnostic utility of ^{99m}Tc labelled Methionine Brain SPECT/CT in differentiating residual / progressive disease and radiation necrosis in patients with primary brain tumors: A comparison with contrast enhanced MRI

H. Singh, B. Singh, B. R. Mittal, R. K. Basher; Postgraduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim: The aim of the present study was to assess the diagnostic utility of 99mTc labelled Methionine Brain SPECT/CT in differentiating residual / progressive disease from radiation necrosis in patients with primary brain tumors and to compare its efficacy with that of ceMRI (contrast enhanced

MRI). **Materials and methods:** In this prospective study, seventeen patients with previously treated primary brain tumors (surgical excision, ± chemotherapy / radiotherapy) referred for evaluation of residual / recurrent disease were enrolled. ^{99m}Tc-methionine brain SPECT and ceMRI were performed at the time of presentation and at 6 months follow up. The time interval between the two scans was less than 2 weeks in all the patients. Brain SPECT and ceMRI findings were validated by reference standard (clinical course and imaging follow-up). **Results:** A total of 26 studies of 17 patients were evaluated (13 males & 4 females; age range 19-65 years; mean age 45.05 years). All the cases were of high grade gliomas (WHO grade III and IV) and most common histological subtype (according to WHO classification) was Glioblastoma Multiforme (GBM) 76.4% (13/17). Of the 17 baseline studies, 9 had SPECT e/o residual / recurrent disease, while 8 scans showed no e/o disease. Based on the reference standard used for evaluation of this study, 10/17 patients showed disease recurrence while 7 were deemed disease free. In the present study, sensitivity, specificity, positive and negative predictive value were 94%, 100%, 100% and 90% for Methionine Brain SPECT and 100%, 88.8%, 94.7% and 100% for ceMRI respectively when compared to the reference standard. Excellent agreement (kappa value = 0.83) was also found between Brain SPECT and ceMRI findings.**Conclusion:** ^{99m}Tc-methionine brain SPECT supplements ceMRI in diagnosis of recurrent disease due to its very high specificity and positive predictive value. Thus it has potential role in equivocal cases to confirm the presence of disease. Additional advantages of low cost, easy availability, imaging with a SPECT gamma camera and lower radiation burden encourage its promising utility.

EP024

Accurate Differentiation of Radiation Injury from rcurrent Glioma by 99mTc-Tetrofosmin SPECT
