Aim Cardiac phase-correlated (4D) imaging is employed in small animal models of cardiovascular diseases (CVD). When 4D-PET and 4D-CT are combined together, a comprehensive view of the cardiac function and morphology is obtained, allowing a motion artifact-free quantification of PET tracer regional distribution in the myocardium along with LV regional kinetics. This work presents the results of 4D-PET/CT imaging of small animals obtained with the IRIS PET/CT scanner (Inviscan, France). **Materials and methods** The PET component of the IRIS scanner consists of 16 modular detectors arranged in two octagonal rings. The PET field-of-view is 95mm axial × 80mm diameter. PET images are reconstructed with 3D-OSEM. The CT section is equipped with a X-ray source with tungsten anode (35-80kV, 80W) and a flat-panel CMOS-based detector. The FOV diameter of the CT is 90mm, and the maximum FOV length is 110mm. CT images are reconstructed using a Feldkamp algorithm. The PET ring and the CT components are placed on the same rotating gantry having a total rotation range of [+190°; -190°]. The offset between the centers of the PET and CT fields of view (FOV) is 120mm. For PET imaging ECG gating is used to extract the individual cardiac phases. The gating signal from the physiological monitoring system (SA instrument Inc. Model 1030) was fed into the PET acquisition system. For each cycle, 8 equally spaced frames are produced and then retrospectively rearranged to generate list-mode files corresponding to an equal number of phases. Respiratory gating is also applied, excluding from the list-mode file all events recorded in the end-inspiration phase. For CT, the gated scanning protocol consisted in a multi-arc rotating acquisition with 1000-20000 projections over the entire rotation (360°), with a total scan times from 2 to 6 minutes. The absorbed dose was 200-400 mGy. The physiological signals are derived analyzing the projection data, and the cardiac cycle was partitioned in 8-40 frames. Each projection was assigned to one or more cardiac phases with proper weights, excluding all projections in the end-inspiration respiratory phase. **Results and Conclusions** Phase-correlated cardiac images have been obtained on mice and rats with the IRIS scanner for both PET and CT modality. Multimodal 4D-PET/CT cardiac images are presented, along with example of quantification of cardiac morphofunctional parameters.

EP774

Clinical Results from a Novel CZT-based Digital SPECT System

E. Goshen[1], E. Stern[2], R. Goldkorn[1], S. Ben Haim[1]; [1]Chaim Sheba Medical Center, Ramat Gan, ISRAEL, [2]Molecular Dynamics, Caesarea, ISRAEL.

PURPOSE: Cadmium-Zinc-Telluride (CZT)-based digital gamma cameras can provide improved image resolution and greater sensitivity, thereby allowing faster acquisitions and/or reduced administered dose compared to standard scintillator-based analog (Anger) systems. Evaluation of clinical feasibility, image quality, and diagnostic performance of a prototype of a novel CZT-based digital SPECT general purpose camera was performed. Results were compared to analog SPECT studies of the same patients. MATERIALS AND METHODS: The digital SPECT system (Valiance X12 prototype, Molecular Dynamics, Hamilton, Bermuda) is equipped with CZT detectors, fitted with a high-sensitivity collimator and mounted on a ring shaped gantry. The detectors are capable of independent motion to acquire data from multiple angular views. The flexible architecture also enables focusing the detection units on a specific region of interest to obtain enhanced images of a specific target. Data are reconstructed using an iterative reconstruction algorithm. Twenty-three digital SPECT scans were performed immediately following analog SPECT in 20 patients (14M, age 26-74yrs). The group consisted of 5 Tc-99m ECD brain scans , 2 Tc-99m MAA lung perfusion studies and 1 Tc99m HMPAO labeled leukocyte study, while 12 patients underwent a total of 15 Tc-99m MDP bone studies (knees (n=7), lumbar spine/pelvis/hips (n=4) and ankles/feet (n=4)). Both sets of images were compared by experienced Nuclear Medicine physicians and were graded on a scale of 1 (poor) to 4 (very good) for sharpness, contrast, overall quality and diagnostic confidence. RESULTS: Digital SPECT studies were all diagnostic and were of good or very good quality. Mean grades for digital SPECT exceeded those of analog SPECT for sharpness (3.7 vs. 3.1), and contrast (3.9 vs. 3.3). Overall image quality and diagnostic confidence of digital and analog SPECT were comparable (3.7 vs. 3.6, and 3.8 vs. 3.9, respectively). CONCLUSION: The results indicate improved contrast and sharpness of digital SPECT compared to analog SPECT in several clinical settings. General purpose digital SPECT with high sensitivity collimators, together with improved sharpness and contrast as compared to analog SPECT technology are expected to have significant clinical impact. Further research will assess other general nuclear medicine applications, as well as the contribution of focused imaging, a unique capability of this CZT-based digital SPECT system.

EP775

Comparison of 3/8“ and 5/8“ NaI(Tl)-scintillation crystal (NaI) efficiency for different radioisotopes

C. Happel, M. Groothuis, A. Mader, B. Bockisch, F. Grünwald, W. T. Kranert; University Medical Center, Frankfurt, GERMANY.

Introduction: For scintillation cameras different NaI are available commercially. Common thickness of NaI for general purposes is 3/8”. Thickness used to be attended by an improvement of efficiency, especially for high energy radionuclides due to the higher probability of interaction. Therefore, 5/8” NaI are available as well. Aim of this study was to evaluate the improvement in efficiency. Material and Methods: Measurements were performed on two identical uncollimated scintillation cameras (DST-XL/-XLi; GE) equipped with a 3/8” NaI and a 5/8” NaI respectively using ^{57}Co, ^{99m}Tc, ^{131}I and ^{177}Lu due to their predominant use in nuclear medicine. Samples were placed centric on the lower detector with a distance of 68 cm to the upper detector. As ^{57}Co sample a calibration point source, for ^{131}I sample a test capsule was used. ^{99m}Tc and ^{177}Lu were dissolved in liquid solution (50 µl). Doses ranged from 0.36 to 2.9 MBq. A 512x512 acquisition matrix and corresponding energy windows were used. Evaluation was performed by ROI analysis of the central field of view (56x56 pixel) due to the best comparability to the geometric conditions of a parallel hole collimator. Results: Efficiency was calculated decay and background corrected in [cps/kBq]. Efficiencies of the 3/8” NaI were 42 for ^{57}Co, 34 for ^{99m}Tc, 2.3 for ^{177}Lu (208 keV) and 7.9 for ^{131}I respectively. In contrast, efficiencies of the 5/8” NaI were 47 for ^{57}Co (13% improvement), 40 for ^{99m}Tc (16%), 2.9 for ^{177}Lu (24%) and even 12 for ^{131}I (49%). Conclusion: Due to different modes of decay, efficiencies are not directly comparable, but the percentage of

improvement is. For high energy isotopes, efficiency is significantly improved by the 5/8“ NaI. Especially for ^{131}I-scans (370-1,100 MBq), an almost 50% improvement in efficiency leading to considerably improved count statistic and therefore image quality justifies the higher prizes of the 5/8“ NaI. For diagnostic purposes with ^{99m}Tc, a 3/8“ NaI is adequate.

EP776

Detector performance evaluation for Cerenkov luminescence imaging

E. Ciarrocchi[1,2], N. Belcari[1,2], P. A. Erba[3], A. Del Guerra[1,2]; [1]Department of Physics, University of Pisa, Pisa, ITALY, [2]INFN, Pisa, ITALY, [3]Department of Translational Research and New Technologies in Medicine and Surgery, Azienda Ospedaliera Universitaria Pisana, Pisa, ITALY.

We are looking for a method for Cerenkov luminescence imaging to provide the absolute quantitative information on the source activity concentration. We believe that this goal can be obtained with the combination of a quantitative detection system and a Monte Carlo model to reconstruct the source activity from the measured signal. To this aim we are investigating the performances of two photodetectors, a conventional charge coupled-device (CCD) and an electron multiplying CCD (EMCCD) during Cerenkov luminescence measurements. Our final goal is to demonstrate that the number of photons impinging on the detector can be recovered from the measured quantity, and that the source activity can be reconstructed from this number with the Monte Carlo code. We are acquiring images with a lens in a light-tight box, with simple geometries that will be easily simulated to determine the quantitative capabilities. Two Na-22 point sources embedded in a 23.5 mm x 11 mm x 2 mm clear Plexiglass plate, with activity of 7 kBq and 15 kBq respectively, were imaged with both CCDs for exposure times between 1 and 5 minutes (reasonable for *in-vivo* applications). Preliminary results suggest that the EMCCD is more sensitive than the conventional CCD, since the EMCCD was able to detect the 7 kBq source by the Cerenkov radiation produced in its container, while the conventional CCD was able to detect only the 15 kBq source in the same experimental conditions. Lower and intermediate levels of Na-22 activities were not investigated. These two sources will be used also to study the spatial resolution of the two detectors. The measurements were repeated with F-18 diluted in 3 ml of water, and the minimum detectable activity with the EMCCD in this geometry was approximately 0.5 kBq, while lower activity levels produced a signal that depended on the acquisition settings (the differences between signals varied more than 20% with acquisition settings such as binning, exposure time and multiplication gain). To determine quantitatively the absolute number of photons impinging on the detection system, we will repeat the measurements with a set of filters and with a pure β^- emitter, to reduce uncertainties on experimental factors like the sensor efficiency and the focusing optics transmission and to remove noise due to high energy photons coming from the source. This experimental result for both CCDs will be compared with Monte Carlo predictions.

EP777

Image-based method for estimation of global calibration factor for SPECT images

A. Halty[1,2], J. N. Badel[2], D. Kryza[3], A. L. Giraudet[2], D. Sarrut[1,2]; [1]CREATIS, Villeurbanne, FRANCE, [2]Centre Leon Berard, Lyon, FRANCE, [3]LAGEP, Lyon, FRANCE.

Aims: Calibration is a key factor to perform quantification on SPECT images for dosimetry in Targeted Radionuclide Therapy (TRT). We investigated a new method to estimate a global calibration factor directly from image data, adapted to each patient and to the image acquisition configuration, without requiring additional phantom acquisition. Materials and Method: We proposed to estimate the calibration factor (cps/MBq) by the total number of counts in the SPECT image divided by the patient total activity weighted by the Fraction of Activity in the FOV (FAF). The FAF corresponds to the percentage of the total activity inside the limited SPECT FOV. First, the dimensions and localisation of the SPECT FOV were projected onto the planar images, and the FAF was estimated by the number of counts in this FOV divided by the total number of counts. The total activity within the patient was estimated by the injected activity. This method was applied on 12 patients involved in a TRT clinical trial. The patients were intravenously injected with 187 ±18MBq of 111In-OTSA101, a radiolabeled monoclonal antibody targeting a transmembrane receptor overexpressed in synovial sarcoma and developed by OncoTherapy Science. The SPECT/CT and whole-body planar scintigraphic (anterior and posterior) acquisitions were performed one hour post-injection. The SPECT FOV covers 92cm of the patient. The planar acquisitions were corrected for dead-time and scatter. The geometric mean was applied and the attenuation correction was performed by estimating the patients' thickness from the CT. Since the CT was not whole-body, the missing part, covering the inferior limbs, was estimated by extrapolation of the patient's legs thickness. SPECT images were reconstructed using attenuation corrected OSEM algorithm, and were also corrected from dead-time and scatter. Images were acquired before the urination of patients which limits strongly biological elimination. Patient-specific calibration coefficients were compared to those obtained by conventional source-based calibration. Results: The FAF varied from 76% to 92%. Among patients, the coefficient of variation of patient-specific calibration factor was reasonably low (4.32%). Source-based calibration estimated activities in the SPECT FOV 27% higher than our patient-specific calibration. It would mean that 105% of total injected activities is present in the SPECT FOV, which is unlikely. Conclusion: Image-based estimation of a global calibration factor may provide patient-specific calibration, adapted to the clinical configuration, without the need of an additional phantom acquisition. It only requires a whole-body planar scintigraphy and to prevent patient biological elimination.

Breast-Torso Phantom for Bimodal Nuclear-Optical Imaging Research

J. Peter; German Cancer Research Center, Heidelberg, GERMANY.

Objective: To propose an anthropomorphic breast-torso phantom for Monte Carlo simulation of radiolabeled (SPECT, PET, PEM) and/or near-infrared fluorescent tracer distributions for breast imaging research applications. **Methods:** The phantom consists of an upper torso including lungs (with optional respiratory motion dynamics affecting geometry of all organs), heart (with optional cardiac movement), liver, gallbladder, kidneys, rib cage, sternum, spine, and various breast attachments for prone as well as mammography specific geometries. There are various options for incorporating simple-geometry tumor lesions. To enable direct, un-discretized comparison of simulation results with experimentally acquired data of the same phantom geometry, planned at a later stage of this scientific project, phantom geometry is represented solely by super-quadric shapes. Analytic shape representation has also been chosen because intersection calculations of photon trajectories with all involved surfaces can be performed in simulations at exceptional accuracy at comparatively low computational cost. All solids can be freely parameterized (e.g. radiotracer/energy distribution, fluorochrome/wavelength distribution, scatter and attenuation coefficients for light photon propagation). **Results:** Monte Carlo simulations have been performed for whole-body

(SPECT, PET) and dedicated breast imaging systems. For SPECT, cameras following arbitrary application-specific orbits were included for simulation. For PEM, simulation design was being tailored particularly towards the clearPEM system. Fluorescence optical imaging was simulated for conventional light cameras and, for the first time, for novel plenoptic detectors allowing for three-dimensional optical imaging. Photon trajectories were resolved with no discretization error involved which is particularly crucial for light photon propagation abandoning the breast and thorax shapes. **Discussion**: The proposed breast-torso phantom constitutes an intentional compromise between anthropomorphic realism on one hand and its intended use for prevailing imaging research such as the development and validation of bimodal image reconstruction algorithms or the optimization of data acquisition management involving either type of labelling component. Simulation setup, specifically phantom definition and modification, is straightforward as phantom shapes are being defined only by 5 or 7 geometric parameters, each, and is exact also with respect to predefined organ/tumor volumes because of the analytical phantom model. The anthropomorphic breast-torso phantom can be used directly within Monte Carlo simulation codes that accept super-quadric shape representation. The simulation code at hand is, in addition to tomographic and higher-order point mesh representation models, suitable for including super-quadric shapes. However, a discretization routine has been developed such that researchers can employ the breast-torso phantom in a voxelized form as well.

EP779

Semi-automated CT Image Segmentation Provides Accurate LBM Measurements

J. Devriese[1], L. Beels[2], A. Maes[2], C. Van de Wiele[2], H. Pottel[1]; [1]KU Leuven campus Kulak, Kortrijk, BELGIUM, [2]AZ Groeninge, Kortrijk, BELGIUM.

Aim Standardized uptake value (SUV), a semi-quantitative parameter used in positron emission tomography/computed tomography (PET/CT), is defined as the ratio of measured radioactivity concentration to the injected dose per distribution volume unit. It is usually normalized for body weight (BW) and other proposed normalizations include e.g. lean body mass (LBM) since ^{18}F-FDG distribution in fatty tissues is limited. LBM can be estimated by predictive equations or measured by e.g. CT. Since cancer patients often experience weight loss during treatment or disease progression, their body composition may vary. LBM estimated by predictive, generalizing, equations may therefore introduce error at individual patient level. Accurate individual LBM measurements through CT might lead to more accurate and reproducible LBM, and consequently more accurate and reproducible LBM-normalized SUVs. The goal of this study was to segment human CT images into tissue types based on Hounsfield unit (HU) thresholds, and to test the validity of the LBM thus obtained. **Materials and methods** PET/CT examinations covering head to toe were retrospectively retrieved and semi-automatically segmented into tissue types based on thresholding of CT HU. The following HU ranges were used: 180 to 7 for adipose tissue (AT), 6 to 142 for LT, and 143 to 3010 for bone tissue (BT). Total body volumes (V) per tissue type were determined and tissue masses calculated, using tissue densities of 0.90, 1.05, 1.85 kg/L for AT, LT, and BT, respectively. Besides these literature tissue densities, other coefficient sets were determined through regression in order to compensate for e.g. partial volume effect (PVE) and uncertainty concerning bone tissue density. The segmentation method was validated in an independent dataset by comparing patient BW to total CT-estimated BW (BW_{CT}). **Results** Three regression equations were tested in an independent dataset, of whichBW_{CT}(kg)=0.95*AT+0.99*LT+2.11*BTyielded the best results. Comparison of actual BW to BW_{CT}, shows a non-significant bias of 0.8 kg (95%CI: -1.3 to 4.1), with R2 = 0.989, RMSE = 1.626 and Lin's concordance correlation coefficient (CCC) = 0.993. **Conclusion** Although this is not a direct validation of our method, we are convinced that our segmentation method can reliably be used to accurately estimate AT, LT, and BT, and thus LBM, from CT images.

Tele Nuclear Medicine : Comparison of data transfer methods

W. PILLOY, V. Kritzinger, A. Van Niekerk, B. Ramjee; KVNR, Pretoria, SOUTH AFRICA.

Aim: To determine the advantages and disadvantages of three telemedicine methods, in terms of data transfer and compatibility. The issue of the transfer and storage of clinical data is not dealt with here. Material and methods Multi-sites private Nuclear Medicine (NM) firms collect NM data from various types of machines. Three telemedicine options are compared: P to P transfer; remote desktop; cloud computing. *P to P transfer of data:* Acquisition of data on a workstation and transfer to another workstation for processing and reporting. *Remote desktop:* One workstation accesses another workstation AND interacts with it. Two options: Remote desktop through direct (VNC) access to the framebuffer of the other station, and Remote desktop through Teamviewer ™ (TV) proxy servers *Cloud computing:* Remote sites send their data to a central server; data can be accessed (thin client :VNC-like) by several users (floating licences). Servers can be local (Intranet) or remote (Internet). Experience based on Hermes. Results: *P to P*: Disadvantages: Requires some level of standardization between the sites- same dataset name & specifications; same software; standard identification of patient. Advantages: Speed, bandwidth, stability of the network is irrelevant (transfer is a background task). Screen size & resolution and processing power & speed of a workstation. Acquisition and interpretation on two distinct systems: no "cross-lines". Duplication of archives *Remote desktop*: Disadvantages: Multiple interactions with the (acquisition) station: possibility of "cross-lines", at the risk of confusing patients or data. VNC and TV image quality drops with low bandwidth: poor image resolution, refreshing rate, and control of commands. Cheap option: reporting often done on a monitor of small size with poor graphic card. Images spill over the edges and must be constantly shifted to see the whole picture. Archiving at the site of acquisition and no central archive Advantages: Reporting doctor can directly see the patient's images during the acquisition. No issue of compatibility of software *Cloud computing*: Disadvantages: Expensive system. Possible network problems (Internet) Advantages: Safety of the central storage of data on a secure server. All data processed by software stored on secure server. Always up to date software (Hermes: very flexible). Powerful database management system also checking patient ID. No cross-lines (floating licenses). Conclusion: Cloud computing is the better option, with the server close to the computer of the reviewing doctors. An add-on Remote Desktop option allows visualization of the acquisition.

Comparison of Ejection Fraction Values Measured by G-SPECT Studies with a use of Dynamic Heart Phantom Performed Both on Scintillation Gamma Camera and CZT Scanner

A. Budzynska[1], J. Gaweł[2], I. Głowacka[2], M. Dziuk[1], D. Kluszczyński[2]; [1]Military Institute of Medicine, Warsaw, POLAND, [2]National Centre for Radiation Protection in Health Care, Łódź, POLAND.

Aim: To optimize the procedure of evaluation of functional parameters of myocardial G-SPECT on the base of phantom studies and to test accuracy

of quantification algorithms available in different commercial applications for different types of cameras. **Material/Methods**: The dynamic heart phantom with automatic application assembly was used for 49 G-SPECT studies. Acquisitions were done on CZT solid-state scanner with ejection fraction (EF) settings from 45% to 70% (increment by 5%) and heart rate (HR) from 40 to 80 beats/min (increment by 10 beats/min). On standard SPECT-CT gamma camera one series of measurements programmed for 50 beats/min was acquired. All studies were performed with standard acquisition protocols. Data from SPECT-CT system were reconstructed with CT based attenuation correction. Two applications: Myometrix and Quantitative Gated SPECT (QGS) available on Xeleris workstation, were used for processing. **Results**: EF values [%] estimations were comparable with the phantom reference settings (mean absolute error was -0.54%; $p<0.05$) for CZT scanner and QGS application. Estimations done with Myometrix were significantly underestimated (mean absolute error was -7.6%; $p<0.05$) EF underestimation resulted from both lower end-diastolic volume (60.4 vs. 62.8; $p<0.05$) and higher end-systolic volume (29.9 vs. 26.7; $p<0.05$). Results of EF estimations for SPECT-CT gamma camera for QGS were significantly overestimated. For the same studies results from Myometrix, were comparable to the phantom settings (mean absolute errors were 6.5% and -0.3% respectively; $p<0.05$). Overestimations were results of higher end-diastolic volume (47.2 vs. 43.7; $p<0.05$), the differences in the end-systolic volume were not significant. Researches didn't observe relation between EF and heart rate ($p>0.1$).**Conclusions**: Clinical interpretation of functional parameters of myocardial G-SPECT should be performed with awareness of correlation between acquisition system and processing software.

EP782

The influence of ^{18}F in ^{111}In images in dual isotope preclinical SPECT

J. de Swart, M. Segbers, M. W. Konijnenberg, M. de Jong, M. R. Bernsen; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: Multi-pinhole preclinical scanners are capable of simultaneous imaging over a wide energy range. Imaging ^{18}F and ^{111}In simultaneously, inevitably creates down scatter from ^{18}F into the ^{111}In energy windows. We investigated the presence of ^{18}F on absolute quantification, resolution and contrast of the ^{111}In images in phantom studies. Methods: All experiments were performed with the VECTor (MIlabs, Utrecht, the Netherlands). A 30mL plastic syringe was filled with 4.66mL water (solution) containing 17.0MBq [^{111}In]-diethylenetriaminepentaacetic acid ([^{111}In]-DTPA) and 73.2MBq 2-deoxy-2-[^{18}F]fluoro-D-glucose ([^{18}F]FDG) to determine camera sensitivity. The syringe was scanned in list mode for 16 frames of 45 minutes. A micro Jaszczak phantom with hollow rods (diameter range 0.7 - 1.5mm) was filled with 47.2MBq [^{111}In]-DTPA and 114.8MBq [^{18}F]FDG. It was scanned for 7 frames of 45 minutes to determine resolution by visual assessment. The ^{111}In energy window (171 and 245keV, width 20%, summed) and the ^{18}F energy window (511keV, width 16%) was reconstructed separately for all images. Scatter, including down scatter of ^{18}F, was corrected by using the triple-energy-method. 7keV, 10keV and 17keV scatter windows were placed adjacent to the 171keV, 245keV and 511keV energy window respectively. All images were iteratively reconstructed using the POSEM algorithm, 30 iterations, 4 subsets and 0.4mm voxel size. By drawing ROIs in ('hot') and between the rods ('cold') (1.0, 1.2 and 1.5mm) on the Jaszczak images contrast C was calculated using the formula C=(hot-cold)/(hot+cold). Results: From the syringe scans the measured ^{111}In activity in each frame was compared to the known activity (recovery coefficient (RC)), and was related to the ^{18}F/^{111}In ratio in radioactivity. The RC was within ±10% compared to the single ^{111}In RC for a ^{18}F/^{111}In activity-ratio ≤ 1. A ratio > 1 showed a rise of the RC up to 1.66 at a ratio of 4.3. All rods were visible on the Jaszczak images using the ^{111}In window but with a noticeable higher background from a ^{18}F/^{111}In activity-ratio of 1.1 and higher. Contrast values were comparable for all measured rods and decreased from 0.87 at the lowest to 0.77 at the highest ratio. Conclusion: The influence of ^{18}F in the ^{111}In images was limited when the activity of ^{18}F was lower or comparable to the activity of ^{111}In. Higher relative activity of ^{18}F lead to errors in absolute quantification of ^{111}In and decreased the image contrast. Triple energy window correction may be insufficient for (down) scatter correction for this activity ratio.

EP783

NEMA and Gaussian fit results for spatial resolution determination in PET

A. Attarwala[1], D. Hardiansyah[1], C. Romanó[1], M. Roscher[2], B. Wängler[2], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Molecular Imaging and Radiochemistry, Institute for Clinical Radiology and Nuclear Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY.

Aim: The National Electrical Manufacture Association (NEMA) based method to determine the spatial resolution of a system does not take into account the spatial distribution, quality check of the fitting and error of the estimated full width at half maximum (FWHM). A procedure based on three-dimensional Gaussian functions is investigated to develop a step-by-step approach to accurately determine the spatial resolution of a device. Materials and Methods: The spatial resolution of the ALBIRA II PET (Bruker BioSpin MRI GmbH, Ettlingen, Germany) sub-system was determined using a 370 kBq ^{22}Na point source. The measurement data were reconstructed with a maximum likelihood expectation maximization (MLEM) algorithm. Spatial resolution was calculated based on the NEMA NU-4 2008 protocol and the alternative method based on three 3-dimensional fitting functions: a 3-dimensional Gaussian function (3D Gauss) and convolutions of this function with pixel size (3D Gauss$_p$) of 0.5 mm and with the spherical source dimension of Ø 0.25 mm (3D Gauss$_s$). The Akaike information criterion (AIC) and Akaike weights were used for choosing the best-fit function. Simulation of convolutions between a mathematical source with Gaussian distributions using the FWHMs from all methods were performed to see the effect of calculated FWHMs on image quantification.Results: Based on the NEMA protocol, the FWHM in x, y and z directions were 1.68, 1.51 and 1.50 mm. The corresponding results using 3D Gauss and 3D Gauss$_s$ functions were 1.87 ±0.01, 1.70±0.01 and 1.50±0.01 mm and for 3D Gauss$_p$ were 1.84±0.01, 1.67 ±0.01 and 1.47±0.01 mm. All coefficients of variances of the fitted parameters were ≤ 0.50 % and the adjusted R^2 values were ≥ 0.98. Based on Akaike weights, all 3D Gauss methods were similarly supported by the data. The simulation study showed relative error in quantification of spherical lesions up to 22 % with the FWHM calculated from the NEMA method. Conclusion: An alternative method to calculate the spatial resolution to overcome shortcomings of the NEMA methodology was demonstrated. The proposed methods include fitting of three dimensional functions, validation of fitting quality and choosing the best function based on the distribution of the data along with an estimation of the uncertainty. The corrections for pixel size and source dimensions would become more relevant for larger dimensions and should then be included in the calculation of the FWHM.

EP784

Method for spatial resolution description in preclinical PET using a sum of Gaussian functions

A. Attarwala[1], D. Hardiansyah[1], C. Romanó[1], M. Roscher[2], B. Wängler[2], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Molecular Imaging and Radiochemistry, Institute for Clinical Radiology and Nuclear Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY.

Aim: A method to determine the spatial resolution of a device based on multiple three-dimensional Gaussian functions, taking into account the complete data distribution, was investigated as an alternative to the currently used NEMA NU-4 protocol. **Materials and Methods**: A 370 kBq ^{22}Na spherical point source with a diameter of 0.25 mm was used to determine the spatial resolution of the ALBIRA II PET (Bruker BioSpin MRI GmbH, Ettlingen, Germany) sub-system. Image reconstruction was performed with a maximum likelihood expectation maximization (MLEM) algorithm. The full width at half maximum (FWHM) was calculated based on the NEMA NU-4 2008 protocol and the alternative method based on multiple three 3-dimensional fitting functions: a single 3-dimensional Gaussian function (3D $Gauss_1$), the sum of two 3-dimensional Gaussian functions (3D $Gauss_2$) and the sum of three 3-dimensional Gaussian functions (3D $Gauss_3$). The Akaike information criterion (AIC) and Akaike weights were used for choosing the best-fit function. A mathematical source simulation study was performed to see the effect of the spatial resolution model function calculated from the two methods on image quantification. **Results**: The FWHM based on the NEMA protocol in the x, y and z orientations were 1.68, 1.51 and 1.50 respectively. The corresponding values using the alternate method were 1.87±0.01, 1.70±0.01, 1.50±0.01 (3D $Gauss_1$), 1.78±0.01, 1.74±0.01, 1.83±0.01 (3D $Gauss_2$) and 1.76±0.03, 1.72±0.03, 1.78±0.03 (3D $Gauss_3$), respectively. Coefficients of variance of the fitted parameters were ≤ 29 % and the adjusted R^2 were ≥ 0.99. Based on Akaike weights, the 3D $Gauss_3$ function showed the highest probability to describe the data. The simulation study showed relative error in quantification of spherical lesions up to 46 % with the FWHM calculated from the NEMA method. However, no relevant difference in quantification was observed between the 3D $Gauss_2$ and 3D $Gauss_3$ functions. **Conclusion**: Different mathematical model functions for calculating the spatial resolution were investigated. The proposed methods include fitting sum of three dimensional functions to take into account the non-Gaussian tail, validation of fitting quality and choosing the best function based on the distribution of the data along with an estimation of the error. At least two Gaussian functions should be used to describe a point source when determining the spatial resolution of the system for quantification studies.

EP785

Multicentric 68Ge phantom-based evaluation of quantification reproducibility with Block Sequential Regularized Expectation Maximization (BSREM) algorithm in PET

E. De Ponti[1], S. Morzenti[1], D. Vallot[2], C. Spadavecchia[1], O. CASELLES[2]; [1]Medical Physics Department - ASST, MONZA, ITALY, [2]Institut Claudius REGAUD -IUCT Oncopole, TOULOUSE, FRANCE.

Aim: Accurate and reproducible SUV measurements in PET imaging are becoming mandatory for assessing therapy response and for reliable detection of lesion's uptake changes over time. The BSREM algorithm allows to reach full convergence without the detrimental effects of excessive noise found with OSEM and consequently with higher reproducibility in SUV quantification in small lesion. The performance of this regularized algorithm was evaluated in a phantom study in two European Centres. Material and methods: Acquisitions were performed with a 68Ge-NEMA phantom based on standard NEMA-IQ phantom body, which adheres to the dimensions of NEMA-IQ phantom prescribed in the NEMA-NU2-2012 standard. Phantom filling was done by Eckert & Ziegler Isotope Products Inc. and fillable spheres were replaced with wall-less spheres of 68Ge. The ratio of sphere to background activity was 4:1 and the lung insert was filled following the phantom manufacturer's procedure. Phantom was acquired 5 times in 5 different days with different repositioning and for each phantom positioning 5 iterations were acquired. Data from 25 different acquisitions for each Centre were averaged to evaluate statistical variability. NEMA-NU2-2012 contrast recovery (CR), background variability (BKG) and lung error from standard OSEM and BSREM algorithm reconstructions were compared. Results. Results for all spheres are presented. 10mm sphere: CR was 39.0±4.6 and 29.1±3.8; BKG 9.3±0.9 and 8.5±0.9 (difference 9%) for BSREM and OSEM algorithms respectively. 13mm sphere: CR was 53.5±6.1 and 43.0±4.9; BKG 7.6±0.8 and 6.7±0.7 for BSREM and OSEM algorithms respectively. 17mm sphere: CR was 61.0±4.6 and 53.4±4.0; BKG 5.8 ±0.6 and 5.2±0.5 for BSREM and OSEM algorithms respectively. 22mm sphere: CR was 68.0±3.3 and 61.1±2.5; BKG 4.4±0.5 and 4.0 ±0.4 for BSREM and OSEM algorithms respectively. 28mm sphere: CR was 77.1±2.3 and 67.4±1.7; BKG 3.3±0.5 and 3.2±0.3 for BSREM and OSEM algorithms respectively. 37mm sphere: CR was 83.7±1.3 and 74.9±1.2; BKG 2.6±0.3 and 2.6±0.2 for BSREM and OSEM algorithms respectively. Lung error was 12.5±0.4 and 16.9±0.4 for BSREM and OSEM algorithms respectively. Anova test presented $p<0.0001$ for differences between BSREM and OSEM for all comparison. Coefficient of variability for CR was between 11% and 13% for 10mm and 13mm and less than 8% for bigger spheres. Coefficient of variability for BKG was between 9% and 15% for all spheres. Conclusion: CR were 11% to 38% higher with BSREM compared to OSEM algorithm while BKG remained statistically the same. Good reproducibility for both methods is probably associated to the high sensitivity scanners used for acquisitions.

EP786

Metrics for Assessing Quantitative Accuracy of PET/CT Systems

D. Byrd[1], S. Wollenweber[2], A. Alessio[1], C. Stearns[2], **P. E. Kinahan**[1]; [1]University of Washington, Seattle, WA, UNITED STATES, [2]GE Healthcare, Waukesha, WI, UNITED STATES.

The quantitative accuracy of PET/CT systems is typically not characterized or reported in a meaningful manner. We have developed quantitative performance measurements that relate to estimation of uptake of radiotracers by lesions for typical 18F-FDG-PET/CT oncology scans. METHODS: We used the IEC 61675-1 / NEMA NU-2 body phantom, but activated with 68Ge/68Ga in epoxy, to enable estimation of ensemble variance across multiple scans. The activity level was 2.6 kBq/ml, roughly equivalent to a background SUV of 0.72 for a 370 MBq injection of 18F-FDG followed by a 60 min uptake period. The sphere diameters were 10, 13, 17 and 22 mm, with an SUV of 2.75. Images were reconstructed using multiple reconstruction algorithms, including regular OSEM with eight iterations, OSEM with detector point-spread-function (PSF) modeling, and a convergent algorithm (BRSEM). We evaluated absolute and relative recovery coefficients (RCs), standard deviation (SDEV) using repeated scans and the IEC and NEMA protocols, the root-mean-square-error (RMSE), and total deviation index. The proposed measurements were evaluated using two time-of-flight PET scanners. The scanners used similar crystal sizes, but different timing resolutions (550 vs. 380ps) and axial length (15 vs. 25cm). The longer scanner utilized silicon photomultiplier technology. The 25cm system had a sensitivity that was approximately 3-fold higher than the reference system. Sets of 50 repeated scans of 2.5 min each were acquired on both systems. RESULTS: For mean regions of interest values, the least bias was with BRSEM, followed by OSEM+PSF, then OSEM. In all cases the bias was less for the 25cm+ 380ps system. The results for SDEV were consistent, although there were some variations. The summary RMSE values followed the same trends, ranging from 12% to 14.5% for the 10mm diameter sphere, down to 6% to 11% for the 23mm sphere. When image roughness noise was matched, the variability of the recovery coefficients for the spherical test objects was reduced by 33% for the 25cm+380ps system, averaged over a range of reconstruction parameters. CONCLUSIONS: These tests provide a clinically relevant methodology for comparing performance of current and next generation PET systems. As expected, the 25cm system with improved sensitivity and TOF timing resolution, but roughly equivalent crystal sizes, showed improved quantitative accuracy: 33% reduction in

estimation variability, and a 50% noise reduction for matched resolution. These tests and comparisons could be used to augment standards specifically for performance assessment of the quantitative accuracy of PET/CT scanners.

EP787

Optimization of acquisition and reconstruction parameters of combined CT angiography and 18F-NaF PET for preclinical assessment of vascular mineralisation in mice

G. Rucher[1], L. Camelière[1], A. Abbas[2], D. Nicolas[3], A. Manrique[1]; [1]EA4650, Université de Caen Normandie, Caen, FRANCE, [2]Inserm UMR-S1077, Université de Caen Normandie, Caen, FRANCE, [3]CNRS UMS 4308 - GIP Cyceron, Caen, FRANCE.

Introduction. Preclinical assessment of bone 18F-NaF uptake requires co-registration of high resolution anatomical and functional modalities. The aim of this study was to optimize acquisition and reconstruction parameters to favour the spatial resolution for both modalities. **Material and methods**. A custom-made resolution phantom consisting of 5 longitudinal line sources at 1-cm intervals filled with a 18F solution was imaged using a dedicated preclinical PET-CT (Inveon, Siemens). A 600 sec list mode acquisition was performed with low dose CT for attenuation correction, and reconstructed using filtered backprojection (FBP) and 3D-OSEM (4, 8 and 16 iterations), with and without scatter correction and with and without reconstruction zoom (factor 2). Using the FWHM of activity profiles across each line source, we determined the spatial resolution at the centre of rotation and the coefficient of variation of FWHM across the 5 line sources (COV). The CT resolution was calculated from the in-plane modulation transfer function curves measured as a function of detector binning (binning 1, 2 and 4) using a tungsten wire (18 microns diameter). All CT acquisitions were performed using a high acquisition magnification (FOV: 1.9x2.8 cm). Finally, a micro-CT resolution bar pattern phantom (QRM, GmbH, Möhrendorf, Germany) was used to qualitatively evaluate the cross-plane spatial resolution of the CT system. **Results**. Both central resolution and COV were improved by using 3D-OSEM vs. FBP (FWHM: 1.28±0.33 mm vs. 1.90±0.11, $p<0.0001$, and COV: 10.4%±1.42 vs. 7.57%±2.14, $p=0.001$ for 3D-OSEM and FBP respectively). A linear model analysis demonstrated that a zoom factor 2 but not scatter correction further improved the FWHM ($p<0.0001$) and COV ($p<0.01$) of 3D-OSEM reconstruction. Finally, using 3D-OSEM and zoom 2, FWHM was optimized using ≥8 iterations (FWHM = 0.9 mm). The CT in-plane spatial resolution was measured at 163 microns (binning 4), 87 microns (binning 2) and 62 microns (binning 1). The bar pattern phantom allowed the visualisation of bar pattern structures of 100 (binning 4) to 50 microns (binning 1 and 2). The acquisition time was reduced from 22 with binning 1 to 7 min with binning 4. **Conclusion**. Using 3D-OSEM with a reconstruction zoom (factor 2) without scatter correction optimized the spatial resolution of microPET. CT scan using a high acquisition magnification with binning 4 provided a good compromise between acquisition time and resolution. These parameters were confirmed on image quality in a mouse undergoing a combine assessment of 18F-NaF PET and bone CT scan.

EP788

Quantitative Imaging of Lu-177: Maximising counts from Lu-177 patients by using high count rate mode to reduce deadtime effects on a GE Optima 640 SPECT/CT gamma camera

J. Merrett[1,2,3], J. Scuffham[3,1], A. Fenwick[2], G. Schettino[2], A. Nisbet[3,1]; [1]University of Surrey, Guildford, Surrey, UNITED KINGDOM, [2]National Physical Laboratory, Teddington, London, UNITED KINGDOM, [3]Royal Surrey County Hospital, Guildford, Surrey, UNITED KINGDOM.

Aim: GE SPECT/CT systems can be manually set-up in high count rate mode, which reduces deadtime losses when performing Nuclear Medicine imaging. The aim of this work was to assess the efficacy of using the high count rate mode for quantitative imaging of Lu-177 at the maximum likely administered activity (7.4GBq + 5% = 7.8GBq). Materials and Methods: The measurement procedure recommended by the National Electrical Manufacturers Association (NEMA) in report NU 1-2012 for measuring count rate performance in scatter was used. In this method a disc of liquid activity (170mm diameter, 20mm depth) is measured in the centre of an acrylic phantom (300mm diameter, 150mm depth) to provide scatter. The phantom is positioned such that it is in contact with the detector, and there is 50mm of acrylic between the disc of activity and the face of the detector. A further 80mm of acrylic is positioned behind the disc of activity. Locally, this test was also performed with the disc of activity measured in air at the same distance from the detector for comparison. The measurements were performed with the camera operating in both high and low count rate mode. The disc source was measured repeatedly over several weeks as it decayed, with an initial activity of 7.8GBq of radiochemically pure Lu-177. The observed count rate for each measurement was defined as the total counts acquired divided by the acquisition time. Results: Observed count rate was plotted against source activity. It was assumed that there were negligible deadtime losses at low count rates, and the linear relationship between observed count rate and source activity at these count rates were extrapolated back to the initial activity to allow quantification of deadtime losses. When imaging in low count rate mode, there were maximum deadtime losses of around 35%, whilst imaging in high count rate mode gave maximum losses of around 20%. Marginally reduced deadtime losses were observed for the scatter-free measurements, compared to the measurements made in the acrylic phantom. Conclusion: This work demonstrates a method by which deadtime losses can be reduced to around 20% at the maximum activity typically administered to a patient, resulting in higher count densities in the patient images. However, the remaining deadtime losses need to be compensated for in order to perform quantitative imaging. Further investigation into how to best perform deadtime corrections for both planar and SPECT/CT Lu-177 quantitative imaging is ongoing.

EP789

Image quality and acquisition time in integrated PET/MR scanner: a phantom study

A. Zorz[1], P. Turco[2], A. Scaggion[1], F. Roppo[3], D. Cecchin[2], F. Bui[2], P. Zucchetta[2], M. Paiusco[1]; [1]Medical Physics Department, Veneto Institute of Oncology IOV-IRCCS, Padova, ITALY, [2]Division of Nuclear Medicine, University Hospital of Padua, Padova, ITALY, [3]School for Radiology Technicians, University Hospital of Padua, Padova, ITALY.

Integrated PET/MR scanners reduce the overall patient dose if compared to PET/CT. Further potential for dose reduction resides in the possibility of decreasing the injected activity, taking advantage of the forced prolonged acquisition time of the MR acquisition. The aim of this study was to verify if an increased acquisition time could compensate for a reduced tracer activity. Tests were performed following the NU 2-2012 NEMA image quality protocol. The effect of different reconstruction parameters was also evaluated. The NEMA body phantom with different sphere to background ratio was acquired on Siemens Biograph mMR PET/MR integrated scanner, which uses lutetium oxy-orthosilicate scintillator crystals read out by avalanche photodiodes and a 3 T static magnetic field. A scatter line with 110 MBq was positioned contiguous to the IQ phantom. A 30 minutes list-mode PET image was acquired and reconstructed using 3D Poisson OSEM iterative algorithm with 3 iterations, 21 subset, 172x172 matrix size and 4 mm gaussian filter. A CT-based attenuation map was manually registered to the acquired data and used for the attenuation correction. A second acquisition was performed after a time

interval corresponding to the radioisotope half-life. Datasets with standard NEMA activity were retrospectively reconstructed at different times (12, 5, 2, 1 and 0.5 min); half activity images were reconstructed with double acquisition times (24, 10, 4, 2 and 1 min). On each image, the percentage of contrast and background variability were calculated according to NEMA protocol. In order to verify the effect of reconstruction parameters on the two datasets, 12 minutes images with standard and half radiotracer concentration were reconstructed with different iterations and matrix size. No significant differences were found comparing images with half radiotracer concentration and double acquisition time with the standard ones. Contrast of the standard activity images remained stable within the reconstructions of 12, 5, and 2 minutes datasets, with an acceptable noise level. All the spheres were almost visible also in the 30 seconds reconstruction. Contrast and background variability increased with the iteration number. Background variability increases from 128 to 256 matrix size, but no further variation is found when reconstructing with largest matrix size. The same trend was observed both in standard and half activity images. Increasing the acquisition time can compensate for reduced tracer activity injection. Image quality is acceptable until 2 minutes acquisition/bed. Changing the reconstruction parameters have the same effect on images with standard and half activity.

EP790

Development of a new phantom for spatial frequency response measurements of nuclear medicine imaging devices

A. Hoekstra, A. D. van het Schip, G. C. Krijger; Department of Radiology and Nuclear Medicine University Medical Center Utrecht, Utrecht, NETHERLANDS.

Objective. A key parameter of a nuclear imaging device is its spatial resolution response. This is usually measured with bar phantoms (planar gamma cameras) or with line sources (planar gamma cameras, SPECT or PET systems). For bar phantoms the spacing between lead bars (mm) is visually interpreted. For line sources results are expressed as FWHM (mm). As resolution depends on the spatial frequency response, a phantom was developed to measure the response at different frequencies to quantify the resolution. Methods. The new phantom is a box (220 x 125 x 17 mm) containing a 5 mm thick perspex plate with sinusoidal shaped free spaces each representing a geometrical frequency to simulate the modulation of a constant value. Modulation frequencies are: 0.25, 0.50, 0.75, 1.00, 1.25, 1.50, 1.75, 2.00 cycles/cm. The spaces were filled with a radionuclide to get a sinusoidal radionuclide-intensity distribution. Measurements were performed on a planar, SPECT and PET camera. The image data were analysed with the open source software ImageJ and a sinusoidal count distribution was created. The data were processed in Microsoft Excel to fit the frequency response. Results. A modulation index was calculated for each fitted image frequency result. This index was divided by the source modulation index resulting in a modulation factor. With these factors a modulation transfer function (MTF) was created and fitted as a polynomial curve. From this, a contrast function of the response data was calculated. The contrast is defined as the modulation depth of the response data to a square wave at different frequencies. A resolution criterion based on this contrast function is the frequency at a 20% contrast level, resulting in a resolution value and expressed in mm. The resolution value at 20% contrast for Tc-99m of the used gamma camera, with HR collimator, was 3.6 mm. For In-111 (ME) this value was 6.4 mm. A Tc-99m SPECT study with the same device resulted in 8.8 mm. An I-124 study with a PET/CT scanner resulted in a value of 5.6 mm. Conclusion. The inverse Fourier transform of our MTF data results in a Line Spread Function to determine the FWHM of the imaging devices. This value showed good agreement with specifications of the devices used, with the advantage of being the result of a more quantitative method. Therefore, this phantom has the potential to become a valuable tool for resolution specification determination of nuclear medicine imaging devices.

EP791

SUV Recovery on a Continuous Acquisition PET/CT: Influence of Table Speed, Noise Level and Reconstruction Settings

K. Jaspers[1,2], A. Talsma[1], R. Boellaard[2]; [1]Martini Hospital, Groningen, NETHERLANDS, [2]University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim: To investigate the impact of table speed settings, noise level and the use of point spread function (PSF) on SUV recovery on a continuous acquisition PET/CT using the EARL image quality protocol. **Materials and methods**: Measurements were performed according to EARL standard operating procedures on a Siemens Biograph mCT 20 Flow PET/CT (Siemens, Erlangen, Germany) using the NEMA NU-2 image quality phantom. The FDG-activity in the spheres equalled 20 MBq/L with a background activity of 2 MBq/L at time of first acquisition (T0). Datasets were acquired at T0, and after 1 and 2 half-lives (T1 and T2, respectively) with varying table speeds (0.5, 1, 2, 4 mm/s). The data were reconstructed with time-of-flight ordered subset expectation maximisation method using 2 iterations and 21 subsets, with and without the use of PSF (standard protocol and research protocol, respectively) and with a Gaussian filter of 5 mm. Reconstructed voxel size equalled 4x4x3 mm^3. Analysis was performed using the EARL software tool providing maximum and mean SUV recovery coefficient (RC) curves (RC_{max} and RC_{mean}). To assess the influence of table speed, datasets with varying combinations of activity and table speeds were grouped based on noise level, determined by the coefficient of variation (COV) of voxel values in the background compartment of the phantom **Results**: PSF reconstruction resulted in RC curves that exceeded the EARL criteria for both RC_{max} and RC_{mean}. The overshoot was most prominent for the smaller spheres. Without PSF, the EARL criteria were met for sufficiently low noise levels (COV < 15%). For sufficiently high statistics, recovery coefficients at a specific noise level were independent of the combination of activity and table speed. In the case of poorer statistics (COV > 15%), higher table speeds (≥ 2mm/s) resulted in higher RC that exceeded the EARL criteria. **Conclusions:** The mCT PET/CT can comply to EARL criteria regarding SUV recovery if no PSF is used. For sufficiently high statistics, table speed does not influence SUV recovery when scanning the phantom at matched noise levels. For poorer statistics, however, table speed appears to affect SUV recovery.

EP792

Validation and Optimization of Quantitative SPECT/CT

S. Razavi, R. Klein, P. Martineau, S. Dinning, M. Bryanton, W. Zeng, L. Zuckier; Dept of Nuclear Medicine The Ottawa Hospital, Ottawa, ON, CANADA.

Objective: To rigorously investigate factors influencing the accuracy and precision of quantitative ^{99m}Tc SPECT-CT under actual clinical conditions using known activity concentration phantoms. **Method:** Patients referred for ^{99m}Tc-MDP Bone or ^{99m}Tc- SestaMIBI parathyroid scans using SPECT-CT system were recruited for this REB approved study. After patient positioning on the scanner-bed and prior to image acquisition, 2-3 cylinders of varying sizes filled with a known concentration (MBq/cc) of ^{99m}Tc activity were placed under the armpits and/or between the legs. Patient image acquisition followed the clinical protocol. Quantitative (MBq/cc) tomographic images were reconstructed using Hermes HybridRecon and activity concentrations in the sources were measured using 10 mm diameter spherical volumes of interest (VOI) which were compared to known phantom concentrations and reported as percent-error. Accuracy and precision of measured activity was evaluated for intra-operator variability, acquisition types and reconstruction types. For operator-variability, VOIs were placed at the center of each of 38 phantoms (in 15 patients) on four different occasions. Acquisition

types (circular vs. contouring orbit and step-and-shoot vs. continuous) were evaluated in a physical phantom study with all sized phantoms in the field of view. To study the effect of OSEM reconstruction parameter the number of iterations was increased from 4 to 20 iterations, with and without collimator corrections. In a subset of 10 patients (27 phantoms) Maximum a-posteriori (MAP) reconstruction algorithms with smoothing, median root prior (MRP), anatomy-based (AMAP), and finite-impulse-response median hybrid (MRP-FMH) priors were compared along with our standard OSEM 4-iterations reconstruction. **Results:** Operator variability was excellent with 2.8% average standard-error. Based on a single phantom experiment with 4 cylinders of varying sizes, orbit type and camera-head motion did not significantly impact quantitative accuracy and no significant systematic quantification error was detected ($p>0.9$). Likewise, OSEM reconstruction parameters (4 iteration, 20 iteration, 20 iterations with collimator corrections) did not significantly change accuracy ($p>0.9$), but precision tended (6% vs. 9% for 4 vs. 20 iterations, $p=0.052$) to degrade with higher number of iterations. OSEM underestimated activity concentrations by 13% ($p<0.001$), whereas all MAP reconstruction methods improved on accuracy, with average MAP-MRP error at only 4% and not significantly greater than 0 ($p>0.1$). Precision was between 8% and 14% standard-error for OSEM 4-iterations and MAP-MRP respectively. **Conclusion:** Quantification of tracer concentrations in clinical applications is technically possible and robust to operator variability, acquisition types, and OSEM iterations. MAP reconstruction can achieve improved accuracy, but partial volume effects may persist.

EP793

Ge-68 based normalisation and SUV measurements on a Siemens PET-CT system: Implications of variations in Ge-68 cylinder source properties

S. J. McQuaid[1], J. W. Scuffham[1], J. R. W. Hall[2], V. Prakash[3], P. J. Hinton[1]; [1]Royal Surrey County Hospital NHS Trust, Guildford, UNITED KINGDOM, [2]Frimley Park Hospital NHS Trust, Frimley, UNITED KINGDOM, [3]Ashford and St. Peter's NHS Hospital Trust, Chertsey, UNITED KINGDOM.

Aim: Siemens mCT systems perform normalisation with a uniform Ge-68 cylinder. On one system, repeated low Ge-68-based SUV measurements (0.88 rather than the expected value of 1.00) were obtained, with potential implications for patient imaging quantification. The aim was to determine the cause of these anomalous measurements. *Materials and Methods:* The following were investigated as possible causes of the Ge-68 SUV error: 1) inaccurate reference activity 2) inaccurate stated cylinder volume 3) the presence of contaminants in the source (affecting the half-life) 4) non-uniformities in the cylinder construction and 5) differences in the source attenuation to that assumed by the PET-CT during normalisation. These were investigated by performing a normalisation followed by a 1-bed PET-CT acquisition for 8 Ge-68 cylinder sources: one manufactured by Eckhert & Ziegler (for which the error had been observed) and 7 manufactured by Siemens (for which SUV measurements were close to 1.00). The mean SUV and Hounsfield Units (HU) were measured from large regions-of-interest (ROIs) on 3 slices of the reconstructed PET and CT images respectively. Line profiles across the PET images of the cylinders were also compared. *Results:* Inaccuracies in source activity and volume may have been present in the E&Z source, but were ruled out as sources of Ge-68 SUV error, since the same values were used for the normalisation and SUV-check acquisition, cancelling out any errors present. Contaminants were also ruled out as the cause of the low SUV, since the E&Z source normalisation was repeated using the test-date activity (instead of the reference activity), which did not affect the result (0.88+/-0.07 using reference information, 0.87+/-0.08 using test-date information). Variations in activity concentration were comparable between the sources (approximately 5%) and are largely mitigated in SUV measurements by averaging large ROI results over multiple slices. Mean HUs were 7.4 HU (E&Z source) and 64.7+/-1.6 HU (7 Siemens sources), which equates to attenuation differences of up to 12% over the gamma ray paths. This is comparable to the difference in SUV observed. *Conclusions:* Ge-68 SUV measurements are insensitive to errors in Ge-68 cylinder reference activity and source volume, but are affected by the attenuation of the Ge-68 cylinder. Ge-68 SUV errors due to attenuation effects could be indicative of F-18 SUV errors, due to inaccurate normalisation, which would affect image quantification. This should therefore be checked with a uniform F-18 cylinder and corrections applied to change the F-18 SUV to 1 where necessary.

EP794

How do French nuclear physicians deal with ethical aspects of communication results to patients after PET performed for oncological indications? A national french survey

S. Gonzalez, P. Le Coz, A. Loundou, A. Abdullah, C. Colavolpe, O. Mundler, D. Taieb; university-affiliated hospital Timone, Marseille, FRANCE.

Context: Delivery of information to patients in France is governed by regulated and non regulated obligations, the latter being very general. There is exists no available guidelines or consensus regarding the content of information to be delivered, especially when taking into account the differences of each specialty. Current legislative texts require physicians to uphold the concepts of loyalty and transparency when dealing with patients. However, these texts do not well deep into the practical modalities of communicating information. The moment and method of breaking bad news varies according to the nature of the disease and the personal judgment of the physician. The patient-nuclear physician relationship is very unique. Objective: The goal of our study was to evaluate the practice of French nuclear physicians concerning the communication of results to patients undergoing PETs for oncological indications. Methods: An ad hoc questionnaire was developed in collaboration with the departments of public health and of medical ethics. All French nuclear physicians registered with the French Society of Nuclear Medicine, and all third and fourth year residents in nuclear medicine programs in France were contacted by email for completing an electronic questionnaire between the 25th of June 2015 and the 20th of July 2015. Results: 250 nuclear senior physicians and residents were included (31.3 % response rate). It was found that there was large heterogeneity among French nuclear physicians regarding their practice of information delivery post PET explorations for oncological indications. Concerning the consultations, 56 % see their patients systematically, while 35% adapt their practice on a case-to-case basis, and only 9 % state that they never see their patients. When it comes to orally communicating results to patients, 63 % adapt their approach on a case-to-case basis, 24 % never do, while 13% do so systematically. After multivariate analysis, the following factors were found to be associated with communicating results to patients; older age of physician ($p=0.0020$), more years of experience ($p=0.001$), private versus public practice ($p=0.033$), and the regular and systematic practice of consultations post PET ($p<0.001$). Finally, 80 % of physicians admit that current recommendations are not clear enough. Conclusion: This heterogeneity of practice methods among nuclear physicians concerning the communication of PET results to patients, stems from the lack of specific recommendations. An inter-collegial, ethical and multi-disciplinary reflection is needed in order to better guide nuclear physicians when it comes to communicating results to patients suffering from serious disease.

EP795

Administered dose optimization aiming for constant image quality in 3D 18F-FDG whole body PET/CT studies: Clinical implementation of the quadratic relation between dose and patient's body mass on two systems

M. Kotzasarlidou[1], M. Metaxas[2], A. Georgakopoulos[2], A. Pashali[1], N. Pianou[2], S. Hatziioannou[2], V. Hatzipavlidou[1]; [1]Nuclear Medicine Dept., "THEAGENIO"Cancer Hospital, Thessaloniki, GREECE, [2]PET-CT Department, Centre for Clinical, Experimental Surgery and Translational Research. Biomedical Research Foundation of the Academy of Athens, BRFAA, Athens, GREECE.

Quality of 18F-FDG PET/CT images, measured by the signal-to-noise ratio(SNR_L)in liver, depends on injected activity(A) and acquisition time, for certain scanning mode, percentage bed overlap and reconstruction parameters. According to EANM procedure guidelines, (version 2), quadratic scheme between prescribed FDG activity, patient's weight(w[kg]) and PET acquisition time per bed position(t[min]) results to constant image quality as patient weight increases. **Aim:** This study aims to determine the system specific quadratic relation between dose and patient's body mass for two PET/CT systems and evaluate its performance, when applied. **Method and materials:** Image quality was determined by SNR_L in 150 anonymized adult clinical data, (weight 45-125kg)., who performed FDG-PET/CT scans, on two systems, GE Discovery PET/CT710 (ToF) and Siemens BIOGRAPH 6 (non ToF) applying a linear scheme between FDG dose(A) and patient's weight(w), A=0.17*w using OSEM reconstruction and A=0.07*w, using 3-dimensional iterative reconstruction(3D-IR, 24subsets, 2iterations.) respectively. SNR_L was normalised for injected activity(A) and time per bed position(t), deriving $SNR_{norm}= SNR_L/(A*t)^{1/2}$. Data were fitted to a first order polynomial, $SNR_{norm}=a*w^{-d}$. Parameters a, d were calculated. For constant image quality SNR_L should have an acceptable value, suggested equal to SNR_{mean}. Therefore optimized dose A[mCi], is given by the following equation:$A=(1/t)* (SNR_{mean}/a)^2*w^{2d}$Optimized dose regimen was implemented for both PET/CT systems. 130 scans were analysed to investigate the effect on image quality, by comparing plots of SNR_L vs weight for linear and quadratic dose regimes. Statistical analysis for t-distribution was performed using SPSS Statistics 19.**Results:** For Discovery PET/CT 710, since SNR_{mean}=8.16±1.5, parameters a,d were a:33.9±16.5, d:0.655 ±0.11 the derived formula was: $A[mCi]=0.019*w^{1.31}$For BIOGRAPH 6, SNR_{mean}=6.79±1.5, parameters a,d were a:78±35, d:0.95±0.1 the derived formula was: $A[mCi]=0.0025*w^{1.31}$.In both cases time per bed position,t, was set equal to 3min. Applying quadratic scheme to both systems SNR_L remained almost constant ($p<0.05$). **Conclusions:** Application of the quadratic dose regimen is recommended in order to ensure constant image quality of 18F-FDG whole body PET/CT scans across a big range of patient weights. Comparing with linear model, it results to higher administered activities for patient weights less than70kg but this fact can be compensated by increasing acquisition time per bed position($min \cdot bed^{-1}$).

EP796

Validation of an adaptative re-planning algorithm for delineation of an internal target volume

C. GUILLERMINET, M. Lacombe, S. Girault, P. Gustin, A. Testard, O. Morel, D. Autret; ICO Paul Papin, Angers, FRANCE.

Aim : The delineation of internal target volumes (ITVs) in radiation therapy of esophaegal tumors is commonly performed by the help of free-breathing positron emission tomography/computed tomography (FB-PET/CT) scan. Nevertheless, technologic advances in the field of radiation oncology have reinforced the importance of accurate target delineation. In this report we validate, in our routine tasks, the use of 4-dimensional (4D)-PET/CT for the delineation of target volumes in a phantom using the new algorithm called «adaptative re-planning » of GE Medical System (GEMS). This algorithm permits to take in account the elastic deformation of the segmented lesion from a CT/scan to an other. Materials and methods : A phantom with 3 hollow spheres was prepared surrounded by water. The spheres and the water were filled with 18F-FDG to obtain a background with an activity concentration of 5 kBq/mL and a contrast respectively of 2, 4 and 6. A 4D-PET/CT of the phantom scan was performed while moving in a cos4 breathing pattern. This scan was reconstructed under different phases (10, 6, 5 and 4). The spheres were contoured by 2 contouring method (41% of maximum and an objective segmentation based on a gradient algorithm) on the FB-PET/CT, the 4D PET/CT before and after the adaptative re-planning and the 4D/CT. The concordance between the different volumes was calculated using a DICE coefficient (DC). Results : The average DC in the phantom using the 2 contouring methods, respectively, was lowest for FB-PET/CT and highest for 4D-PET/CT. Non significant difference were noticed between the 2 contouring for 4D-PET/CT before and after the « adaptative re-planning ». The number of phases has an impact on the contouring of the lesions. If consensus is a 6 phases 4D-PET/CT for the delineation with radiotherapy goal, 10 phases 4D-PET/CT has an interest in the case of small lesions. Conclusion : As expected, FB-PET/CT consistently underestimates the ITV when compared with 4D-PET/CT for a lesion affected by respiration. 4D-PET/CT replanned by the adaptative algorithme produces volumes with high concordance with 4D-CT across multiple contrast and lesion sizes. This work will continue with a focus on the use of different breathing patterns in order to take in account lung contrast and real patient breathing periods. Our 4D-PET/CT patient protocol will be modified according to the conclusions of this work and the impact of 4D-PET/CT will be investigated in delineation of patients lesions.

EP797

Noise characteristics of PET images reconstructed with OSEM algorithm

P. Castro[1], C. Huerga[2], P. Chamorro[1], M. Roch[1], G. Pozo[1], L. Pérez[1]; [1]La Princesa Hospital, Madrid, SPAIN, [2]La Paz Hospital, Madrid, SPAIN.

Aim: The magnitude and structure of noise in PET can have various origins. The statistical nature of the emission process follows a Poisson model. Electronic noise, dead time and the loss of photons that do not reach the detector are other contributions associated with the detection system. Other important sources of noise in PET are the scattered counts generated in the patient and the random counts. The attenuation correction or the blank scan correction also assumes additional contributions to noise. Finally, the process of tomographic reconstruction determines the way in which the various sources of noise are presented in the image. The effect of adding all of these contributions of various statistical behaviors could result in the pixel values tend to have a Gaussian distribution (central limit theorem). The aim of the study is to characterize the noise present in PET images reconstructed with the Ordered-Subset Expectation Maximization (OSEM) algorithm through the standard deviation and the probability density distribution. Materials and Methods: The study is based on PET images acquired in 2D mode with a cylindrical phantom injected with 18FDG which provides a uniform activity distribution. Images are reconstructed with OSEM algorithm. Standard deviation provides information about the noise magnitude. Circular ROIs of 10 pixels diameter are used to analyse the spatial variation of noise magnitude. For axial dependence ROIs are centered on the phantom for each of the slices; for radial dependence the ROI position will vary from one end of the phantom to the opposite end through the centre, in different radial directions. Histograms of the experimental data are used to calculate the probability distribution. The obtained distribution is compared to different noise models (Poisson, Gaussian, Negative Binomial, Lognormal, and

Gamma). The Kolmogorov-Smirnov test is used to assess the goodness of fit. Results: There is an increase of noise at the edge slices consistent with the lower number of coincidence lines. The radial dependence shows a slight reduction in noise towards the edges of the phantom (<10%). The function that produces the best goodness of fit and lower differences with experimental statistical moments is the log-normal distribution. Results show the noise distribution is not well modeled by a Poisson model. Conclusion: The noise present in PET images, after all corrections and OSEM reconstruction algorithm have been applied, is non-Poisson. The OSEM reconstruction also tends to equalize noise over the entire phantom.

EP798

Alginates to simulate tumor lesions in phantoms for 3D SPECT and an alternative to Jaszak phantom in the quality assurance process

R. Ringler, M. Stich, K. Schuller, M. Lindner; Technische Hochschule Amberg-Weiden, Weiden, GERMANY.

MOTIVATION The quality assurance (QA) in nuclear medicine is defined by (inter-)national standards. During the ½ yearly QA to check the performance of the 3D resolution of SPECT system passive spheres in a phantom are used. The aim of our work was to develop a phantom with geometry similar to the patient and active alginate beads to simulate tumor structures. MATERIALS & METHODS Alginate beads with a six different diameters (31.8; 25.4; 19.1; 15.9; 12.7 and 9.5 mm) were placed in a cylindrical phantom. The physical properties of the spheres strongly dependent on the composition, structure and molecular size of the polymers of the alginate. With alginate spheres two different approaches can be choosen. One setup are alginate spheres with no activity in a water environment with Tc-99m (750, 600 and 50 MBq). The second approach are active alginate spheres with Tc-99m (35, 30 and 17 MBq). The data evaluation was done using MATLAB with various algorithms - Otsu, Fast Marching, Active Contour or edge enhancement - to segment the spheres and compare the calculated size to its original size. RESULTS In a watery environment the volume of the spheres increase in the first three hours for about 5% and continue to up to 9% of total volume increase in the next 2 days. The standard for QA demands that at least 4 of 6 cold spheres could be detected which was fulfilled. Active alginate showed a very good detectability (4 of 6 spheres) even with low activity (17 MBq). With increasing background activity, this number decreases. CONCLUSION & DISCUSSION The spheres made of alginate with Tc-99m could easily be used to simulate tumor structure in a phantom and perform the QA in terms of 3D resolution. With MATLAB and the Active-Contour or Otsu algorithm the spheres can easily segmented from the reconstructed SPECT image.

EP799

Performance Evaluation of the New Discovery IQ Five Rings PET/CT Scanner According to NEMA NU-2 Standard and the Image Quality Test with Low Activity Protocols

G. Reynes-Llompart[1], E. Montes[2], P. Saldaña[2], I. Romero-Zayas[1], S. Rustarazo-Losada[1], D. Mateo-Navarro[1], C. Picón[2], C. Gámez-Cenzano[1], J. Martí-Climent[3]; [1]PET Unit. Nuclear Medicine. IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Medical Physics Department. ICO. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Nuclear Medicine. Clínica Universidad de Navarra, Pamplona, SPAIN.

Aim: The aim of this work was the assessment of the physical performance of the PET/CT Discovery IQ 5 rings of General Electric Healthcare (GE DIQ). **Material and Methods**: PET physical performance was measured following NEMA NU-2- 2012 procedures. For the mage quality test (IQ), initial radioactivity concentration was 5.5 kBq/cc. Data were acquired in list mode in order to study different time acquisitions and reconstructions, including NEMA specifications and clinical protocols; the latter were: VPHD, VPHD-S (12-subsets, 4-iterations, 8.8 mm FWHM) and Q.Clear with a beta value of 350. **Results**: Spatial resolutions on axial/tangential/radial planes were 4.8/4.7/4.2 mm at 1 cm, 4.8/5.1/5.6 mm at 10 cm and 4.8/5.5/8.5 mm at 20 cm. Sensitivity in the center and at 10 cm was 22.8 and 20.4c kps/kBq, respectively. The NECR peak was 124 kcps at 9.1 kBq/cc, with a 3D scatter fraction at NEACR peak of 36.2%. The accuracy of correction for the count losses and randoms was 3.9 % below the NECR peak. Average energy and timing resolution were 12.4% and 544 ps, respectively. The IQ test results for VPHD/VPHDS/Q.Clear, using 2 min acquisition were: Hot contrast for 10, 13, 17, and 22 mm spheres: 31/30/34, 40/44/47, 57/65/69, 63/67/75 for a contrast of 8:1, 35/31/25, 43/46/47, 54/59/61, 65/68/73, for a contrast of 4:1, and 16/17/13, 37/34/33, 68/68/67 and 70/73/76 for a contrast of 2:1. Cold contrasts for 28 and 37 mm spheres: 64/63/70 and 64/63/78 for a contrast of 8:1, 58/59/70 and 63/63/75 for a contrast of 4:1, and 60/60/71 and 65/64/77 for a contrast of 2:1. Lung residual: 25/26/12 for a contrast of 8:1; 24/25/11 for a contrast of 4:1, and 26/27/12 for a contrast of 2:1. Mean background variation: 7.0/6.2/4.7 for a contrast of 8:1, 5.6/5.0/4.0 for a contrast of 4:1 and 5.4/4.4/3.3 for a contrast of 2:1. For shorter acquisition times, simulating acquisitions with less activity concentration, Q.Clear has better performance than the other reconstruction methods, allowing to decrease the noise. A variation of the image quality parameters was found when changing the reconstructed field of view. **Conclusion**: Discovery IQ shows very good PET physical performance for all the standard NEMA NU-2-2012 measurements, especially for sensitivity an NECR. Furthermore, under simulated clinical conditions, the reconstruction algorithm Q.Clear available for PET data allows further improvement of the image quality performance that in further studies could be exploited in the clinical protocols.

EP800

Evaluation of the effects of different microCT parameters on microPET/CT imaging

W. McDougald, R. Collins, M. Green, A. Tavares; University of Edinburgh, Edinburgh, UNITED KINGDOM.

As the use of micro positron and computer tomography (microPET/CT) increases in preclinical small animal research so does the need for developing standardized acquisition and reconstruction protocols to ensure a reliable and consistent translation of preclinical findings to clinical use. Although there is a need for standardization of imaging protocols, in-depth analysis of the effects of different acquisition settings on image quality and biases is lacking. This study aims to investigate the effects of different microCT acquisition settings on image quality and data quantification. **Methods** All images were acquired using a Mediso nanoPET/CT scanner (Mediso, Hungary) and the following phantoms: air/water CT phantom and the CIRS model-91 water-filled tissue equivalent phantom (TEM). Collected imaging data was quantified and analyzed using PMOD image analysis software. **Results** Air/water CT phantom: Decreasing the microCT binning parameter resulted in an increase of the image noise (standard deviation (SD) of measured Hounsfield Units (HU) in water ranged from 33.15 to 215.27 for 1:16 to 1:1 binning). Increasing the exposure time resulted in higher bias compared with known HU for water (up to 27% for the highest exposure of 450 ms) and increased the noise (SD ranged from 33.15 to 46.89 for 170ms to 450ms). Tube voltage had minimal effect on the measured bias and image noise (SD of 77, 71 and 82 for 45, 55 and 75 kVp, respectively). TEM phantom: The greatest percent difference in measured HU for different tube voltage (ranging from 45 to 75 kVp) was determined in the adipose and muscle phantom rods and it was as great as ~60% in muscle and ~30% in adipose. Increasing the exposure time from 170ms to 300ms resulted in an increase of 230% of the measured HU values in the muscle,

while the HU difference in other TEM rods remained below 10%. Measured HU values in the TEM lung rod remained relatively consistent as the tube voltage or the exposure times increased (<5% difference). **Conclusion** The data has demonstrated the need to carefully evaluate the effects of different microCT settings on image quality and quantification. Increasing exposure time or tube voltage does not directly translate improvement of image results and, consequently, it will increase animal absorbed doses unnecessarily. Our data collected so far supports the need to assess the microCT parameters in a wider multi-center approach, while working towards standardization of scanning protocols for small animal imaging.

EP801

SPECT Characterisation and Quantification of Preclinical Scanners

T. J. Spinks[1], G. Flux[1], J. Sosabowski[2], C. Finucane[2], S. Macholl[2]; [1]Institute of Cancer Research and Royal Marsden NHS Trust Joint Department of Physics, Sutton, UNITED KINGDOM, [2]Barts Cancer Institute, Queen Mary University of London, London, UNITED KINGDOM.

Introduction. Radionuclide imaging systems are routinely characterised using standard physical performance tests. Formalised (NEMA) tests have been published for preclinical PET but not for SPECT. Despite greatly improved spatial resolution, quantification for small structures remains a significant problem in preclinical imaging. In addition, spatial uniformity of response is a crucial parameter. The NEMA PET performance standards go some way to addressing these issues but it is pertinent to consider other approaches. The aim of this study was to carry out tests on two preclinical SPECT systems, based on NEMA PET and using alternative methods. **Methods**. Tests were performed on two preclinical systems: (i) an Albira Tri-Modal PET/SPECT/CT and (ii) a Mediso NanoSPECT/CT, using ^{99m}Tc and ^{111}In. Recovery Coefficients (RCs) were measured with (a) the NEMA Image Quality (NEMAIQ) phantom as defined for PET and (ii) a phantom consisting of multiple spheres of varying diameter (MS). Image uniformity was determined by defining a grid of spherical VOIs (diam 5 mm, spacing 5 mm) in the image of a uniform cylinder covering the FOV. **Results**. RCs were observed to reach a plateau, indicating full recovery, for a rod diam of 5 mm (NEMAIQ) and for a sphere diam of 8 mm (MS). The data were similar for ^{99m}Tc and ^{111}In. The coefficient of variation of the grid VOIs over the FOV was 4% (Albira) and 3% (NanoSPECT/CT). **Conclusion**. The NEMA preclinical standard tests for PET provide some basic parameters of a system but do have limitations, and suggestions for extending these are made in this study, specifically for SPECT. The NEMA RC values are determined from rod sources and so do not account for object size in the axial direction. Clearly significantly lower values are obtained in this study for the MS phantom, which is intended to represent spherical lesions. The preclinical NEMA PET prescription for image uniformity only encompasses a 10 mm axial range and it is proposed that a uniformity measurement using a grid of VOIS over the axial FOV occupied by an animal (e.g. about 50 mm for a mouse) is more realistic and interpretable, for example when tumours are located at different positions.

EP802

Survey on radionuclide therapy facilities in Japan with grants by Ministry of Health, Labour, and Welfare

M. Hosono[1], H. Ikebuchi[2], Y. Nakamura[2], N. Nakamura[2], S. Yanagida[2], A. Kitaoka[2]; [1]Kindai University, Faculty of Medicine, Osaka-Sayama, JAPAN, [2]Japan Radioisotope Association, Tokyo, JAPAN.

Aim: The number of radionuclide therapy (RNT) has doubled from 2002 to 2012 in Japan. Yet the number per capita remains small (82.4 per million inhabitants in 2012) as compared with 191 per million inhabitants (1993) in European Union. One of the reasons is attributable to shortage of RNT beds. Methods: To investigate the actual situations surrounding RNT in Japan, in the framework of a focused study granted by Ministry of Health, Labour, and Welfare (MHLW), we conducted a survey by sending questionnaire by mail during 3rd and 4th quarter in 2013. The subjects of the survey was 606 hospitals, consisting of 394 university hospitals or cancer base hospitals designated by MHLW, and other 212 hospitals providing radionuclide therapy, out of totally 1274 hospitals that carry out nuclear medicine practices across Japan. Among 14 survey items, main items included Q1) hospital bed capacity, Q5) monthly number of nuclear medicine examinations, Q6) number of RNT beds, Q7) number of RNT and breakdowns (thyroid cancer, hyperthyroidism, lymphoma, bone pain relief, etc.), Q9) what department leads RNT, Q11) licensed radionuclides and quantities for RNT, Q12) interest in new RNT procedures, Q13) exhaust ability of facility, Q14) drainage ability of facility, survey meters. Results: The recovery of the questionnaire was 72.6% (440 of 606). Q1) In the range of 300≤, <700 bed capacity were 303 hospitals (68.9%). Q2) Mean and median of monthly number were 165.1 and 150. Q6) Of 320 hospital providing RNT, 59 (18.4%) had RNT beds, and mean and median were 2.3 and 2.0 beds. Q7) Of 320 hospitals, 174 (54.4%) provided therapy with radioiodine, 273 (85.3%) with Sr-89, and 61 (19.1%) with Zevalin. Q11) Annual licensed radioactivity was 26,640 MBq (range:7,723 to 74,500) for I-131 in 235 hospitals, 8,460 MBq (5,460 to 15,600) for Sr-89 in 290, and 44,400 MBq (22,200 to 88,800) for Y-90 in 118. For 202 hospitals in which data were available, based on Q11, Q13 and Q14, capacity reserves of radioactivity were calculated by considering exhaust and drainage maximum capacity, and 152 showed a reserve of less than 20% of the actual capacity if without diluting drainage. Conclusions: Effective utilization of existing facility capacity through deregulation may contribute to increasing number of RNT, while further healthcare investments in RNT are eagerly anticipated by patients and healthcare professionals.

EP803

Using a 3D-printed anatomical pancreas-kidneys phantom in body casings of varying size to simulate beta cell imaging with ^{68}Ga-exendin PET/CT in obese patients

L. N. Deden[1], A. P. W. Meeuwis[2], F. J. Berends[1], M. Gotthardt[2], E. P. Visser[2]; [1]Rijnstate, Arnhem, NETHERLANDS, [2]Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim To increase our knowledge of the role of beta cells in type 2 diabetes mellitus (T2DM), ^{68}Ga- exendin PET/CT can be used to quantify the pancreatic uptake of ^{68}Ga-exendin, which is considered as a measure for the beta cell mass. The occurrence of T2DM and body weight are correlated, therefore we examined the effect of increasing body weight on quantitative PET/CT with ^{68}Ga-exendin. In PET/CT imaging, several phenomena are body size dependent, among which are photon attenuation and scatter, and the ratio of random to true coincidences. In standard image quality (IQ) characterization of PET/CT scanners, normal sized phantoms, such as the NEMA NU2 IQ phantom are used. In our study, a 3D-printed pancreas-kidneys insert in the standard NEMA phantom casing and in two customized, larger casings were used. The sizes of the casings were chosen in correspondence with the subdivision into normal, obese and morbidly obese (MO) patients as derived from patient CT scans. **Materials and Methods** The standard, obese, and MO casings had circumferences of 86, 101, and 133 cm, respectively. The compartments were filled with a ^{68}Ga solution such that the activity concentration (AC) ratios of kidney-to-pancreas and pancreas-to-background were 16:1 and 540:1, respectively. Image reconstructions were performed using OSEM3D with TOF and PSF in 3 iterations and 21 subsets, using 10 and 20 min of list mode data. Volumes of interest (VOI) for the pancreas and both kidneys were delineated in the CT images. Recovery

coefficients (RC) for the pancreas and kidneys were calculated. Additionally, 10 cylindrical background VOIs were drawn to determine the background AC. **Results** For the 10 min reconstructions RC_{panc} were 0.68, 0.66 and 0.77, and RC_{kidn} were 0.80, 0.75 and 0.78 for the standard, obese, and MO casings, respectively. The background AC was comparable to the real AC for the standard and the obese phantom. In the MO phantom the background AC was 30 times higher than the real AC, with largest AC in the area around the kidneys. The 20 min reconstructions led to a small increase in RC_{panc} and to similar results in the kidneys and background. **Conclusion** RC_{kidn} was comparable for all phantoms. However, RC_{panc} was largest in the MO phantom. This may be the result of scattered photons originating from kidneys inaccurately attributed to the background and pancreas due to inadequate scatter correction. This effect will be further investigated.

EP804

The impact of using tube-current-modulation technique for attenuation correction of PET/CT images on image quality and patient dose

y. Salimi[1], P. Ghafarian[2,3], M. Deevband[1], M. Bakhshayesh Karam[4,3], H. Jamaati[2], M. Ay[5,6]; [1]Department of Bioengineering and Medical Physics, Faculty of medicine, Shahid-Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Pediatric Respiratory Diseases Research Centre,National Research Institute of Tuberculosis and Lung Diseases (NRITLD), ShahidBeheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: It is well known that the attenuation correction is vital in PET/CT imaging, however the radiation dose received during CT imaging is considerably high for patients in PET/CT examination. The aim of this study was to evaluate the impact of automatic tube current modulation technique for patient dose reduction with respect to optimal image quality for diagnostic purpose. **Materials and methods**: At the first, CTDI and DLP, were calibrated by head and body PMMA phantom. In the next step, QA and cylindrical Phantom with 20 cm and 30cm in diameter were scanned with Discovery 690 GE PET/CT scanner that equipped with 64-slice CT. CT images were reconstructed with slice thicknesses of 2.5 and 3.75mm. Smart mA technique with noise indexes of 18 and 19, tube voltage of 80, 100 and 120kVp, tube current between 50 and 120mA, pitch number 0.984:1 and 1s rotation time were utilized. Image quality was assessed both qualitative and quantitative. MTF, image noise, $CTDI_{vol}$ and DLP parameters were also considered. **Results:** With increasing of slice thickness from 2.5 to 3.75 mm, in noise index (NI) of 18 with regard to 80kVp and 100kVP, the image noise was decreased from 10.74 and 6.72 HU to 3.63 and 2.71 HU respectively, when tube current was 80mAs. With increasing of tube voltage from 100 to 120 kVp, at 70mAs, in NI of 19, the noise diminished 56.76% and 17.44% when slice thickness varied from 2.5 to 3.75mm respectively. It would be clarify that, the CTDI changed from 1.95 to 4.64 mGy when tube voltages varied from 80 to 120kVp. CT images with 2.5 mm slice thickness were considered for 1mm resolution in QA phantom. It was shown that, the MTF increased from 0.20 to 0.32, with decreasing of tube voltage from 120 to 100kVp. **Conclusion**: significant lower image noise was observed with increasing slice thickness, however with regard to clinical purpose, the image quality for diagnostic issue was also valuable. It should be clarified that, the noise level was decreased with increasing of tube voltage and the intensity of this behavior is more prominent in the lower slice thickness. Our results illustrated that, 3.75 mm slice thickness with noise index 19 and tube voltage of 120 kVp could be one of the optimal images with consideration of image noise and diagnostic purpose. **Keywords:** Computed tomography, Tube current modulation, Dose, Image noise, MTF

National Survey of Radionuclide Dose Calibrators used in Nuclear Medicine Departments in Bulgaria

M. Dimcheva[1], P. Trindev[2]; [1]Sofia Cancer Center, Sofia, BULGARIA, [2]QC in Nuclear Medicine Consultant, Sofia, BULGARIA.

The main objective of this national survey was to provide data on the accuracy of activity measurements of the radionuclide dose calibrators used in nuclear medicine departments. Materials and Methods: In 2015 over a period of two months, measurements were performed on 24 dose calibrators in all 18 nuclear medicine departments in Bulgaria. The dose calibrators included in the survey were delivered in the last 37 years by 7 manufacturers as follows: Picker - 2 pcs, Robotron - 1 pc, Isomed - 3 pcs, Atomlab -1pc, Capintec CRC-15R - 1pc, Curiementor - 12 pcs, Comecer - 4pcs). For the purpose of our survey, a certified source of Cs-137 with manufacturer serial number LB 165 was used. After correction the decay between the date of certificate and the time of measurement the difference between the expected activity and the measured activity was expressed as a percentage of expected activity. Twenty measurements were performed for each dose calibrators thus collecting data for precision estimation according to χ^2 criteria. Results: Bulgarian State Regulations require that deviation between measured and expected values must be within ±5 percent of the average. Errors greater than ±5 % in the interval from -20.5 % to +16 % were found in 18 of the 24 dose calibrators. It is interesting to note that the result which was close to the expected one (error of 0.3 %) was delivered by the oldest dose calibrator - Picker. The precision of measurement was estimated for each dose calibrator according to $\chi 2$ criteria. An acceptable $\chi 2$ for 20 measurements would be in the range $11.7 < \chi 2 < 27.2$ since this is the $0.9 > P > 0.10$ range. It is common convention that fixes the P = 0.90 - 0.10 range as acceptable. All results for $\chi 2$ in our survey were less than 1 which means that too little variation is shown. Conclusion: According to the results of this survey, the accuracy of dose calibrators does not meet the requirements of National regulations and need special attention and immediate reaction.

EP806

Quantification of pancreatic uptake in beta cell imaging with ^{68}Ga-exendin PET/CT using a 3D-printed anatomical pancreas-kidneys phantom and the NEMA NU2 Image Quality phantom

L. N. Deden[1], M. Buitinga[2], A. P. W. Meeuwis[2], S. Ruiter[3], D. Lobeek[2], M. Gotthardt[2], E. P. Visser[2]; [1]Rijnstate, Arnhem, NETHERLANDS, [2]Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]University of Twente, Enschede, NETHERLANDS.

Aim Recently, ^{68}Ga-labeled exendin has become available for beta cell imaging using PET/CT. Quantification in PET/CT has extensively been described, mostly for FDG whole body scanning in oncology. Pancreatic beta cell imaging using ^{68}Ga-exendin differs in several aspects: (i) pancreatic uptake is much lower than the unspecific uptake in the nearby kidneys, which could lead to artifacts and quantification errors, (ii) uptake in the remainder of the body is extremely low, and (iii) the larger positron range of ^{68}Ga (R_{max}=8.9 mm) as compared to ^{18}F (R_{max}=2.4 mm) may lead to decreased spatial resolution. To study image quality and to optimize quantification for ^{68}Ga-exendin PET/CT, experiments were performed using the NEMA NU2 phantom, and a 3D printed, realistic organ

phantom containing fillable pancreas and kidneys and a background compartment. **Materials and Methods** The NEMA-phantom was filled with ^{68}Ga solutions with 10:1 sphere-to-background ratio with activity concentrations as specified by the EARL criteria [1]. The pancreas, kidneys, and background in the pancreas-kidneys-phantom were filled with ^{68}Ga solutions of respectively 2.2, 35.5 and 4.1x10^{-3} kBq/ml (ratios 1:16:0.002), based on typical patient data. Both phantoms were scanned during 10 min in a Siemens mCT scanner. Image reconstruction was performed using OSEM3D with TOF and PSF using varying numbers of iterations and subsets. Recovery coefficients (RC) for the NEMA spheres were calculated using the EARL A50 VOI settings. The pancreas was delineated manually on CT. **Results** Using our standard settings (3 iterations, 21 subsets, TOF, PSF, Gaussian filter 3 mm FWHM, transaxial pixel size 2 mm), RC_{A50} were 0.48, 0.66, 0.69, 0.76, 0.77 and 0.81 for increasing sphere diameters. Recovery of the pancreatic activity was 0.69. However, when dilating the CT-based VOI by 6 mm, this increased to 0.89. Increasing the number of iterations resulted in an inhomogeneous distribution of pancreatic activity. **Conclusion** The RC_{A50} values are higher than the "maximum values" using the EARL settings, which can be attributed to our smaller Gaussian filter size, smaller pixels and the use of PSF, which is more in line with state-of-the-art PET/CT scanners. Accurate quantification for the pancreas (≈10% deviation from the real activity value), can be obtained for ^{68}Ga using our standard settings in the Siemens mCT scanner. However, to obtain the proper pancreatic activity, dilation of the VOI by 6 mm was necessary. This might partly be contributed to the larger positron range of ^{68}Ga as compared to ^{18}F. Adaptative posology: toward a new compromise between acquisition duration and administred activity with a new high sensitivity PET/CT

O. CASELLES[1], E. GABIACHE[1], B. Delpuech[1], D. VALLOT[1], S. BRILLOUET[1], V. ROBERT[2], S. ZERDOUD[1], L. DIERICKX[1], F. COURBON[1]; [1]Institut Claudius REGAUD -IUCT Oncopole, TOULOUSE, FRANCE, [2]CIMOF, TOULOUSE, FRANCE.

PURPOSE To take benefit of a new generation of high sensitivity BGO non-TOF PET/CT system, new prescription rules have been established for FDG exams mainly to reduce injected doses. A double benefit was expected: both reduction of patient exposure and staff safety. **METHOD AND MATERIALS** Dose prescriptions corresponding to 944 ^{18}FDG PET scans were analyzed (480 men and 464 women). Dose calculation was based on average weight posology of 1.9 MBq.kg^{-1}, but adapted to patient's morphology. For this purpose, this posology was multiplied by the ratio between patient's actual weight and an Ideal Body Weight (IBW) given by the Devine's formula. Thanks to a homemade online software linked to an SQL database, gender, weight, height and injected activity were recorded and further analyzed. Minimum and maximum doses were set respectively to 80 MBq and 400 MBq (due to French law restriction). Patient effective dose was estimated from ICRP 106 tables. Staff exposure was assessed using both electronic and passive whole body and extremities dosimeters during 1 month. **RESULTS** Patient's statistics are summarized in the following table: Average staff Hp*(10) were respectively 3 and 2 μSv/patient using thermoluminescence and electronic personal dosimeters, leading to annual average individual exposures of 4.5 and 3 mSv. Extremity dose Hp(0.07) was in average 40 μSv/patient being 61.5 mSv per year and per technologist. **DISCUSSION** Devine's formula trends to give low ideal weights, in particular for short women. For this reason, average weight doses are respectively 10% and 20 % higher than expected for men and women. This weight posology remains significantly lower than recommended prescriptions from EANM guidelines: for our routine 2 min.bed^{-1}, the injected dose should be FDG(MBq)=7*weight(kg) giving respectively 3.25 and 2.95 times our average dose for men and women. Staff exposure is well under applicable annual limits in France (respectively 20 mSv and 500 mSv for body and extremities), and were significantly lower than exposures recorded during previous studies performed in our facility. **CONCLUSION** New high sensitivity PET/CTs allow to dramatically reduce both patient and staff exposure, and it is now worth considering to increase patient per day workflow with no concern for staff radiation protection.

EP808

Evaluation of Radiation Exposure Dose Rates: A comparative study between the two commercially available Y-90 microsphere products TheraSphere and SIR-Spheres

H. Tanyildizi[1], M. Demir[2], M. Abuqebitah[2], I. Cavdar[3], L. Kabasakal[2], K. Sonmezoglu[2]; [1]Istanbul Kemerburgaz University, Vocational School of Health Services, Istanbul, TURKEY, [2]Istanbul University, Cerrahpasa Medical Faculty, Istanbul, TURKEY, [3]Istanbul University, Science Faculty, Istanbul, TURKEY.

AİM: In this study, we aimed to measure Bremsstrahlung radiation dose rates which emitted into the environment in Y-90 radioembolisation and to evaluate the radiation safety precautions. **MATERIALS AND METHODS:** 19 patients were included in this study. The activity amounts to be applied for treatment was determined by making a specific radiation dosimetry. The results of the evaluation of physicians, 12 patients underwent with SIR-Sphere, 7 patients underwent with TheraSphere. The dose rate measurements were taken with Geiger Muller probe in activity preparation, in the course of injection to the patients, in occuring radioactive wastes and during the patients' being discharged. **RESULTS:** It was found that staff was exposured in Therasphere application per unit activity, 1,3.10^{-4} μSv/MBq.h^{-1} in the stage of preparation, 2,4.10^{-4} μSv/MBq.h^{-1} in the stage of injection, and SIR-Sphere application per unit activity 24,5.10^{-4} μSv/MBq.h^{-1} in the stage of preparation, 10,1.10^{-4} μSv/MBq.h^{-1} in the stage of injection. Mean effective dose per application of staff with considering the working time of them, 0.92 ±0.48 μSv and 3.22 ±0.89 μSv were calculated in TheraSphere and SIR-Sphere applications, respectively. The measurement of mean dose rate which was taken at 1 meter from patients to be discharged was found 4 ± 0.28 μSv/h in Therasphere, 3.2 ± 0.15 μSv/h in SIR-Spheres. The dose rate measured in the surface of plastic container in which the radioactive wastes were put was found 0.5 ± 0.1 μSv/h for Therasphere, 1.1 ± 0.08 μSv/h for SIR-Sphere. **CONCLUSIONS:** As a result, it was assigned that Y-90 Therasphere application provided the radiation safety, in Therasphere and SIR-Sphere applications dose rate measured around patient was low, and the short term storage of radioactive wastes was sufficient.

EP809

Occupational exposure incurring from PET/CT patients

P. Fragoso Costa, M. J. Reinhardt, B. Poppe; Pius Hospital Oldenburg, Oldenburg, GERMANY.

Introduction: In this paper we evaluate the whole body occupational exposure of Nuclear Medicine technologists to annihilation photon fields resulting from F-18-FDG administration in the context of PET/CT imaging. This study aims to assess the whole body exposure of a team of 6 nuclear medicine technologists, with no previous PET/CT work experience. Furthermore, it is intended to examine separately the exposure resulting from each procedural step of the PET/CT technique. Methods:

In our department personal dosimetry motorisation is performed using Electronic Personal Dosimeters (EPD - RADOS-60E, Hamburg, Germany) and film dosimeters (MPA - MPA NRW Gliding Shadow Dosimeter GD01, Dortmund, Germany). The assessed group consisted of 6 technologists involved in Nuclear Medicine conventional procedures (diagnostic and therapy) and PET/CT. To identify the PET/CT specific exposure, all 6 technologists were encouraged to register their whole body personal dose equivalent [Hp(10)] read on EPD referring to each PET/CT procedural step. The PET/CT examination was divided in its constituent steps, which included: F-18-FDG dispensing, F-18-FDG withdrawal F-18-FDG administration and patient positioning. Included in this study were all the monthly official dosimetry records in the period from 2009-2014 (both EPD and MPA) and the step-wise evaluation exposure resulting from 2142 PET/CT investigations in the same period. Radiation protection measures (i.e. syringe shielding, wall shielding and video surveillance) were applied constantly over the whole study. Results: The average yearly personal dose equivalent registered on MPA was 577 ± 294 μSv/year and EPD 840 ± 346 μSv/year. The personal dose equivalent for the 6 technologists performing PET/CT ranged from 11.52 to 23.77 nSv/MBq, averaged over the 5-year period. Whole body radiation dose to health professionals originated mainly from radiopharmaceutical administration (41.5%) and patient positioning (51.1%). In the interval from 2009-2014 the yearly average PET/CT specific personal dose was, respectively 19.74, 19.66, 19.71, 17.65, 20.23 and 16.53 nSv per injected MBq. Conclusion: The final results showed that the existing radiation protection measures are sufficient to keep exposures below 1 mSv/year. The observed intra-technologist PET/CT exposure range is mostly related to personal experience and patient-care strategies. Results referring to the exposure evolution over time indicate that there is no increasing tendency with the passing of years. We suggest carrying out an internal quality assurance program for radiation protection in order to keep occupational exposures at a minimum.

EP810

Monte Carlo simulations of risky non-standard operations during handling radiopharmaceuticals

M. Fulop[1], J. Hudzietzova[2], J. Sabol[3], P. Ragan[4], P. Povinec[5], D. Bacek[5]; [1]Slovak Medical University, Bratislava, SLOVAKIA, [2]Faculty of Biomedical Engineering, CTU, Prague, CZECH REPUBLIC, [3]Crisis Management Department, PACR, Prague, CZECH REPUBLIC, [4]ABRS, Ltd., Bratislava, SLOVAKIA, [5]Bratislava Ion Technologies, Bratislava, SLOVAKIA.

Aim: The aim of this work is to introduce an identifying the non-standard risky operations and determining the values of personal dose equivalent $H_p(0,07)$ at the point of maximum exposure on hands. Materials and methods: The non-standard risky operations have been identified by interviews with staff, by control of video records or by reading of personal ring dosimeter. The MCNPX code and three voxel phantoms simulating various hand operations were used for searching of locality on hand with point of maximum exposure. Validation of MCNPX simulations of the voxel phantoms were performed in comparison with experiments with the physical phantoms. The thermoluminescent dosimeters of type MCP-Ns for measurements of the dose equivalent H_p (0.07) were used. Results: The proposed method for identification of the non-standard risky operations during the administration to patient the liquid ^{131}I in cup and ^{18}F-FDG in syringe has been used. The MC simulations of voxel phantom of hand holding unshielded syringe with ^{18}F-FDG have shown significant (more than 4- fold) increase of the dose H_p (0.07) on the hands at the points of maximum exposure that were in different localities than these that were monitored by TLD. By simulations of the voxel phantom of the hand has been shown to penetrating of ^{18}F positrons through walls of unshielded syringe with ^{18}F-FDG and the contribution of positron dose to hand irradiation was determined. Similarly, the contribution to the local electron irradiation of the skin in the palm handling unshielded cup with ^{131}I was calculated.Conclusion: A method of identifying and modelling of the non-standard risky operations by the Monte Carlo simulation of voxel hand phantoms and determining the values of the relevant personal dose equivalent at the point of maximum exposure was introduced. The method can introduce appropriate measures for improving radiation protection that lead to a significant reduction of radiation burden to workers handling radiopharmaceuticals.Literature: 1) P. EP811

Change of collective effective dose of patients examined for suspective pulmonary embolism after introduction of multislice CT (MDCT) into a diagnostic process - single center experience

O. Lang[1,2], I. Kunikova[1]; [1]Charles Univ, 3rd Med Fac, Dept Nucl Med, Prague 10, CZECH REPUBLIC, [2]District Hosp, Dept Nucl Med, Pribram, CZECH REPUBLIC.

Aim: To compare radiation burden of patients with suspected pulmonary embolism evaluated by lung perfusion scintigraphy and multislice CT pulmonary angiography (MDCTPA) and to evaluate change of number of negative scintigraphic results after introduction of MDCTPA in our teaching hospital. Material and methods: We recorded number of patients examined in our department per year from 1991 to 2015 before and after introduction of MDCTPA (2009 - this year was not included). Effective dose was determined according to National radiological standards and UNSCEAR report 2008. We consider dose equivalent to lung parenchyma and total body effective dose from scintigraphy using 150 MBq of ^{99m}Tc MAA per patient. Dose from MDCTPA was calculated from DLP and tables of UNSCEAR report, number of patients was hypothetical (difference between average number of scintigraphy patients before and after introduction of MDCT). Percentage of negative results of lung perfusion scintigraphy during 1 year before and after introduction of MDCT was also recorded. Values are expressed as a median (min-max). Results: Number of patients examined by scintigraphy per year was 1718 (1304-2411), collective dose equivalent was 17008 (12910-23869) mSv for lung parenchyma and collective effective dose was 2835 (2152-3978) mSv for total body from 1991 to 2008. Number of patients examined by scintigraphy per year was 369 (290-475), collective dose equivalent was 3648 (2871-4703) mSv for lung parenchyma and collective effective dose was 608 (479-784) mSv for total body from 2010 to 2015. Hypothetical number of patients examined by MDCT per year was then 1350 (1243-1428) with collective effective dose of 9447 (8701-9996) mSv from lung CT and 20243 (18645-21420) mSv from MDCTPA) from 2010 to 2015. 77 % of all scintigraphic reports both 1 year before (1496 patients) and 1 year after (452 patients) introduction of MDCT were negative, excluded pulmonary embolism. Conclusion: Number of patients sent to our department for lung scintigraphy due to suspective pulmonary embolism was stable for many years, so we can assume it would be stable also after introduction of MDCTPA. This assumption was used to estimate collective effective dose from CT examination. It was more than 7 times higher per year comparing to scintigraphy and even more than 10 times higher if we assume performing lung CT together with CTPA. The percentage of negative scintigraphic results remained unchanged. We can, therefore, assumed that 77 % of all MDCTPA examinations was also negative and irradiation of these patients was unnecessarily high.

EP812

Radiation Risk Assessment In Preclinical Imaging: Protective Techniques And Handling Procedures Developed To Minimize Occupational Exposures

S. PREVOT[1], A. OUDOT[1], M. GUILLEMIN[1], M. MOREAU[2], J. VRIGNEAUD[1], K. CHAPELIER[3], O. RAGUIN[3], L. HOUOT[1], A. COCHET[1], B. COLLIN[1,2], F. BRUNOTTE[1]; [1]Centre Georges François Leclerc, Dijon, FRANCE, [2]ICMUB - UMR CNRS 6302, Dijon, FRANCE, [3]Oncodesign, Dijon, FRANCE.

Introduction: Introduction of PET in preclinical imaging gave rise to new radiation safety concerns. Specific protective techniques and handling procedures have been developed to optimize staff exposures. The aim of this study was to evaluate the protection benefit focusing on 2 steps: injections, gaining a good IV access before handling activity and dissections, using a preclinical custom-made lead bench screen. A series of measurements was performed when holding an antibody derivative labelled with 64Cu. Material & methods: A prospective series of 20 mice was studied. A 27G catheter was placed in the lateral vein of the tail to minimize injection time. Activity was handled in a shielded syringe (W, 5 mm, Medisystem). Dissections were performed behind a bench screen (Pb, 30 mm, Orion) 24 hours post injection. Time was registered for all tasks. Individual Whole-body (WB) doses Hp(10) were monitored with electronic dosimeters (DMC2000 XB, Mirion). Screen attenuation was evaluated with 2 dosimeters: one in front of the lead glass, the other behind. TLD rings (Landauer) were used to investigate finger doses Hp(0.07). Exposure rates were measured with a dose ratemeter (fieldSPEC, Aries) during injections and dissections at distances of 1 & 30 cm. Mean activity of 5-dose syringes was 138.7 ± 6.4 MBq. Mean injected activity was 19.1 ± 4.3 MBq per animal. Results: Average time was 8 seconds per injection, 6 minutes per dissection performed by an experienced operator. Hp(10) without a shield was 11 μSv for injections, 9 μSv for dissections. WB dose was kept below 1 μSv behind the bench screen. Mean exposure rates measured at short distances are high: 1500 μSv.h-1 at 1 cm from the shielded syringe (5 doses), from 25 to 10 μSv.h-1 at 30 cm during injections, 83 μSv.h-1 at 1 cm from the animal during dissections. Finger dose Hp(0.07) at the left index was about 30 μSv per injection, below 100 μSv (minimum exposure range) for dissections. Discussion: Injection time was divided by a minimum factor of 8 since fine gauge catheters have replaced needles. This technique also contributes to minimize the number of sticks, the risk of needlestick injuries and the uncontrolled movements linked to the weight of the shield that can lead to extravasation. Despite activities injected to small animals are low compared to medical practice, appropriate shielded devices together with minimizing time spent at short distance from sources are key factors to maintain WB & finger doses ALARA.

EP813

Optimization of radiation shielding of ^{68}Ga sources for positron emission tomography

L. Auditore[1], E. Amato[2], M. E. Stipo[2], E. Grassi[3], F. Fioroni[3]; [1]University Hospital G. Martino, MESSINA, ITALY, [2]University of Messina, MESSINA, ITALY, [3]Arcispedale S. Maria Nuova - IRCCS, Reggio Emilia, ITALY.

Aim: The use of ^{68}Ga positron emitter is gaining diffusion due to the advantages of its compact generator source combined with the increasing variety of labeling kits. However, the high energy of positrons (E_{max} = 1.898 MeV) can request special precautions during handling. We studied the radiation shielding of that isotope by means of Monte Carlo simulations and experimental measurements. Materials and Methods: We set up two independent Monte Carlo simulations, in Geant4 and MCNPX, reproducing a glass vial containing 9 ml of ^{68}Ga solution enclosed in a single lead shield or a double-layered shield made of PMMA plus lead; different thicknesses were tested. The dose was scored in 0.8-mm thick LiF detectors. We also set up a measurement to evaluate the contribution of different shielding materials on absorbed doses. We put a glass vial of ^{68}Ga solution in a double-layered shield and we measured the doses on the external shield surface with and without the inner layer. The doses measurements were performed by 0.8-mm thick LiF detectors (174 mg cm^{-2}) and thin active layer ultra-sensitive LiF dosimeters (8.5 mg cm^{-2}) . Results: the dose rates estimated from simulations (Geant4/MCNPX) were: 12.0/12.8 μGy/GBqs after 10 mm of lead, and 11.4/11.9 μGy/GBqs after 6 mm of PMMA plus 10 mm of lead. The experimental measurements confirmed that the use of an adequate lead thickness is sufficient to stop the beta and any bremsstrahlung x-rays produced. Conclusions: Adding an inner layer of low-Z plastic material gives a negligible contribution in radiation protection, since the bremsstrahlung radiation originating from positron slowing down is effectively shielded by the high-Z layer devoted to the attenuation of annihilation radiation.

EP814

Dose optimization is feasible in PET-CT protocols

E. Prieto, V. Morán, B. García-García, E. F. Guillén-Valderrama, L. Sancho, J. M. Madrid, M. Rodríguez-Fraile, M. J. García-Velloso, J. A. Richter, J. M. Martí-Climent; Clínica Universidad de Navarra, Pamplona, SPAIN.

The standard protocol for whole body FDG PET/CT examination in our center consisted of an administration of 5.18 MBq/Kg, a PET acquisition of 3 min/bed, and a CT acquisition with 120 kV and a reference current-time product of 120 mAs with automatic current modulation. **Objective**: To evaluate the impact in patient effective dose and image quality of the reduction of reference current-time-product for the CT scan and the PET tracer activity in PET/CT protocols. **Methods**: A Siemens Biograph mCT TrueV PET/CT tomograph is available in our center. In February 2016, PET/CT protocol was modified within recommendations of international guidelines. Particularly, FDG activity was reduced from 5.18 to 4.44 MBq/Kg and reference CT current-time-product was reduced from 120 to 100 mAs. A total of 197 consecutive patients referred for a clinical oncological FDG-PET/CT scan were evaluated in this retrospective study. For each patient, demographic data, clinical characteristics, CT parameters (kV, effective mAs, dose-length-product DLP) and actual FDG activity (MBq) were recorded. Effective dose associated to the CT examination was calculated from DLP using the AAPM conversion factors while the effective dose associated with the radiotracer was calculated based on the ICRP values. The overall image quality (IQ score) was subjectively rated by the referring physician on a 4-point scale: 1 meant excellent, 2 good, 3 poor but interpretable, 4 poor not interpretable. Analyses were performed with STATA/IC 12. **Results**: A comparison of patient characteristics revealed no differences in patient's age, weight and gender among groups. *CT Results:* Effective current-time-product was 84.85±25.25 and 70.87 ±20.18 mAs for the 120 ref.mAs group (N=99) and the 100 ref.mAs group (N=98) respectively, and the related effective dose was 8.12 ±2.99 mSv and 6.69±2.31 mSv (U-Mann-Whitney p<0.001). However, there was a significant reduction in the IQ score (mean 1.55 vs 1.25, Chi-squared test p<0.001). Specifically, the number of excellent images decreased (77% to 47%) while the number of good images increased (21% to 51%). The number of poor studies (IQ score >2) did not changed. *PET Results:* The final mean administered activity of FDG for each group was 4.83 MBq/Kg (N=102) and 4.21 MBq/Kg (N=99), leading to a mean effective dose of 6.61±1.41 and 5.76±1.38 mSv in each group (t-test p<0.001). Both groups of images were graded of equal image quality (mean IQ score 1.22 vs 1.17, Chi-squared test p=0.189). **Conclusions:** Dose reduction is feasible in PET/CT protocols without a substantial impact in clinical diagnosis.

EP815

18F-Fluorodeoxyglucose (18F-FDG) Dose in Paediatrics: Comparison between our Protocol and the EANM Recommendations

P. C. Gil, J. Isidoro, P. Lapa, G. Costa, J. Pedroso de Lima; Centro Hospitalar Universitário de Coimbra, Coimbra, PORTUGAL.

Aim: Paediatric patient dose optimization is an important issue in nuclear medicine practice, because the risk to radiation exposure is much higher in children than in adults when the same effective dose is delivered. This is particularly relevant in PET/CT, where this technique combines two imaging modalities with potential high radiation dose to patients. With this work we aimed to compare the activities administered in our department, using our specific protocol, with the recommended values given by the EANM Paediatric Dosage Card (v 01.02.2014). **Material and methods:** By using our Protocol, FDG PET/CT procedures in adults are performed with 3minutes/bed acquisition time, 60 minutes after administration of 4-6MBq/kg. Paediatric protocols were designed in order to associate a risk equivalent to that for adults (not the effective dose). With this in mind (and ensuring good quality of the images), we reduced the administered activity in children and increased the acquisition time (using, if necessary, a vacuum bag to assure children immobilization). For the comparison, we used the data of 433 exams (patients <18 years-old) performed between 2012 and 2015 in a General Electric Discovery ST4 PET/CT scanner. Then, patients have been divided in 3 groups according to their weight: G1 (<14kg, 3MBq/kg and 4minutes/bed); G2 (14-40kg, 3.5MBq/kg and 3.5minutes/bed) and G3 (>40kg, 4MBq/kg and 3minutes/bed), the mean administered activities were calculated and compared with the mean theoretical activities given by the Paediatric Dosage Card (PDC). **Results**: The mean administered activity and the mean theoretical activity were, respectively, for each one of the 3 groups: G1 (15 cases) 3.5MBq/kg versus 7MBq/kg (50% reduction); G2 (224 cases) 3.6MBq/kg versus 6.1MBq/kg (41% reduction) and in G3 (194 cases) 3.7MBq/kg versus 5.5MBq/kg (32% reduction). **Conclusion:** Protocol optimization should take in consideration the PET scanner performance and acquisition settings. In our department, without any compromise of the image quality, the administered activities are significantly inferior to the EANM dosage card recommendations for all weight categories considered.

EP816

Dosimetry for ^{90}Y DOTATOC therapies, calculation of absorbed dose to kidney

D. Krstic[1], M. Jeremic[2], D. Nikezic[1], M. Matovic[2], R. Krstic[3]; [1]University of Kragujevac, Faculty of Science, Kragujevac, SERBIA, [2]Clinical Center Kragujevac, Kragujevac, SERBIA, [3]KVARK Company, Kragujevac, Kragujevac, SERBIA.

Peptide receptor radionuclide therapy (PRRNT) is a molecular radiation therapy which is used for the treatment of neuroendocrine tumors (NET). Depending on the size of the tumor, ^{90}Y-DOTATOC ([^{90}Y-DOTA0,Tyr3]-octreotide), ^{177}Lu - DOTATATE ([^{177}Lu-DOTA0, Tyr3,Thr8] - octreotide, or their combination in the form of a cocktail is applied. The kidney is the organ which receive the large dose at the activities normally used for PRRNT. During the several successive applications of therapy the renal function of kidney are deteriorated with the time (Barone et al., 2005; Hindorf et al., 2007). Previously, human ORNL phantoms were developed and applied for dose calculation in various irradiation situations (Krstic and Nikezic 2007). In this work, absorbed dose in kidneys were calculated for ORNL human phantom, by means of MCNP5/X software (Monte Carlo Neutron Particle transport code, version 5/X). One option is to calculate doses from left and right kidney separately, since any of them is a separate source of beta radiation. This could be overcome in MCNP by presenting the source as the union of two regions (left and right kidney). Absorbed dose per one emitted beta particle in kidney of $6{\cdot}10^{-14}$ Gy was obtained as result of calculation in this work. This result should be multiplied with the number of disintegration of beta emitter in kidney in order to estimate absorbed dose in this organ. To estimate the number of disintegration in organs, it is necessary to develop biokinetic model which describes behavior of radionuclide in human body. Parameters of such model should be determined based on activity of ^{90}Y measured in urine and blood of patients. **References** 1. Estimation of radiation dose for Radiation worker staff in Nuclear Medicine department

h. A. aldousari, m. Izzeldin.; jabeer alahmad for nuclear medicine and molecular imagingministry of health, alsolebekat, KUWAIT.

Objective: The aim of this study was to estimate the radiation dose for the radiation workers staff in Nuclear medicine department (Jaber Al Ahmad center for Nuclear medicine & molecular imaging center) in order to determine whether rotation of the radiation workers staff, is necessary and if the staff need more training about the ALARA principle. **Materials and Methods:**The effective radiation dose was measured for Radiation workers staff (Physician -Medical Physicist - Technologist - Nurse) in Nuclear medicine department, using (Thermoluminescent dosimeter TLD) the data collected annually - month by month from (January to December 2015) .The total staff 24 , 3 Physician , 2 Medical Physicist , 8 Technologist and 11 Nurse) . **Results:** The results show that the values of annual reading radiation dose for 28 radiation workers in nuclear medicine department ,the result obtained between (2.624 msv to 0.979 msv) for the staff , to comparing this result with the annual dose recommended from the (IAEA) 20 msv per year. (13.12% - 4.895%) . Physician received the highest dose (2.624 msv - 2.401 msv - 2.310 msv) - (13.12% - 12.005% - 11.55 %) from the recommended dose from (IAEA) and 2 of the Technologist also received high dose (2.48 msv - 2.311 msv)- (12.4 % - 11.56 %) from the recommended dose from (IAEA). **Conclusion:** This study showed that effective radiation doses to the radiation workers staff were within the annual dose recommended from the (IAEA). The highest dose was received by the physician because they regularly performed radionuclide injection using the butterfly technique with a syringe without shielding. The technologist receive high dose from the patient during the scan acquisition and when handling the radionuclide dose from hot lab to the scan room. The two technologist work in both camera PET/CT and SPECT/CT. All the staff have high awareness of radiation safety

and ALARA Principle. **Key Words:** Radiation dose, Thermoluminescent dosimeter TLD , Nuclear medicine department, radiation safety ,ALARA Principle.

Diagnostic nuclear medicine procedures and resulting radiation dose of Tehran population in 2011-2014

F. Tabeie[1], P. Honari[1], I. Neshandar Asli[1], B. Shafiei[1], M. Amoui[1], M. Ansari[1], M. Eftekhari[2], D. Beygi[2]; [1]Shahid Beheshti university of medical sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research center for nuclear medicine, Shariati hospital, Tehran university of medical sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Nuclear medicine diagnostic procedures has developed during the past four decades in Iran. This paper reports tends of diagnostic nuclear medicine procedures in Tehran and the resultant population effective dose during 2011-2014. **Materials and methods**: The data including type and number of procedures , type of radiopharmaceuticals used, range of administered activities for each examination were collected from 61(out of 65) nuclear medicine centers in Tehran from 2011 to 2014. The gender and age distributions of the patients are also collected from 10 different centers. The effective dose for each examination was calculated based on the effective doses per unit administered activities given by ICRP publications 53, 80 and 106. **Results**: Total number of examinations increased from 155199 in 4011 to 264099 in 2014 with an increase of 70.16 %. The annual number of examinations per 1000 population increased from 13.66 in 2011 to 22.59 in 2014 with an increase of 65.37% during four years. Most frequent were examinations of the cardiac (69.22%), the skeleton (9.54%) and the thyroid (7.06%) averaged over the five years. Also the contributions of these three procedures to the collective effective dose were 50.20%, 6.4%, and 2.22%, respectively. **Conclusion**: Compared to an earlier investigation in 2003 considerable changes were found in the trends of nuclear medicine in Tehran during a decade. The frequency of cardiac examinations increased from 43.2% in 2003 to 69,22% in 2014. Thyroid examinations with the relative frequency of 26.7% in 2003 decreased to 7.06% in 2014. The number of overall examinations per 1,000 population of Tehran increased from 8.8 in 2003 to 22.59 in this study. The decrease in relative frequency of thyroid examinations could be due to the decreased incidence of goiter and the introduction of new techniques for diagnosis of thyroid disease. The large increase in relative frequency of cardiac examinations could be due to two main reasons. Firstly the increased reliance of cardiologists on values of nuclear cardiology in diagnosis and follow up. Secondly the considerable decrease in frequency of several nuclear medicine examinations such as thyroid, liver/Spleen hepatobiliary and renal. The increase of collective effective dose from 529.76 person-Sv in 2003 to 1439.98 person-Sv and hence the effective dose per capita from 44.06 μSv in 2003 to 13.18 μSv in 2014,could be explained because of an about 70% increase of examinations but about 6.5% increase in Tehran population.

EP819

Remarks on using F18 automatic dispenser and injector system

F. Zenone[1], A. Bruno[1], G. Belli[1], A. Baldoncini[2]; [1]Medical Physics dep. USL SUDEST Toscana, Arezzo, ITALY, [2]Nuclear Medicine dep. USL SUDEST Toscana, Arezzo, ITALY.

AimIn Arezzo Nuclear Medicine Department, Karl-100 automatic dispenser, equipped with automatic injector, was used to prepare F-18 syringe. The aim of this work is to investigate the advantage on using automatic system, compared with traditional system, in terms of occupational exposure to radiation, injection time and patient comfort. **Materials and Methods**For comparison of exposure levels, three personal dosimeters Polimaster-PM1610 were assigned for a week to several people working with hot cells designed for manual preparation of doses of F-18. We sampled separately exposures in the phases of preparation (approximately 260MBq), administration and removal of needles, using three different dosimeters (43 measurements for each phase). Operators were asked to write down the duration of each exposure.Subsequently, during the training phase, the same measurements were repeated using the Karl system (34 measurements for each phase). To improve the protection of operators, we have monitored the dose rate with an ionization chamber around the dispenser and injector.After injection, the residual activity in syringe and in tube was measured with a dose calibrator. The duration of each phase was preset. A form was provided to operators for reporting any problems that could result in the lengthening of the exposure time.The interview was conducted with patients to register if they had experienced any discomfort during the automatic injection.**Results**Based on the dose rate measurements, it was suggested operators: to place the bottom of the dispenser next to the wall, to stay near to the display only when necessary, far from the top and the sides especially when F-18 flows. Handling the injector is problematic for the bottom unshielded.No difference resulted between the manual and automatic methods for preparation, neither for exposure during needle extraction; while average dose rate measurements showed a decrease of about 83% during the preparation of syringes (21μSv/h vs 122μSv/h; [66÷10]μSv/h vs [256÷26]μSv/h) and about 79% during the injection stage (17μSv/h vs 83μSv/h; [66÷10]μSv/h vs [256÷26]).The residual activity contained in the waste was comparable with the background.Patients have felt comfortable and relaxed.Some problems related to automatic system occurred during the dispensing and the injection with a little increasing in working time, but still it showed an overall benefit. **Conclusions**It was developed an appropriate protocol for exposure measurements relating to the dispensing system. The automatic system showed appreciable dosimetric advantages and comfortable for the patient.

EP820

The impact of selected factors on the exposure of hands of workers during handling radiopharmaceuticals in nuclear medicine in the Czech Republic

J. Hudzietzova[1], M. Fulop[2], J. Sabol[3], J. Doležal[4], J. Kubinyi[5]; [1]Faculty of Biomedical Engineering, CTU Prague, Kladno, CZECH REPUBLIC, [2]Slovak Medical University, Bratislava, SLOVAKIA, [3]Department of Crisis Mangement, PACR, Prague, CZECH REPUBLIC, [4]Department of Nuclear Medicine, University Hospital, Hradec Králové, CZECH REPUBLIC, [5]Institute of Nuclear Medicine, GUH, Prague, CZECH REPUBLIC.

Aim: The fingers of workers that prepare and apply radiopharmaceuticals at nuclear medicine departments are often the most exposed parts of their body. The paper analyses the effects of basic factors, such as the technological equipment, the maintaining of operating procedures and the duration of practice on the size of the local exposure of workers' hands. Material and method: In order to determine the maximum exposure to the skin in terms of the personal dose equivalent $H_p(0.07)$, thermoluminescent dosimeters (TLDs) were used in specific positions where higher exposure was normally expected and also in the position where finger dosimeters are usually worn. So far, some 176 measurements in 29 persons from PET centres in the Czech Republic have been carried out. All these centres were equipped with different technological equipment and different procedures for the administration of radiopharmaceuticals were also used. During the measurements video shots were taken; based on these shots risky operations were identified. Results: From the comparison and confrontation of the personal dose equivalent - $H_p(0,07)$ - received by individual workers, it appeared that to a large extent the exposure could be reduced by means of the automatic application of certain procedures (using a cannula), where the average exposure at the relevant workplaces monitored was lower by 3-7 times than in the case of manual

administration (when a cannula was not used). In the absence of the shielding on syringes when radiopharmaceuticals are applied manually, the exposure may be much higher, namely almost 10 times higher (this exposure was around 8 mSv/GBq) compared to average exposure with the shielding. As to the duration of practice, at the beginning of work the exposure is relatively higher than later, when the workers acquire some experience and the skill. However, after some years the exposure tends to go up, mainly due to declining caution after several years of repeated routine operations. Conclusion: Based on the results obtained, appropriate steps aimed at the optimization of radiation protection at the selected nuclear medicine departments have been recommended. In addition, the importance of using shielded syringes has been pointed out, the application of automated procedures (especially during the application) recommended, and the positive impact of the continuous training and education of workers emphasized.Acknowledgements: This work was partially supported by the project SGS15/114/OHK4/1T/17.

EP821

Equivalent dose to the extremities during ^{18}F-FDG dispensing - Influence of manual dose dispenser

J. Oliveira[1], J. Hunter[2], E. Carolino[1], F. Lucena[1]; [1]Escola Superior de Tecnologia da Saúde de Lisboa, Lisboa, PORTUGAL, [2]Clinical Imaging Sciences Centre, Brighton, UNITED KINGDOM.

The radiopharmaceuticals used in PET are beta plus-emitters (β^+) and radiate gamma photons (γ) with energy levels of 511 keV. This is considerably higher in comparison with conventional nuclear medicine (NM), implying that the conventional amounts of lead and tungsten in shields are not enough for an appropriate radiation protection of the NM practitioners (NMp). Therefore, the need arose to develop dose dispensers that enables withdraw the ^{18}F-FDG activity administering to the patient, reducing the occupational exposure to radiation. The main objective of this study is to compare two dispensers, in relation to the equivalent dose (ED) to the extremities, the time spent on each procedure and the precision and accuracy of the measured activities. Two different manual dose dispensers were compared (D_A and D_B). ED to the extremities was calculated from the measurements of an automatic electronic meter (data logger) and a calibration factor. Variables were analyzed with Statistical Package for the Social Sciences (SPSS) and non-parametric tests were applied: Wilcoxon test (ED-both hands; ED-left hand; ED-right hand; time of procedure), Kruskal-Wallis test (reproducibility) and Pearson Correlation (time/activity and ED). Differences were assumed statistically significant for p-values<0.05. Accuracy and precision were evaluated through control chart. Although NMp received more ED with the D_B, there were no statistically significant differences (p>0.05) between dispensers for both hands. Also, ED for right hand compared with left hand for D_A and D_B found p>0.05. The dominant hand does not contribute to higher ED to the hands suggesting a bigger contribute to the ED from the practical procedure. There were statistically significant differences between the times of procedure with the two dispensers (p=0.007), which is related with the lack of practice from NMp with D_B. It was found that both instruments are robust and accurate, although not precise.

EP822

Patient and staff radioprotection aspects in cardiologic nuclear medicine examinations

P. Saletti[1], M. Bartoli[2], L. Capaccioli[1], G. Belli[1]; [1]Health Physics Unit - Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY, [2]University of Florence, Florence, ITALY.

Introduction: Cardiovascular diseases are nowadays spread pathologies and early diagnostic staging may support an adequate therapeutic treatment. In nuclear medicine, both PET and SPET are currently used depending on clinical question with specific radiopharmaceuticals, activities and procedures resulting in significant absorbed doses by staff and patients. The aim of this work is an evaluation of dosimetric impact on patients and staff in nuclear medicine cardiologi by means respectively of ICRP 53 and 80 evaluations and measured dose rates from manipulated syringes and patients. **Materials and methods**: At our centre, cardiac scintigraphies are carried out with GE Ventri gammacamera by means of 370MBq of ^{99m}Tc-MIBI administered for both rest and stress acquisition. PET cardiac examinations are instead performed at Philips Gemini TF PET/CT with 555-740 MBq of ^{13}N produced by a GE Minitrace cyclotron installed at radiopharmacy. For both procedures, a total amount of 10+10 patients were analysed, meaning that syringe and patient dose rate were measured at representative distances and normalised to 1GBq at measurement time. Moreover, permanence times in proximity to radioactive sources were recorded relating them to different actions (syringe manipulation, radiopharmaceutical administration, patient positioning···) in order to calculate absorbed dose by a simple multiplication. Patient dosimetry was assessed for ^{13}N and ^{99m}Tc-MIBI data from literature data. **Results**: Permanence times where measured for the whole process starting from syringe extraction from hot cell (10s), radiopharmaceutical administration (30s), patient preparation/assistance (300s) and positioning (70s) on scan bed for both PET and SPET procedures. Dose rate related to described operations was measured and equivalent doses was then calculated and normalized at 1GBq, ranging from 0.6μSv to 12μSv for total body exposure and from 25μSv to 80μSv for extremity exposure from ^{13}N, while, in case of ^{99m}Tc-MIBI, total body exposure and extremity were found to be respectively less than 1μSv and 3μSv. About patient internal dosimetry, effective dose from ^{99m}Tc-MIBI was found to be 4-9 mSv/GBq while, concerning ^{13}N, was less than 2mSv/GBq. **Conclusion**: A simple and practical method for staff exposure evaluation was assessed for cardiologic procedures in nuclear medicine, while literature data were used to account for patient internal dosimetry. Even if a small sample of patients was analyzed, it clearly appears that staff exposure is greater in PET cardiologic examinations with ^{13}N while, due to physical and pharmacological characteristics, is preferable in terms of patient radioprotection even if restricted to cyclotron-equipped centres.

EP823

First Impressions on a Commercial Patient Dose Management System in Nuclear Medicine

T. Tolvanen[1,1], A. Karlsson[2], C. Lafay[3], F. Zanca[3], **M. Teräs**[1,4]; [1]Dep of Medical Physics, Turku University Hospital, Turku, FINLAND, [2]Turku PET Centre, Turku University Hospital, Turku, FINLAND, [3]GE Healthcare, Büc, FRANCE, [4]Institute of Biomedicine, University of Turku, Turku, FINLAND.

Authorities require the use of ALARA principle and have developed Diagnostic Reference levels (DRL). EANM have launched guides like the paediatric dose chart and have efforts to standardise and harmonise protocols with the help of EARL (ResEARch 4 Life).In Radiology several commercial or freeware dose management systems exist. The purpose of current study is to outline how the implementation of software for NM data management can help setting up best practices as it relates to injected activity and protocol standardisation, in order to achieve better patient outcomes. **Materials and Methods:** In November2015 an existing dose monitoring system DoseWatch (GE Healthcare) was upgraded with a module for monitoring NM data and connected to two PET/CT scanners (GEDVCT, GED690). Between November 2015 and April 2016 data from more than 700 single-injection exams have been collected including radiopharmaceutical type, activity, effective dose, protocol and operator name associated with the exam. Protocol standardisation, protocol selection and administered activity for oncology follow up patients and impact of BMI on administered activity was assessed. **Results**: From present

reporting it is possible to compare protocol doses with DRLs. One difficulty is that although weight and height are present in database the reporting tool has BMI as preference. Data collection shows non-standardised protocol names across the scanners as well as some variability in administered activity for the same clinical indication for the two devices. For the D690 device, the most used Whole body protocol was analysed in more in details. The analysis of activity by BMI shows that the administered activity is not always tailored to the BMI: median activity is almost the same for [18,5 - 25] and [25 - 30] BMI categories (280 and 286 MBq respectively). Data from follow-up exams (oncology) have also been analysed. Although the same device is always used for the follow, the protocol changes in 50% of the case. Program development needs actions to handle dynamic studies where tracer information is normally set after the end of the study as well as IQ assessment. **Discussion**: The implementation of NM data management as complementary tool to dose management allows identifying variation within the same protocol, driving protocol optimization and standardization. The tool works best as the number of devices connected grows (hospitals or national database). The effort made so far is a good start as dose management will have a role in developing national and international standards.

Abnormal PSMA Accumulation in Chronic Inflammation

K. Oksuzoglu, T. Ones, H. T. Turoglu, T. Y. Erdil; Marmara University School of Medicine, Nuclear Medicine Department, Istanbul, TURKEY.

Introduction: Prostate-specific membrane antigen (PSMA) is a specific type II membrane glycoprotein. 68Ga-PSMA PET/CT is a new modality for imaging prostate carcinoma. We present the case of a 72-year-old man with a history of prostatic adenocarcinoma who had a PSMA PET/CT scan for staging. 68Ga-PSMA PET images showed moderate uptake in the right hemithorax, corresponding to pleural thickening seen on the CT images. Histopathologic examination revealed the diagnosis of chronic inflammation. It is important to keep in mind other alternative diagnoses such as chronic inflammation when PSMA PET/CT identifies uptake at an atypical site. Case Presentation: A 72-Year-Old male patient with prostate cancer (PSA değeri:12.47ng/ml) underwent skeletal scintigraphy. Suspicious Tc-99m MDP uptake was seen on right hemithorax. 68Ga-PSMA PET revealed increased heterogeneous uptake in the right posterolateral segment of prostate gland compatible with prostate needle biopsy findings (adenocarcinoma). 68Ga-PSMA PET images showed non-expected moderate uptake in the right hemithorax too, corresponding to pleural thickening seen on the CT images (first intercostals space) and neighbourhood of the 4 and 6 rib. Thoracoscopic biopsy was performed to establish a definitive diagnosis. The results of histopathological examination indicated the features of chronic inflammation. Conclusion: Prostate-specific membrane antigen (PSMA) is a specific type II membrane glycoprotein and its expression is suppressed by androgen in prostate cancer. PSMA is a promising target for both therapy with monoclonal antibodies and imaging. PSMA is not specific to the epithelium of prostate gland and is expressed in normal other tissues too, for example urinary bladder, proximal tubules of kidney, liver, salivary glands, oesophagus, stomach, small intestine and neuroendocrine cells in the colon. Some malignant lesions such as transitional cell carcinoma, renal cell carcinoma, colon carcinoma, bronchial carcinoma, adrenocortical carcinoma, follicular and papillary thyroid carcinoma, glioblastoma, follicular lymphoma; and some benign lesions (schwannomas, thyroid and adrenal adenoma, desmoid tumour) can cause abnormal PSMA-ligand uptake that may be confused with metastases. Also, PSMA is expressed in non-neoplastic reparative and regenerative neovasculature tissues like endothelial cells in keloids, granulation tissue from heart valves and pleura, and different phases of cycling endometrium. Chronic inflammation should be kept in mind when interpreting whole-body PSMA PET/CT images and PSMA-avid lesions should be confirmed with tissue biopsy before treatment. As far as we know, this is the first case report of a patient with PSMA accumulation associated with chronic inflammation.

Preclinical *In Vivo* and *In Vitro* Comparison of the Translocator Protein PET Ligands ^{18}F-PBR102 and ^{18}F-PBR111: Metabolism studies

M. Peyronneau[1], C. Loch[2], S. Eberl[2,3], L. Wen[2,3], D. Henderson[2], I. Greguric[4], J. Verschuer[2], T. Pham[4], P. Lam[2], F. Mattner[2], T. Bourdier[2], A. Mohamed[2,5], A. Katsifis[2,6], M. Fulham[2,3,5]; [1]IMIV, CEA, Inserm, Univ.Paris-Sud, CNRS, Université Paris-Saclay, CEA-SHFJ, Orsay, FRANCE, [2]Department of Molecular Imaging (PET and Nuclear Medicine), Royal Prince Alfred Hospital, Missenden Road, Camperdown, NSW 2050, AUSTRALIA, [3]Faculty of Engineering and Information Technologies, University of Sydney, Sydney, NSW 2006, AUSTRALIA, [4]Life Sciences, ANSTO, New Illawarra Road, Lucas Heights, NSW 2234, AUSTRALIA, [5]Sydney Medical School, University of Sydney, Sydney, NSW 2006, AUSTRALIA, [6]Faculty of Pharmacy, Unviversity of Sydney, Sydney, NSW 2006, AUSTRALIA.

Aim: [^{18}F]PBR111 and [^{18}F]PBR102 have been characterized as high affinity radioligands for imaging the translocator protein (TSPO) using PET in several animal models of neuroinflammation [1, 2]. Cerebral white matter inflammation has been recently assessed by PET with [^{18}F]PBR111 in Multiple Sclerosis [3]. In this study, our aim was to evaluate and compare the *in-vitro* metabolic profile of PBR102 and PBR111 in rat and human microsomes to the *in-vivo* binding and metabolite uptake in the brain of non-human primates (Papio Hamadryas). **Materials and Methods:** The *in vitro* metabolism of PBR102 and PBR111 was carried out using rat and human liver microsomes followed by LC/MS and MS-MS analysis. [^{18}F]PBR102 and [^{18}F]PBR111 were prepared by nucleophilic substitution of their corresponding *p*-toluenesulfonyl precursors with ^{18}F-fluoride. PET-CT brain imaging with arterial blood sampling and metabolite analysis [4] was performed in non-human primates, providing a metabolite-corrected input function for kinetic model fitting. Blocking and displacement PET-CT scans, using PK11195, were also performed. **Results**: Rat and human liver microsomal incubation-LC/MS analyses identified three main metabolites: O-dealkylated, hydroxylated and N-deethylated derivatives of PBR102 and PBR111. The O-dealkylated compounds were the major metabolites in both species; human liver microsomes were less active than those in rat. In vivo, the radiotracers decreased quickly in baboon plasma to 20% for [^{18}F]PBR102 and 15% for [^{18}F]PBR111 at 110 min post injection. The higher bone uptake for [^{18}F]PBR111 observed during the displacement and blocking whole-body PET-CT studies (due to [^{18}F]fluoride) may result from differences in the metabolism of [^{18}F]fluoroacetate ([^{18}F]PBR102) and [^{18}F]fluoropropionate ([^{18}F]PBR111), generated by O-dealkylation in the liver and further oxidation in plasma. Excretion of both tracers was through the urinary and biliary systems. Brain PET-CT studies showed similar kinetic parameters for baseline and blocking studies for tracer delivery to the brain (K_1) with low non-specific binding and lack of significant metabolite uptake in the brain. **Conclusions**: [^{18}F]PBR102 and [^{18}F]PBR111 display distinct metabolic profiles in rat and non-human primates, in agreement with in-vitro data. Whereas radiometabolites contributed to non-specific binding and confounded in-vivo brain analysis in rodents, their impact in primates was less pronounced and should be even less in humans. Hence, both [^{18}F]PBR102 and [^{18}F]PBR111 appear suitable for TSPO imaging with PET. In-vitro metabolite studies can be useful to predict in vivo radioligand metabolism and can assist in the improved design and development of radioligands for neuroreceptor imaging.[1]Fookes et al.,JMedChem,2008;51 (13):3700-12. [2]Amhaoul et al.,NeurobiolDis,2015;85:526-539.

EP826

Radiosynthesis of fluorinated quinuclidine 1,2,3-triazole derivatives to image α7-nicotinic acetylcholine receptor by PET

J. Vercouillie[1], P. Tangpong[1], C. Mothes[1], A. Ouach[2], F. Suzenet[2], F. Buron[2], A. Domene[1], S. Routier[2], S. Chalon[1], D. Guilloteau[1]; [1]INSERM 930, Tours, FRANCE, [2]ICOA, Orléans, FRANCE.

Objective: Changes in brain alpha-7 nicotinic acetylcholine receptor (α7 nAChR) density has been associated with various disorders such as Alzheimer's disease, schizophrenia and depression. To understand physiopathology of these disorders and to develop therapeutic approaches molecular imaging such as PET will be suitable. In this aim we developed fluorinated PET ligands of α7 nAChR based on a quinuclidine-1,2,3-triazole scaffolds[(1,2)]. The present study reports the radiosynthesis of six highly potent ligands (affinity for the target ranging from 0.18 to 16 nM) their radiochemical stability and their biological evaluation in rodents. **Method**: The $^{18}F^-$ was prepared by nuclear reaction $^{18}O(p,n)^{18}F$ and then was transferred to a synthesizer module and was passed through a Sep-Pak® QMA cartridge. Reactivity of ^{18}F was exalted by conventional procedure prior to the addition of the precursors diluted either in ACN or in DMSO. As two derivatives display an ortho fluoro pyridine moiety DMSO was used instead of ACN for the preparation of fluoroalkyls compounds. Reactions were conducted under conventional heating or under microwave when required. All tracers were purified, formulated and their radiochemical stability was checked up to 4h in the vehicle and in rat plasma solution. Radiotracers were evaluated by μPET and/or biobistribution studies using sham and rats pretreated with methyllycaconitine (MLA), a selective alpha 7 receptor antagonist to determine their nonspecific binding. **Results**: Depending of the tracers, radioligands were obtained in low to moderates yields 7-30% (decay-corrected). Their radiochemical purity was >98% of all products and specific activity in the range of 10-86 GBq/μmol. All derivatives were radiochemically stable in the formulation media and in rat plasma up to 4h. Evaluation of the tracers demonstrated a moderate blood brain barrier uptake but a quite homogenous distribution in the CNS areas and a high nonspecific binding in comparison to the current ^{18}F α7 reference ligand [^{18}F]ASEM.**Conclusion**: We developed new high affinity α7 nAChR ligands that we radiolabeled with ^{18}F. However, they showed a mainly nonspecific binding in vivo in rats in comparison to [^{18}F]ASEM. This result will contribute to a better knowledge of the relationships between the chemical structure and in vivo brain binding of α7 nAChR tracers. **Research Support:** This research was supported by grants from the Région Centre (IMAD, BIAlz), the ANR programs (ANR-10-MALZ-0004, ANR-11-LABX-0018-01) and France Alzheimer. EP827

Dosimetry and whole body distribution of [^{18}F]PE2I in healthy volunteers

H. Lizana[1], L. Johansson[1], A. Larsson[1], J. Axelsson[1], J. Linder[1], M. Ögren[1], A. Varrone[2], C. Halldin[2], S. Jakobson Mo[1]; [1]Umeå University, Umeå, SWEDEN, [2]Karolinska Institutet, Stockholm, SWEDEN.

Aim: The recently developed radioligand [^{18}F]FE-PE2I is a promising tracer for PET imaging of the dopamine transporter (DAT) in human brain. The higher DAT selectivity of the tracer compared to [^{123}I]FP-CIT and the higher temporal and spatial resolution in PET compared to SPECT offers detailed imaging of the DAT distribution in striatal and extrastriatal compartments. The aim of this study was to ensure that diagnostic imaging with [^{18}F]FE-PE2I is performed with acceptable radiation doses in patients. Effective dose estimation has previously been done in cynomolgus monkeys. This is the first whole body (WB) distribution and dosimetry study of [^{18}F]FE-PE2I in humans, conducted within the clinical trial PEARL-PD (Eudra CT: 2015-003045-26). **Materials and methods:** Five healthy volunteers (>60 y), mean weight 69.5 kg, received a mean [^{18}F]FE-PE2I activity of 2.40 MBq/kg. Three PET scans from head to thigh were performed within the first 30 minutes. PET/CT WB scans (head-feet) were performed at 30 minutes, 2 h, 4 h and 6 h post injection. The first PET/CT WB scan was done with low-dose CT (30mA) for attenuation correction and anatomical localisation, whereas ultra-low dose CT (10mA) were used for remaining scans. Blood radioactivity was sampled at each scan and total activity in voided urine was measured. VOIs were drawn around 17 organs and absorbed and effective doses were calculated using the IDAC software. **Results**: Preliminary analyses showed that immediately after injection the highest activity concentrations (10-20 kBq/ml) were seen in the stomach, liver and heart (4.5%, 14% and 1.8% of the injected activity, respectively). Thirty minutes post injection the activity concentration was highest in the gallbladder (15 kBq/ml, 0.2% of injected activity). The stomach and liver received the highest absorbed doses (0.03 mGy/MBq), followed by the kidneys (0.02 mGy/MBq). Within the first 7 hours about 9% of the injected activity was excreted with the urine. The effective dose was 0.017 mSv/MBq, resulting in an effective dose of 3.4 mSv for 200 MBq. **Conclusion**: The most frequently used ^{18}F -labelled tracer [^{18}F]FDG gives an effective dose of 0.019 mSv/MBq, similar to the 0.017 mSv/MBq calculated in this study. The effective dose mentioned above is in the same range as previously published data for [^{18}F]FE-PE2I in non-human primates. The effective dose is somewhat lower than for 185MBq [^{123}I]FP-CIT (4.6 mSv). These preliminary human dosimetry data, together with the suitable imaging properties of [^{18}F]FE-PE2I suggest its utility as a diagnostic agent for DAT imaging.

EP828

Demonstration of $\alpha_v\beta_6$ target engagement in healthy rat using [^{18}F]IMAFIB

M. Onega, S. Tang, S. Ashworth, C. Plisson, C. Coello, L. Wells, J. Passchier; Imanova Limited, London, UNITED KINGDOM.

Background/ Aim: Expression of the epithelial-specific integrin receptor $\alpha_v\beta_6$ is up-regulated during the formation of scar tissue following injury as well as in certain carcinomas. Significant efforts are ongoing to develop new therapeutics for this target, particularly in the areas of lung, liver and kidney fibrosis. The fluorine-18 labelled peptide [^{18}F]IMAFIB (aka [^{18}F]A20FMDV2), was previously demonstrated to be a potent and selective ligand for delineation of $\alpha_v\beta_6$ receptors *in vivo* with PET[1,2] and is currently under evaluation in patient populations in our institution to assess its clinical utility. Previous MicroPET studies with [^{18}F]IMAFIB in healthy rat under baseline conditions and following administration of homologous block of IMAFIB (2 mg/kg; *i.v.*) demonstrated a reduction in V_T in the aforementioned tissues as assessed by quantitative kinetic analysis using the metabolite corrected plasma arterial input function.[3] Evidence suggests $\alpha_v\beta_6$ receptors are expressed in healthy tissue such as liver, stomach and lung, albeit in low concentrations. The objective of the present work was to test if [^{18}F]IMAFIB could be used in healthy animals using a simple and efficient tissue dissection protocol to demonstrate target engagement of novel therapeutics. **Materials and Methods**: [^{18}F]IMAFIB was labelled using a GMP compliant and fully automated process as described previously.[3] Anaesthetised Sprague-Dawley rats were injected with [^{18}F]IMAFIB (*i.v.*) under baseline conditions (n=6) or following pre-dosing with 2 mg/kg unlabelled IMAFIB (n=6). Animals were sacrificed at 30 min post injection of [^{18}F]IMAFIB and tissues and blood removed for measurement of radioactivity using an automated gamma counter. Subsequently, tissues were weighed and SUV values calculated. **Results and Conclusion**: Uptake of [^{18}F]IMAFIB was significantly reduced in lung, liver, stomach wall and

kidney medulla following pre-treatment with unlabelled IMAFIB (SUV_R baseline vs post-dose $_{(mean\pm SD)}$: lung, 1.56±0.76 vs 0.40±0.06; liver, 4.08 ±1.11 vs 2.45±0.90; stomach wall 1.99±1.05 vs 0.51±0.17 and kidney medulla 115.1±55.7 vs 41.6±24.0; unpaired t-test $P<0.05$). These results demonstrate a specific binding signal in healthy rats and support the data obtained from dynamic PET scans. In summary, this study shows that [^{18}F]IMAFIB may be used to demonstrate target engagement in healthy tissues such as lung, liver, stomach wall and kidney medulla without the need for an animal model of disease. **References**: [1] S. High Affinity F-18 Labeled Prostate Specific Membrane Antigen (PSMA) Inhibitors: In Search of a Facile Approach to High Radiochemical Yield

A. Amor-Coarasa, J. M. Kelly, S. Ponnala, W. Qu, J. W. Babich; Division of Radiopharmaceutical Sciences, Department of Radiology, Weill Cornell Medicine, New York, USA, New York, NY, UNITED STATES.

Aim: Despite the value of an ^{18}F-labeled ligand targeting PSMA, few promising candidates have been reported to date. Furthermore, those currently in clinical use multiple step, prosthetic group labeling approach rather than direct fluorination. We sought to address these inconveniences by developing a high yield, high specific activity radiosynthesis of ^{18}F-labeled PSMA inhibitors while minimizing synthetic steps and time. *Methods:* Fluorination was carried out with no-carrier-added [^{18}F]fluoride on a range of substrates and prosthetic groups. Four strategies were employed to label a series of *EuK* containing PSMA inhibitors: direct [^{18}F]fluorination, [^{18}F]fluorination via isotopic exchange, [^{18}F]fluoroethylation using either 2-[^{18}F]fluoroethyltosylate ([^{18}F]FET) or 2-[^{18}F]fluoroethylbromide ([^{18}F]FEBr), and [^{18}F]fluorination via click chemistry with 2-[^{18}F]fluoroethylazide ([^{18}F]FEA). [^{18}F] incorporation was determined using radioHPLC. *Results:* Direct fluorination via nucleophilic aromatic or aliphatic substitution was unsuccessful, with decay corrected RCY (dcRCY) <1%. Isotopic exchange was attempted on an activated fluorophenylurea moiety and conversion was 2-5%. When a 4-nitrophenylurea was used as precursor, the labeling reaction underwent a series of color changes consistent with proton transfer from the urea to fluoride. [^{18}F]FET was prepared from ethylene ditosylate in 5 min at 100°C in >70% dcRCY. Reactivity towards primary and secondary amines was poor and evidence of base-catalyzed decomposition of [^{18}F]FET via elimination of TsOH. [^{18}F]FEBr was prepared from 2-bromoethyltriflate in 8 min and purified by distillation at 100°C at approximately 30% dcRCY. Reactivity towards secondary amine groups remained low in both neutral and basic conditions. [^{18}F]FEA was prepared from 2-azidoethyltosylate (>90% dcRCY) for later click reaction in 10 min at 80°C. [^{18}F]FEA was isolated by distillation at 130°C in >60% dcRCY and >97% RCP. The subsequent reaction between [^{18}F]FEA and a PSMA-targeting alkyne precursor was achieved in 30-50% dcRCY at 100°C/Cu^+. A series of six PSMA inhibitors were [^{18}F]fluorinated by this approach and evaluated in preclinical mouse models. *Conclusions;* Direct [^{18}F]fluorination of urea-based PSMA inhibitors is highly disfavored due to the interaction between [^{18}F]fluoride and the urea protons. Therefore a prosthetic group approach to the [^{18}F]fluorination of PSMA inhibitors is preferred. Both the 2-[^{18}F]fluoroethyltosylate and [^{18}F]fluoroethylbromide synthons were prepared in reasonable dcRCY and high specific activity, but alkylation of precursors was unreliable and required extensive protection/deprotection chemistry. In contrast, the 2-[^{18}F]fluoroethylazide synthon was synthesized with high dcRCY and chemical purity and reacted rapidly with alkyne precursors without requiring protecting groups. This strategy was employed to synthesize six high affinity (IC_{50} <35 nM) PSMA inhibitors for PET imaging of prostate cancer.

EP830

First-in-human studies of imidazopyridineacetamide, [^{11}C]CB184, as a novel 18 kDa translator protein seeker

J. Toyohara[1], M. Sakata[1], K. Ishibashi[1], K. Wagatsuma[1], K. Hatano[2], K. Ishiwata[1,3,4], K. Ishii[1]; [1]Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, [2]University of Tsukuba, Tsukuba, JAPAN, [3]Souther TOHOKU Research Institute for Neuroscience, Koriyama, JAPAN, [4]Fukushima Medical University, Fukushima, JAPAN.

Aim: An imidazopyridineacetamide, *N*,*N*-di-*n*-propyl-2-[2-(4-[^{11}C]methoxyphenyl)-6,8-dichloroimidazol[1,2-a]pyridine-3-yl]acetamide ([^{11}C]CB184), is a potential radioligand for evaluation of 18 kD translocator protein (TSPO) overexpression in the brain by positron emission tomography (PET). In the present study, we performed safety evaluation and initial brain imaging of [^{11}C]CB184 in healthy human subjects. **Materials and methods**: Five healthy male subjects underwent 90-min dynamic [^{11}C]CB184 scans of brain regions with arterial blood sampling. For anatomic coregistration, T1-weighted magnetic resonance imaging was performed. Metabolites in plasma and urine were analysed by high performance liquid chromatography (HPLC). The total distribution volume (V_T) for [^{11}C]CB184 was evaluated by Logan graphical analysis ($t^* = 30$min). **Results and conclusion**: The administered activity and mass of [^{11}C]CB184 were 571 ± 165 MBq and 4.1 ± 2.5 μg, respectively. There were no adverse or clinically detectable pharmacologic effects in any subjects throughout the study period. No clinically important trends indicative of a safety signal were noted for laboratory parameters, vital signs, or electrocardiogram parameters. A 90-min dynamic scan showed a rapid initial uptake of the radioactivity in the brain followed by prompt clearance. The [^{11}C]CB184 was homogeneously distributed in the grey matter. The V_T of [^{11}C]CB184 was highest in the thalamus (5.1 ± 0.4 ml/cm^3) followed by cerebellar cortex (4.6 ± 0.3 ml/cm^3) and others. The lowest V_T of [^{11}C]CB184 was observed in the head of caudate nucleus (3.2 ± 0.4 ml/cm^3). Although regional differences were small, the observed [^{11}C]CB184 biding pattern was consistent with the TSPO distribution in the normal human brain. Furthermore, V_T values of [^{11}C]CB184 are 3 to 5 times higher than those of standard TSPO ligand (*R*)-[^{11}C]PK11195. Peripherally, [^{11}C]CB184 was metabolized in human: 34% ± 2% of the radioactivity in plasma was detected as the unchanged form after 60 min. In urine obtained approximately 100 min post-injection, 0.3% of the total injected radioactivity was recovered. HPLC analysis of urine showed a major hydrophilic metabolite, and [^{11}C]CB184 itself was negligible. In this preliminary study, we could not observe low affinity binder of [^{11}C]CB184. These results demonstrate that [^{11}C]CB184 is a suitable radioligand to use in clinical trials for imaging TSPO in the human brain, providing acceptable pharmacological safety at the dose required for adequate PET imaging. Further clinical studies with [^{11}C]CB184 are needed to assess the added value of this new TSPO radioligand and to determine whether [^{11}C]CB184 could replace (*R*)-[^{11}C]PK11195.

EP831

Detection rate of PET/CT imaging in patients with biochemical relapse of prostate cancer using 68Ga-PSMA I&T

C. Berliner[1], M. Tienken[1], T. Frenzel[2], Y. Kobayashi[1], A. Helberg[1], S. Klutmann[1], D. Beyersdorff[1], L. Budäus[3], H. Wester[4], J. Mester[1], P. Bannas[1]; [1]Department of Interventional and Diagnostic Radiology and Nuclear Medicine, University Medical Centre Hamburg-Eppendorf, Hamburg, GERMANY, [2]Department of Radiotherapy and Radiation Oncology, Hamburg, GERMANY, [3]Martini Clinic, University Medical Centre Hamburg-Eppendorf, Hamburg, GERMANY, [4]Pharmaceutical Radiochemistry, Technical University Munich, Garching, GERMANY.

Purpose: To evaluate 68Ga-PSMA I&T detection rates in biochemical relapse of prostate cancer. **Methods**: We performed a retrospective analysis in 76 consecutive men undergoing whole body 68Ga-PSMA PET/CT from July 2015 to April 2016. Only patients with documented biochemical relapse after definite treatment of prostate cancer were included. Median prostate specific antigen (PSA) was 1.1 (0.01 - 128) ng/ml. Median patient age was 68 (50-85) years. 68Ga-PSMA I&T was applied to patients via an intravenous bolus of 154+/- 17 MBq (SD). PET scans with low dose and contrast enhanced CT scans were performed 60 minutes after injection. Subsequent CT image evaluation included multiplanar reconstruction in three standard planes. The detection rates were correlated with PSA levels. **Results**: PSMA positive lesions were detected in 64.5 % of all patients (49/76). Divided into subgroups no PSMA positive lesions was detected in patients with PSA below 0.2 ng/ml (0/6), in 39.1 % (9/23) of patients with PSA ≥0.2-<0.5 ng/ml, in 42,9 % with a PSA ≥0.5-<1.0 ng/ml (3/7), in 70 % (7/10) with a PSA of ≥1.0-<2.0 ng/ml, in 93.8 % (15/16) with a PSA of ≥2.0-<5.0 and in 100% in patients with a PSA ≥5.0-<10.0 (9/9) or ≥10 ng/ml (3/3). **Conclusions:** Our detection rates with PSMA I&T in patients with a PSA levels <1 ng/ml were below of those reported by Afshari et al. and Eiber et al using 68Ga-HBED-CC. Above PSA levels of 1 ng/ml the detection rates are comparable or even higher. Further improvement of detection rates is currently tested using forced diuresis one hour after tracer application and additional scanning after two hours. **References:** Eiber M et al. EP832

Synthesis, radiochemistry and utilization of a novel 18F-synthon for indirect radiolabelling of biological vectors

B. Zhang[1,2], G. Pascali[2], L. Matesic[2], A. J. Robinson[1], B. H. Fraser[2]; [1]Monash University, Melbourne, AUSTRALIA, [2]ANSTO, Sydney, AUSTRALIA.

AIM: Ethenesulfonyl fluoride (ESF) is one of the strongest Michael acceptor molecules reported in the chemical literature. ESF reacts with various nucleophiles including amines, thiols, enamines, dienes, phosphines and activated methylene groups under relatively mild conditions. Furthermore, the sulfonyl fluoride moiety is reported to be stable in biological conditions. Consequently, [18F]ESF has significant potential as a minimalistic prosthetic group for radiolabelling macromolecules that contain 'soft' nucleophilic groups such as lysine or free cysteine residues. In this work we aim to explore and optimise the synthesis of [18F]ESF and its utilisation in the radiofluorination of model amino acids and oligopeptides as one of the smallest 18F prosthetic groups available. **MATERIALS AND METHODS**: Radiolabelling of [^{18}F]ESF was attempted using a microfluidic system (Advion NanoTek), either using a two-step route from 2-chloroethanesulfonyl chloride or by fluorine exchange on [19F]ESF. Exchange reactions were also performed under traditional vessel conditions and yields were compared with the microfluidic approach. These exchange reactions were performed in aqueous solvents (e.g. 0.9% saline) at 100°C. After cartridge purification of [18F]ESF, the coupling reaction was tested on several model amino acids (carboxy-protected) and oligopeptides in different solvent systems at room temperature. **RESULTS**: The 2-chloroethanesulfonyl chloride route was not successful in synthesizing [18F]ESF, while the exchange reactions in the microfluidic system provided high yields (>95%). The incorporation in vessel conditions was always lower yielding and required longer reaction times. All model amino acids and oligopeptides tested, with the notable exception of histidine, reacted with [18F]ESF in DMF/saline medium with incorporation yields over 40%. All the synthesized adducts were stable in their employed solvent over a period of 12 hours. **CONCLUSIONS**: We found a facile method to produce carrier added [18F]ESF via a 19F-18F fluoride exchange reaction in aqueous solvents, using a microfluidic system. The cartridge purified prosthetic molecule was successfully used in coupling reactions with a set of model amino acids and oligopeptides at room temperature with good yields. Further studies are ongoing on the stability of the obtained radiofluorinated adducts in injectable formulations. In addition, novel routes leading to non-carried-added [18F]ESF are being designed. These efforts would lead to a general, simple and minimalistic method for [18F]radiofluorinating biomolecules.

[^{11}C]NS14444, a new radiotracer for alpha-7 nACh receptors. Synthesis and preclinical evaluation

K. Någren[1], J. H. Dam[1], C. Baun[1], T. Andersen[1], A. Šačkus[2], O. Paliulis[2], D. Peters[3]; [1]Odense University Hospital, Odense C, DENMARK, [2]Kaunas University of Technology, Kaunas, LITHUANIA, [3]DanPET AB, Malmö, SWEDEN.

Introduction: The $_7$ nAChRs are involved in neuropsychiatric diseases such as Alzheimer's disease, Parkinson's disease and schizophrenia. They are also located in the spleen, in various cancers and in vulnerable plaques in arteries. Although a number of $_7$ PET tracers have been developed, none of them are in clinical routine use. NS14444, 2-(1,4-diazabicyclo[3.2.2]nonan-4-yl)-5-(1-methyl-indol-6-yl)-1,3,4-oxadiazole, developed by Dan Peters et. al.,[1] is a high affinity (IC_{50} 12 nM) ligand for the $_7$ nACh receptor, and is selective over a wide range of receptors and transporters. *Methods*: Methylation of the indole nitrogen of NS14540 was attempted using [^{11}C]methyl iodide or [^{11}C]methyl triflate using a variety of bases. PET studies (a baseline and a blocking study) were performed in a Sprague-Dawley rat on a Siemens Inveon system after tail vein injection of 42 and 49 MBq (153 and 509 ng) of [^{11}C]NS14444. For the blocking study, 10 mg/kg of SSR180711 was injected 16 min. before [^{11}C]NS14444 administration. *Results*: The only successful methylation combination found was [^{11}C]methyl iodide and NaH as a base in acetonitrile, with 3 min. heating at 90°C. The ^{11}C methylation yield was about 50%. Purification was performed on an Onyx HPLC column using ethanol in dilute phosphoric acid, giving 1.6-3.0 GBq of [^{11}C]NS14444 with radiochemical purity higher than 99% and specific radioactivity of 60-180 MBq/nmol. A rather uniform and low uptake, max. 0.05% of injected dose, was obtained in the rat brain. Blocking with SSR180711 reduced the brain uptake at 45-60 min with 33%. In the baseline study, uptake in the spleen was relatively high, and this uptake was blocked almost completely by SSR180711 pre-administration. *Conclusion*: An effective method for the synthesis and purification of [^{11}C]NS14444 was established. Although the low brain uptake in rat indicates that [^{11}C]NS14444 might not be ideal for studies of neuropsychiatric diseases, it might be useful for studies of cancer, vulnerable plaques or diseases of the spleen. These topics will be addressed in future research. 1: Patent US 8,778,928, including NS14444, including isotopes.

EP834

Synthesis of N-[^{11}C]methyl-rhodamine derivatives for Pgp-pump study

E. V. Németh[1], G. Horváth[2], T. Miklovicz[1], P. Mikecz[1], J. P. Szabó[1], A. Fekete[1], D. Szikra[1], G. Trencsényi[1], T. Márián[1], J. Varga[1]; [1]Department of Nuclear Medicine, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY, [2]Isotoptech Pty, Debrecen, HUNGARY.

Objective: Members of the rhodamine family are Pgp-pump substrates, which accumulate in the mitochondria; therefore the multidrug resistance can be tested using them. Earlier rhodamine was labeled by ^{18}F and ^{11}C isotopes through the ester group. *In vivo* studies showed that the esterase

enzymes cut off the labeling part of the molecule. Our aim was to work out a synthesis for N-labeled derivatives, since they are expected to show higher stability *in vivo*. Direct methylation of amino group of rhodamine derivatives was unsuccessful, so we tested another way of labeling: the first step was N-acetylation followed by N-methylation, finally acid hydrolysis was performed to remove the acetyl groups. **Methods:** We produced our precursor N,N-diacetyl-R110 by the acetylation of R110 with acetic anhydride in pyridine. Its methylation with [^{11}C]CH_3OTf in DMF solution in the presence NaH as base gave N-[^{11}C]methyl-N,N-diacetyl-R110. After dilution with water, it was adsorbed on a C18 SepPak, purified by washing it with water, and eluted with ethanol. Following the addition of 3 M HCl, hydrolysis was carried out for 5 minutes at 120 °C, then the reaction mixture was neutralized with aqueous NaOH and Na-acetate. The resulting solution was injected onto a 250 mm long, 10 mm diameter Nucleodur C18 Pyramid 5μm semipreparative column, and eluted with ammonium formate (10 mM, pH=3): MeCN = 65:35; detection was performed at 254 nm. The fraction containing N-[^{11}C]methyl-rodamin110 was collected and identified by analytical HPLC, using a similar column (250 / 4.6 mm), and the purity was also determined. The solvent ratio was 70:30 in this case as well. For the *in vitro* tests KB-3-1 Pgp-negative and KB-V-1 Pgp-positive human epidermoid carcinoma cell lines were used. **Results:** The alkylation of the precursor with [^{11}C]MeTriflate to N[^{11}C]methyl-N,N-diacetyl-R110 occurred with 60±5% yield. N-[11C]methyl-rodamin110 was obtained with 94 ±3 % yield after acid hydrolysis. The radioactive end-product was isolated with semipreparative HPLC, the radiochemical purity was 97 ±2 %. Serum stability was studied by analytical HPLC for 55 min: no change was detected. The N-[^{11}C]methyl-rodamin110 accumulation in the Pgp-negative cells (KB-3-1) was approximately 2.5-fold higher than in the Pgp positive cells (KB-V-1), at all time points. Treatment with cyclosporin-A (CSA) - which is a Pgp-inhibitor - increased the N-[^{11}C]methyl-rodamin110 uptake of KB-V-1 cells close to the level of the KB-3-1 cells. **Conclusion:** We have successfully N methylation of rhodamine derivatives. This is a way useful to Pgp pump's functions test in vitro experiment.

EP835

Safety Analysis of a Novel Fatty Acid Analog 18-F FCPHA, Data from a Phase II Study

H. Strauss[1], O. Gheysens[2], R. Hustinx[3], S. Goldman[4], K. Eissler[5], E. Lyons[6], V. Roelants[7]; [1]Memorial Sloan Kettering, New York, NY, UNITED STATES, [2]UZ Leuven, Leuven, BELGIUM, [3]CHU Liege, Liege, BELGIUM, [4]Hospital Erasme ULB, Brussels, BELGIUM, [5]InsightRX Consulting LLC, Phoenixville, PA, UNITED STATES, [6]FluoroPharma Medical, Inc., Montclair, NJ, UNITED STATES, [7]Cliniques universitaires Saint-Luc, Brussels, BELGIUM.

Background: Myocardial perfusion imaging (MPI) is useful to detect myocardial ischemia and scar. Ischemia alters cardiac metabolism by converting from free fatty acid (FFA) to glucose. A Phase II study was conducted in Belgium to assess the safety and imaging characteristics of a novel FFA analog 18-F Fluoro-cyclopropylhexadecanoic acid (18-F FCPHA; CardioPET) in a population with known or suspected coronary artery disease (CAD), in comparison with Tc-99m SPECT and coronary angiography. Previous reports on safety and image quality did not reflect the full study cohort. **Methods:** Subjects referred for angiography after a positive SPECT MPI (sestamibi or tetrofosmin) or stress echocardiography underwent PET/CT imaging following 18-F FCPHA injection. Physical exam, vital signs, 12-lead ECG, hematology, chemistry and urinalysis were collected at baseline (day of study), at one hour after dosing with study drug and at 24-hours. Monitoring of vital signs via 3-lead ECG continued for 60-minutes during PET serial imaging. **Results**: Study cohort consisted of 31 subjects (mean age 67). CAD subjects presented with a variety of symptoms including dyspnea, angina and NYHA II heart failure. 18-FCPHA was injected at either rest (n=14) or stress (exercise (n=14) and dipyridamole (n=3)); doses ranged from 136.9 to 358.9 MBq. Four adverse events (AE's) were reported (hyperventilation, anxiety, diarrhea, antiphospholipid antibodies positive); all were mild to moderate in severity; none were attributed to study drug. Three subjects with increased blood pressure deemed clinically significant (CS) at either 60 minutes or 24 hours were also CS at baseline. One subject had CS respiration at 60 minutes and was recorded as an AE. No other vital signs were considered to be CS by investigators. All ECG's flagged as potentially CS were medically monitored and considered to be within normal limits for the study population. Lab values out of range were examined by the medical monitor against the subjects' medical conditions and study drug, and determined to be unrelated to 18-F FCPHA. **Conclusions:** In this Phase II study, the FFA analog 18-F FCPHA could be safely administered in a high-prevalence CAD population. Four AE's were reported, but all of them were mild to moderate in severity. No other changes to vital signs or laboratory values were related to administration of the study drug.

Gold Nanoparticles with Stably Embedded Cu-64 and Their Use in Nanoparticle Research

A. I. Jensen[1], A. F. Frellsen[1], A. E. Hansen[2], R. I. Jølck[3], G. W. Severin[1], S. Tietze[1], P. Kempen[3], P. H. Rasmussen[1], A. Kjær[2], T. L. Andresen[3]; [1]Center for Nuclear Technologies (DTU Nutech), Technical University of Denmark, Roskilde, DENMARK, [2]Nuclear Medicine & PET and Cluster for Molecular Imaging, University of Copenhagen, Copenhagen, DENMARK, [3]DTU Nanotech, Center for Nanomedicine & Theranostics, Technical University of Denmark, Lyngby, DENMARK.

^{64}Cu is a popular radionuclide for PET imaging and when $^{64}Cu^{2+}$ is mixed with gold nanoparticles (AuNPs) it adheres to the gold surface. Taking advantage of this, we developed methods to trap the ^{64}Cu within the AuNPs by embedding under additional layers of gold. This resulted in radiolabeling efficiencies around 53 ± 6%. EDTA challenge for two days revealed the embedded ^{64}Cu to possess excellent stability with 94-98% of the radioactivity remaining associated with the AuNPs. Testing for two days against serum likewise showed no loss of ^{64}Cu from the ^{64}Cu-AuNPs. Accordingly, the technology was shown to yield a very stable radiolabel that can accurately trace AuNPs *in vivo*. Such chelator-free radiolabeling removes traditional concerns over the use of chelators for ^{64}Cu, notably instabilities of chelators, such as DOTA, and their ability to alter the surface and thus the biodistribution of the compounds onto which they are attached. Radiolabeled ^{64}Cu-AuNPs were prepared in biomedically relevant sizes of 20-30 nm and decorated with three different coatings, in order to investigate their *in vivo* performance by PET imaging in a murine xenograft model. We found the longest plasma half-life ($T_{½}$ about 9 hours) to result from a polyethylene glycol (PEG) coating, while faster elimination from the bloodstream was observed for both a Tween-20 stabilized coating and a zwitterionic coating based on sulfonic acids and quaternary amines. Accordingly, our data concluded the PEG coating to be most benefical for long circulation *in vivo*. In the *in vivo* model, the ^{64}Cu was observed to closely follow the AuNPs for each coating, again attributing to the excellent stability of the radiolabel. Further, ^{64}Cu-AuNPs were prepared in three different sizes ranging from 30 to 70 nm and injected intravenously (I.V.) or intratumorally (I.T.) in murine xenograft models, either coated with PEG or stabilized by citrate (only 30 nm). In the I.T. experiments, citrate-stabilized ^{64}Cu-AuNPs were retained best in the tumors with about 100 %ID/g after 24 hours. For the PEG-coated ^{64}Cu-AuNPs, a tendency for increased retention as larger particles were injected was observed (30 nm: ~ 30 %ID/g, 70 nm: ~ 60%ID/g). In the I.V. experiments, the opposite tendency was observed, with smaller particles showing higher tumor accumulation and citrate-stabilized ^{64}Cu-AuNPs being rapidly taken up in liver and spleen. Our

group continues work with embedding of radionuclides in solid nanoparticles and further results will be presented as available.

EP837

Production of [^{18}F]F-Py-TFP as a secondary labelling precursor on a cassette based synthesis unit towards a GMP-compliant and convenient fluoroarylation of [^{18}F]-peptides and [^{18}F]-peptidomimetics

O. C. Neels, Y. Remde, M. Schäfer, D. Burkert, K. Kopka, J. Cardinale; German Cancer Research Center, Heidelberg, GERMANY.

Aim: The synthesis and purification of prosthetic groups for the radiofluorination of peptides are sophisticated and therefore difficult to translate into routine production. The aim is to transfer the synthesis of [^{18}F]F-Py-TFP (6-[^{18}F]fluoronicotinic acid 2,3,5,6-tetrafluorophenyl ester) as reported by Olberg *et al.* onto a cassette-based radiosynthesizer for large-scale GMP-compliant automated production ready for subsequent labelling of peptides. Materials and Methods: An aqueous solution containing [^{18}F]fluoride was obtained by nuclear reaction (^{18}O(p,n)^{18}F) from a Scanditronix MC32NI cyclotron, transferred to a Trasis All in One synthesis module, trapped on and eluted from a QMA cartridge using TBA-HCO_3 in water and acetonitrile as the eluent. After azeotropic drying, 10 mg of precursor *N,N,N*-trimethyl-5-((2,3,5,6-tetrafluorophenoxy)-carbonyl)pyridin-2-aminium trifluoromethanesulfonate in 1.2 mL tert.-BuOH and 0.3 mL acetonitrile was added and heated. The reaction mixture was cooled down to room temperature and diluted with 5 mL of water. The crude mixture was trapped on a pre-conditioned Oasis MCX SPE cartridge and rinsed with 10 mL of water. Impurities were removed from the cartridge using the first fraction of acetonitrile. [^{18}F]F-Py-TFP was obtained by further elution with acetonitrile and dried using a Sep-Pak Dry Sodium Sulfate cartridge. [^{18}F]F-Py-TFP was then used to label the novel PSMA-ligand PSMA-1007 in a mixture of DMSO, acetonitrile and *N,N*-diisopropylethylamine at elevated temperature. The radiolabelled peptidomimetic was purified by HPLC and diluted with PBS buffer and sterile-filtered. Results and Conclusion: The secondary labelling precursor [^{18}F]F-Py-TPF was obtained within 30 minutes in dry acetonitrile and radiochemical yields higher than 25% (d.c.) on an automated cassette based synthesis module. The radiochemical purity of the product after simple cartridge extraction was sufficiently high and further investigations on the major impurity resulting from hydrolysis are in progress. Nevertheless, [^{18}F]F-Py-TPF was used on the same radiosynthesizer for direct radiolabeling of a wide range of peptides including the novel small PSMA-ligand PSMA-1007 which was obtained in high radiochemical purity. Hence, this fully automated procedure represents a step forward towards the GMP-compliant production of promising F-18 labelled peptides and peptidomimetics.

EP838

In vitro and in vivo evaluation of ^{18}F-Labelled Chitosan-Based Nanoparticles to target folate receptor-positive tumor cells

A. LIMA OUBIÑA[1], J. SZABÓ[1], T. NAGY[1], G. TRENCSÉNYI[1], E. FAZEKAS[2], T. MIKLOVICZ[1], J. VARGA[1], J. BORBÉLY[2], P. MIKECZ[1]; [1]Nuclear Medicine Institute, DEBRECEN, HUNGARY, [2]BBS NanoTech, DEBRECEN, HUNGARY.

INTRODUCTION: Folate receptors (FR-α), are expressed on different epithelial malignant neoplasms, such as ovarian cancer, breast cancer, which represents a promising cell membrane-associated target for PET imaging of cancer. **AIM:** The purpose of this study was to label chitosan-based nanoparticles with F-18 via [^{18}F]-4-fluorobenzaldehyde ([^{18}F]-FBA) to target FR-α. These nanoparticles are composed of chitosan (polycation), and poly-γ-glutamic acid binding folic acid (polyanion, γ-PGA-FA) through 1-[3-(dimethylamino) propyl]-3-ethyl carbodiimide methiodide (EDC) technique. **METHODS**: Chitosan-Based Nanoparticles labelling was performed by direct reductive amination at 70°C during 30 minutes, reacting [^{18}F]-FBA, synthesized from 3-4mg 4-Formyl-N,N,N-Trimethylanilinium triflate in DMSO, in a 5 minutes reaction at 80°C, with the free amine group of the polymer in a first step. After that ^{18}F-labelled chitosan 0.3mg/mL was self-assembled with the γ-PGA-FA 0.3mg/mL by gelation process through ion-ion interaction. Purification of labelled nanoparticles was achieved using PD10-column. Dynamic Light Scattering (DLS) measurements were done to study nanoparticles size. Radiochemical conversion (RCC) as well as radiochemical purity (RCP) were determined by radio-TLC. A parallel assay was performed between labelled chitosan and labelled nanoparticles to study the specific cellular accumulation in three different cell lines: KB(positive FR-α), MDA-MB-231(negative FR-α) and 4T-1(negative FR-α). The labelled nanoparticles was evaluated *in vivo* in normal mice BALB/C by PET-MRI, adquisition at 80 minutes post-injection. **RESULTS:** ^{18}F-labelled chitosan RCC via [^{18}F]-FBA using direct reductive amination, was 79±9%. Nanoparticles labelling efficiency after purification no decay corrected was 16±8%. RCP 100% and nanoparticles size: 131±19nm. The *in vitro* studies showed non-specific binding, where ^{18}F-labelled chitosan as well as labelled nanoparticles presented similar profiles after 60 minutes of incubation: MDA-MB-231: 12±2% and 8±1%, and for 4T-1: 14±2% and 7±1% respectively. In regard to KB cells: ^{18}F-labelled chitosan 7±1% and 5±1% of injected dose for labelled nanoparticles. *In vivo* preliminary assay showed liver and spleen uptake with an unusual high renal cortical uptake after 80 minutes post-injection. **CONCLUSIONS:** ^{18}F-Labelling of Chitosan-Based Nanoparticles was performed successfully. Self-assembly between labelled chitosan and poly-γ-glutamic acid-Folic acid was confirmed by DLS, and nanoparticles were completely purified. Preliminary *in vitro* results showed unspecific binding to the FR-α. More biological studies are currently ongoing to achieve a clear conclusion about the behaviour ^{18}F-Chitosan-Based Nanoparticles to target folate receptor-positive tumor cells. **ACKNOWLEDGEMENTS**: This work was supported by FP7-PEOPLE-2012-ITN (316882 RADIOMI project).

Preliminary Biological Evaluation of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V as a Apoptosis Imaging Agent

C. Lu, Q. Jiang; Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Objectives: One novel Annexin V derivative (Cys-Annexin V) with a single cysteine residue at its C-terminal and site-specific labeling of it with thiol-reactive prosthetic group such as ^{18}F-N-[2-(4-Fluorobenzamido)ethyl]maleimide (^{18}F-FBEM) have been developed. However, the synthesis of 18F-FBEM-Cys-Annexin V was time consuming. To overcome this challenge, we developed a novel ^{18}F-AlF-NOTA-MAL-Cys-Annexin V as a apoptosis imaging agent, which has great potential for clinical translation. **Methods:** ^{18}F-AlF-NOTA-MAL was prepared as previously described using a semi-automatic method with some modification. ^{18}F-AlF-NOTA-MAL in 100μL(185-370MBq) of 10% acetonitrile was added to a solution of Cys-Annexin V (50-100μg in 100μL) PBS, and the mixture was allowed to react at room temperature for 30 min and then was purified by using a PD-10 column. The radiolabeling yield (RLY) and radiochemical purity (RCP) of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V were determined by high performance liquid chromatography (HPLC) with a TSK GEL column. In this study, eight male SD rats were divided into two groups, one group were treated with 10 mg/kg cycloheximide (CHX) to induce liver apoptosis and the other group were treated with saline as the control group. 3 h after the treatment, rats were injected via the tail vein with 0.2mL (7.4MBq) ^{18}F-AlF-NOTA-MAL- Cys-Annexin V. Ten-minute static scans were acquired at 1h after injection with a MicroPET, respectively. At the end of the scan the livers were harvested for terminal deoxynucleotide end-

labeling (TUNEL) staining. **Results:** The total synthesis time of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V from [^{18}F]fluoride was about 60 min, however that of ^{18}F-FBEM-Cys-Annexin V was over 2h. RLY and RCP of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V were over 78% and 95% (based on the starting ^{18}F-AlF-NOTA-MAL, non-decay corrected, n=5) respectively. HPLC retention time of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V was about 10.7 min with the flow rate was 1.0mL/min. In rat models of hepatic apoptosis there were 6.23±0.23 times (n=4) increase in hepatic uptake of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V as compared to normal mice at 1h p.i. TUNEL staining showed good correlation of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V uptake with TUNEL-positive cells. **Conclusions:** MicroPET studies combined with TUNEL staining showed that uptake of ^{18}F-AlF-NOTA-MAL-Cys-Annexin V correlates well with the level of apoptotic cells in this CHX induced liver apoptosis model. ^{18}F-AlF-NOTA-MAL-Cys-Annexin V is a potential apoptosis imaging agent and further study is needed. **Research Support:** Supported by Natural Science Foundation of Jiangsu Province (no.BK20151119) and Ministry of Health Foundation of China (W201207).

EP840

Fast Production of [^{11}C]Metomidate using Solid Phase Extraction Purification

E. Arponen, S. Helin, S. Forsback, P. Lehikoinen; Turku PET Centre, Turku, FINLAND.

Aim The objective of this work was to develop a rapid solid phase extraction (SPE) purification method for [^{11}C]metomidate and to validate the synthesis for clinical use according to GMP regulations at Turku PET Centre. Metomidate is an inhibitor of 11β-hydroxylase, a key enzyme in the biosynthesis of cortisol and aldosterone by the adrenal cortex. [^{11}C]Metomidate (O-[methyl-^{11}C]-(R)-1-(1-phenylethyl)-1H-imidazole-5-carboxylic acid methyl ester) is used for PET imaging of the adrenal cortex and its tumours. **Materials and methods** [^{11}C]Metomidate production was done using a commercial GE Tracerlab $FX_{C\text{-}Pro}$ synthesizer placed in a validated clean room hot cell. [^{11}C]Metomidate was synthesized by ^{11}C-methylation of the desethyl-etomidate precursor with [^{11}C]methyl triflate prepared from cyclotron-produced [^{11}C]carbon dioxide. [^{11}C]Carbon dioxide was first converted to [^{11}C]methane. [^{11}C]Methyl iodide was synthesized from [^{11}C]methane and iodine in a gas phase reaction at 720 °C. [^{11}C]Methyl triflate was prepared online by passing [^{11}C]methyl iodide through a silver triflate/graphitized carbon column at 200 °C and bubbled into the reaction solution containing the precursor for metomidate. The reaction solution was diluted with 10% ethanol in sterile water and transferred through the SPE cartridge (Waters, Sep-pak C18 light), which retained the [^{11}C]metomidate fraction. The cartridge was then washed with 10% ethanol in sterile water. [^{11}C]Metomidate was eluted from the SPE cartridge with ethanol and formulated in ethanol/propylene glycol/0.1 M phosphate buffer (10/15/85). Finally, the product solution was filtered through a sterile non-pyrogenic single use syringe filter into a sterile vial. The filter integrity was assessed as a part of sterile filtration using a pressure hold test. **Results and Conclusion** An efficient and robust routine procedure for the production of [^{11}C]metomidate was developed using Tracerlab $FX_{C\text{-}Pro}$ module and SPE purification. The average synthesis time was 20 minutes including purification, formulation and online sterile filter integrity test. [^{11}C]Metomidate was purified by a SPE cartridge. The dilution of the reaction mixture and washing eluent for the cartridge were optimized to separate the precursor and other major chemical and radiochemical impurities from the end product. The SPE recovery yield for [^{11}C]metomidate was >95%. The identity, radiochemical purity and concentrations of the end product and desethyl-etomidate were determined using a validated analytical HPLC method. [^{11}C]Metomidate was obtained in high radiochemical yield, sufficiently for several clinical doses. The radiochemical purity exceeded 99% in all syntheses.

EP841

Automated synthesis of 4-[^{18}F]fluoroanisole, [^{18}F]DAA1106 and 4-[^{18}F]FPhe using Cu-mediated radiofluorination under "minimalist" conditions

J. Zischler[1,2,3], P. Krapf[1,2,3], R. Richarz[1,2,3], B. D. Zlatopolsky[2,3], B. Neumaier[1,2,3]; [1]Forschungszentrum Jülich, Jülich, GERMANY, [2]University Clinic Cologne, Cologne, GERMANY, [3]Max Plack Institute for Metabolism Research, Cologne, GERMANY.

The growing clinical impact of PET imaging result in the increasing demand of large-scale cGMP-compliant syntheses of various PET-tracers in a safe and reproducible manner. Therefore, the novel preparation procedures have to be transferred to automated synthesis modules in order to be applied for the production of the clinically relevant probes. Recently, we showed that the Cu-mediated radiofluorination of (mesityl)aryl iodonium salts under "minimalist" conditions enables the operationally simple and rapid production of various radiofluorinated arenes. The aim of this work was to study amenability of this radiolabeling procedure to automation in commercially available synthesis modules and, consequently, its suitability for clinical PET applications. All radiosyntheses were carried out in a Scintomics hotbox^{three} module (Scintomics GmbH, Fürstenfeldbruck, Germany). [^{18}F]Fluoride was traped on a QMA cartridge and eluted with the corresponding iodonium salt precursor dissolved in MeOH. Afterwards MeOH was removed and $(MeCN)_4CuOTf$ in DMF was added and the resulting mixture was heated at 85 °C for 20 min. The radiolabeled products were isolated by SPE or HPLC. In the case of 4-[^{18}F]Phe the *N*,*O*-protected intermediate, Boc-4-[^{18}F]FPhe-OMe was hydrolyzed with 12 M HCl at 140 °C for 10 min to give the desired PET-tracer. Under optimized reaction conditions 4-[^{18}F]fluoroanisole, 4-[^{18}F]FPhe and [^{18}F]DAA1106 were prepared in isolated radiochemical yields of 41-61% and radiochemical purities of > 95% within 30-60 min. 4-[^{18}F]FPhe and [^{18}F]DAA1106 could be purified by RP-SPE avoiding any HPLC purification steps. We have demonstrated that Cu-mediated nucleophilic aromatic radiofluorination under "minimalist" conditions can be easily transferred to a commercially available synthesis module. The utility of the developed procedure was confirmed by a successful preparation of [^{18}F]DAA1106 and 4-[^{18}F]FPhe in good RCYs and excellent RCPs. The evident simplicity as well as the high efficacy and versatility of the developed protocol enable a broad application of Cu-mediated radiofluorination in PET-chemistry in the very near future.

EP842

S-[^{18}F]THK-5117 production implementation at Turku PET Centre

J. Rokka, J. Uotinen, T. Saarinen, E. Kokkomäki, O. Solin; Turku PET Centre, University of Turku, Turku, FINLAND.

Aim The purpose of this work was to implement and validate the synthesis of *S*-[^{18}F]THK-5117 for clinical use according to GMP regulations at Turku PET Centre (TPC). *S*-[^{18}F]THK-5117 is an arylquinoline derivative developed for tau PET imaging of Alzheimer's disease (AD). This tracer binds specifically to tau aggregates and has fast washout from the healthy brain, and longitudinal PET studies have shown that *S*-[^{18}F]THK-5117 binding is significantly higher in the AD patient brain compared to healthy controls [Okamura et al., 2013, Ishiki et al., 2015]. **Material and methods** *S*-[^{18}F]THK-5117 was synthesized using a two-step reaction. First, the precursor was ^{18}F-fluorinated using nucleophilic ^{18}F-fluorination, and then the protecting group was hydrolyzed. During the implementation, the amount of reagents, reaction temperature, and time for ^{18}F-fluorination and hydrolysis were optimized. The final product was separated from the reaction mixture by semi-preparative HPLC. The HPLC eluent containing the end-product fraction was removed by solid-phase extraction (SPE). HPLC and SPE eluents were adjusted to avoid

radiolysis and separate major chemical impurities. Finally, the end product was eluted from the SPE cartridge using ethanol and formulated in a 0.1 M phosphate-buffered solution (pH 7.4). The formulated product was sterile filtered using an in-house-built sterile filtration unit. *S*-[^{18}F]THK-5117 synthesis was performed using a validated, in-house-built, remote-controlled device in a validated clean room hot cell. The device is fully automated and has a validated program to perform the synthesis from start to finish. The operator can intervene in the synthesis using the pause/continue and skip buttons. GM tubes are used to monitor the radioactivity during the synthesis steps. **Results and Conclusions** *S*-[^{18}F]THK-5117 has been implemented and validated at TPC. By diminishing the amount of precursor, we can lower the chemical impurity of the final product without compromising the radiochemical yield of *S*-[^{18}F]THK-5117. The radiochemical yield of *S*-[^{18}F]THK-5117 is 19 ± 8%, specific activity is >1 TBq/μmol, radiochemical purity is >99%, and chemical purity is <0.3 μg/ml. *S*-[^{18}F]THK-5117 is currently in clinical use at TPC. This work received funding from the Academy of Finland (project 266891). We acknowledge Professor Okamura from Tohoku University for providing the precursor and reference compounds and for his knowledge and help in this implementation. EP844

A fluorine-18 radiolabelled celecoxib-based PET probe for cyclooxygenase-2 monitoring - COX-2 affinity, radiosynthesis and in vitro studies

T. Kniess, N. Bechmann, J. Steinbach, J. Pietzsch; Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY.

Aim: Cyclooxygenase-2 is an inducible enzyme overexpressed in inflammatory conditions and is assumed to play a key role in carcinogenesis. Functional imaging of COX-2 with PET is a challenging approach e.g., for monitoring tumours with COX-2 expression and for characterization of inflammatory response in radiotherapy. Celecoxib is an established COX-2 inhibitor and a successful imaging of inflamed tissue was demonstrated using a celecoxib-based radiotracer [^{18}F]1 (IC_{50} COX-2 = 160 nM) having an aminosulfonyl group [1]. Since the aminosulfonyl functionality is known to cause slow blood clearance *in vivo* [2] we developed a [^{18}F]fluoromethyl-substituted celecoxib analogue [^{18}F]2, characterized by a methylsulfonyl moiety. **Materials and methods** Two fluoromethyl-substituted diaryl-1*H*-pyrazoles with an aminosulfonyl 1 and a methylsulfonyl moiety 2 were synthesized, and their COX-2 affinity was determined by a fluorescence-based assay. The appropriate tosylated precursor for fluorine-18 radiolabelling was received by a four-step synthesis sequence starting from 4-methyl-acetophenone. The radiotracer 3-([^{18}F]fluoromethyl)-5-(4-methylphenyl)-1-[4-(methylsulfonyl)phenyl]-1*H*-pyrazole [^{18}F]2 was obtained by nucleophilic [^{18}F]fluoride substitution of the tosyl-precursor ([^{18}F]KF/K_{222}/MeCN, 10 min, 110°C) using an automated synthesiser module $Tracerlab_{FXN}$ (GE) and purified by semi-preparative HPLC. In preliminary *in vitro* studies [^{18}F]2 was evaluated using pro-inflammatory stimulated human monocyte (THP-1) and COX expressing human melanoma cell lines (A2058, A375). **Results:** The *in vitro* COX assay of 1 and 2 revealed that submicromolar COX-2 inhibitory activity is preserved by replacing the aminosulfonyl function in 1 with a methylsulfonyl moiety in 2 (IC_{50} = 100 nM / 170 nM). The COX-1/COX-2 selectivity ratio was found to be <1000 and <590 for 1 and 2, respectively. Automated radiosynthesis and purification yielded [^{18}F]2 in 27-37% RCY (uncorrected, n=7) in >95% radiochemical and 88% chemical purity within 55 min overall synthesis time in a specific activity of 41-70 GBq/μmol at end of synthesis. The uptake of [^{18}F]2 *in vitro* could be substantially blocked by both the reference 2 and by celecoxib, but was not shown to be correlated with varying cellular levels of COX-2 protein. **Conclusion:** A new [^{18}F]fluoromethyl-substituted analogue of celecoxib [^{18}F]2 with submicromolar affinity to COX-2 was synthesized in good radiochemical yield and high purity. Cellular studies demonstrated an uptake and blocking of the radiotracer in COX expressing human melanoma cells. The pharmacological behaviour of [^{18}F]2 *in vivo* regarding blood clearance and metabolic stability (^{18}F-defluorination) have to be evaluated. [1] Uddin J., et al. Cancer Prev. Res. 4, (2011), 1536 [2] Kuge Y., et al. Nucl. Med. Biol. 33, (2006), 21

EP845

Synthesis and In Vitro Evaluation of ^{18}F Radiolabeled AMO Targeting Tumor Overexpressed miRNA-155

L. Kang[1], Y. Huo[1], R. Wang[1], X. Xu[2]; [1]Peking University First Hospital, Beijing, CHINA, [2]Academy of Military Medical Sciences, Beijing, CHINA.

Objective: MicroRNA-155 (miR-155) is first found frequently up-regulated in various malignant tumors and is reported as an oncogene biomarker. Antisense oligonucleotides have been used for effective target recognization and gene therapy studies. We previously labeled anti-miR-155 oligonucleotide (AMO-155) with ^{99m}Tc for in vivo visualization. PET imaging based on fluorine-18 gained high interest due to the favorable nuclear and physical characteristics of ^{18}F. Therefore, we explored the optimized methods in the preparation of ^{18}F radiolabeled AMO-155 with further in vitro evaluation. Methods: AMO-155 with chemical and structural modifications was designed and synthesized. This probe was radiolabelled with ^{18}F using a direct Al^{18}F labeling method. After conjugated with NOTA via an amine linker of NH2 and six barbon, AMO-155 was successfully chelated with Al^{18}F. Different reaction conditions were evaluated by HPLC for optimization. The product was identified by gel electrophoresis and gel imaging. Its serum stability and cellular uptake in MCF-7 cells were evaluated. Results: AMO-155 was synthesized with partial 2′-OMe and PS modification to improve its stability. Increasing the temperature in conjugation could improve the conjugated yield from 15% to 47%. After purification with HPLC, the conjugated product was labeled with ^{18}F using Al^{18}F method. The labeling is typically done at 100 °C for 15 min and the labeling efficiency reached to nearly 98%. Therefore, there is no need for further purification for labeled product. However, the labeling efficiency was only 35% when no purification was performed on NOTA conjugated AMO. The radiochemical purity of ^{18}F-AMO in fresh human serum at 37 °C could maintain more than 95% during 6 h. The gel electrophoresis result showed that the location of radioactivity, which was imaged by micro-PET, coincided with the position of the AMO band and there was no degradation. The cellular uptake of ^{18}F-AMO increased from 9% to 57% during the incubation of 6 h, whereas that of ^{18}F did not increase significantly. Conclusion: The labeling efficiency can be improved greatly with optimized conjugation and reaction conditions. Moreover, this ^{18}F labeled probe has a good serum stability and could be prepared easily and simply for in vivo imaging without further purification.

EP846

Simple and fully automatic production of [^{18}F]THK-5351 using All-in-One chemistry module

S. LEE[1], S. OH[1], E. CHO[1], D. CHO[1], S. FURUMOTO[2], N. OKAMURA[2], J. KIM[1]; [1]ASAN Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Tohoku University, Sendai, JAPAN.

Objectives: THK series radiotracers which have aryl quinolone chemical structure are promising radiopharmaceutical for imaging of tau protein in Alzhemier's Disease. [^{18}F]THK-5351 is one of the THK series compounds with pure S-enantiomer. It has faster pharmacokinetics, higher contrast, and lower retention in subcortical white matter than previous

THK series compound such as [^{18}F]THK-5117. The purpose of our study was to develop the fully automatic preparation procedure with disposable cassette type chemistry module to have clinical feasibility. **Methods**: After trapping of 71.1±11.1 GBq of [^{18}F]F$^-$ on QMA cartridge, we eluted it with KOMs (pH 7.8)/K_{222} mixture as elution buffer and base. After completely drying, [^{18}F]fluorination was performed with 3 mg of precursor dissolved in 1000 μL of DMSO at 110°C for 10 min. After hydrolysis with 1 N HCl and neutralization with 0.8M AcOK, crude [^{18}F]THK-5351 was trapped on the C_{18} cartridge and then the C_{18} cartridge was washed using distlled water to remove reaction solvent. Trapped [^{18}F]THK-5351 was eluted from the C_{18} cartridge with 60% ethanol and purified with HPLC. Isolated [^{18}F]THK-5351 was trapped in 2nd C_{18} cartridge to remove HPLC solvent and formulated with EtOH and ascorbic acid solution. Optimized reaction and purification condition were applied to All-in-One chemistry module (Trasis). **Results**: KOMs(pH 7.8)/K_{222} and DMSO showed good [^{18}F]-incorporation yield as > 60%. 34.3±5.5% (n=9) of non-decay corrected radiochemical yield was obtained with All-in-One chemistry module after complete synthesis. Total synthesis time including HPLC purification and formulation was 75±5 min. Radiochemical purity and specific activity were 99.9±0.2% and > 74GBq/μmol, respectively. **Conclusion**: We developed fully automatic synthesis method with disposable cassette for routine production of [^{18}F]THK-5351. Our method showed high radiochemical yield with high reproducibility and [^{18}F]THK-5351 could be used to clinical trial.

EP847

Fully automatic production of [^{18}F]FP-CIT with new chemistry including SPE purification

S. LEE[1], E. CHO[1], D. KIM[1], H. LEE[2], D. MOON[1], J. KIM[1], S. OH[1]; [1]ASAN Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Duchemio, Seoul, KOREA, REPUBLIC OF.

Objectives: [^{18}F]FP-CIT(fluoropropyl-carbomethoxyiodophenyl-nortropane) is a widely used radiopharmaceutical for dopamine transporter imaging in Korea. In our previous reports, we optimized production condition using protic solvent such as *t*-amyl alcohol and base for [^{18}F]fluorination step. The *t*-amyl alcohol is efficient reaction solvent for production of [^{18}F]FP-CIT but *t*-amyl alcohol does not mix with water and it is drawback for purification such as SPE purification. The purpose of our study was to develop the SPE purification method of [^{18}F]FP-CIT using All-in-One chemistry module from Trasis company. **Methods:** [^{18}F]Fluoride trapped on QMA was eluted with KOMs solution (pH=7.8) instead of inorganic base such as K_2CO_3, $KHCO_3$. After evaporation of water, precursor (N-[3'-(mesyloxy)propyl]-2β-carbomethoxy-3β -(4'-iodophenyl)nortropane dissolved in 0.1 mL of CH_3CN and 1-methoxy-2-methyl-2-propanol was added. [^{18}F]Fluorination was conducted at 100°C for 10 min. After fluorination, the crude mixture of [^{18}F]FP-CIT was diluted with 20 mL of water without reaction solvent drying and passed through the C18 cartridges for trapping of the [^{18}F]FP-CIT. After washing the C18 cartridge to remove the polar impurities, eluted it with EtOH solution passed through anion exchange cartridge (CM, WAX and MAX) to remove the organic impurities which have plus charge. Crude mixtures, waste solution, and final product were completely analyzed using HPLC to check the all amount of chemical impurities. Optimized reaction and purification condition were applied to All-in-One chemistry module from Trasis company. **Results:** After [^{18}F]fluorination, 28.7±2.9% (n=7) of starting activity was trapped in the C18 cartridge and after SPE purification, non-decay corrected radiochemical yield was 16.3 ±4.9% (n=3). Total synthesis time including SPE purification was 45±5 min. In the crude mixture, main organic impurity was the precursor and 93.8% of precursor was remained after [^{18}F]fluorination. After purification with anion exchange cartridge (CM WAX and MAX), 2.7%, 7.6% and 0.92% of precursor was detected, respectively. Radiochemical purity was > 98% and the amount of residual precursor was 5.5~46.5 ppm. **Conclusion:** We developed new automatic production method of [^{18}F]FP-CIT with new reaction solvent and SPE purification method. Our disposable cassette including SPE purification showed short preparation time and reasonable radiochemical yield without production failure.

EP848

Radiofluorination and characterization of a novel hybrid peptide analogs based on mucin and folic acid as potential breast/ovarian cancers PET imaging agent

I. Aljammaz, B. Al-Otaibi, S. Bin Amer, A. Abousekhrah, S. Okarvi; King Faisal Specialist Hospital and Research Centre, Riyadh, SAUDI ARABIA.

Epithelial mucin (MUC1) and folic acid (FA) are overexpressed by most epithelial cancers hence attracting increasing interest as potential targets for imaging and therapy. The high expression of MUC1 and FA on breast and ovarian cancers and low expression on normal tissues makes them potential targets for diagnosis and therapy of cancers. To develop an efficient ^{18}F-labeled radiopharmaceutical with enhanced breast/ovarian cancer targeting capacity we have designed and synthesized a novel MUC1-derived peptide and also conjugated MUC1 to FA in order to formulate MUC1-FA hybrid peptide conjugate for targeting MUC1/FA receptors. MUC1 and hybrid MUC1-FA were prepared by solid-phase synthesis following Fmoc/HBTU method. FA was attached to MUC1 via terminal Lys by manual conjugation. The synthetic approaches for radiofluorination of MUC1 and MUC1-FA entailed a one-step reaction through the primary amine of the Lys residues. The key precursors 4-N,N,N-trimethylammonium benzoate-MUC1 and MUC1-FA triflates were treated using catalyzed nucleophilic no-carrier-added ^{18}F in ACN at 80°C for 5 min. The radiofluorinated conjugates were purified by C18 Sep-Pak column. *In vitro* receptor binding was performed on T47D, MCF7 and KB cell lines and biological evaluation was done in normal and mice bearing MCF7 and KB cells xenografts. The structure and purity of conjugates were confirmed by mass spectrometry and HPLC. As determined by HPLC, the radiofluorination efficiency of these radioconjugates were >70% and radiochemical purities always >95% in less than 30 min. These synthetic approaches hold considerable promise as a rapid and efficient method amenable for automation for the radiofluorination of peptides with high radiochemical yield and short synthesis time. *In vitro* tests have shown that significant amount of the [^{18}F]-MUC1 and [^{18}F]-MUC1-FA associated with cancer cell fractions. *In vivo* characterization in normal mice revealed rapid blood clearance of hybrid [^{18}F]-MUC1-FA with excretion by both urinary and hepatobiliary pathways. Biodistribution of [^{18}F]-MUC1 and hybrid [^{18}F]-MUC1-FA in mice bearing KB and MCF7 xenografts demonstrated significant tumor uptakes (6% and 11%, respectively). These uptakes were blocked by excess co-injection of FA and MUC1 suggesting receptor-mediated process. *In vivo* imaging using animal PET/CT is in progress and will be reported. These results demonstrate that [^{18}F]-MUC1 and [^{18}F]-MUC1-FA may be useful as molecular probes for detecting and staging of breast and ovarian cancers and their metastasis as well as monitoring tumor response to treatment and deserves further evaluation.

EP849

I-124 labeled diblock-co-polymeric micelles based on PLGA-PEG for drug delivery system

S. Lee[1,2], J. Park[1], J. Lee[1,2], G. Kim[1,2], M. Hur[1], S. Yang[1], S. Kim[2]; [1]Korea Atomic Energy Research Institute, Jeongeup, KOREA, REPUBLIC OF, [2]Dongguk University, Gyeongju, KOREA, REPUBLIC OF.

Aim : We have developed folate conjugated biodegradable poly (lactide-co-glycolide)(PLGA) nanoparticles for targeted delivery by a modified solvent extraction/evaporation single emulsion method. The biodegradability and biocompatibility of PLGA have been approved by FDA. Polyethylene glycol(PEG) is used as the coupling agent in the composition of the systems, which bridges folate with PLGA to form a chain PLGA-PEG-Folate. Diblock-co-polymeric micells including I-124 labeled PLGA-PEG and folate conjugated PLGA-PEG was developed for the diagnosis of folate receptor overexpression in KB or CT-26 for drug delivery system. Material and Methods : Folate was conjugated with H_2N-PEG-NH_2 using a modified method described elsewhere. Folate was activated by EDC and NHS in the presence of pyridine. And final step was conjutaed PEG-folate with activated PLGA in DMSO. Another step PEG conjugated PLGA and labeling of radioisotope at I-124 in DMF. PLGA-PEG-folate was characterized by spectroscopic analysis method and mass spectrometry(FT-IR, ^{1}H-NMR and ^{13}C-NMR). Briefly, PLGA-PEG-^{124}I and PLGA-PEG-folate co-polymer were dissolved in ACN and vortexed as organic phase. And then, PLGA-PEG-^{124}I and PLGA-PEG-folate organic solution was slowly dropped into aqueous solution. To determine the lipophilicity test of PLGA-PEG-folate&^{124}I was dissolved in a mixture of saline and 1-octanol in the E.P tube. The in vitro stability test of PLGA-PEG-folate&^{124}I was measured by incubating a probe with human serum. The cellular uptake of PLGA-PEG-folate&^{124}I was evaluated using CT-26, KB and A549 cells. Results and Conclusions : The products were obtained in >65% radiochemical yields with a radiochemical purity of >91% as checked by radio-TLC. The partition coefficient (logP) was measured as -1.169, which is an indication of the hydrophilic nature of the agent. Cellular uptake values of PLGA-PEG-folate&^{124}I was KB, CT-26 and A549 cells over incubation periods of 15, 30, 60, 120 min and 12h(KB : 1.06 % at 15 min, 0.74 % at 30 min, 0.72 % at 60 min, 0.55 % at 120 min and 0.55 % at 12 h, CT-26 : 0.78 % at 15 min, 0.42 % at 30 min, 0.33 % at 60 min, 0.29 % at 120 min and 0.28 % at 12 h, A549 : 0.43 % at 15 min, 0.23 % at 30 min, 0.21 % at 60 min, 0.21 % at 120 min and 0.23 % at 12 h). The PLGA-PEG-Folate&^{124}I nanoparticles have greatly increased the folate receptor targeting efficiency and specificity. This study has reported their application in selective delivery of anticancer drug to the FR-overexpressed cancer cells.

Identification of the Precursor of [^{68}Ga]Ga PSMA-HBED-CC and Its Impurities by Mass Spectrometer

J. Laine[1], T. Lipponen[1], J. Parshintsev[2], G. Duporte[2], K. Bergström[1]; [1]HUS Medical Imaging Center, Helsinki University Central Hospital, Helsinki, FINLAND, [2]Laboratory of Analytical Chemistry, Department of Chemistry, University of Helsinki, Helsinki, FINLAND.

Aim Owing to its rapidly increasing clinical impact, we studied the stability of the precursor of [^{68}Ga]Ga-PSMA-HBED-CC (Ga-68 PSMA) and relevant aspects of its radiopharmaceutical production. During method development and validation, concern was raised since an impurity peak in a radio-HPLC chromatogram seemed to increase from synthesis to synthesis. The impurity was not detected when the precursor was diluted right before the synthesis, but it was more frequent and prominent the longer the precursor was diluted in water and stored in a freezer at -20°C before the synthesis. In this study, the precursor and the end product of Ga-68 PSMA were analyzed with radio-HPLC, and the precursor and its impurities were further identified with UHPLC-mass spectrometer. **Materials and methods** Ga-68 PSMA syntheses (n=20) were performed with a prepurification method using Eckert&Ziegler Pharmtracer and Ge-68/Ga-68 generator IGG100 or GalliaPharm. The PSMA-precursor was diluted in Trace select water (Fluka) 1 mg/ml and distributed to 20 µl quantities in Eppendorf tubes, after which it was stored in a freezer at -20°C. Chemical and radiochemical purity, including the ratio of the stereoisomers of the Ga-68 PSMA-product, was analyzed with a Shimadzu Prominence LC-20A HPLC-UV instrument coupled with a Bioscan FC-3200 flow count detector. The Ga-68 colloids and hydroxides of the product were analyzed with a TLC method. The identification of the PSMA precursor and its impurities were further studied with a Thermo Ultimate 3000 UHPLC coupled with an Orbitrap Fusion Tribrid mass spectrometer (UHPLC-MS). **Results** The radiochemical purity (HPLC x TLC) of Ga-68 PSMA was decreased close to the acceptance criteria (90%) and the area of the impurity peak, following the Ga-68 PSMA in the radio-HPLC chromatogram, was increased from 0% to 7% when PSMA was diluted in water and stored in a freezer over one month. In the UHPLC-MS analysis, the main impurity peak of the PSMA precursor was separated, and the analysis of tandem mass spectra revealed a slow carboxylation of HBED-chelate, most probably in its phenol groups. **Conclusions** PSMA-HBED, a precursor of Ga-68 PSMA synthesis, is not stable when diluted in water and stored in a freezer. To improve the radiochemical purity of the Ga-68 PSMA product, PSMA-HBED should be freshly diluted to the buffer immediately before the synthesis.

EP851

HPLC and TLC methods for analysis of [^{18}F]flumazenil and its metabolites from biological samples

K. Grafinger[1,2], **T. Keller**[1], A. Krzyczmonik[1], L. Pfeifer[3], F. R. Lopez-Picon[1,2], S. Forsback[1], O. Solin[1,4,5], V. Gouverneur[3], M. Haaparanta-Solin[1,2]; [1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]MediCity Research Laboratory, University of Turku, Turku, FINLAND, [3]Chemistry Research Laboratory, University of Oxford, Oxford, UNITED KINGDOM, [4]Accelerator Laboratory, Åbo Akademi University, Turku, FINLAND, [5]Department of Chemistry, University of Turku, Turku, FINLAND.

Aim: The radioligand [^{18}F]flumazenil binds specifically to the central benzodiazepine receptor site of the $GABA_A$ receptor. The aim of the study was to develop and compare radioHPLC and radioTLC methods for analysis of [^{18}F]flumazenil and its radioactive metabolites in plasma and brain homogenate of rats. Materials and methods: [^{18}F]Flumazenil was synthesized at the Turku PET Centre Radiopharmaceutical Chemistry Laboratory using copper-mediated nucleophilic [^{18}F]fluorination of a boronic ester [1,2]. Sprague Dawley rats (n=15) were anaesthetized and 15 ± 3 MBq of [^{18}F]flumazenil was injected into a tail vein. The rats were sacrificed at 5, 15, 30, 60, 90 min post injection. Cardiac blood samples were collected, centrifuged and plasma proteins were precipitated with acetonitrile. The brain samples were homogenized with the chromatographic mobile phase and centrifuged. The supernatants were analysed with both TLC combined with digital autoradiography (radioTLC), and HPLC combined with a radioactivity detector on the HPLC column outflow (radioHPLC). The amount of intact [^{18}F]flumazenil and its radioactive metabolites was analysed as % of total ^{18}F-radioactivity in the sample. Results: In plasma the amount of intact [^{18}F]flumazenil rapidly decreased. At 15 min after tracer injection the amount of [^{18}F]flumazenil in plasma was about 20%. Two major radioactive metabolites, one more polar and one less polar than [^{18}F]flumazenil were found in plasma. The radioactive metabolites were not identified. In brain no radioactive metabolites were observed at any time point. RadioTLC and radioHPLC analysis results were comparable for all samples. Conclusion: RadioHPLC and radioTLC methods were developed for analysis of [^{18}F]flumazenil and its radioactive metabolites in rat plasma and brain. Both methods are useful for the analysis of the [^{18}F]flumazenil metabolic profile. With the radioHPLC method, [^{18}F]flumazenil metabolites can be analysed with high resolution. RadioTLC enables analysis of multiple samples simultaneously and is preferred, when sample volumes are small and radioactivity concentrations are low. [68Ga] peptide high-output production on commercially available MiniAIO® synthesizer

C. COLLET[1,2], S. Remy[1,2], R. Didier[1,2], N. Véran[3], G. Karcher[1,2,3]; [1]Nancyclotep, Vandoeuvre-les-Nancy, FRANCE, [2]Université de Lorraine, Vandoeuvre-les-Nancy, FRANCE, [3]CHRU Nancy-Brabois, Vandoeuvre-les-Nancy, FRANCE.

Introduction: Gallium-68 is a metallic positron emitter with a half-life of 68 min that is ideal for labelling small peptides as radiopharmaceuticals thanks to the use of a chelating agent with several clinical applications. Numerous gallium-68 labelled peptides (eg. [^{68}Ga]DOTA-TOC/-NOC, [^{68}Ga]HBED-PSMA-11, [^{68}Ga]NODAGA-RGD) have shown their interest [1,2]. Developing an easy, rapid and performant labelling method is important. Different methods for the pre-purification of the generator eluate have been explored in the literature, although recent improvement on some generator brands (i.e. low ^{68}Ge breakthrough and low metallic impurities content), makes this pre-purification unnecessary. Development of a labelling process, GMP-compatible and reproducible, using a commercial synthesis module for every peptide labelling is a real challenge for the nuclear medicine. The method presented herein uses a cassette-based approach and a MiniAIO (mAIO, Trasis®) module and has been tested with the IGG100 ^{68}Ge/^{68}Ga generators. **Materials & Methods:** Preclinical IGG100 was used as ^{68}Ge/^{68}Ga generator. Precursors of radiolabelling were bought from ABX. Automated ^{68}Ga-labelling was performed without pre-purification in mAIO module. Reaction parameters such as sodium acetate concentration, precursor quantity, temperature and time were optimized for each peptide. Labelling efficiency was determined on Waters HPLC system. **Results**: DOTANOC, DOTATOC, HBED-PSMA-11 and NODAGA-RGD were tested for ^{68}Ga-labelling without pre-purification. Optimal and reproducible conditions were determined for each peptide. ^{68}Ga-peptides were synthesised with excellent incorporation yields, (90-99%) and high synthesis yields > 60% in less than 15 min. **Discussion/Conclusion:** We developed an efficient automated strategy for peptide labelling with gallium-68. [^{68}Ga]DOTANOC, DOTATOC, [^{68}Ga]HBED-PSMA-11, [^{68}Ga]NODAGA-RGD were obtained in high radiochemical yield. Their preparation could be performed with this automation and their use in human could be done under clinical trial. **References:** [1] Breeman W, de Blois E, Chan HS, *et al*. The Use of [^{18}F]Selectfluor bis(triflate) in Electrophilic Fluorination

S. Lahdenpohja[1], A. Kirjavainen[1], S. Forsback[1,2], O. Solin[1,2]; [1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]Department of Chemistry, University of Turku, Turku, FINLAND.

Aim Various aryl molecules can be labelled with reasonable reaction times and conditions only by electrophilic ^{18}F-fluorination. In electrophilic ^{18}F-labelling with [^{18}F]F_2-gas the major problems are low specific activity (SA) and possible formation of numerous by-products. Less reactive labelling reagents have been developed in order to better control the reactions. One novel "mild" ^{18}F-labelling reagent is [^{18}F]Selectfluor bis(triflate) ([^{18}F]SF). It has been successfully used in the synthesis of several radiotracers. **Materials and Methods** [^{18}F]SF was produced from [^{18}F]F^- produced [^{18}F]F_2 [1,2]. 6-[^{18}F]FDOPA, [^{18}F]NS12137 and [^{18}F]6-fluoro-marsanidine were produced by fluorodestannylation of suitable stannylated precursors [3-5]. ^{18}F-labelled ketones and allylic fluorides were produced by fluorodesilylation [1] and ^{18}F-labelled tri- and difluoromethylarenes by fluorodecarboxylation [6]. After ^{18}F-labelling, protecting groups were removed if needed and the obtained radiotracers were purified by HPLC. Total synthesis times were ~60 minutes. [^{18}F]NS12137 and [^{18}F]6-fluoro-marsanidine were evaluated in animals (*in vivo* with PET and *ex vivo* by autoradiography) [4,5]. **Results** [^{18}F]Aryl fluorides were obtained with >95 % radiochemical purity, radiochemical yields were 2 - 20 % and SAs were 1 - 6 GBq/μmol [1,3-5]. Additionally, the quality of 6-[^{18}F]FDOPA produced from [^{18}F]SF was comparable to the one produced for clinical use from [^{18}F]F_2. ^{18}F-labelled ketones and allylic fluorides were obtained with ~15 % radiochemical yields [1]. ^{18}F-labelled tri- and difluoromethylarenes were obtained with radiochemical yields up to 18 % and SAs up to 2,5 GBq/μmol [6]. **Conclusions** [^{18}F]SF is an excellent labelling reagent in electrophilic ^{18}F-fluorination. With [^{18}F]SF, it is possible to label tracers which could not be labelled selectively with [^{18}F]F_2. Work is ongoing in our laboratory to explore further [^{18}F]SF and its applicability in the preparation of clinically useful radiotracers. **Acknowledgments** This work was supported by the Academy of Finland (grant no. 266891). The most stable and fully automatic production of [^{18}F]FP-CIT using All-in-One chemistry module

S. LEE, E. CHO, D. KIM, J. KIM, S. OH; ASAN Medical Center, Seoul, KOREA, REPUBLIC OF.

Objectives: Radiolabeled FP-CIT(fluoropropyl-carbomethoxyiodophenyl-nor-tropane) is a widely used radiopharmaceutical for dopamine transporter imaging using SPECT or PET. The 1st full automatic production of [^{18}F]FP-CIT was developed in our group with non disposable cassette type chemistry module and used for clinical diagnosis of Parkinson's disease in Korea since 2008. In our previous reports, we optimized production condition using protic solvent such as *t*-amyl alcohol and base for [^{18}F]fluorination step. The purpose of our study was to develop the production method of [^{18}F]FP-CIT using disposable cassette with new reactor design with All-in-One chemistry module from Trasis company for routine clinical application. **Methods:** Two kinds of reaction vessel were applied into the disposable cassette design. One is conventional type (long recovery tube which was reached to reactor bottom, generally, type A) and new type has short recovery tube (type B). The recovery tube in type B reactor does not reach to reactor bottom and it has 0.5mm gap from the end of tube to the bottom. After trapping of 70~150 GBq of [^{18}F]F^- on QMA cartridge, we eluted it with KOMs (pH 7.8)/K_{222} mixture as elution buffer and base. After completely drying, [^{18}F]fluorination was performed with 4~8 mg of precursor dissolved in 100 μL of MeCN and 1000 μL of *t*-amyl alcohol at 100°C for 10 min. After fluorination, crude [^{18}F]FP-CIT was purified using semi prep HPLC isolated [^{18}F]FP-CIT was trapped in C_{18} cartridge and formulated with EtOH and ascorbic acid solution. Optimized reaction with new type reaction vessel was applied to All-in-One chemistry module from Trasis company. **Results**: Type A reaction vessel with 4 and 8 mg precursor showed 4.6±3.3% (n=7) and 18.9±5.0% (n=7) of non-decay corrected radiochemical yield, respectively. Type B reaction vessel with 4 and 8 mg precursor showed 15.5±4.4% (n=7) and 28.9±4.0% (n=7) of non-decay corrected radiochemical yield, respectively. New synthesis method with disposable cassette and type B reactor showed never synthesis failure. Total synthesis time including HPLC purification and formulation was 65

±5 min. Radiochemical purity and specific activity were 93.7±2.2% and > 74 GBq/μmol, respectively. **Conclusion:** We developed new type reaction vessel and fully automatic production method with disposable cassette and All-in-One chemistry module for [^{18}F]FP-CIT routine production. Our disposable cassette including new type reaction vessel showed high radiochemical yield as 28.9% without production failure.

Quality control procedure for [^{18}F]FECNT: A PET ligand for imaging of dopamine transporter (DAT)

J. Pijarowska-Kruszyna, A. Jaron, P. Garnuszek, R. Mikolajczak; National Center for Nuclear Research Radioisotope Center POLATOM, Otwock, POLAND.

Aim: Previously, we reported the rapid and efficient synthesis of 2β-carbomethoxy-3β-(4-chlorophenyl)-8-(2-[^{18}F]fluoroethyl)-nortropane ([^{18}F]FECNT), a dopamine transporter (DAT) ligand [1]. Prior to its administration to humans the appropriate quality testing needs to be performed. The aim of this work was to establish the quality specification and quality control methodology for the [^{18}F]FECNT final drug formulation, according to the Ph. Eur. and ICH requirements [2,3]. **Methods**: [^{18}F]FECNT was prepared by one-step automated synthesis from the chlorinated precursor as previously described [1]. The quality testing included: appearance (clarity, absence of color and particles; visually inspected), pH (4.5-8.5; indicator strip test), radionuclidic identity as an approximate half-life of ^{18}F (105-115 min; radioactivity measurement), radionuclidic purity (>99.5% of the observed γ-emission; gamma-ray spectrometry), radiochemical identity (comparison of [^{18}F]FECNT retention time with retention time of non-radioactive FECNT reference; HPLC), radiochemical purity (RCP ≥97% of [^{18}F]FECNT, ≤2% of [^{18}F]F$^-$ and ≤1% of α-isomer of [^{18}F]FECNT; HPLC), chemical purity as content of Kryptofix®2.2.2 (≤2.2 mg per maximum dose; spot test) and precursor (≤0.1 mg per maximum dose; HPLC), residual solvents (≤10% of ethanol, ≤0.04% of acetonitrile; GC), specific activity (≥37 GBq/μmol; HPLC), sterility (sterile; membrane filtration) and bacterial endotoxins (≤175 IU/mL; Gel-Clot). Selection of analytical methods and acceptance criteria for each parameter was based on the official guidelines [2, 3]. Radiochemical and chemical purity, radiochemical identity and specific activity were determined using the same HPLC method (Luna C18(2) column and mobile phase consisted of ethanol:water (57:43) pH=8, flow rate 1.0 mL/min, detection at 220 nm). **Results and Discussion:** Three batches of [^{18}F]FECNT were examined. All tested parameters met the acceptance criteria for drug release. The final [^{18}F]FECNT products were clear and colorless with pH 5-7. The radiochemical and radionuclidic identity were confirmed. The HPLC analyses demonstrated RCP of more than 99%. The preparation was free from the starting precursor (<0.1 mg) and undesired [^{18}F]FECNT α-isomer. The amounts of Kryptofix®2.2.2 and residual solvents were below acceptance limits. The specific activity of [^{18}F]FECNT at the EOS was 55 GBq/μmol. **Conclusions:** The quality specification for the radioactive preparation of [^{18}F]FECNT was established and testing performed according to it confirmed that product [^{18}F]FECNT was of proper quality and safe for application in human studies. **References**: [1] Pijarowska-Kruszyna J et al., [2016] J Label Comp. 68Ga radiolabeling of minigastrin analogues and automation for possible clinical use

M. Kroselj, A. Socan, P. Kolenc Peitl; University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Aim Targeting of receptors, overexpressed in different cancers, has an important diagnostic and therapeutic potential in Nuclear medicine. Successful story of somatostatin analogues lead to a development of many different radiolabeled regulatory peptides, including gastrin analogues. For targeting cholecystokinin-2 receptors different minigastrin (MG) analogues have been developed, mostly ^{111}In radiolabeled. ^{111}In radiolabeled PP11 or CP04 is currently in Phase 1 clinical study. In preclinical studies in Balb/C animal model it was shown that ^{68}Ga-labeled PP11 has favorable characteristics over ^{111}In-labeled radiopeptide for imaging of CCK2R positive tumours (*Roosenburg et al., 2014*). Recently, we showed that norleucin congeners have similar in vivo characteristics to oxidation prone methionin analogues, so they could be potentially used in clinic. In this study we aimed to develop a robust automated method for ^{68}Ga labeling of different MG analogues. *Methodology* 20μg of the MG analogues PP11 (CP04) and its Nle congener PP11B (DOTA-(D-Glu)$_6$-Ala-Tyr-Gly-Trp-Met/Nle-Asp-Phe-NH$_2$) and PP16B (DOTA-(D-Gln-D-Glu)$_3$-Ala-Tyr-Gly-Trp-Nle-Asp-Phe-NH$_2$) were used as a probes. ^{68}Ge/^{68}Ga generator (IGG100, EZAG) was eluted with 0.1M HCl. NaCl (Müller) method was used for prepurification and concentration of ^{68}Ga eluate. Reaction conditions such as buffers, pH range, radical scavenger, reaction temperature and time and volume of reaction solution were optimized for labelling MG analogues. Full automation of the processes was developed using self-shielded radiosynthesis box (MicroCell, EZAG). Quality testing of the final products was done. *Results* 500-650 μL of NaCl/HCl solution was needed to efficiently elute 300-400 MBq of ^{68}Ga from preloaded stron cation exchange column (Bond Elute SCX). Optimal pH of sodium acetate/HCl buffer for radiolabeling PP11 was 4.6 ±0.1 and for PP11B and PP16B 4.3±0.1. Heating for 5 minutes at 95°C was sufficient to get radiochemical yields over 90%. A fully automated synthesis was developed for NaCl method using SepPak purification and final MB filtration. Total synthesis time was 18 minutes with radiosynthesis yields >70% and final radiochemical purities of >95% for all peptides. ^{68}Ge contamination in the final product was not detected and all other quality tests (pH, ethanol content, filter integrity, endotoxin testing, sterility) passed. *Conclusion* Due to well know advantages of ^{68}Ga and potentially better in vivo characteristics we succesfully optimized 68Ga radiolabeling conditions for 3 minigastrin analogues and developed a fully automated robust procedure for a possible clinical use. Clinical studies comparing ^{68}Ga vs. ^{111}In radiolabeled analogues ones are needed to explore possible advantages of ^{68}Ga MG analogues over ^{111}In ones.

EP857

GMP Compliant Automated ^{18}F-Flumazenil Production using Chemically Resistant Single-Use Disposable Cassettes

P. Lam, M. Aistleitner, R. Eichinger, C. Artner; IASON GmbH, Graz, AUSTRIA.

Introduction Production of ^{18}F-flumazenil from 2-nitroflumazenil under GMP conditions is primarily performed with manipulators or custom built radiosynthesis modules with fixed components, as the use of *N,N*-dimethylformamide (DMF) at 160 °C prohibits the use of commonly available disposable cassettes. Cassettes for the GE TRACERlab MX$_{FDG}$ synthesis modules are commercially available in different materials, and it is known that most of the polymers used are not compatible with DMF. The aim of this work was to establish a robust automated radiosynthesis procedure for ^{18}F-flumazenil on the GE TRACERlab MX$_{FDG}$ with the appropriate cassette material, where staff previously trained on the same equipment can easily perform the radiosynthesis. **Materials & Methods** Fragments of the ABX FDG cassette and chemically resistant manifolds were exposed for 1 or 24 h to various solvents including DMF at room temperature (RT) or 60 °C to assess its chemical resistance. A new synthesis sequence was written for the GE TRACERlab MX$_{FDG}$. A non-radioactive test run was performed with

the ABX FDG cassette, and radiosynthesis was carried out with the cassette components replaced by chemically resistance manifolds (ABX). **Results** Incubation of the ABX FDG cassette fragments in acetonitrile at RT showed no macroscopic influence on the polymer while the fragment became soft and mouldable at 60 °C. Visible changes occurred after 1 h incubation with DMF, with the polymer having completely dissolved after 24 h, regardless of temperature. To verify the implication of these results on a 1 h radiosynthesis, a test run was performed using the same cassette material and synthesis conditions without radioactivity. Parts of the manifold was found to have cracked, and a valve blockade was observed due to polymer melting. On the other hand, chemically resistant manifold showed no changes in DMF for up to 24 h at 60 °C. Radiosynthesis was carried out with the manifolds replaced by chemically resistant ones, and ^{18}F-flumazenil was successfully obtained in 4 % decay corrected yield. **Conclusions** Disposable cassettes assembled with chemically resistant manifolds is a requirement for the automated synthesis of ^{18}F-flumazenil from 2-nitroflumazenil using the GE TRACERlab MX_{FDG} synthesis module. Neither reagent kits nor program sequences are hitherto commercially available, but automated GMP grade production of ^{18}F-flumazenil with single-use cassettes can nonetheless be successfully carried out with minor modifications on existing equipment.

Preparation of (^{18}F)FDOPA in a fully automated radiochemical synthesizer: a tertiary university hospital experience

H. PEHLIVANOGLU[1], E. Karayel[1], A. Aygün[1], R. Tutar[2], A. Kurt[1], M. Ocak[3], L. Kabasakal[1], K. Sönmezoğlu[1]; [1]Department of Nuclear Medicine,Cerrahpaşa Medical Faculty,ISTANBUL UNIVERSITY, ISTANBUL, TURKEY, [2]Department of Physicochemistry, Engineering Faculty,ISTANBUL UNIVERSITY, ISTANBUL, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty,ISTANBUL UNIVERSITY, ISTANBUL, TURKEY.

Introduction: 3,4-dihydroxy-6-18F-fluoro-L-phenylalanine (FDOPA) has proven to be a useful radiopharmaceutical for the evaluation of presynaptic dopaminergic function in central nervous system. FDOPA is also taken up into cell by aminoacid transporters (predominantly L-type), which are overexpressed in several types of cancer. Recently encouraging results with FDOPA PET imaging have been reported in neuroendocrine tumors particularly in medullary thyroid carcinomas and phaeochromocytomas. FDOPA can be synthesized either via electrophilic or nucleophilic substitution reaction methods. In comparison to electrophilic synthesis, the nucleophilic method has several advantages. Here we present our preliminary results of synthesizing FDOPA with nucleophilic method using a fully automated radiopharmaceutical synthesis device at Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul **Material and methods**: The radiosynthesis was performed by using a fully automated synthesizer (Trasis, all-in-one, Belgium). Automated synthesis of FDOPA is consisted of five synthetic steps: fluorination, reductive iodination, alkylation, hydrolysis and purification. Purification was performed using a reversed phase semi-preparative HPLC. Radiochemical purity of FDOPA was determined by RP-HPLC using sodium dihydrogen phosphate adjusted to pH 2.4 with solution of phosphoric acid. Enantiomeric purity was determined by RP-HPLC using perchloric acid pH 2. Residual solvents purity determined by GC. **Results:** Both radiochemical purity and enantiomeric excess are higher than 95%.The non-decay corrected yield of the system is %30 ± 3. Residual solvents excess are follows: N,N-Dimethylformamide < 880 ppm, Dichloromethane < 600 ppm, Methanol < 3000, ppm, and Ethanol < 5000 ppm. **Conclusion**: The synthetiser and described methods allow us a satisfactory automated preparation of FDOPA with desired QC parameters that is a suitable radiopharmaceutical for human use.

Nuclear Medicine Assessment in management of Patients with Atrial Fibrillation Treated with PUFAs

V. Sukhov, K. Zaplatnikov, V. Nikiforov, P. Kirichenko, A. Ismailov, S. Grishaev; Military Medical Academy, ST. PETERSBURG, RUSSIAN FEDERATION.

Objective. This study examined the effects of polyunsaturated fatty acids (PUFAs) on myocardial perfusion and metabolism in patients with atrial fibrillation (AF) using well known in clinical practice myocardial gated single photon emission computered tomography (G-SPECT) with 99mTc-tetrofosmine (TF) and 123I-beta-metyl-iod-phenyl-pentadecanoic acid (BMIPP) as in vivo methods for diagnostics of different heart diseases. Material and Methods. 56 male patients 45-69 y.o. with persistent AF treated with standard anti-ischemic and anti-arrhythmic agents (control group) were compared with 51 male patients 44-66 y.o. with AF I-II FC NYHA treated with standard anti-arrhythmic + PUFAs. All of them underwent standard clinical investigation, Bruce protocol ETT, EchoCG and rest/stress G-SPECT with 99mTc-TF and 123I-BMIPP. Both tracers SPECT data were analyzed with 17-segment model.Results. Definite regional abnormality of perfusion tracer uptake at rest/stress were concordant with metabolic defects at the same site. While comparing regions of repolarization disturbancies, shifted metabolism and decreased perfusion tracer uptake in 95 patients, 93% of them were considered match (di=0,615-0,998), 7% - mismatch (di=0,002-0,385). Though sensitivity in detecting of impaired repolarization by ECG and decreased 99mTc-TF/123I-BMIPP uptake regions by SPECT were 19.6% vs 87.1%./89.2%.Moreover, number of sectors with low 99mTc-tetrofosmine and/or 123I-BMIPP uptake (<70%) and with EchoCG signs of cardiac insufficiency, ECG abnormalities and decrease of tracers uptake were equal.Repeated gated SPECT studies after treatment with PUFAs showed increase of perfusion tracer uptake in previously altered sectors compared to patients treated with only standard therapeutic schemeConclusion. Metabolic activity and myocardial perfusion as shown by 123I-BMIPP and 99mTc-TFSPECT allow to perform adequate assessment of changing (decreasing) of myocardial metabolizm(i.e. levels of beta-oxydation in cardiomyocytes) that together with perfusion data can fully represent the state of heart tissue impairments in AF patients. Therefore, this method is feasible and highly informative for assessment of PUFAs effects during metabolic treatment and follow-up.

P012

Early and late follow-up myocardial perfusion scan in patients with breast cancer after external radiotherapy

M. Eftekhari[1], A. Emami-Ardekani[1], F. Kalantari[1], M. Abbasi[2], S. Farzanefar[2], A. Fard-Esfahani[1], B. Fallahi[1], D. Beiki[1], A. Hassanzadeh-Rad[1]; [1]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Nuclear Medicine, Vali-asr Hospital, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF.

Aim: Radiotherapy induced myocardial injury may increase cardiovascular morbidity and mortality especially in left sided breast cancer. To evaluate the prevalence of myocardial perfusion abnormalities following radiation therapy, in left and right-sided breast cancer patients, early and delay term myocardial perfusion imaging (MPI) findings were compared. Materials and Methods: Patients with low 10-year Framingham risk scoring of coronary artery disease were included in the study. Modified radical mastectomy and postoperative 3D Conformal Radiation Therapy (CRT) were considered as the standard treatment for all patients. The surgical bed with an additional 1-cm margin was selected to deliver 46-50 Gy (in 2 Gy daily fractions) over a 5-week course and the same dose-adjusted chemotherapy regimen (including anthracyclines, cyclophosphamide and taxol) was administered. Three years after radiation therapy, all patients underwent MPI for the evaluation of myocardial perfusion. These patients also have been evaluated for possible early adverse effects 6 months after radiotherapy. General linear model for repeated measures was designed to assess the ischemic changes over time. Results: Forty patients with a mean age of 46±7.1 years [20 patients with left sided breast cancer (exposed) and 20 patients with right-sided cancer (controls)] were enrolled. Dose-volume histogram (DVH) [showing the percentage of the heart exposed to >50% of radiation] was significantly higher in patients with left-sided breast cancer. The prevalence of ischemia showed significant changes between groups in follow-up study (P value=0.001). The extent of ischemia decreased from the baseline to the second study in right sided mastectomy group. Apex and anterolateral walls were the most common segments demonstrating significant perfusion abnormality in the early study, while only apical abnormality was more prevalent at the delayed study (P value<0.05). Conclusion: Radiation induced myocardial perfusion injury is not uncommon in patients with left hemi thorax radiotherapy. It is recommended to apply precise radiation planning techniques to minimize the volume of the heart in the field of radiation therapy. MPI-SPECT is a sensitive and non-invasive technique for early detection and proper management of potential myocardial abnormality in these patients following radiotherapy.

P013

Prediction of symptomatic cardiac toxicity in the patients who underwent chemoradiotherapy for esophageal cancer by myocardial fatty acid metabolic imaging using I-123 BMIPP SPECT/CT

K. Takanami, A. Arai, R. Umezawa, K. Jingu, K. Takase; Tohoku University Hospital, Sendai, JAPAN.

Aim: The aim of this study was to determine the value of myocardial fatty acid metabolic imaging by using I-123-labeled long-chain fatty acid analogue, 15-(p-iodophenyl)-3-(R,S)-methyl-pentadecanoic acid (BMIPP), and SPECT/CT in the prediction of symptomatic cardiac toxicity in the patients who underwent chemoradiotherapy (CRT) for esophageal cancer. Materials and methods: We included 36 patients (29 men, 7 women; mean age, 64.3 years) with no history of heart disease who had undergone CRT for esophageal cancer. They underwent I-123 BMIPP SPECT/CT at a median of 463 days after the completion of CRT and have been followed up. Myocardial I-123 BMIPP summed defect scores were semi-quantified using a 17-segment 5-point system (normal, 0; absent, 4). The patients' data including the cardiac toxicity measured by RTOG and CTCAE v4.0 criteria were extracted from a prospectively collected database. Cox proportional hazards regression analysis was applied to determine the independent predictors of symptomatic cardiac toxicity as an endpoint. Statistical significance was defined as $P < 0.05$. Results: During a median follow-up period of 1048 days after SPECT/CT, 6 (16.7%) of 36 patients were identified with symptomatic cardiac toxicity, including myocardial infarction (n = 2), angina pectoris (n = 1), hypotension due to pericardial effusion (n = 1) , and arrhythmia (n = 2). In the patients with symptomatic cardiac toxicity and the other patients, the median (interquatile range) of I-123 BMIPP summed defect score was 11 (6-14) and 6 (4-8), respectively, and that of the percentage volume of the left ventricle receiving 40 Gy or more was 16.6% (8.4% - 31.0%) and 20.5% (12.9% - 31.5%), respectively. Cox proportional hazards regression analysis showed that the most powerful predictor of symptomatic cardiac toxicity was I-123 BMIPP summed defect scores with hazard

ratio of 1.5 ($p < 0.05$). Conclusions: The results of this preliminary study indicate that myocardial fatty acid metabolic impairment found by I-123 BMIPP SPECT/CT may predict symptomatic cardiac toxicity in the patients who had undergone CRT for esophageal cancer.

Introducing a pre-reconstruction cardiac motion compensation technique in gated myocardial perfusion SPECT

N. Salehi[1,2], M. Farahani[2], E. Fatemizadeh[3], S. Farzanefar[4], **M. AY**[1,2]; [1]Department of medical physics and biomedical engineering,Tehran university of medical sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Electrical Engineering Department, Sharif University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Nuclear Medicine, Vali-Asr Hospital, School of Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: Cardiac contraction and respiratory movement are two main factors which degrade gated myocardial perfusion SPECT images quality by inducing image blurring and quantification inaccuracies. As images are acquired in different time frames and gamma photons recorded in each time frame is limited the reconstructed "low-count" images, have poor statistical image quality. Therefore motion compensated temporal processing can have a major impact on gated images quality. **Material and Method**: In this study , mathematical four-dimensional NURBS-based Cardiac-Torso phantom of two heart sizes (124 ml and 100 ml left ventricular cavities) were constructed for male and female body, respectively. SIMIND Monte Carlo simulation package was used to simulate a clinical Tc99-mibi perfusion SPECT acquisition protocol on the dual headed Philips (ADAC-forte) gamma camera (Philips Medical Systems, Cleveland, Ohio), with Low Energy High Resolution (LEHR) collimators ,32 projection data of phantoms were obtained for each gate. We have warped each frame with respect to end diastolic frame, using a 3D dimensional non-parametric diffeomorphic algorithm based on Thirion demon registration technique in MATLAB 2015. 4D sequence of motion compensated projections and original projection data were reconstructed using OSEM algorithm. Myocardial thickness and myocardium versus ventricle contrast were measured in original different image phases and motion compensated image phases. Quantitative study of Image sequences were conducted after importing image sequences to cardiac SPECT system's work station. Gated and summed image parameters were automatically derived and calculated on the basis of sex specific normal limits obtained from the same healthy population using standard Cedars-Sinai software. **Result**: The compensated images were less noisy. Compensated images has higher myocardium versus ventricle contrast than the corresponding summed images (18.63 vs. 14.89). Myocardial thickness between 8 phases were calculated, sum of squared difference between the wall thickness in end-systolic and end-diastolic phases were reduced from 0.44 to 0.16 after motion compensation. In QPS study original heart volume was 81 ml, 39 ml and the corresponding motion compensated volume was 92ml and 52 ml for male and female phantoms respectively. TPD (Total Perfusion Defect) was reported 11% and 31% for original male and female phantom images and the compensated data TPD was reported 9% and 28% respectively. **Conclusion:** Motion compensation increases image quality by increasing resolution and contrast and higher SNR is obtained due to summation of all morphed frames. It is highly recommended that with compensation we can improve defect detectability and diagnosis sensitivity.

P015

Comparison of phase dyssynchrony analysis among different software programs in patients with suspected or known coronary artery disease

S. Matsuo[1], K. Nakajima[1], K. Okuda[2], Y. Kunita[1], S. Kinuya[1]; [1]Kanazawa University, Kanazawa, JAPAN, [2]Kanazawa Medical University, Uchinada, JAPAN.

Cardiac dyssynchrony occurs during periods of post-stress myocardial ischemia. The feature of contractile discordance can be detected by phase analysis using gated myocardial perfusion SPECT (GMPS). Previous studies have shown that the histogram bandwidth (BW), phase standard deviation (SD) and phase entropy show good correlation with left ventricular (LV) dyssynchrony. In the evaluation of LV dyssynchrony, phase analysis of GMPS can be performed by commercially available different types of software. However, the comparison among programs has not been fully evaluated as yet. The aims of this study are to compare phase analysis parameters among software programs in patients with suspected or known coronary artery disease (CAD). Methods: Adenosine pharmacological stress myocardial perfusion imaging was performed in patients (n=20, aged 70.0 ± 10.1, male 65%) with suspected or known CAD, using ^{99m}Tc-agents by a 1-day protocol. LV mechanical dyssynchrony was evaluated using the quantitative gated-SPECT (QGS) software of Cedars Sinai Medical Center, the Emory Cardiac Tool Box (ECTB) of Emory University, and cardioREPO (cREPO). The stress and rest defect scores were determined automatically. Ischemia was defined to exist when perfusion defects on post-stress images were completely or partially corrected on rest images, and summed difference score was more than one. The histogram BW, phase SD and phase entropy were calculated. Results: The fair correlation among software programs was observed. Mean values ± SD of rest BW in QGS, cREPO and ECTB were 55.5 ± 47, 54.2 ± 31.8 and 46.3 ± 17.5, respectively. The values of phase SD in QGS, cREPO and ECTB were 11.0 ± 11.1, 13.7 ± 7.9, and 16.9 ± 7.8, respectively. Delta BW (stress BW-rest BW) and delta phase SD (stress phase SD-rest phase SD) in QGS, cREPO, ECTB were 5.9 ± 38.4, 13.6 ± 23.8 and 11.0 ± 41.3, respectively. There was a difference between phase entropy of cREPO and that of QGS (48.4 ± 11.1 vs. 34 ± 15.9, $p<0.01$). Delta phase SDs of ECTB and cREPO were significantly higher than that of QGS ($p<0.01$). The delta-SD of subjects with ischemia had higher than that without ischemia in cREPO ($p<0.05$). There were no difference in delta-SD between subjects with ischemia and without on QGS and ECTB. In conclusion, phase analysis parameters derived from GMPS in CAD patients depend on software programs and ischemic phase expression may differ in each program. The results of phase analysis cannot be interchangeably used in the same CAD patients.

P016

Relationship between Tc-99m MIBI GATED SPECT myocardial perfusion, quantified functional analysis, and dyssynchrony assessment in patients with left bundle branch block (LBBB) and no evidence of Ischemic heart disease-An approach to the real facts

G. A. VILLORIA[1], S. Rodado Marina[1], P. catalan[2], J. Castro-Beiras[2], B. Lorente[2], Y. RAMIREZ[1], L. Dominguez Gadea[1], M. Gomez[3]; [1]LA PAZ UNIVERSITY HOSPITAL, MADRID, SPAIN, [2]ramon y cajal UNIVERSITY HOSPITAL, MADRID, SPAIN, [3]RAMON Y CAJAL UNIVERSITY HOSPITAL, MADRID, SPAIN.

objectives: The left bundle branch block (LBBB) is associated with increased overall mortality, and poses a challenge for the diagnosis of ischemic heart disease. It is often associated with a perfusion defect at the septal region during exercise. We evidenced this as an artifact due to conduction disorder but does not correspond to an actual or structural abnormality or perfusion. Our objective was to evaluate Tc-99mMIBI

GATED myocardial perfusion SPECT (GMPS) in patients with LBBB with normal coronary arteries, and thus determine the relationship between perfusion and functional quantification data in order to determine the possible value of the latter to rule out ischemic heart disease. We have also included analysis of dyssynchrony of the left ventricle in these patients to evaluate the possibility to be suitable candidates for resynchronization therapy. Material and methods: We studied 31 patients (mean age 70+/-9; males: 22+/-2). They underwent stress test followed by a myocardial perfusion and function quantified study with Tc-99mMIBI GATED myocardial perfusion SPECT (GMPS) in the territory of the left anterior descending artery (ADA). The absence of coronary disease was established by coronary angiography, echocardiography or angioCT. LV dyssynchrony assessment in 12 patients with LBBB compared with 18 patients without evidence of conduction anomaly with software corridor 4DM. Results: The perfusion defect in stress was 38%+/-21 and the rest of 33%+/-18 percent of total infarction (p = NS). The endocardial thickening defect was 12% + / - 14 in stress, 7% + / - 12 in rest (P = 0.033). Contractility defect 13% +/- 15, and 4% +/- 15 at rest. The perfusion defect was greater than abnormal thickening and contractility (p = 0.000). LV Dyssynchrony assessment was obtained for normal patients, EF: 72+/- 7, showing a mean peak of 45.3 +/- 5.6, mean SD = 4.7 +/- 2, Patients with LBBB had an EF: 46.3+/-9, mean peak = 48.7 +/- 6.2 NS between groups, and mean SD 10.15 +/- = 3.2 with differences (P = 0.05). Conclusions: LBBB produces stress perfusion defects that may seem important in patients without evidence of heart disease. The perfusion defects also appear at rest. The size of the apparent defect is similar in stress and rest. Perfusion defects appeared in these patients were not related with thickening and contractility quantified values. LBBB patients have a degree of left ventricular dyssynchrony and dysfunction potentially significant for these patients.

P017

Assessment of Mechanical Dyssynchrony by Myocardial SPECT imaging is Predictor of Mortality in Congestive Heart Failure patients With Normal QRS Duration

S. T. BUTT; NORI, ISLAMABAD, PAKISTAN.

Researchers have assessed the prevalence of mechanical dyssynchrony in patients with CHF with normal QRS duration by echocardiography techniques such as tissue Doppler imaging. It is established now that mechanical dyssynchrony has some role in prognosis of congestive heart failure patients. In a developing country like Pakistan although echocardiography technique is widely available but lack of expertise in newer echocardiography techniques of dyssynchrony analysis such as TDI and Speckle tracking echo limits its use as predictor of future cardiac events.In comparison Myocardial SPECT imaging is not only widely available, its negligible interobserver variability can make it a valuable tool for assessment of myocardial dyssynchrony as a predictor of mortality and morbidity in CHF patients with normal QRS duration.Group A consisted of 50 patient with congestive heart failure with normal QRS complex who met the following criteria were retrospectively analyzed, Patients with NYHA function class II, III, IV for at least three months; bilateral pulmonary congestion on admission; and LV EF less than 35% and QRS duration more than or equal to120 ms at the time of presentation. Patients having Atrial fibrillation, significant structural valvular disease, cardiac or cerebral ischemic event within the previous three months, coexisting malignant disease, coronary revascularization during the study period and with age above 80 years were excluded. Group B comprised control group. A total 50 age and sex matched normal patients were assessed as control for calculation of normal values of standard deviation (SD) and histogram bandwidth (HBW) in our population. Dyssynchrony analysis was performed in patients and control group. Patients record was analyzed at 6 months follow up for cardiac events and mortality and it was correlated with SD and HBW in CHF patients with normal QRS complex. Detection of LV systolic dyssynchrony using Tc99m Myocardial SPECT was found an important independent predictor of clinical events and cause of mortality in CHF with normal QRS duration (significance value P less than 0.05) regardless of age, EF, QRS duration, etiology of CHF, and use of beta-blockers.

P018

Are echocardiography and radionuclide ventriculography reliable methods for left ventricle volume measurements? Significant underestimation of end-diastolic and end-systolic volumes of impaired left ventricle in 2D-echocaradiography and tomographic SPECT radionuclide ventriculography in comparison with cardiac magnetic resonance as the golden standard

W. Cytawa[1], M. Gruchala[1], K. Dorniak[1], R. Galaska[1], P. Lass[1,2]; [1]Medical University of Gdansk, Gdansk, POLAND, [2]University of Gdansk, Gdansk, POLAND.

Aim: The aim of the study was to compare left ventricle volumes in patients with impaired contractile function measured by 2D-echocardiography, tomographic (SPECT) radionuclide ventriculography and cardiac magnetic resonance. Materials and methods: We examined 31 patients (20 males, 11 females, aged from 26 to 82, mean age 54, standard deviation (SD) 14,7), with various cardiac conditions leading to impaired systolic function (dilated cardiomyopathy, segmental contractile dysfunction or contractile dyssynchrony due to LBBB). Every patient had 2D-echocardiography (Echo), SPECT radionuclide ventriculography and cardiac magnetic resonance (CMR) with volume measurements, performed within one week. Results: The linear correlations between end-diastolic volumes in Echo (Echo EDV) and SPECT EDV comparing to CMR EDV were high and significant, with r=0,90-0.91. The mean values, however, were significantly different: mean Echo EDV was 189.4 ±91.2ml (range=74-410), mean SPECT EDV was 164.1±80.8ml (range=41-349) and mean CMR EDV was 283.8±127.9ml (range=112-603). The mean differences between CMR EDV and other modalities were considerable and significant: CMR EDV vs. SPECT EDV mean diff.=119,77 and CMR EDV vs. Echo EDV mean diff.=94.39. BA limits of agreement between CMR EDV and SPECT EDV were 12.48 252.02, and between CMR EDV and Echo EDV -22.9 211.67. Similar discrepancies were observed in case of end-systolic volumes. Linear correlations were high and significant: r=0.93-0.94. The mean values: mean Echo ESV 140.3±89.6ml (range=27-364), mean SPECT ESV 124.1±76.8ml (range=16-297), mean CMR ESV 214.4±129ml (range=55-534). Mean differences were again considerable and significant: CMR ESV vs. SPECT ESV mean diff.=90.29, BA limits: -37.83 218.41; CMR ESV vs. ECHO ESV mean diff.=74.06, BA limits: -32.36 180.49. r - linear correlation coefficient BA - Bland-Altman 95% limits of agreement Conclusions: In patients with cardiac conditions leading to impaired function of left ventricle precise volume measurement is necessary for ejection fraction calculation and hence proper clinical management. Our results revealed big discrepancies between 2D-echocardiographic and SPECT radionuclide ventriculography volume measurements comparing to cardiac magnetic resonance treated as the “golden standard”. We reported systemic bias - both Echo and SPECT significantly and considerably underestimated EDV and ESV comparing to CMR.

P019

Evaluation of Diastolic Dysfunction in multivessel coronary artery disease using 16 Gated SPECT Myocardial Perfusion Imaging

M. Prabhu; Narayana Health City, Bangalore, INDIA.

INTRODUCTION: In the cascade of ischemia, after flow heterogeneity diastolic dysfunction precedes systolic dysfunction. We intended to

examine if this pathophysiological precedence can influence interpretation of myocardial perfusion imaging (MPI) in multivessel coronary artery disease (CAD). **AIMS AND OBJECTIVES OF THE STUDY**: 1. To detect the presence of Diastolic Dysfunction in multivessel coronary artery disease. 2. To evaluate the role of Diastolic Dysfunction in interpretation of MPI for detection of ischemia in multivessel CAD. **MATERIAL AND METHODS:** 100 coronary angiogram proven multivessel CAD patients were enrolled in this study. MPI was performed according to standard guidelines and images were acquired using dedicated CZT based cardiac gamma camera. Acquired data were processed on ECTool box and companion software on QGS. The cut off limits for PFR and TTPF for men were taken as 1.73 EDV/s and 211.4ms and for women, 1.87 EDV/s and 194.1ms. Two independent Nuclear Medicine physicians were made to interpret the perfusion images with and without diastolic parameters. Inter observer variability was assessed using kappa statistic. **RESULTS:** 24/100 patients developed stress induced diastolic dysfunction. 22 patients had diastolic dysfunction with preserved systolic function. Moderate agreement between observers was noted for interpretation of ischemia without diastolic parameters (k = 0.49) which improved to substantial agreement with the knowledge of diastolic parameters (k = 0.66). Also, 30% probable interpretation was changed to definite interpretation by observer 1 with the provision of diastolic parameters ($p<0.001$). **CONCLUSIONS**: Diastolic dysfunction can occur at stress even in the absence of systolic dysfunction. Substantial agreement between the observers in interpretation of ischemia using diastolic parameters indicates its potential role in evaluation of multivessel CAD. Hence, identification of stress induced diastolic dysfunction in multivessel CAD adds value in identifying balance ischemia.KEYWORDS: CAD: Coronary artery disease, MPI: Myocardial Perfusion Imaging, PFR: peak filling rate, TTPF: Time to peak filling.

Relationship between cardiac electrical and mechanical dyssynchrony

S. Sillanmäki[1,2], J. Lipponen[3], T. Laitinen[1], M. Tarvainen[3], T. Laitinen[1,2]; [1]Department of Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, Kuopio, FINLAND, [2]Department of Clinical Physiology and Nuclear Medicin, University of Eastern Finland, Kuopio, FINLAND, [3]Department of Applied Physics, University of Eastern Finland, Kuopio, FINLAND.

Aim: The aim of this study was to find vector electrocardiography parameters (VECG) which associate with mechanical dyssynchrony assessed by myocardial perfusion imaging (MPI) phase analysis. **Materials and Methods**: Study population consisted of 16 patients with left bundle branch block (LBBB) and 14 healthy controls. All subjects underwent a standard ECG -gated MPI. 12 -lead resting ECG -data was collected using Mason-Likar leads and was analysed using custom made VECG analysis software. Gained VECG parameters were compared with MPI phase analysis parameters known to associate with left ventricular systolic dyssychrony. VECG signals were analysed by estimating orientation, morphology and heterogeneity of depolarization wave front from the 5 minutes ECG-recording. *X-, Y-* and *Z*-leads were synthetized using Kors matrix and averaged beat segments (P-QRS-T) were produced for above-mentioned leads. Mean QRS vector loop angles were defined in frontal (α_{fro}), transverse (α_{tra}) and sagittal (α_{sag}) planes. Heterogeneity of the depolarization and repolarization sequences were parameterized using QRS-T angle. Also, QRS loop non-planarity measure ($QRS_{\sigma 3}$) describing irregularity of the QRS complex were estimated. MPI studies were performed with Siemens Symbia SPECT-CT camera (^{99m}Tc-tetrofosmin, 64 angles, 25s/view, 128x128 matrix, 16 frame ECG). Reconstructions were done with HERMES HybridRecon Cardiology and data was analysed with Cedars-Sinai QGS2012 program. The bandwidth (BW), standard deviation (SD) and entropy% of the histogram were calculated as mechanical dyssynchrony measures. **Results:** QRS vector loop of a typical LBBB subject is narrow and pointing towards the back of the subject. Healthy subject's QRS loop is on the other hand wider and pointing towards the left leg. Heterogeneity of the repolarization and depolarization sequences is also significantly increased in LBBB subjects. In both groups significant negative correlation was found between α_{sag} and SD ($r = -0.65$, $p<0.05$) and positive between SD and $QRS_{\sigma 3}$ ($r=0.53$-0.69, $p<0.05$). In LBBB group, all mechanical dyssynchrony parameters showed strong negative association with mean QRS vector in sagittal plane ($r = -0.66$ - -0.65, $p<0.01$) and positive in transversal plane ($r = 0.62$ - 0.77, $p<0.01$). Also all mechanical dyssynchrony parameters in LBBB group correlated significantly with $QRS_{\sigma 3}$ ($r = 0.60$ - 0.69, $p<0.05$) and α_{fro} ($r = -0.53$ - -0.62, $p<0.05$). **Conclusion**: The form of QRS vector loop in LBBB group is different from control group's loop. Several VECG parameters correlate with MPI dyssynchrony parameters. This observation may help to understand electrical background of mechanical dyssynchrony in LBBB patients.

P021

Assessment of diastolic function in patients with type 2 diabetes mellitus with gated SPECT

A. Korkmaz[1], B. Caliskan[1], F. Erdem[2]; [1]Abant Izzet Baysal University Department of Nuclear Medicine, Bolu, TURKEY, [2]Abant Izzet Baysal University Department of Cardiology, Bolu, TURKEY.

Aim Diabetes mellitus (DM) is one of the major risk factors for cardiovascular disease. In patients with DM, heart disease may remain silent until an advanced stage. Early identification of diastolic dysfunction of patients with diabetes is important in preventing cardiac events. In this study, we compared diastolic function parameters obtained with gated SPECT (G SPECT) in patients with DM without known coronary artery disease (CAD) and no ischaemia with those of individuals without DM. We assessed whether G SPECT can be used to evaluate both myocardial perfusion and systolic and diastolic functions in patients with DM with atypical cardiac symptoms. ***Materials and methods*** We examined 80 patients: 40 with and 40 without diabetes. The patients were compared in terms of systolic and diastolic parameters obtained using G SPECT. Tc-99m sestamibi was used to obtain 8-frame images in each cardiac cycle, with calculation of the left ventricular ejection fraction (LVEF), peak filling rate (PFR), mean filling rate during the first third of diastolic time (MFR3), and time to peak filling (TTPF) using the QGS software. ***Results*** G SPECT results were compared in 40 diabetic and 40 non-diabetic patients of similar age, sex and coronary artery disease risk factors. Of the diastolic function parameters, PFR was found to be lower in patients with than without diabetes (2.31 ± 0.68 vs. 2.76 ± 0.68, respectively; $p= 0.004$). The TTPF and MFR3 in both groups were similar. PFR was negatively correlated with end-diastolic volume (EDV) and end-systolic volume (ESV) and positively correlated with LVEF. This correlation was stronger in patients with diabetes. ***Conclusion*** In conclusion, in the present study patients with DM with normal myocardial perfusion were shown to have disrupted cardiac relaxation and a low PFR compared with patients without DM using G SPECT. These results illustrate disruption in diastolic function in patients with DM in the early period and earlier occurring cardiac events. G SPECT is frequently used in daily practice at most nuclear medicine centres, and because it is a repeatable, highly accurate test independent of the operator, it can be used to evaluate diastolic function parameters in addition to myocardial perfusion with no time or financial loss. Thus, we believe that evaluation of diastolic function parameters with G SPECT may help to identify patients with DM requiring more aggressive treatment in the early period.

P022

Comparison between three different gated myocardial perfusion software programs in measuring left ventricular ejection fraction and volumes

S. Alexiou[1,2], P. Georgoulias[2], V. Valotassiou[2], I. Tsougos[3], D. Psimadas[2], A. Ziaka[2], E. Baniora[2], C. Ziangas[2], V. Lakiotis[1], D. Alexopoulos[4], D. Apostolopoulos[1], P. Vassilakos[1]; [1]Department of Nuclear Medicine, University Hospital of Patras, Patras, GREECE, [2]Department of Nuclear Medicine, University Hospital of Larissa, Larissa, GREECE, [3]Department of Medical Physics, Medical School, University of Thessaly, Larissa, GREECE, [4]Cardiology Department, University Hospital of Patras, Patras, GREECE.

Purpose Left ventricular ejection fraction (LVEF), end diastolic volume (EDV) and end systolic volume (ESV) are functional parameters obtained using gated myocardial perfusion scintigraphy (G-SPECT). For the automatic calculation of the aforementioned variables, Emory Cardiac Toolbox (ECTb), Myovation and Quantitative gated single-photon emission tomography (QGS), are three of the most commonly used computer processing software packages. In the present study, we sought to evaluate and compare these three programs in measuring left ventricular quantitative parameters. **Materials and Methods** 634 consecutive patients (419 men and 215 women, mean age 64.0years ±10.6 years) comprised our study cohort. All patients were properly referred for myocardial perfusion imaging, for the evaluation of known or suspected coronary artery disease and patient risk stratification. Patients with valvular or congenital heart disease, cardiomyopathies, with low quality SPECT studies and those with inability to obtain gated SPECT data (atrial fibrillation or other severe arrhythmias) were excluded. Myocardial perfusion scintigrams were performed according to the one day stress/rest Tc99m Tetrofosmin protocol. The high-count rest scans were acquired as gated-SPECT studies (eight frames per cardiac cycle). Rest LVEF, EDV and ESV were calculated using ECTb, Myovation and QGS, on Xeleris 3 central workstation (GE Healthcare). The agreement between the three processing programs was assessed with the calculation of intraclass correlation coefficients (ICC) for random effects models. **Results** An excellent concordance was found between the three software algorithms according to ICCs values, ranging from 0.92 to 0.99. Nevertheless, pair comparisons among the software programs revealed some differences. Myovation software displayed lower values in all rest parameters compared to both ECTb and QGS algorithms. In addition, ECTb displayed higher values in all parameters except for LVEF as compared to QGS software. Rest LVEF were categorized as normal (>50%), mild-moderate (35-49%), and severe abnormal (<35%) and the agreement between the three software programs was examined. The overall concordance between the three software algorithms was 1.7% for severely abnormal rest LVEF, 5.9% for mild-moderately abnormal rest LVEF and 81.4% for normal rest LVEF, resulting in a 11.0% overall discordance. **Conclusion** ECTb, Myovation and QGS were highly correlated in evaluation of left ventricular functional parameters. Nevertheless, the differences in absolute values and categorization of LV systolic dysfunction, should be accounted for and the interchangeable use of software packages should be avoided in estimation of consecutive GSPECT studies.

Assessment the impacts of the rejected heart beats on Left Ventricle Ejection Fraction and images quality in the gated SPECT cardiac perfusion imaging

M. H. Khedr[1], M. A. Abd El Aziz[2], A. Soltan[2]; [1]Helwan University, Cairo, EGYPT, [2]Cairo University, Cairo, EGYPT.

The impact of rejected heartbeats percentage on the evaluation of Left Ventricle Ejection Fraction(LVEF) from myocardial gated SPECT has been assessed by comparing the gated SPECT by accepted beats dependent and time dependent acquisition with echocardiography data. Whether gating-related artifacts may have a clinically relevant on the evaluation of perfusion and Ejection Fraction in arrhythmic patients is still uncertain. ***The aim*** of this study was to examine the difference in Left Ventricle Ejection Fraction and images quality between simultaneously acquired gated SPECT dependent on time and gated SPECT dependent on accepted heartbeats data in arrhythmic and nonarrhythmic patients. ***Methods***: In 51 consecutive patients classified into two group 40 nonarrhythmic patients (group 1) and 11 arrhythmic patients (Group 2) who underwent myocardial perfusion SPECT for standard clinical indications, both a gated SPECT dependent on time and gated SPECT dependent on accepted heartbeats study were simultaneously acquired and compared with Ejection Fraction from Echocardiogram. Perfusion was estimated in a masked manner on a 20-segment model using Total perfusion defect (TPD) and imaging quality was estimated by contrast. ***Results*** The mean LVEF was significantly different between gated SPECT dependent on time and Echocardiogram for arrhythmic patients $p<0.005$ but not significantly different between gated SPECT dependent on accepted heartbeats and Echocardiogram $p=0.62$ and not significantly different between both gated SPECT accepted heartbeats dependent and time dependent with Echocardiogram for nonarrhythmic patients.$p>0.1$ Contrast and TPD significantly different between gated SPECT dependent on time and gated SPECT dependent on accepted heartbeats $p < o.o5$ ***Conclusion***: time and accepted heartbeats parameter in gated SPECT acquisition have a clinically relevant impact on summed gated perfusion images and LVEF, in arrhythmic and nonarrhythmic patients Therefore, acquisition of a gated SPECT accepted heartbeats dependent study is imperative for accurate assessment of arrhythmic patients LVEF

Feasibility of myocardial flow reserve prediction without using dynamic data of myocardial perfusion PET

H. Hashimoto; Toho University Faculty of Medicine, Tokyo, Japan, Oomori-nishi/ootaku/tokyo, JAPAN.

Aim: The quantification of myocardial flow reserve (MFR) provides not only diagnostic value for detection of cardiovascular artery disease but also predictive value for major adverse cardiac events (MACE). ^{13}N-ammonia myocardial perfusion positron emission tomography (MP-PET) can calculate MFR noninvasively. However, the common calculation method for MFR requires dynamic acquisition and specific software. The aim of this study was to estimate MFR using solely static images in ^{13}N-ammonia MP-PET scans. Materials and methods: 34 consecutive patients suspected of ischemic heart disease and 6 healthy participants (28 men and 12 women, 70 ± 11 years) were included in this study. All participants underwent adenosine stress and rest ^{13}N-ammonia MP-PET. In the dynamic images, MFR in the entire-left-ventricular myocardium (ELV) and each of the 3 vessel-areas' MFR were calculated by dividing each stress myocardial blood flow (MBF) by rest MBF. In the static images, myocardium-to-background ratio (MBR) was calculated by dividing the entire-left-ventricular myocardial counts/voxel and each of the three vessel areas' counts/voxel by background upper thoracic aorta counts/voxel in both stress and rest images. Myocardium-to-background ratio increasing rate (MBR-IR) was calculated by dividing stress MBR by rest MBR. A relationship between MFR and MBR-IR in ELV and the three vessel areas was examined. Furthermore, the relationship between MFR and MBR-IR in ischemic myocardium and in non-ischemic myocardium was also examined. Results: Median MFR and MBR-IR in ELV were 1.84 (1.42-2.15) and 1.50 (1.16-1.83),

respectively. MBR-IR was correlated well with MFR in ELV (r = 0.890, p < 0.001). In the LAD territory, MBR-IR was the most correlated with MFR in 3-vessel area (r = 0.900, p < 0.001). MBR-IR was more correlated with MFR in non-ischemic coronary artery territory than in ischemic myocardium (0.930, p < 0.001 vs. 0.862, p < 0.001). Conclusions: This study demonstrated that MFR can be estimated using solely MP-PET static images.

Rb-82 PET-CT Cold Pressor Test-CPT in the evaluation of the left ventricular flow reserve (VFR) in patients with metabolic syndrome(MS)

A. Fathinul Fikri, N. Abdul Jalil; University Putra Malaysia, Serdang, MALAYSIA.

Aims Rb-82 PET-CT image analysis is potentially valuable in evaluating risks of coronary artery disease (CAD) on the ventricular flow reserve(VFR; ml/g/m) of the left ventricle. We sought to determine the predictive markers for the VFR of the left ventricle in patient with MS. **Methods**: We considered 16 Rb-82 PET-CT CPT in (12 male, 4 female; 52.43 ±4.87y) with mean BMI of 27.44± 4.49kg/m^2 in patients with MS (WHO 1999). The dual-phased CPT was performed during 5 minutes ice cube emersion (CPT) for the stress phase and at rest to underpin physiological changes of the left ventricular reserve flow being evaluated by the Rb-82 PET-CT. Utilising the acquisition of the list mode CT in static and dynamic phases to reconstruct CT images for attenuation correction and the dynamic data acquisition were processed to obtain quantification value of VFR of the left ventricle using FlowQuant software(Ottawa) on the PET polar map . Clinical risk factors (NIDDM, HPT, BMI) and doppler sonographic parameters [intima media thickness (IMT), peak systolic velocity(PSv)] of common carotid artery were analysed for potential predictors of the VFR . **Results**: There was a significant CPT-induced haemodynamic stress in all patients with (mean prestress BP:126.25 ±16.37/77.75±6.06mm/Hg vs post stress BP:163.00 ±20.53/91.50 ± 10.43mm/Hg, p <0.05) respectively. There was a significant differences of the mean weight between group of VFR < 2.0 ml/g/m (81.52± 8.92kg vs 69.95 ±12.02kg,p<0.05). NIDDM was found as a sole predictor for VFR of the left ventricle(p=0.039: Mc Nemar Test)IMT>0.05mm is a good predictor in patient with low VFR(p<0.05). **Conclusion**: Rb-82 PET-CT CPT may be a useful tool as a surrogate marker for inotropic agents in evaluating risks of low left ventricular flow reserve in patient with metabolic syndromme.

P027

Clinical validation of the Shine 16 quantitative noise reduction in myocardial SPECT

P. Hannequin[1], P. BUFFAZ[1,2], C. GIULIANI[1], R. ZGIMOND[1]; [1]Centre d'Imagerie Nucléaire d'Annecy, METZ-TESSY, FRANCE, [2]Centre d'Imagerie Nucléaire d'Annecy, Metz-tessy, FRANCE.

Introduction: Statistical Poisson noise is one of the physical factors which degrades qualitative and quantitative properties of scintigraphic images. It implies that the higher the number of counts, the higher the signal to noise ratio. Administated activity and/or acqusition duration must be sufficient to produce scintigraphic images with an acceptable clinical quality. Shine 16, an original algorithm, enables to reduce statistical noise while preserving images properties (Phys Med Biol 60 (2015) 4581-4599). The first clinical myocardial SPECT results including 60 patients are presented. Material and Methods: Forty abnormal and 20 normal consecutive myocardial SPECT studies have been acquired with a one-day procedure: 220 MBq rest injection - 50 s/projection acquisition - 660 MBq stress injection - 30 s/projection acquisition. Number of counts in initial reference data have been halved using a Poisson resampling method for simulating reduced counts (Phys. Med. Biol. 60 (2015) N167-N176). Halved data have been processed using Shine 16. Reference and Shine16-Halved slices have been reconstructed using the same parameters. They have been interpreted by two independent blind observers with a 17-segments display and quantitatively processed with QPS/QGS software. Results: Visual analysis: A difference superior to one ischemic segments between the Shine16-Halved and the reference visual scores occurs for two patients with observer n°1 and one patient with observer n°2. Quantitative analysis: The mean of the differences between Shine16-Halved and reference Sum Stress Scores and between Shine16-Halved and reference Reversibility Scores is 1.05 (p=0.03) and 0.196 (NS) respectively. The correlation coefficient between Shine16-Halved and reference Stress Ejection fraction (EF), Rest EF and Stress Telediastolic Volume is 0.92, 0.88 and 0.94 respectively. Conclusion: Shine16 allows to decrease the number of counts in SPECT myocardial data while preserving their clinical value. Further studies are necessary to confirm these results and their practical interests : using lower dose to reduce patient irradiation or shortening acquisition duration to improve patient comfort, to minimize motion blur and to optimize camera throughout.

P028

^{99m}Technetium tetrofosmin myocardial perfusion imaging in patients with ischemic stroke

C. Sioka, **K. Papadimitropoulos**, M. Spiliotopoulou, S. Markoula, S. Zouroudi, K. Naka, L. Michalis, A. Behlioulis, A. Fotopoulos, A. Papadopoulos, A. Papadopoulos, A. Kyritsis, S. Giannopoulos; University Hospital of Ioannina, Ioannina, GREECE.

Aim: Single photon emission computer tomography (SPECT) with ^{99m}Technetium-tetrofosmin (^{99m}Tc-TF) is an imaging technique for evaluation of myocardial perfusion (MPI). In our study, we evaluated myocardial status in patients with stroke. **Materials and methods**: We performed ^{99m}Tc-TF-SPECT MPI using polar map of 17 segments in 53 patients with ischemic stroke within 1 month after stroke. Myocardial ischemia (MIS) was defined as mild when the summed stress score SSS was 4-8, and moderate or severe when SSS was equal or more than 9. These MPIs were compared to patients with SSS less than 4, which was considered as nonsignificant MIS. Parameters such as age, BMI, abdominal perimeter, alcohol consumption, smoking habits and medical history (diabetes mellitus, dyslipidemia, etc) were evaluating according to MPI results. None of the patients had any history or symptoms of coronary artery (CAD) or other heart disease. **Results**: There was a significant number of stroke patients with abnormal MPI [32/52 (61.53%, p less than 0.05)] with the majority of patients exhibiting mild abnormalities (20/32, 62%) and 12/32 (38%) patients moderate or severe MPI abnormalities. Abdominal perimeter was found to be a risk factor in this group of patients independently of the severity of MIS (p less than 0.05). **Conclusion**: Most of the stroke patients (more than 50%) in our study had clinically silent MIS, with the majority of them mild, as depicted with ^{99m}Tc-TF-SPECT MPI. We recommend a thorough cardiological evaluation including MPI in stroke patients, in order to rule out MIS or diagnose it early for proper management and prevention of future symptomatic cardiac disease.

P029

Prospects Of Quantitative Scintigraphic Assessment Of Myocardial Blood Flow In Patients With Coronary Artery Disease

N. Krivonogov[1], A. Mochula[1], K. Zavadovsky[1,2], Y. Lishmanov[1,2]; [1]«Research Institute for Cardiology», Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim: The aim of the study was to evaluate capabilities of myocardial scintigraphy with Tc-99m-methoxyisobutylisonitrile (^{99m}Tc-MIBI) for assessment of myocardial perfusion in patients with coronary artery disease (CAD). Materials and Methods: The study comprised 12 patients diagnosed with CAD. Radionuclide angiopneumography (RNA) and myocardial perfusion scintigraphy with ^{99m}Tc-MIBI were performed. Cardiac output (CO) was calculated based on RNA data; myocardial perfusion was evaluated based on perfusion scintigraphy data; coronary fraction (CF) of radiopharmaceutical accumulation was determined by original method developed by authors. For verification of coronary ejection fraction (CEF) assessment with subsequent calculation of myocardial blood flow (MBF), the same patients received myocardial scintigraphy with macroaggregates of human serum albumin labelled with ^{99m}Tc (^{99m}Tc-MAA). ^{99m}Tc-MAA was introduced into the left ventricular cavity. Values of CEF and MBF were calculated using the following formulas: CEF = Cc/Ci x 100%, where Cc was scintigraphic count from the area of interest over the heart, Ci was scintigraphic count for the introduced dose of radiopharmaceutical; MBF = CO x CEF (mL/min). Results: For scintigraphic determination of myocardial blood flow, we proposed and evaluated the original method of RNA data processing consisting in summation of second-by-second frames corresponding to the first passing of the ^{99m}Tc-MIBI bolus and in determination of maximum amplitude of activity-time curve (counts/s) in the area of interest corresponding to the visual field of gamma-camera detector. According to data of scintigraphic studies, abnormalities of myocardial perfusion of various degrees were observed in all study patients. Coronary fraction of ^{99m}Tc-MIBI accumulation varied from 1.9% to 2.95% dependined on myocardial perfusion. CEF obtained with ^{99m}Tc-MAA scintigraphy also directly depended on myocardial microcirculation. Minimum and maximum CEF values were 1.9% and 3.35%, respectivley. Non-parametric Wilcoxon criterion did not detect significant differences (p=0.866) between ^{99m}Tc-MIBI-based CF accumulation and ^{99m}Tc-MAA-based CEF which allowed for considering ^{99m}Tc-MIBI-based CF accumulation a ^{99m}Tc-MIBI-based CEF. Values of CO calculated based on ^{99m}Tc-MAA-based CEF and ^{99m}Tc-MIBI CEF also did not significantly differ between each other (p=0.886) and ranged from 85 to 35 mL/min. Conclusion: Proposed method of quantitative ^{99m}Tc-MIBI-based scintigraphic evaluation of MBF in CAD patients is a non-invasive, affordable, and reproducible method for the detection of coronary insufficiency and may be used in diffuse atherosclerosis of coronary arteries as well as in non-coronarogenic pathology of the cardiac muscle. The study was supported by a grant from the Russian Science Foundation (№14-15-00178).

P030
^{99m}Technetium tetrofosmin myocardial perfusion imaging in women with non specific cardiac complaints

C. Sioka, A. Papadopoulos, K. Papadimitropoulos, L. Lakkas, K. Pappas, E. Gkika, M. Spiliotopoulou, T. D. Kotrotsios, S. Tsiouris, X. Xourgia, J. al Boucharali, **A. Fotopoulos**; University Hospital of Ioannina, Ioannina, GREECE.

Purpose: To assess the myocardial status in female patients with non-specific cardiac complaints evaluated with ^{99m}Technetium-tetrofosmin (^{99m}Tc-TF) single photon emission computer tomography (SPECT) myocardial perfusion imaging (MPI). **Method-material**: Forty female were subjected to ^{99m}Tc-TF-SPECT MPI for evaluation of non-specific cardiac complaints. Various types of complaints were noted, such as chest wall pains, palpitations or shortness of breath. All patients had negative clinical cardiology examination and normal ECG. The patients' mean age was 58.4 years old (41 to 76 years). MPI was evaluated visually using polar map of 17 segments. Myocardial ischemia (MIS) was defined as mild when the summed stress score (SSS) was 4-8, and moderate or severe when SSS was equal or more than 9. According to MPI results, the role of factors such as obesity, diabetes mellitus, hypertension, dyslipidemia and cardiac heredity was assessed. **Results:** Abnormal MPI was found in 14/40 (35%) patients, all defined as mild MIS. Hypertension was reported in the majority of them followed by obesity, dyslipidemia, medical history of cardiac heredity and diabetes mellitus [12/14 (86%), 8/14 (57%), 7/14 (50%), 7/14 (50%), and 4/14 (29%) patients respectively]. Furthermore, 11/14 (79%) patients had at least two and 7/14 (50%) at least three risk factors. None of the patients were smokers. **Conclusions:** The study suggested that adult females with non-specific cardiac complaints and a history of either hypertension or at least two cardiac risk factors are at risk for MIS and should have cardiological evaluation, including ^{99m}Tc-TF-SPECT MPI.

P031
SPECT imaging with 123I-BMIPP and 99mTc-MIBI in prediction of left ventricular remodeling after the surgical treatment of ischemic cardiomyopathy

M. Gulya[1,2], **K. Zavadovsky**[1,2], S. Andreev[1], Y. Lishmanov[1,2]; [1]RI Cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Purpose of the study was to study perfusion and metabolism of the left ventricular (LV) myocardium in patients with ischemic cardiomyopathy (ICMP) and to identify the scintigraphic predictors of the efficacy of comprehensive surgical treatment of the left ventricular dysfunction. Material and Methods. The study comprised 32 patients with ICMP who underwent comprehensive surgical correction of the LV dysfunction (coronary artery bypass grafting + surgical ventricular reconstruction + mitral valve surgery if necessary). Inclusion criteria: >75% stenosis of coronary arteries; one and more myocardial infarctions in the medical history; heart failure (HF) III-IV NYHA functional class; LV ejection fraction (EF)60 mL/m2; and the presence of akinetic and dyskinetic areas of the LV according to data of echocardiography. Before surgical treatment, all patients received SPECT with 99mTc-MIBI and with 123I-BMIPP for evaluation of myocardial perfusion and metabolism, respectively. In early follow-up (four weeks) and 12 months after the surgery, all patients underwent echocardiography study to estimate intracardiac hemodynamics. Results. Twelve months after surgical treatment, patients were assigned to two groups: group 1 (n=18) patients with beneficial outcome of the operation that stopped the process of LV remodeling (increase LVESVI ≤ 15% one year after surgery compared with the early postoperative period). Group 2 comprised patients (n=14) in whom LV remodeling was progressing despite successful performance of the surgery (increase LVESVI > 15% compared with the early postoperative period). Prior to surgery and in the early postoperative period LV contractile function (LVEF, LVESV, LVEDV) didn't significantly differ between groups. Also groups didn't significantly differ in the following scintigraphic parameters: myocardial perfusion defect size and metabolic defect size. Groups differed significantly in size of perfusion-metabolic mismatch (13.23 ±11.7% and 4.1±11.5%, p<0.01). The best cut of value 12% for perfusion-metabolic mismatch size can predicted the efficacy of comprehensive surgical treatment for the left ventricular dysfunction with the sensitivity and specificity of 100% and 56%, respectively. Conclusions. The results of myocardial perfusion-metabolic scintigraphy can be used as a method for prediction of the progressing cardiac remodeling in the postoperative period of complex surgical correction of LV dysfunction in patients with ICMP.This work was financially supported by Federal Target Program №14.604.21.0071(project unique identifier №RFMEFI60414X0071).

P032
The influence of hibernation volume according to PET/CT on the recovery of myocardial contractility, depending on the treatment type in patients with coronary artery disease

I. Shurupova, I. Aslanidis, L. Bockerija, E. Derevyanko, T. Katunina; Bakoulev Scientific Center for Cardiovascular Surgery, Moscow, RUSSIAN FEDERATION.

Purpose: to identify the dependence of the improvement of the left ventricle (LV) contractility from the original volume of hibernation myocardium (HM) and type of treatment - revascularization without plastics of the LV or common medical therapy (CMT). **Methods**: we examined 63 patients with ejection fraction (EF) &lt 55% as a result of CAD and myocardial infarction (55,8±9.3 years), the functional class (FC) of heart failure (HF) by NYHA averaged 2.23±0.87. All patients underwent myocardial positron emission tomography with 18F-fluorodeoxyglucose (18FDG) and 13N-ammonium. HM was defined as the hypoperfusion area with the accumulation of 18FDG &gt 50% and exceed the 13N-ammonium by more than 10%. In 26 patients with CMT 5 had HM &gt 15% (1gr), 21 - HM &lt 15% (2gr), 38 patients with revascularization: 20 of them had HM &gt 15% (3gr), 17 patients with HM &lt 15% (4gr). End diastolic and systolic volumes (EDV, ESV) and EF LV was calculated according to ECHO as the original and remote via 243.8±145.2 days after revascularization, and through 229.3±185.2 days of observation in CMT patients presented as median and percentiles. **Results**: significant increase in EF from 46%(40;50) to 50%(41;55) (p=0.03) was observed only in the 3 group of patients with revascularization and HM &gt 15%. Non significant increase in EF from 40%(38;48) to 44%(42;50) (p=0,4) was observed in patients with revascularization and HM &lt 15%. In CMT patients the increase of EF is not detected (40%(30;44) vs. 40%(29;47) in 1gr and 44%(35;46) vs. 44%(36;51) in 2gr). The most, but not significant reduction of EDV and ESV was also detected in 3 gr: with 165ml(142;192) to 147ml(126;192) and 90ml(76;113) to 72ml(60;112) (p=NA), respectively. In patients of 4thgr (HM &lt 15%) EDV non-significant decreased after revascularization with 176ml(147;229) to 170ml(138;237), p=0.4, ESV has not changed (93ml(77;137) vs. 92ml(71;131), p=NA. Significant reduction of LV volumes in patients without revascularization (1 and 2gr) was not detected. When we have compared baseline severity of HF in patients group of with revascularization, the FCHF 3gr. was significantly less (1.6±1.0), than 4gr (2.41±0.8 p=0.015). **Conclusion**: 1. Myocardial revascularization leads to a significant increase EF LV in the long-term observation only in patients with HM &gt 15%. 2. Significant positive dynamics of LV volumes after revascularization were not observed in any of the groups with different amount of HM. 3. The weakest dynamics of LV contractility noted in the groups with CMT.

P033

The accumulation quantification of ^{99m}Tc-DPD in the myocardium of patients with transthyretin (TTR) cardiac amyloidosis

M. Buncová, J. Terš, A. Čepa, A. Krebsová, M. Kubánek; Institute for Clinical and Experimental Medicine, Prague, CZECH REPUBLIC.

Aim: comparison of 2 different ways of accumulation quantification of ^{99m}Tc-DPD ([99mTc] 3.3-diphosphono-1.2-propanedicarboxylic acid) in the myocardium in patients with TTR cardiac amyloidosis as instruments for diagnostics and evaluation of accumulation changes during the therapy. **Materials and Methods**: for the accumulation quantification of ^{99m}Tc-DPD (TECEOS®) a SPECT/CT scan of thorax 3-6 hours after the injection of 740 MBq was used. A quantitative index of local maximum accumulation of ^{99m}Tc-DPD in the myocardium (QMA) consisted of the determination of the ratio of the highest count/voxel in the area of the heart to the reference count density. The reference count density is the average value calculated from the highest count/voxel values estimated on the 2-8th ribs on the right side of the chest in the coronary plane identical to the localization of max. count/voxel value in the myocardium. QMA index reflects maximum accumulation of DPD in myocardium. The second way of quantification represents the ratio of accumulation of ^{99m}Tc-DPD in the myocardium (RAM) and the total activity of the tracer in the part of thorax containing all transaxial myocardium slices. From the total 9 patients (78-90 years old) with TTR amyloidosis the scans were repeated in the distance of several months on 2 of those patients being treated with unspecified drug from drug study and on 1 man without any therapy treatment. The results of quantification using QMA and RAM were correlated and the indexes changes were observed in the course of repeated scans. **Results**: for the comparison of QMA and RAM a group of 13 patients positive on TTR amyloidosis was used. QMA index values in the range of 3.8-7.9 and RAM index values in the range of 16-36 % (13 pairs of index values) significantly correlated (correlation coefficient of R=0.81). Repeated examination of indexes of both patients undergoing unspecified treatment indicate decrease of accumulation in the myocardium. 1 man with TTR amyloidosis without any therapy treatment shows the growth of both indexes. **Conclusion:** the indexes of accumulation of ^{99m}Tc-DPD in myocardium correlate - QMA is better for the initial diagnosis of TTR, while RAM is more suitable for observation of long term therapy effects and the progressing disease. The advantage of both those quantification methods in contrast to the evaluation from whole body scans as presented in other articles is the limitation of subjective approach of the worker and more sensitive and wider numerical scale of the index values.

P034

Senile Transthyretin Amyloidosis And ^{99m}Tc-HDP Scintygraphy

A. HERRERO MUÑOZ, L. CASTILLEJOS RODRIGUEZ, P. GARCIA ALONSO, M. BALSA BRETÓN, A. ORTEGA VALLE, C. PANIAGUA CORREA, C. SANDOVAL MORENO, M. FERNANDEZ RODRIGUEZ, F. PENIN GONZALEZ; HOSPITAL UNIVERSITARIO GETAFE, GETAFE, SPAIN.

Senile Transthyrethin amyloidosis is an underdiagnosed cause of heart failure with preserved ejection fraction. Endomyocardial biopsy remains the gold standard for definitive diagnosis but, due to elderly patients, its not often possible. **AIMS** We try to determine utility of ^{99m}Tc-HDP scintography in the diagnosis of senile transthyretin amyloidosis in elderly patients admitted due to heart failure wiht preserved ejection fraction, whom endomyocardial biopsy involves a hight rate of adverse effects. **MATERIALS AND METHODS** We retrospectively screened 14 patients >65 years old admited due to heart failuire wiht preserved ejection fraction (left ventricular ejection fraction >50% with left ventricular hipertrophy). All elegible patients were offered a $^{99-m}$Tc-HDP scintigraphy. We administered 740 MBq intravenously and made plannar images (antero-posterior, left lateral and left-oblique) and SPECT-CT 90 minutes later. Cardiac retention was assessed with a semi-quantitative visual score in relation to ribs uptake (0- no cardiac uptake; 1-less than ribs uptake, 2 similar uptake to ribs, 3- uptake greater than bone). We consider positive uptake equal to or greater than 2. **RESULTS** There were no differences in age, hypertension, diabetes and coronary artery disease between patients with senile transthyretin amyloidosis and patients with other causes of heart failure with preserved ejection fraction. A total of 3 patients showed severe uptake (3 scale) on the ^{99m}Tc- HDP scintigraphy and we considered them true positive cases. Endomyocardial biopsy was performed in one, confirming transthyretin amyloidosis. The other 11 patients didn´t show pathological uptake on the ^{99m}Tc- HDP scintigraphy (0-1 scale). They were considered true negative cases and another causes of heart failure with preserved ejection fraction were finally diagnosed. Senile Transthyretin amyloidosis is an underdiagnosed disease that accounts for a significant number (21,4%) of heart failure with preserved ejection fraction **Conclusion** ^{99m}Tc- HDP scintygraphy is a good noninvasively method to diagnose senile transthyretin amyloidosis in elderly patients, whom endomyocardial biopsy involves a hight rate of adverse effects.

P035

V/P SPECT perfusion gradients as a non-invasive method to follow-up patients with severe heart failure after heart transplantation. Validation with right-heart catheterization

M. Al-Mashat[1], G. Rådegran[2], H. Arheden[1], J. Jögi[1]; [1]Lund University, Department of Clinical Sciences Lund, Clinical Physiology, Skane University Hospital, Lund, Lund, SWEDEN, [2]Lund University, Department of Clinical Sciences Lund, Cardiology, and The Section for Heart Failure and Valvular Disease, VO. Heart and Lung Medicine, Skane University Hospital, Lund, Lund, SWEDEN.

Background: Heart transplantation is the ultimate treatment alternative in patients with severe heart failure (HF). Right-heart catheterization (RHC), with the invasive measure of pulmonary artery wedge pressure (PAWP), is regarded as the reference method in diagnosing pulmonary congestion in HF. The non-invasive V/P SPECT method can be used in the assessment of pulmonary perfusion distribution in HF by quantitative perfusion gradients and qualitative visual assessment. It has not previously been investigated if V/P SPECT could be used to assess the treatment effect of heart transplantation. **Aim**: Therefore, the aim of the present study was to investigate if qualitative visual assessment of V/P SPECT and quantitative perfusion gradients can be used to follow-up effect on congestion in patients with severe HF who have undergone heart transplantation. **Method:** Nine patients with severe HF who were under consideration for heart transplantation were included. The patients underwent V/P SPECT and RHC before and 6 months after heart transplantation. The perfusion gradients were automatically derived from V/P SPECT images using a previously published algorithm. **Results**: Before treatment, seven out of 9 patients showed a redistribution of pulmonary perfusion to anterior parts of the lungs and/or positive dorso-ventral perfusion gradients. The perfusion gradients in seven patients were improved (normalized) after heart transplantation (P=0.02). After treatment, there was a significant decrease in mean PAWP (P=0.01) from 16.8 to 8.3 mmHg before vs. after heart transplantation, reflecting an improvement after transplantation. In three patients, the visual assessment of the images made by the clinical physicians was improved (normalized) after heart transplantation. For the rest of the patients, the visual assessment was unchanged. **Conclusion:** V/P SPECT perfusion gradients is a quantitative and non-invasive method that could have a role in the follow-up of patients who have undergone heart transplantation. Quantitative perfusion gradients seem to be more sensitive than qualitative visual assessment in the evaluation after heart transplantation.

P036

Usefulness of SPECT/CT fusion image of perfusion lung scan in patients with chronic thromboembolic pulmonary hypertension

K. Hirose, T. Chikamori, S. Hida, Y. Igarashi, M. Watanabe, T. Saitoh, K. Suzuki, N. Koizumi, M. Yoshimura, H. Ogino, A. Yamashina; tokyo medical university hospital, tokyo, JAPAN.

Aim: We evaluated the effectiveness of fusion image of perfusion lung scan using 99mTc-MAA SPECT/CT for detecting lung perfusion abnormality and estimating the severity of chronic thromboembolic pulmonary hypertension (CTEPH). **Materials and methods:** Thirty-one patients with CTEPH underwent 99mTc-MAA SPECT/CT and right heart catheterization within 1 month intervals. Perfusion scores were assessed visually on a 4-point scale (0=normal perfusion, 1=mild hypoperfusion, 2=moderate-to-severe hypoperfusion and 3=absent perfusion) in 18 lung segments. Summed score was defined as total perfusion score adding each segmental perfusion score. Percentage of abnormal perfusion was calculated as summed score/36×100. Total lung volume and perfusion defect volume were calculated automatically with CT and SPECT using the threshold width from 25% to 100% of maximal counts of 99mTc-MAA on SPECT images. Percentage of defect volume was calculated as (perfusion defect volume) / (total lung volume) ×100. Pulmonary vascular resistance (PVR), total pulmonary vascular resistance (TVR), mean pulmonary artery pressure (PAP) and mean pulmonary artery wedge pressure (PAWP) were measured by right heart catheterization. **Results:** The average age of patients was 60±14 years, and 8 patients were men and 23 women. Of these 31 patients, mean PAP was 37±11 mmHg, mean PAWP was 10±4 mmHg, mean PVR was 619±417 dyne/s/cm^{-5}, and mean TVR was 820±484 dyne/s/cm^{-5}. Average percentage of abnormal perfusion was 50±8.4%. Among 3 right and 2 left lung lobes, significant perfusion defects were visually observed in the right upper lobe in 29% of the patients, in the middle lobe in 58%, and in the lower lobe in 35%, whereas defects were observed in the left upper lung lobe in 6% of the patients and in the lower lobe in 13%. Total lung volume was 2578±468 ml. Although there were no significant correlations of percentage of abnormal perfusion with PVR, TVR and mean PAP (p for all=NS), there was significant correlation of percentage of perfusion defect volume with PVR (r=0.41, P=0.02). **Conclusion**: Fusion image of perfusion lung scan using SPECT/CT is useful not only to detect the distribution of perfusion abnormality, but also to estimate the severity of CTEPH.

P037

Quantitative perfusion gradients from V/P SPECT could be used to monitor treatment effect in patients with heart failure after receiving cardiac resynchronization therapy

M. Al-Mashat[1], R. Borgqvist[2], H. Arheden[1], J. Jögi[1]; [1]Lund University, Department of Clinical Sciences Lund, Clinical Physiology, Skane University Hospital, Lund, SWEDEN, [2]Lund University, Institution for Clinical Sciences, Arrhythmia Dept, Skane University Hospital, Lund, SWEDEN.

Background: Currently, there is a lack of diagnostic methods to assess the effect of cardiac resynchronization therapy (CRT) in heart failure. Tomographic lung scintigraphy (V/P SPECT) can be used to quantify the redistribution of pulmonary blood flow in patients with heart failure using quantitative perfusion gradients and qualitative visual assessment of the images. The role of V/P SPECT in the assessment of CRT treatment effect is unknown. Aim: The aim of this study was therefore to investigate if V/P SPECT, with quantitative perfusion gradients and qualitative visual assessment of the images, could be used to monitor treatment effect in patients with heart failure before and after receiving CRT. **Material and methods**: Fourteen patients with heart failure who were candidates for receiving CRT were included. The patients were examined with V/P SPECT before and 6 months after the treatment. Of these, eleven patients have been followed up and 3 patients were lost to follow up. The perfusion gradients were automatically derived from V/P SPECT images using a 3D-regression algorithm that has previously been published. **Results:** Before treatment, a redistribution of pulmonary perfusion and/or positive dorso-ventral perfusion gradients were found in 7 of the CRT patients. After treatment, there was a significant decrease in perfusion gradients, reflecting an improvement in pulmonary perfusion distribution (P=0.03), although the visual assessment of the images made by the clinical physicians was unchanged. **Conclusion**: Quantitative perfusion gradients are more sensitive to the improvement in pulmonary perfusion pattern after CRT than the qualitative visual assessment of the V/P SPECT images, and could therefore have a role in monitoring treatment effect in patients receiving CRT.

P038

Isolated perfusion scan and SPECT/CT-angiography for pulmonary embolism diagnostic in chronic obstructive lung disease patients

E. V. Migunova, N. E. Kudryashova, O. V. Nikitina, I. P. Mikhailov, G. A. Nefyodova; Sklifosovsky Inst.for Emerg. Medicine, Moscow, RUSSIAN FEDERATION.

Every year our hospital receives 450 patients with acute venous thrombosis and suspicion of PE. In most cases at clinical picture of PE it was enough to use the following diagnostic pattern: X-ray to exclude lung diseases and injuries → venous ultrasonography → pulmonary perfusion scan (PPS). However, in 10% cases there were doubts about PE diagnosis of the patients with COLD and fibrotic changes of lung tissue after perfusion scan, which required SPECT/CT lung angiography. Purpose. To define diagnostic significance rate of isolated PPS of the patients with massive PE on the background of COLD in comparison with lung SPECT/CT. Materials and techniques. Examined 44 patients, age 64,8 ±15,3 with venous thrombosis, clinical signs of PE, apparent respiratory distress on the background of COLD, perfusion edge defects and total perfusion deficiency of more than 45% according to isolated PPS. In all cases there remained doubts about the diagnosis and further examinations on hybrid system SPECT/CT «Discovery NM/CT 670» (GE, USA) with 120 MBκ ^{99m}Tc-macroaggregated albumin and 70 ml of iso-osmolar nonionic contrast agent Iodixanol were performed. Results and discussion. SPECT/CT-angiography allowed to estimate kind and volume of lungs blood stream damage on subsegmental level. With diagnostic findings of SPECT/CT-angiography, which was performed for verification, PE diagnosis was confirmed in 30 cases of 44 total. In 14 cases after SPECT/CT-angiography conclusions were changed: 9 false positive results of isolated perfusion scan resulted from perfusion defect in COLD lung tissue fibrosis sites, 5 false negative resulted from presence of thromboembolism sites of segment level, which did not close the lumen. Diagnostic significance at PE after isolated PPS were: accuracy 68,2% (95% confidence interval 55,4%; 80,6%), sensitivity 83,3% (95% confidence interval 73,9%; 92,5%), specifity 35,7%. Besides refinement of PE diagnosis, results of SPECT/CT-angiography affected the treatment of the patients with contra-indications for system thrombolytic therapy. A number of patients with thromboembolia of major lung vessels got reological clot extraction. Conclusions. Isolated PPS in PE diagnostics of patients with COLD has low specifity and accuracy; it is advisable to perform lungs SPECT/CT-angiography for these patients, which helps to make accurate diagnosis, estimate total perfusion deficiency and exact localization of clots or rule out presence of clots on the lung artery system at lung perfusion defects of other origin. SPECT/CT method allows to choose the most suitable treatment at massive thromboembolia, i. e. to decide if system thrombolytic therapy or reological clot extraction is reasonable.

P039

Pulmonary perfusion in patients with hypoplastic left heart syndrome (HLHS) after surgical correction of the defect

K. Kovačević-Kuśmierek[1], A. Mazurek-Kula[2], T. Moszura[2], J. Moll[2], J. Moll[3], A. Płachcińska[1], J. Kuśmierek[4]; [1]Department of Quality Control and Radiological Protection Medical University of Lodz, Poland, Lodź, POLAND, [2]Cardiology Department Polish Mother's Memorial Hospital, Research Institute Lodz, Poland, Lodź, POLAND, [3]Cardiosurgery Department Polish Mother's Memorial Hospital, Research Institute, Lodz, Poland, Lodź, POLAND, [4]Department of Nuclear Medicine, Medical University of Lodz, Poland, Lodź, POLAND.

HLHS can be treated with a multistage surgery including an anastomosis of superior vena cava and inferior vena cava with the right pulmonary artery. Aim: assessment of pulmonary perfusion in patients with HLHS after completion of a surgical treatment (Fontan operation). Material and methods: In 76 patients (52 boys and 24 girls) aged 3-20 (mean 9) years a planar lung perfusion study was performed twice(after administration of a radiopharmaceutical into upper and lower limb) in anterior and posterior projections after intravenous injection of activities of 99mTc-macroaggregates adjusted for body weight. Administration of a radiopharmaceutical into upper limb aimed at the assessment of blood distribution between both lungs through the anastomosis of superior vena cava with right pulmonary artery (SVC-RPA) and into lower limb - through anastomosis of inferior vena cava with right pulmonary artery (IVC-RPA). Relative perfusion of both lungs was assessed with a software "Lung perfusion analysis" on Xeleris workstation as a geometric mean of percentages in anterior and posterior views. Distribution of perfusion not exceeding 50±10% was recognized as symmetrical. Results: Blood distribution between both lungs through SVC-RPA was diverse: in 27/76 (35%) patients it was symmetrical, in 28/76 (37%) hypoperfusion of the left and in 21/76 (28%) hypoperfusion of the right lung were observed. However, IVC-RPA provided lower relative perfusion of the left lung in 64/76 (84%) as compared with SVC-RPA (p<0,0001), symmetrical lung perfusion was observed in a lower percentage of patients - 12/76 (16%) as compared with SVC-RPA (p=0,015) and no cases of a relative hypoperfusion of the right lung were found. Moreover, in 9 (12%) patients an uptake of the radiopharmaceutical in kidneys was detected indicating right-to-left shunt, probably as a result of lung arteries malformations. Conclusions: Lung perfusion study revealed that in patients after surgical correction of HLHS blood distribution between both lungs is diverse, with predominance of a relatively lower perfusion of the left lung through the anastomosis of inferior vena cava with right pulmonary artery. Lung perfusion study additionally revealed right-to-left shunt in several patients.

The role of serum 25 Hydroxy vitamin D levels, in patients with Coronary Artery Disease. Correlation with SPECT Myocardial scintigraphy

A. S. ZISSIMOPOULOS[1,2], L. Baloka[3], S. Floros[4], P. Pavlidis[5], A. Thomaidou-Ntanasel Antina[6], O. Zissimopoulou[7], A. Tsartsarakis[7], R. Sotiropoulou[8], A. Strataki[7], E. Karathanos[7]; [1]Democritus University of Thrace, Alexandroupolis, GREECE, [2]Nuclear Medicine Dept., Alexandroupolis, GREECE, [3]Molecular Biology and Genetics School Democritus University of Thrace, Alexandroupolis, GREECE, [4]Cardiology Clinic 401 Army Hospital, Athens, GREECE, [5]Laboratory of Forensic Sciences Democritus University of Thrace, Alexandroupolis, GREECE, [6]Cardiology Clinic Democritus University of Thrace, Alexandroupolis, GREECE, [7]Nuclear Medicine Dept Democritus University of Thrace, Alexandroupolis, GREECE, [8]Medical School Democritus University of Thrace, Alexandroupolis, GREECE.

Introduction: Recent studies have reported that low serum vitamin D levels are associated with a variety of diseases, including cardiovascular disease and in particular ischemic heart disease (IHD). Possible mechanisms underlying this association include increased inflammation, renin-angiotensin system upregulation, insulin resistance, altered lipid metabolism, and altered vascular smooth muscle growth and function that lead to hypertension, diabetes, dyslipidemia and atherosclerosis. Aim: The aim of this study is to evaluate the serum levels of 25 hydroxy- vitamin D [25(OH) D] in patients with Coronary Artery Disease (CAD), as a prognostic factor of the severity of the disease, in correlation with SPECT myocardial scintigraphy. Patients and method: We study 78 patients (48 male and 30 female) aged between 37 and 73 years old (median age of 58 ±9 years) who suffer from CAD. 61 were patients of the University Cardiology Clinic of the University Hospital of Evros and the rest of other cardiologists. In all patient's blood samples were taken for (25-OH-D) determination and after this in everyone SPECT myocardial scintigraphy with ^{99m} Tc-MIBI and tomographic γ-camera was performed. The serum was collected and kept refrigerated at -70 ° C. The vitamin D status was measured by radioimmunoassay (RIA) method with I^{125}[25(OH)D] kits Diasorin at in- vitro laboratory of Nuclear Medicine Dept. Statistical analysis: Was performed by the Pearson correlation test and statistical significance was considered to be p <0.005. Results: 37 patients with myocardial infarction had low values of vitamin D, 0-20 ng/mL , (p <0.005). In this group there is statistical significance in the relationship between very low values of

vitamin D and patients with extensive myocardial infarction. (p <0.005). Therefore the very low prices associated with the severity of disease and the impending death of patients. These patients might need more intensive monitoring.32 patients with reversible myocardial ischemia had low values of vitamin D 20-40 ng/mL. (p <0.005). Therefore the very low levels associated with the progression of the disease.9 patients who had normal myocardial scintigraphy had values of vitamin D to normal levels > 40 ng/mL (p <0.005). Conclusions: In conclusion low vitamin (25-OH-D) levels may underlie established cardiovascular risk factors. The very low levels associated with the severity of (CAD) disease and the impending death of patients. The determination of vitamin D levels in patients with coronary artery disease is essential to monitor patients in the treatment and outcome of disease.

P041

99mTc-HMPAO SPECT For Evaluation Of The Renal Denervation Effects On Cerebral Perfusion: Correlation With Cognitive Function In Patients With Resistant Arterial Hypertension

N. Efimova[1,2], I. Efimova[1], V. Lichikaki[1], V. Mordovin[1], Y. Lishmanov[1,2]; [1]«Research Institute for Cardiology», Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim: The aim of the study was to elucidate the effects of radiofrequency ablation of renal arteries on regional cerebral blood flow (rCBF) and cognitive function in patients with resistant arterial hypertension (AH). Materials and methods: The study involved 21 patients (pts) with resistant AH examined by SPECT with 99mTc-HMPAO, 24-h blood pressure monitoring, and comprehensive neuropsychological testing before and after transcatheter renal denervation. Brain SPECT slices were divided into 14 symmetrical (right and left) regions of interest: inferior and superior frontal lobes, temporal, anterior and posterior parietal, occipital lobes, and cerebellar hemispheres. Regional cerebral blood flow (mL/100g/min) in these regions was calculated. Fifteen pts without angiographic signs of carotid atherosclerosis, coronary artery disease, AH, neurological and psychiatric disorders were investigated as control group. Results: Data showed decreases in rCBF in AH pts by 14.2% (p=0.00003) and by 16.0% (p=0.0005) in right and left inferior frontal lobes, respectively; by 12.1% (p=0.006) in right temporal brain region; and by 8.5% (p=0.03) in right and left occipital cortex in comparison with control group. The results of neuropsychological testing showed decreases by 13.1% in mentation (p=0.0002), by 42.4% in long-term verbal memory (p=0.0003), by 21.1% in long-term visual memory (p=0.01), by 21% in learning (p=0.0005), as well as decrease by 26.7% in attention (p=0.001) in pts with AH as compared with control group. Improvements of rCBF, 24-h blood pressure monitoring parameters, and cognitive functions were observed in patients with AH after 6 months of transcatheter renal denervation. Relationships between changes in rCBF, indices of 24-h blood pressure monitoring, and dynamics of cognitive function were found. Improvements of long-term verbal memory correlated well with increases in rCBF in left superior frontal region and right occipital region. Significant correlations between dynamics of mentation and attention and changes of rCBF in right posterior parietal region were demonstrated. Conclusion: Our results suggest that brain SPECT is a useful technique for the evaluation of cerebral perfusion and for understanding of cognitive disorder mechanisms in patients with resistant AH. Transcatheter renal denervation exerts beneficial effects on the levels of mean 24-h BP and load pressure and improves cerebral blood flow and cognitive function in patients with resistant hypertension. The study was supported by a grant from the Russian Science Foundation (№15-15-10016)

Quantitative evaluation of bicompartimental lymphoscintigraphy in lower extremity lymphedema

G. Villa, G. Ferrarazzo, F. Ticconi, F. Boccardo, G. Sambuceti; IRCCS Osp Univ San Martino, Genova, ITALY.

Aim: Lymphoscintigraphy is a simple and noninvasive functional test for the evaluation of the lymphatic system. Quantitative approach offers an objective measure for lymphatic function and has been shown to have higher sensitivity and specificity. Material and method: Forty subjects suffering from monolateral of bilateral lymphedema of lower extremities underwent bicompartimental lymphoscintigraphy. It was performed in different days by injecting 30 MBq of technetium 99m-nanocolloid subcutaneously and 48 hours later subfascially, in order to explore respectively superficial and deep lymphatic circuits. Total body images were recorded after 1 hour. ROIs were drawn on injection sites, inguinal nodes and liver to quantify the tracer accumulation. Kleinhans TI, percentual activity in the inguinal nodes and in the liver were calculated. Differences in continuous variables were evaluated using the Student's t-test and the Chi-squared test was used to evaluate categorical variables. Results: TI and inguinal nodes/sites of injection uptake ratio showed a very high statistical correlation (r -0.79 and -0.61). Average TI was respectively 22,3 ±2.03 and 13.5 ±3.1, percentual nodal activity was 3.6 ±0.84 and 13.5 ±3.1. Statistical correlation between hepatic uptake and TI was not demonstrated (r -0,11 and -0,12). On the other hand, sets of data from hepatic uptake after study of superficial (average 1.34 ± 0.35) and deep circuit (average 1.84 ± 0.26) are significantly different (p<0.01). Conclusion: Inguinal nodes/injection site uptake ratio is significantly higher through the deep lymphatic circuit. This parameter demonstrate an high correlation with the TI in both circuits. The result is partially expected: TI calculation takes into account two objective parameters strictly related to the entity of nodal uptake. Hepatic uptake reflects the patency of the lymphatic ducts until the subclavian vein. This peculiarity allows to express different aspects than the lymphoscintigraphy of the lower limbs and may explain the lack of correlation with the studied parameters. Our study confirms TI as an objective scoring system and quantitative analysis, simply obtainable and well correlated with the inguinal lymph node uptake. Hepatic uptake probably provides different information, not necessarily related to the peripheral lymphatic pathways conditions.

P043

Impact of 18F-FDG PET/CT in patients with suspected infective endocarditis

A. Álvarez Alonso, C. Vigil Díaz, B. Fernández Llana, A. Álvarez Blanco, N. Martín Fernández, L. Díaz Platas, N. Pérez Castro, O. Rodríguez Fonseca, F. González García; Hospital Universitario Central de Asturias, Oviedo, SPAIN.

Objective: Evaluate the diagnostic impact of the high resolution 18F-Fluoro-2-deoxy-D-glucose (FDG) PET/CT in patients with clinical suspicion of infective endocarditis (IE) and negative results for echocardiogram (EC). **Material and Methods**: A retrospective study of 9 patients with clinical suspicion of IE was performed (range 79-92 years). Two patients were male and seven were female. Four of them had prosthetic valves (2 aortic, 1 double aortic and mitral) and the five remaining had native valves (three with implanted pacemaker and one with cardiac implantable electronic devices). All patients underwent a high resolution FDG PET/CT (GE Discovery 710) using specific cardiology protocol between October 2015 and February 2016 (average activity 5.4 mCi). Final diagnosis was established according to the modified Duke´s criteria and clinical follow-up (median 4 months). **Results:** 6 of the 9 cases were classified as positive for EI according to the findings of the FDG PET/CT.

The global diagnostic concordance between final diagnosis and FDG PET/CT was 66% (6/9). Among the 6 cases with positive FDG PET/CT, the IE diagnosis was confirmed in 5 of them. Therefore, PET/CT diagnostic accuracy was superior to the EC and changed the clinical management in 55% of patients (5/9). Among the total patients, there were two false negatives and one false positive results of the FDG PET/CT study. **Conclusion**: In our pilot experience, the use of 18F-FDG PET/CT allowed to change the therapeutic strategy in 55% of patients with suspected infective endocarditis, due to the diagnostic information added to the conventional imaging techniques.

Quantitative analysis of simultaneous dual-isotope SPECT imaging using a cardiac cadmium-zinc-telluride (CZT) camera: Comparison with conventional Anger camera

T. Niimi[1], M. Sugimoto[1], M. Nanasato[1], H. Maeda[2]; [1]Nagoya Daini Red Cross Hospital, NAGOYA, JAPAN, [2]Nagoya University School of Health Sciences, NAGOYA, JAPAN.

Purpose: High-speed and high-energy resolution single-photon emission computerized tomography (SPECT), based on cadmium-zinc-telluride (CZT) detectors (D-SPECT; Spectrum Dynamics, Israel), enables high-sensitivity and high-energy resolution cardiac imaging. Moreover, high-energy resolution presents a new possibility for simultaneous dual-isotope (SDI) SPECT imaging (e.g., Tc-99m/I-123). However, SDI images can be misinterpreted owing to Compton scatter and radionuclide cross-talk artifacts. We performed image reconstitutions with and without scatter correction in order to assess the influence of cross-talk when using Tc-99m/I-123 and Tl-201/I-123 SDI imaging and quantified the simulated transmural defect contrast. Materials and Methods: We evaluated the energy resolution for Tc-99m, I-123, and Tl-201 in phantom experiments using an SDI phantom (with a simulated transmural defect induced by a difference in energy). Data from Tc-99m/I-123 and Tl-201/I-123 imaging were simultaneously acquired in energy windows centered at 140 keV for Tc-99m, 159 keV for I-123, 167 keV for the upper Tl-201 line (10%), and 69-80 keV for the main Tl-201 emission. The data from these energy windows were concurrently obtained, using the CZT or Anger camera acquisition system. Image reconstitutions were carried out with and without scatter correction, to assess the impact of cross-talk when performing use of Tc-99m/I-123 and Tl-201/I-123 SDI imaging. Differences in energy resolution were quantified by measuring the transmural defect contrast from the count value of the SDI images. Results: Upon calculation of CZT-SPECT data from the ratio of simulated transmural defect and myocardium images without scatter correction, the Tc-99m/I-123 SDI imaging improved 21.6%/56.6% and the Tl-201/I-123 improved 53.7%/19.3% compared to Anger-SPECT. In addition, visual inspection of the SDI phantom imaging failed to detect any cross talk on simultaneous dual Tc-99m/I-123 and Tl-201/I-123 CZT-SPECT SDI phantom imaging. Because the CZT detector was highly sensitive, the reduction in acquisition count had little effect, leading to an improvement of approximately 10% with both combination images after scatter correction was applied. Conclusion: The energy resolution of the CZT-SPECT system was largely superior to Anger-SPECT without scatter correction, and the Tc-99m/I-123 SDI SPECT imaging was also reliable. The CZT-SPECT system lowers the radiation dose by changing the nuclide from Tl-201 to Tc-99m, and could lead to greater patient throughput, providing further confirmation of the potential of the CZT camera for SDI acquisition.

P045

Assessment of Left ventricular Function in patients with Left Bundle Branch Block (LBBB) by means of Myocardial Perfusion Gated SPECT using CZT camera

C. Nganoa, D. Agostini, D. Legallois, A. Plane, B. Houdu, T. Salomon, **A. Manrique**; CHU Caen, Caen, FRANCE.

Background: The aim of our study was to assess the LV function of LBBB patients by means of CZT-gated myocardial SPECT compared to patients with low likelihood of CAD. **Methods**: 151 patients with LBBB undergoing a ^{99m}Tc sestamibi or tetrofosmin myocardial perfusion CZT SPECT from December 2011 to February 2014 were compared to 24 controls with low likelihood of CAD, normal perfusion SPECT and without LBBB. Stress (10 min post 2.4 MBq/kg IV) and rest (1h post 7 MBq/kg IV) acquisitions were underwent on CZT camera (D-Spectrum). LBBB patients were divided into 2 groups: "LBBB/MPI+", 75 patients with myocardial perfusion imaging (MPI) showing ischemia, infarction or both and "LBBB/MPI", 76 patients with normal MPI. LV function was assessed in post-stress and rest conditions using QGS software, including LV ejection fraction (LVEF), end-systolic and end-diastolic volumes (ESV and EDV). **Results**: Post-stress and rest LVEF were significantly decreased in LBBB patients compared to controls, with a mean difference of -14.4% in post-stress (IC95 [-17.9;-11] and -12.7% [IC95 [-16.3;-9.1] in rest conditions ($p<0.0001$). LV volumes from LBBB patients were significantly increased compared to controls. The mean difference was +35.5ml for post-stress EDV (IC95 [23.7;47.2]),+32.1ml for post-stress ESV (IC95 [23.9;40.3]) , +34.1ml for rest EDV (IC95 [21.8;43.4]) and +31.1ml for rest ESV (IC95 [22.74;39.8]); ($p<0.0001$). LV function impairment was further exacerbated in patients with LBBB/MPI+ with a declined LVEF, increased EDV and ESV than in patients with LBBB/MPI-. LBBB/MPI- pts had significantly declined LVEF, increased EDV and ESV vs controls. **Conclusion**: LV function assessed by gated SPECT using CZT camera was significantly impaired in LBBB patients with or without myocardial ischemia.

P046

Dynamic single photon emission computer tomography with dedicated CZT camera in assessment of myocardial flow reserve in patients with three-vessel coronary artery disease

A. M. Mochula[1], K. Zavadovsky[1,2], S. Andreev[1], Y. Lishmanov[1,2]; [1]RI Cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Purpose. The purpose of this study was to assess the myocardial flow reserve in patients with three-vessel coronary artery disease (MVCAD) by dynamic SPECT using semiconductor (cadmium-zinc-telluride)-based gamma camera. Material and methods. The study comprised fifteen patients (11 males and 4 females; mean age of 63.3±12.6 years) with MVCAD with the presence of coronary artery stenosis greater than 70% according to invasive coronary angiography. Control group consisted of 7 men and 2 women (25±4 years) without any cardiac diseases (healthy volunteers). All patients and volunteers underwent myocardial SPECT using (cadmium-zinc-telluride)-based gamma camera (GE Discovery NM/CT 570C). We used 99mTc-MIBI as a radiopharmaceutical. Acquisition protocol was as follows: (1) rest radiopharmaceutical injection (volume of 1 mL; dose of 185 MBq); 5-min list-mode acquisition; (2) stress radiopharmaceutical injection (volume of 1 mL; dose of 740 MBq) followed by two-minute adenosine infusion (160 mcg/kg/min); then additional two-minute adenosine infusion. List-mode (5-min duration) was started simultaneously with the injection of the radiopharmaceutical. Using dedicated software we received dynamic data on passage of the radiopharmaceutical in the walls and in the cavity of the left ventricle. To assess myocardial flow reserve, we calculated the ratio of

mean counts from the left ventricular myocardial region (apex, anterior, lateral, and septal walls) to the area under the curve from the left ventricular cavity. The index of myocardial flow reserve was calculated by dividing the ratio acquired in stress test by the ratio obtained at rest. Results. The average value of the global myocardial flow reserve (gMFR) index was lower in a MVCAD group. The gMFR indexes were 1.41±0.48 versus 1.88±0.43 in patients with three-vessel coronary artery disease and healthy volunteers, respectively ($p<0.05$). Regional myocardial blood flow reserve (rMFR) indexes also significantly ($p<0.05$) differed between patients with MVCAD and control group: 1.34±0.43 versus 1.88±0.38 for the apex; 1.44±0.41 versus 1.95± 0.45 for the lateral wall; 1.32±0.44 versus 1.63±0.43 for the anterior wall; and 1.44±0.77 versus 2.06±0.38 for the septal wall, respectively. ROC analysis showed that the gMFR = 1.77 allowed for identifying MVCAD with the sensitivity and specificity rates of 81.8% and 66.7%, respectively. Conclusion. Dynamic myocardial rest-stress SPECT using semiconductor (cadmium-zinc-telluride)-based gamma camera allowed for identifying low myocardial flow reserve in patients with three-vessel coronary artery disease. This approach can be helpful in assessment of the severity of myocardial perfusion abnormalities in these patients. The study was supported by a grant from the Russian Science Foundation (№14-15-00178).

P047

Low dose thallium myocardial perfusion imaging using CZT camera

V. Kincl[1], M. Kamínek[2], J. Vašina[3], M. Havel[2]; [1]St.Anne ´s University Hospital, ICRC, Brno, CZECH REPUBLIC, [2]University Hospital Olomouc, Olomouc, CZECH REPUBLIC, [3]Masaryk Memorial Cancer Institute, Brno, CZECH REPUBLIC.

Aim: To verify the feasibility of ultra low-dose thallium perfusion imaging using CZT SPECT camera. Methods: The study comprised 124 patients (86 men) referred for myocardial perfusion imaging. The one-day stress-redistribution protocol using 201-thallium chloride with administered activity 0.5 megabecquerel (MBq) per kilogram of body weight was performed. The quality of images was assessed by number of recorded counts and visualy by 4-grade scale (1-poor quality, 4-excellent quality). The patients cohort was divided to obese (n=43) and non-obese patients (n = 81). Results: The average quality score was 3,97 for non-obese and 3,90 for obese patients. At stresss both groups had similar number of counts (1100 for non-obese vs 1071 for obese patients, p=NS). At rest was recorded 1044 vs 1061 kilocounts respectivelly (p=NS). The mean administered activity was 39 MBq for non-obese and 49 for obese patients ($p<0.0001$), that resulted in very low effective dose 4 and 5 milisievert respectivelly ($p<0.0001$) for full stress- redistribution protocol. Conclusion: the ultra low-dose thallium myocardial perfusion protocol provides good quality of images with low radiation burden. The diagnostic accuracy will be in focus for further investigation.

P048

Influence of Different SPECT Systems And Radiotracers in Detecting the Presence and Extent of Myocardial Ischemia in the Left Anterior Descending Artery

T. Saitoh[1], T. Chikamori[1], K. Goto[2], S. HIda[1], M. Miyagawa[3], T. Fukuyama[4], T. Mochizuki[3], Y. Igarasahi[1], K. Hirose[1], A. Yamashina[1]; [1]Tokyo medical university, Tokyo, JAPAN, [2]Fukuyama cardiovascular hospital, Hiroshima, JAPAN, [3]Ehime university graduate school of medicine department of radiology, Ehime, JAPAN, [4]Shinkoga hospital, Fukuoka, JAPAN.

Background: In detecting the presence and extent of myocardial ischemia in the left anterior descending (LAD) arterial territory, few studies compared the cadmium-zinc-telluride (CZT) with the Anger cameras using ^{201}Tl or ^{99m}Tc radiotracers. **Methods**: Pooled data of 95 patients having 1-vessel disease limited to LAD (≥75 % diameter narrowing) who underwent stress myocardial SPECT using Discovery NM530c (D-camera), were extracted from the multicenter registry and were compared with the data of 63 patients using Anger camera (A-camera) from our own institution. Patients were divided into 4 groups; 62 patients studied by D-camera with ^{99m}Tc, 33 patients by D-camera with ^{201}Tl, 33 patients by A-camera with ^{99m}Tc and 30 patients by A-camera with ^{201}Tl. Patients with prior MI were excluded. SPECT image was analyzed using a 17-segment model; summed stress score (SSS) and summed difference score (SDS) were calculated, and a regional difference score (DS) limited to LAD territory were also calculated. Myocardial ischemia was defined if regional DS ≥1 was present. **Results**: Using ^{99m}Tc in 95 patients, SSS (6.7±4.2 vs 9.9±4.4; P=0.001), SDS (1.3±5.1 vs 7.5±3.0; P<0.0001), and regional DS (0.6±3.1 vs 5.7±3.6; P<0.0001) were less, and the detection of myocardial ischemia was infrequent (42 % vs 85 %; P<0.0001) by the D-camera than by A-camera. Using ^{201}Tl in 63 patients, however, SSS (12.6±7.1 vs 11.3±4.0; p=NS), SDS (7.9±6.6 vs 8.1±3.2; p=NS), regional DS (5.5±5.4 vs 5.4±3.4; p=NS), and the detection of ischemia (88 % vs 83%; p=NS) were similar either by D-camera or A-camera. In addition, in 95 patients who underwent D-camera study, SSS (6.7±4.2 vs 12.6±7.1 P<0.0001), SDS (1.3±5.1 vs 8.0±6.6 P<0.0001), and regional DS (0.6 ±3.1 vs 5.5±5.4 P<0.0001) were less, and the detection of myocardial ischemia was infrequent (42 % vs 88 % P<0.0001) with ^{99m}Tc than with ^{201}Tl. **Conclusion**: These results based on the evaluation of single-vessel disease limited to LAD, suggested that the detection of the presence and extent of myocardial ischemia in the LAD territory may be underestimated with ^{99m}Tc-radiotracer using the CZT SPECT system.

P049

Impact of Cardiac Motion on Myocardial Blood Flow (MBF) using Dynamic SPECT-CZT Imaging in patients with Coronary Artery Disease

C. Nganoa[1], M. Maguet[1], A. Manrique[1], V. Roule[1], A. Plane[1], D. Peyronnet[1], R. Baavour[2], N. Roth[2], F. Beygui[1], **D. Agostini**[1]; [1]CHU Caen, Caen, FRANCE, [2]Spectrum Dynamics Medical, Caesara, ISRAEL.

Introduction. Quantification of myocardial blood flow is an emerging topic in nuclear cardiology with an expected diagnostic incremental value in patients with CAD. The advent of a novel CZT camera has introduced new perspectives for perfusion quantification using dynamic SPECT acquisitions. However, cardiac motion during acquisition can change estimations of MBF. Therefore, the aim of the study was to compare MBF with and without cardiac motion correction (MC) using a CZT camera in patients with stable angina. **Materials and methods**. 21 patients (17 M, 4 F; 64.5± 8 yo) with stable CAD (intermediate risk factors with angina and-or positive ischemia test were prospectively included during the angiographic procedure. 6-min dynamic SPECT acquisitions using a contrast injector to deliver a bolus injection of ^{99m}Tc-sestamibi (3 MBq/kg at rest and 9 MBq/kg after regadenoson 400 μg, IV) were performed using a CZT camera (D-SPECT, Spectrum Dynamics, Israel). Reconstructed frames were automatically segmented to extract the vascular input function and the myocardial uptake curve. One-compartment kinetic modeling was used to estimate global uptake values, and then MBF was derived using the Leppo correction. Global stress and rest MBF and MFR (as a ratio of stress MBF/rest MBF) were assessed using Corridor 4DM (INVIA-Ann Arbor,USA) with and without MC. **Results**.Rest vs stress injected activity was 310 ±67 vs 817 ±166 MBq, respectively; P<0.05. The total injected dose was 1127±228 MBq. Cardiac motion was identified in all patients on the sinogram and then corrected for left atrium ROIs positioning image-derived input function assessment. Global stress and rest MBF (with MC+ vs without MC-) by SPECT were not significantly different: stress (MC+) = 2.29± 0.76 vs (MC-) 2.73± 0.75 ml/min/g; rest

(MC+) = 0.89± 0.36 vs (MC-) 1.05± 0.35 ml/min/g; (P=NS, unpaired bilateral t-test). CFR was also not significantly different: (MC+) = 2.72± 0.81 vs (MC-) 2.77± 0.81; P= NS. **Conclusion**. Even with cardiac motion present during all dynamic SPECT acquisitions, the additional input of motion correction was not necessary to estimate global MBF and MFR in patients with CAD.

P050

Diagnostic impact of CT attenuation correction on CZT myocardial perfusion SPECT in patients with coronary artery disease compared to cardiac SPECT/CT hybrid imaging

Y. Fukushima, S. Kumita, H. Hashimoto, Y. Sugihara, K. Iwata, T. Hamana; Nippon Medical School Hospital, TOKYO, JAPAN.

Introduction: Cadmium-zinc-telluride (CZT) solid-state detectors have multiple advantages over conventional NaI cameras, such as higher spatial resolution, energy resolution, and sensitivity. However, CZT myocardial SPECT images show noticeable attenuation artifacts in the septal, inferoposterior, and posterolateral walls of the left ventricular myocardium. CT attenuation correction (CTAC) can improve the diagnostic accuracy of myocardial SPECT. Furthermore, myocardial SPECT/coronary CT angiography (CCTA) fused images provide true coronary artery distributions. The aim of this study was to determine the impact of CTAC on the diagnostic performance of CZT myocardial perfusion SPECT for patients with coronary artery disease (CAD) compared to cardiac SPECT/CCTA hybrid imaging. ***Materials and methods:*** The study between April 2015 and March 2016 included a total of 289 consecutive patients who were suspected of CAD and underwent a one-day rest-stress myocardial perfusion SPECT test using a CZT gamma camera: Discovery NM530c. The final study cohort was comprised of 46 patients (65 ± 15 years, 30 men and 16 women) who then underwent CCTA. Using a dedicated software for CTAC, SPECT images were coregistered with low-dose CT images acquired simultaneously with a separate device: Symbia T2. Using the 17-segment model, the summed rest scores (SRS), summed stress scores (SSS), and summed difference scores (SDS) were derived from both non-attenuation corrected (NAC) images and CTAC images. The presence or absence of myocardial ischemia in the left anterior descending artery (LAD), diagonal branch (Dx), left circumflex artery (LCX), or right coronary artery (RCA) territories was confirmed. The presence of CAD (> 50% coronary artery stenosis) was revealed using CCTA with SPECT/CCTA fused analysis, and the diagnostic accuracies of both NAC and CTAC images were compared. ***Results:*** There was a significant difference between NAC and CTAC images concerning both SRS and SDS (12 ± 6 vs. 9 ± 6, p = 0.0003 and 2 ± 4 vs. 4 ± 4, p = 0.0009, respectively) while SSS did not differ (14 ± 8 vs. 13 ± 8, p = 0.253). CTAC improved accuracy globally and in the RCA territory (63% to 71% and 54% to 63%, respectively). Sensitivity was also improved in each individual territory (LAD: 50 to 63%, Dx: 44 to 58%, LCX: 25 to 50%, RCA: 36 to 58%). ***Conclusions:*** CTAC improves the diagnostic performance of CZT myocardial perfusion SPECT for patients with CAD. Furthermore, CTAC images can more accurately detect hemodynamically significant coronary lesions in cardiac SPECT/CCTA fused images.

P051

Myocardial Perfusion Imaging using IQ-SPECT, comparison with Coronary Angiography, Single Center Experience

M. Trogrlic, S. Tezak; University Hospital Centre Zagreb, Zagreb, CROATIA.

AIM: to evaluate the diagnostic performance of myocardial perfusion imaging (MPI) obtained with a multifocal collimator, IQ-SPECT, in the detection of coronary artery disease (CAD) by comparison with invasive coronary angiography (CA).MATERIALS AND METHODS: 106 patients (60 males and 46 females; mean age 60±9 years) with intermediate and high post stress coronary artery disease probability were included in this retrospective study. Patients showing only scar on MPI were excluded from study. All patients underwent two-day protocol perfusion scan (Gated IQ SPECT/CT) after stress test and at rest. Acquisition was performed on a Symbia T (Siemens) equipped with a dual-headed gamma camera system and with a multifocal smartzoom collimator. Acquisition was done in 128x128 matrix, 50 min after tracer injection (370 MBq Tc-99m sestamibi), 17 views per head, 20 sec/view. Flash 3D iterative reconstruction was done. Expert in nuclear cardiology assessed all myocardial perfusion images using 4D-MSPECT software. CAD was defined as ≥50% stenosis of epicardial coronary arteries or their major branches detected on CA. RESULTS: On the basis of scintigraphic results, subjects were divided in two groups: Group A (n=74) with pathological findings on MPI, and group B (n=32) with normal MPI. 52 patients underwent CA within one year after MPI. In group A 64 patients (86.5%) had evidence of ischemia (showing at least one reversible defect - Summed Difference Score SDS>3) while other 10 (13.5%) had evidence of scar with ischemia. The comparison between IQ SPECT and CA (available for 45 patients in group A) showed that in 24.4% (11/45) no evidence of stenosis ≥50% in coronary arteries was found. 16 patients (35.5%) with multivessel CAD had more frequently severe ischemia on MPI. 18 patients (40%) had one-vessel disease. Despite no evidence of CAD on MPI in group B, 21.9% of patients (7/32) underwent CA showing no evidence of coronary artery stenosis in all cases. The comparison between MPI and CA showed that IQ-SPECT had sensitivity of 100% (89.72%-100%), specificity of 38.9% (17.30%-64.25%), accuracy of 78.8%, positive predictive value of 75.6% (60.46%-87.12%), and negative predictive value of 100% (59.04%-100%). CONCLUSIONS: IQ SPECT has excellent sensitivity, very good accuracy and high negative predictive value. Specificity is lower than expected probably due to changes in smaller coronary artery branches not detectable by CA, stenosis in coronary arteries less than 50%, or due to vasospasm. In our study we confirmed CAD in 34 out of 106 patients (32.1%).

P052

Tc99m Myocardial perfusion imaging using IQ SPECT: Prognostic comparison of stres only normal study and stres-rest normal study, one year follow up

F. ÇINARAL SAYIN, Ö. SAVAŞ DEN HARTIGH, M. ÖZHAN, H. MEMİŞ, Ö. MENGİ; KARTAL KOŞUYOLU TRAINING AND RESEARCH HOSPITAL, İSTANBUL, TURKEY.

Aim: Guidelines for myocardial perfusion SPECT (MPS) recommend that if stress examination is performed first and reported as normal, the rest examination can be omitted. (MPS) Studies using IQ-SPECT Symbia S system (Siemens, USA) with SMARTZOOM™ collimators and with dedicated reconstruction software provides shorter scan time using lower levels of radioactivity compared to the conventional SPECT systems. We aimed to evaluate the prognostic value of stres only normal study compared to stres-rest normal study using IQ SPECT. Methods: Three hundred thirty nine patients underwent Tc99m myocardial perfusion scintigraphy with IQ SPECT on February 2013. Patients with abnormal studies were excluded. One hundred seventy four patients with normal MPS studies were enrolled in the study. Two days and stress first protocole was used. Patients with low likelihood of coronary artery disease that had normal stress study, did not have the rest study. Two days rest imaging was performed on patients with equivocal findings or with any abnormality on imaging after stress. The patients hospital data records were checked for follow up in one year. Myocardial perfusion GATED SPECT imaging results are compared with the clinical outcomes of the patients. Results: Stres

only protocole was used for 118 patients (85 Female, age 43-84, mean 63,4), (33 Male, age 42-81, mean 62,6) and two days stress-rest protocole was used for 55 patients (29 Female, age 45-77, mean 64), (26 Male, 38-80, mean 65,7). Among the stress only group 3 patients (2,5%) had cardiac events/ symptoms, one patient had LAD stenting, one patient had RCA stenting and one patient had coronary artery bypass surgery. One patient (1,8%) from the stres-rest study group had cardiac symptoms in one year of follow up and underwent coronary anjiography revealing LAD lesion. Statistical analysis results revealed that there's no significant difference (p value < 0.01) between the two study groups prognosis for one year of follow up. Conclusion: Patients having normal stres imaging only have the same cardiac event rate with the patients having normal stres-rest imaging study. Stress only protocole can be used with the IQ SPECT gamma camera resulting in lower levels of radioactivity consumption and shorter scan time

P053

Keeping the reproducibility of functional parameters of the left ventricle between conventional system and IQ-SPECT

M. Havel, M. Kaminek, L. Henzlova, P. Koranda; Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, CZECH REPUBLIC.

Introduction: Technological progress in myocardial perfusion imaging (MPI) brings to the market new dedicated tomographic devices but also additions to conventional Anger style cameras, such as "IQ-SPECT" system with multifocal "SMARTZOOM" collimators. The possibility to reduce the administered dose or acquisition time with this modern upgrade is progressive. However, in our daily practice we found there are significant differences when comparing results of the functional parameters of the left ventricle acquired with conventional camera equipped with Low Energy High Resolution collimators (LEHR) and "SMARTZOOM" collimators, as we referred previously. We tried to find easy way to keep the reproducibility of the results between the both systems by changing the filter parameters of the "IQ-SPECT" gated studies. Materials and methods: For this purpose we utilised random group of 31 patients, (19 males, 12 females, average age 62.4 +/- 8.4 years). All subjects were examined on both conventional (acquisition matrix 64x64, zoom 1.46) and "IQ-SPECT" (acquisition matrix 128x128, zoom 1.0) system. Acquisition was done on Symbia S dual head SPECT camera, data with LEHR collimators were processed and reconstructed with filtered back projection (applied Butterworth filter of order 5 with cut-off frequency 0.35). Data obtained with "SMARTZOOM" collimators were reconstructed with vendor's Flash3D iterative reconstruction (2 subsets, 15 iterations) and then filtered with the various settings of Butterworth (cut-off frequency range 0.2 - 0.4, order 1 - 8) and Gauss (FWHM 14 - 20 mm) filters - in total of 68 variations. The matrix of the "IQ-SPECT" study was changed to 64x64 prior filtering. The tomograms were processed in CORRIDOR4DM software. We compared ejection fraction values, end-diastolic and end-systolic volumes (EF, EDV, ESV) to find the best correlation between them. Results: Based on the Bland-Altman analysis we found the best agreement for the EF value from IQ-SPECT study processed with the Butterworth filter of order 2 and cut-off frequency 0.35 (mean difference -1.0%EF, the 95% limits of agreement were placed at -11.8%EF and +9.7%EF, Pearson correlation = 0.91). However, the width of the interval was still quite large. With this setting, the Pearson correlations for EDV was 0.96 and for ESV 0.97. Conclusion: The technological effort in MPI must keep the reproducibility of the results during the follow-up, with postprocessing there is possibility to adjust the the outcomes of "IQ-SPECT" to agree better with the conventional system.

P054

IQ-SPECT Positioning Uncertainty in Myocardial Perfusion Studies

T. Mäkelä[1,2], E. Hippeläinen[1,2]; [1]HUS Medical Imaging Center, University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND, [2]Department of Physics, University of Helsinki, Helsinki, FINLAND.

Objective: Myocardial perfusion imaging is one of the most performed examinations in nuclear medicine. Pre-acquisition patient positioning can be challenging e.g. with large patients or if high liver or bowel uptake are present. The importance of correct centring is emphasized when using a cardio-centric orbit with multifocal collimators. Incorrect heart positioning can affect the image reconstruction and produce inaccurate semi-quantitative perfusion results. The aim of this study was to estimate the positioning accuracy in clinical practice. **Materials and methods**: Data from 379 clinical two-day stress-rest perfusion studies were retrospectively evaluated. Approximately 550 MBq of ^{99m}Tc labelled tetrofosmin (Myoview) was administered per day. If the scan was immediately repeated only the latest acquisition was included in the data set. The centring error was estimated as a distance from the SPECT centre-of-rotation (COR) to the middle point of the left ventricle. CORs were derived from the DICOM header values. The left ventricle middle points were determined from the perfusion images using MATLAB code particularly written for this project. The code was verified by comparing the output to ten manually determined ventricle centres. **Results**: The sample mean (± one standard deviation) distance between the program results and manual measurements was 6±3 mm. All automatically determined middle points were visually verified and one study (0.3 %) had to be manually corrected. The heart positions relative to the CORs had mean values of x=-9±12, y=5±9 and z=-1±9 mm for right-to-left, anterior-to-posterior and inferior-to-superior directions, respectively. The mean Euclidean distance was 17±10 mm for the stress and 18±9 mm for the rest images. In 9 % of the images the COR was positioned ≥30 mm from the estimated ventricle centre. **Conclusion:** When considering typical heart sizes and the automated localization uncertainty only a minor directional bias was observed in the patient left-right direction. However, several individual outliers were present. It has been reported based on phantom studies that <2.5 cm offsets are unlikely to affect perfusion results (Caobelli et al. J Nucl Cardiol 2015;22:57-65). Further study is needed to assess at what distances mispositioning becomes clinically significant. Hopefully, a similar on-line verification will be implemented in the imaging systems giving the user instant feedback on positioning accuracy.

P055

A Comparative Study of Half Time Versus Full Time IQSPECT Acquisition in Patients Receiving Half the Standard Weight Based Dose

S. Panchadar, G. Biswas, Y. Al Sayed, M. HJ Garashi; Chest Disease Hospital, MOH, Kuwait, KUWAIT.

Aim: To evaluate IQSPECT semi-quantitative parameters and image quality at half time (HT-12Secs/frame) in comparison to full time (FT-20Secs/frame) in patients receiving standard weight based half dose. **Materials and Methods:** Ninety eight (98) patients (62 males and 36 females; aged between 44-72 yrs) who had come for diagnosis of coronary artery disease (CAD), were randomly selected for myocardial perfusion studies with IQSPECT (SymbiaT16; Siemens) after being given standard weight based half dose (0.142mCi/Kg). Imaging was done 45mins after radiopharmaceutical administration initially with half time (HT) followed immediately by full time (FT) acquisition using single low dose CT for attenuation correction. Half of the Patients were imaged with initial HT acquisition followed immediately by FT acquisition and the other half were imaged with FT acquisition first followed immediately by HT acquisition. **Results:** Summed stress score (SSS), summed

difference score (SDS), summed rest score (SRS), total perfusion defect (TPD) and extent were significantly higher for IQSPECT-HT acquisition vis-à-vis FT acquisition ($p \leq 0.05$). Calculated left ventricular ejection fraction (LVEF) and left ventricular volumes (both end diastolic volume (EDV) and end systolic volume (ESV) were similarly affected by HT acquisition ($p \leq 0.05$). Quality of images on HT acquisition were sub-optimal on visual analysis. **Conclusion:** Full time acquisition on IQSPECT is optimal for good quality images and reflects accurate semi-quantitative parameters in patients receiving half the standard weight based dose in comparison to half time (HT) acquisition in the same setting. Half time (HT) acquisition may be appropriate in patients receiving standard weight based full dose.

P056

Risk assessment using IQ SPECT myocardial perfusion scintigraphy in patients with coronary artery disease

G. Schweighofer Zwink[1], L. Hehenwarter[1], G. Rendl[1], M. Beheshti[2], C. Pirich[1]; [1]Universitätsklinik für Nuklearmedizin und Endokrinologie, Salzburg, AUSTRIA, [2]Abteilung für Nuklearmedizin, Krankenhaus der Barmherzigen Schwestern, Linz, AUSTRIA.

Aim: To assess the value of standard semiquantitative parameters for risk stratification in patients with manifested coronary artery disease undergoing accelerated myocardial perfusion imaging (MPI) using IQ SPECT. Material and Methods: Retrospective analysis of 204 patients with angiographically proven coronary artery disease (CAD) referred to our department for risk stratification with MPI performed using a two-day pharmacological stress protocol with adenosine or regadenoson and gated Tc-99m-Tetrofosmin SPECT (4 MBq per kg body weight). Data were acquired in 17 views (17 sec. each) using a Siemens Symbia T6 camera using IQ-SPECT collimators and the results were generated with Corridor 4DM software. The SSS, SRS, SDS, EF, TID, extent of ischemia and scar tissue in % of left ventricular area and time-to-peak values were analyzed statistically using SPSS software. Results: 204 patients (144 males, 60 females) with a mean age of 68±11 years were included into the study of whom 134 had multivessel disease. Comparing patients with single (SVD) versus multivessel disease (MVD) resting EF (46.4±11.3 % vs. 41.5±13.6 %, p=0.01) SSS (8.0±7.8 vs. 14.7±9.8, p< 0.01), and SRS (5.7±7.2 vs. 11.0±9.7, p=0.01) and the extent of ischemia (5.4±7.4 % vs. 8.6±8.2 %, p< 0.01) and scar tissue (5.8±10.4 % vs. 11.5±11.7 %, p= 0.02) were significantly different in patients with SVD as compared to MVD. Neither TID nor SDS nor additional motion parameters showed a significant difference between those groups. Conclusion: The study employing accelerated MPS with IQ SPECT and a pharmacological stress protocol demonstrates that standard parameters i.e. EF, SSS, SRS and the extent of ischemia and scar tissue are significantly different in patients with SVD as compared to MVD and can be used for risk stratification while TID and time-to-peak analysis were not.

General purpose collimators with resolution recovery enable significant dose reductions while maintaining image quality in myocardial perfusion SPECT

K. J. Saint, I. S. Armstrong, P. Chilra, S. Bartley, C. M. Tonge, P. Arumugam; Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

Introduction. Increasing demand for myocardial perfusion SPECT (MPS) and continuing focus on dose reduction combined with forthcoming shortages of Tc-99m availability motivates a reduction in administered activity. Resolution Recovery (RR) enables reductions in either administered activity or imaging time. A recently published multi-vendor phantom study from our department demonstrates that more sensitive LEGP collimators with RR can provide comparable image quality to LEHR collimators with RR and allow for a reduction in administered activity. This work presents findings from a prospective follow-on patient study. Methods. 29 MPS scans were performed on a GE Infinia sequentially with LEHR collimators and then with LEGP collimators. Patients were administered tetrofosmin using a BMI-based protocol [280 MBq + 14 MBq × (BMI - 25)]. Based on the phantom work, pixel size was set at 6.8 mm for LEHR images and 4.4 mm for LEGP images. Counts in the myocardium were matched, being equivalent to a 40% reduction in administered activity in the LEGP images. Images were reconstructed with and without CT attenuation correction using GE Evolution for Cardiology with 6 iterations, 10 subsets and a Butterworth filter Fc 0.35 cycles/cm and power 10. Summed scores were extracted from a normal database comparison using Corridor 4DM. Functional data (EDV, ESV and LVEF) were analysed in Cedars Sinai QGS. Results. Image quality was comparable for images using each collimator. No significant differences were observed for the summed scores. On average, EDV and ESV were 16% (P<0.01) and 26% (P<0.01) greater in the LEGP images, respectively. On average, the LVEF was 3.1 percentage points lower (P<0.01) in the LEGP images. The LVEF difference showed an inverse relation with the ESV. This is likely to be due to the smaller pixel size and reduced partial volume effects. Conclusion. MPS acquired using general purpose collimators with RR provides an excellent means of reducing administered activity and hence radiation dose, whilst maintaining image quality and quantitative perfusion results. The potential radiation dose for a two-day stress-rest protocol in our department would be between 3 to 4 mSv when using LEGP collimators. Furthermore the reduced Tc-99m usage will increase resilience against anticipated cost increases of radioisotope supply. As the majority of gamma cameras have LEGP collimators available, we believe that this is a highly accessible approach, which will facilitate a widespread reduction to population radiation dose from MPS.

P058

Role of Cardiac Hybrid Imaging (SPECT-CTCA) as a Prognostic Tool in Cardiomyopathy Patients

G. Sankar, S. Gambhir, P. K. Pradhan, N. K. Garg, A. Prashanth, A. K. Singh; SGPGIMS, Lucknow, INDIA.

Background and Aim of the study: Dilated cardiomyopathy (DCM) is a disorder characterised by enlargement of the left ventricular cavity along with systolic dysfunction. Idiopathic is the most common cause followed by myocarditis and ischemic heart disease. Single photon emission computed tomographic myocardial perfusion imaging (SPECT-MPI) shows high sensitivity in diagnosing ischemic component in DCM patients but it has moderate specificity. Similarly computed tomographic coronary angiography (CTCA) has high negative predictive value in ruling out ischemic disease. To incorporate the duality of morphology and function and to overcome individual limitations fusion imaging was done. The aim of this study was to know the value of fusion imaging as a prognostic tool in cardiomyopathy patients. **Materials and methods:** Thirty one patients clinically diagnosed by cardiologists to have DCM were included in this prospective study. They had no prior documented history of coronary artery disease (CAD). Initially they underwent stress-rest SPECT-MPI using Tc-99m labelled sestamibi . Of this only 28 patients underwent CTCA subsequently. Fusion imaging was successfully done using CardIQ software (GE Healthcare). Only those patients who had matched perfusion defects to stenotic segments in fusion imaging were labelled as having CAD. All the patients were followed up prospectively post fusion

imaging. Any cardiac events leading to hospital admission or cardiac death were considered as events. The effect of various parameters over event free survival was calculated using log rank test by Kaplan-Meier method. A p value of <0.05 was considered significant. **Results:** All the 31 patients who were initially included in the study were followed up for a median period of 6.5 months (range: 1 to 20 months; S.D: 6). Events occurred in five of the 31 patients (16%) the follow up period. Only three parameters, total calcium score (p=0.004), the nature of the perfusion defect (non viable, partially viable fixed defect, reversible ischemic and normal perfusion) noted in SPECT-MPI study (p=0.032) and the outcome of the fusion imaging (whether patient was labelled to have ischemic disease based on matched defects in fusion imaging or not) (p=0.038) were found to have a significant impact on event free survival in Kaplan-Meier survival analysis using log rank test. **Conclusion:** Fusion imaging may act as an independent prognostic marker in DCM patients, however longer median follow up period and larger multicentric prospective studies are required to validate these findings.

P059

SPECT MPI in the assessment of post infarct therapeutic attitude

S. E. Bouyoucef, A. Talbi, M. Habbeche, A. Khelifa, s. Rahabi, A. Amimour; CHU Bab El Oued, Algiers, ALGERIA.

Introduction: Prognosis following MI depends on a number of factors including geographic location, patient's health, extent of heart damage, and treatment given. However early risk stratification post-MI and therapeutic strategy is important to determine patients at increased risk for a recurrent ischemic event and those at increased risk for cardiac death (arrhythmic or non-arrhythmic). **Objective:** To assess the therapeutic approach by SPECT MPI Imaging and allows an accurate assessment of prognosis and guide patient post-MI management. **Patients and methods:** 430 patients in early phase of post myocardial infarct have been investigated in by SPECT/MPI. Patients have been classified in two groups: those who have received thrombolysis with or without revascularization and those who have not been thrombolyzed. All patients recruited during two months underwent a two days protocols with physical/pharmacological stress/rest Gated SPECT MPI using tetrofosmine (Myoview) and a dual head gamma camera (Symbia T6) **Results:** Average age of patients was 60.6 years with a ratio Men/woman of 4 :1. Identified risk factors were : Hypertension (56%), Diabetes (43%) smoking (39%) and dyslipidemia (26%). 54% of patients did not received thrombolysis nor revascularization meanwhile 46% received thromblysis treatment (14%) or revascularization by coronary artery bypass grafting (CABG, 12%) or percutaneous coronary intervention (PCI, 20%). Gated SPECT MPI showed in 357 patients (85%) fixed defects in 357 patients (85%) and reversible defects in 270 patients (63%). It was noted that more reversible defects were seen in patients who did not received thrombolysis (57%) than in those patients who did receive a thrombolysis or a revascularization. Patients who benefited from revascularization showed better summed stress score and less stress ischemia in other territories than patients who have not been thrombolyzed (ratio of 0.7). Average post effort ejection fraction was better (59%) in patients who have been revascularized than in not thrombolyzed patients. Average of transient index dilation (TID) was more elevetad (>1.18) in non thrombolyzed patients. **CONCLUSION:** SPECT/MPI is an important tool to assess post MI therapy and it is useful to stratify patients according the MPI findings in order to predict with better accuracy of the outcomes of post infarct therapy strategy.

P060

Gated myocardial perfusion SPECT-CT imaging with coronary calcium scoring in asymptomatic patients after percutaneous coronary intervention

A. Tzonevska[1], M. Garcheva[1], I. Kostadinova[1], L. Chavdarova[2], K. Tzvetkov[2]; [1]City Clinic, SOFIA, BULGARIA, [2]HATO, SOFIA, BULGARIA.

Objective: Restenosis is the main problem in patients who have had percutaneous coronary intervention (PCI). Chest pain following PCI is a poor indicator of restenosis. The purpose of the present study was to assess the usefulness of gated single photon emission tomography/computed tomography ^{99m}Tc-tetrofosmin (gSPECT-CT) combined with coronary calcium scores (CAC) in asymptomatic patients after PCI. **Methods:** 57 asymptomatic patients (32 male and 25 female), mean age 49±16 years, 6 to 27 months after PCI with stent revascularization, were recruited. They were examined by technetium-99m-tetrofosmin gSPECT-CT and CAC scores and standard stress protocol. The quantitative analysis of the myocardial perfusion and function (QGS/QPS) and CAC score calculation with the Agatston method were used. **Results:** In 32 (56%) patients, normal myocardial perfusion and function was found. From twenty five patients with moderate to severe CAC, 9(16%) patients had mild to moderate hypoperfusion and were assessed as with low risk for coronary events and were referred to medical treatment and follow-up. In 16(28%) patients high risk for coronary events was diagnosed and they were referred to PCI. In 6(11%) patients in-stent restenosis was detected. In 8(14%) patients significant stenosis in unstended coronary vessel was assessed. In 2 patients no significant stenosis was found. Sensitivity and specificity were 93% and 84% respectively. **Conclusion:** ^{99m}Tc-tetrofosmin gSPECT-CT plus CAC scores provided combined cardiac assessment and can serve as a reliable screening method to assess asymptomatic patients, passed PCI and define risk stratification and management of these patients.

P061

The Association of Regadenoson and Isometric Exercice Significantly Improves Image Quality of Myocardial Perfusion Scintigraphy

j. Pinaquy, Q. Ceyrat, H. Douard, L. Janvier, L. Bordenave; CHU BORDEAUX, BORDEAUX, FRANCE.

Background: Regadenoson is a selective A2a receptor agonist and it is widely used as vasodilator for the stress test of myocardial perfusion imaging (MPI). This study aimed at assessing whether adding an isometric exercise (i.e. handgrip) to Regadenoson injection would improve image quality and be well tolerated by patients. Methods: Patients referred for MPI were prospectively randomized in either the handgrip-Regadenoson group (HG-Reg, n= 50) or Regadenoson only (Reg, n = 50) group. A Nuclear Medicine physician, blinded to the stress test modalities and clinical characteristics of the patients, analyzed data. As a primary endpoint, the images were classified as good or bad. Secondary endpoints were: the hemodynamic changes, the recovery time and clinical side effects. Results: The images in the HG-Reg group were of significantly better quality than those in the Reg group (88% vs 52%, p<0.00001). Systolic blood pressure fell significantly less often in the HG-Reg group than the Reg group (p=0.0216). The other parameters (heart rate, maximum heart rate and percentage of age-predicted maximum heart rate, systolic blood pressure, recovery time) were not significantly different between the two groups. Fewer subjects in the HG-Reg reported at least one side effect in comparison to Reg subjects (70 vs. 92%, p=0.047). Conclusions: The association of handgrip exercise and Regadenoson administration is well tolerated and allows for a significant improvement in image quality of myocardial perfusion scans.

P062

Myocardial perfusion imaging for evaluation of the borderline coronary stenoses

M. B. Garcheva-Tsacheva[1], V. Gelev[2]; [1]Cityclinic-Sofia, SOFIA, BULGARIA, [2]Tokuda hospital-Sofia, SOFIA, BULGARIA.

Introduction. The stress myocardial perfusion imaging is important for visualization and quantification of the inducible hypoperfusion. The hemodynamic significance of borderline stenosis (BLS) is questionable, even in symptomatic patients. Aim. The aim of the study was to visualize and quantify the inducible ischemia by stress myocardial perfusion imaging (MPI) in patients with borderline stenoses, known from coronary angiography. Material and methods. Seventy six patients (49 men, 27 women aged from 45 to 87) with at least one borderline stenosis were examined by MPI after submaximal or symptoms limited stress. The examination was performed on Symbia 2T Siemens SPECT/CT with attenuation correction. Seven patients with previous myocardial infarction had also rest MPI. A quantitative evaluation was also done by QPS/QGS software with determination of the summed stress score (SSS), or summed differential score (SDS). The number of vessel territories with BLS was 126: 7 left main stenoses (LCA), 52 left anterior descendens (LAD), 29 right coronary arteries (RCA), 26 circumflex arteries (rCx) and 12 others. Thirteen vessels with in stent restenosis more than 40% were included. Results. Iinducible hypoperfusion was visualized in 27.5% of patients and 18 % of lesions. Sixteen patients (from 21 with hypoperfusion) were with SDS between 4 and 8, the others had SDS 3. One patient received inducible left ventricular dysfunction. Two patients (from 13 with restenoses) had inducible ischemia. Discussion. The quantification by SSS, or SDS reflects the inducible hypoperfusion, while the total perfusion defect may include scar, or attenuation phenomenon. In our group of patients with BLS there were no patients with severe degree of hypoperfusion Conclusion. MPI is important not only for visualization, but also for evaluation of the severity of the reversible perfusion changes, due to borderline coronary stenosis for determination of the further management of patients.

P063

The impact of attenuation correction in SPECT / CT on quantitative parameters of myocardial perfusion in patients with intact coronary arteries

E. Khachirova[1], L. Samoylenko[2], O. Shevchenko[1]; [1]Pirogov Russian National Research Medical University, Department of Cardiology FDPO, Moscow, RUSSIAN FEDERATION, [2]Russian Medical Academy of Postgraduate Education Studies , Department of radiotherapy and radiology, Moscow, RUSSIAN FEDERATION.

The aim: to assess the impact of attenuation correction (AC) on quantitative parameters of myocardial perfusion and verification of myocardial ischemia in patients with chest pain and intact coronary arteries (CA). Material and methods: myocardial perfusion rest/stress SPECT/CT ^{99m}Tc -MIBI (SYMBIA T-16, SIEMENS) with and without AC was performed in 35 patients (male/female 15/20, mean age- 62.8 yrs) with a typical chest pain, a positive stress test, and intact CA. Patients with previous myocardial infarction, significant valvular disease, clinical heart failure or depressed systolic left ventricular function were not included. Results: In all patients stress-induced myocardial ischemia was detected both without and with AC images. However, quantitative parameters of myocardial perfusion were lower after the AC: SSS 6.9±1.2 vs. 7.7±1.1; SDS 4.0 ±0.8 vs. 4.9 ± 0.6; Stress ext. Total 11.2±1.8 vs. 13.0±1.9; Stress TPD total 9.3±1.2 vs.10.9±1.2; TPDi 4.1±1.0 vs.5.9±0.9 (for all p<0.05). For SRS, Rest ext. Total, and Rest TPD total difference was not significant. In women, significant difference was obtained for all parameters: SRS, SSS; SDS, Stress ext.Total, Stress TPD total, Rest ext.Total, Rest TPD total, TPDi (2.8±0.8 vs. 3.7±0.9; 7.4±1.4 vs. 9.0±1.6 4;5±0.8 vs. 5.3±0.9; 12.3 ±1.4 vs. 14.7±2.1; 10.3±1.8 vs. 12.7±2.1; 4.5±1.1 vs. 5.6±1.4; 4.0±0.9 vs. 5.5±1.1; 6.4±1.2 vs. 7.1 ± 2.1,for all p<0.05), for men - only for the SSS, SDS, Stress ext. Total, Stress TPD total (6.4±1.3 vs. 7.9±1.1; 3.3±0.8 vs. 4.4±0.7; 12.2±1.6 vs. 14.1±1.8; 9.7±1.2 vs. 10.9±1.4; p<0.05). In patients with BMI ?25 significant difference for all parameters was obtained: SRS 3±0.7 vs.4.5±0.8; SSS 7±1.8 vs. 9.9±2.2; SDS 4.0±0.9 vs.5.3±0.6; Stress ext.Total 13.5±1.8 vs.16.2±2.2; Stress TPD total 10.4±1.9 & 13.3±2.1; Rest ext.Total 5.5±1.6 vs. 7±1.7; Rest TPD total 4.8±1.1 & 6.5±0.8; TPDi 5.5±1.5 & 7±1.9 (for all p<0.05). However, patients with a normal BMI (18,5-24,9;WHO, 2004) significant difference was obtained only for Stress ext. Total, Stress TPD total (11.3±2.4 vs. 12.6±2.6; 9.6±1.6 vs. 10.7±1.8, p<0.05). Ñonclusion: Our results support better diagnostic ability with AC SPECT/CT for detection of the myocardial ischemia. Using AC one could decrease false-positive results and avoid overestimation of the extent and severity of perfusion defects, especially in women and obese patients.

P064

SPECT MPI finding in the prognosis of dilated cardiomyopathy

S. E. Bouyoucef, s. Rahabi, A. Talbi, M. Habbeche, A. Khelifa, A. Amimour; CHU Bab El Oued, Algiers, ALGERIA.

Introduction: The prognosis for dilated cardiomyopathy (DCM) is very specific to an individual and their particular anatomy. Some people with the condition can lead a normal life and remain essentially symptomatic. Others develop symptoms that can progress. MRI and SPECT/MPI are an important imaging modalities to assess and to establish a prognosis of the DC. **Objective:** To assess the role and the place of SPECT/MPI in the therapy management of DCM. **Patients and methods:** 84 patients have been referred to nuclear medicine department for DCM in 4 months. All patients recruited underwent a two days protocols with physical/pharmacological stress/rest Gated SPECT MPI using tetrofosmine (Myoview) and a dual head gamma camera (Symbia T6). A SPECT MPI analysis using the 4DM SPECT was done and comparison done between perfusion findings and clinical, risk factors and echocardiography results. **Results:** Average age of patients was 61 years with a ratio Men/woman almost equal to one (53% vs 47%). The risk factors were dominated by Hypertension (66%) than Diabetes (45%), dyslipidemia (26%), smoking (21%) and heredity (8%). 84% of patients were symptomatic and the dyspnea was the most frequent symptom (68%) followed by pectoris angina (42%). 26% of patients presented and LBBG and underwent a pharmacological stress SPECT MPI. Average ejection fraction obtained by echocardiography was 43%. SPECT MPI showed fixed defects in 66% of patients, reversible defect in 53% and normal patterns in 8% patients. Among patients with fixed defects, 60% have had more than 3 segments involved, 30% between 2 to 3 and 10% less than 2 segments. Regarding patients with reversible defects, 35% have had more than 3 segments involved, 40% between 2 to 3 and 25% less than 2 segments. Number of reversible defects as well as number of fixed defects were correlated to the clinical symptoms. SPECT MPI has helped in most cases to find out an appropriate therapeutic strategy. **Conclusion:** SPECT MPI in dilated cardiomyopathy is an important prognostic tool and has a major place in adjusting initial therapy in order to reduce cardiac events and improve quality of live.

P065

Assessment of myocardial perfusion in patients with chest pain and intact coronary arteries using ^{99m}Tc-MIBI SPECT/CT

E. Khachirova[1], L. Samoylenko[2], O. Shevchenko[1]; [1]Pirogov Russian National Research Medical University, Department of Cardiology FDPO, Moscow, RUSSIAN FEDERATION, [2]Russian Medical Academy of Postgraduate Education Studies , Department of radiotherapy and radiology, Moscow, RUSSIAN FEDERATION.

The aim: assessment of myocardial perfusion and functional coronary flow reserve in patients with chest pain and unchanged coronary arteries (CA) using ^{99m}Tc -MIBI SPECT/CT. Material and methods: Myocardial perfusion rest/stress ^{99m}Tc -MIBI SPECT/CT (SYMBIA T-16, SIEMENS) was performed in 21 patients (male/female 8/13, mean age-61.6 yrs) with a typical chest pain and angiographically intact CA (the study group); in 14 patients (m/f - 8/6, mean age 57.4 yrs) with coronary atherosclerosis (the comparison group) in a two-day protocol. Results: All the patients from the study group showed transient ischemia during stress-test. 15 patients from the study group had arterial hypertension, of those 10 patients showed transient perfusion defects during positive stress-test, and 5 patients during negative stress-test. These findings in the latter patents were considered as secondary microvascular dysfunction associated with arterial hypertension. In 6 patients from the study group without arterial hypertension transient perfusion defects during positive stress-test were found. These findings were considered as primary microvascular dysfunction. Quantitative indicators of the extent and severity of perfusion defects showed moderate changes in the study group, however, they were significantly different vs. the comparison group: SRS 3.2±2.25 vs. 4.7±1.2; p<0.05; SSS 7.3±3.4 vs. 11.8±2.3, p<0.05; SDS 4.3±1.84 vs. 6.8 ±1.8, p<0.05; Stress ext.Total 11.2±7.2 vs. 21.5±3.2, p<0,05; Stress TPD total 10.4±4.2 vs. 17.8±7.7, p<0.05; Rest ext.Total 4.2±2.8 vs. 10.7±2.0, p<0.05; Rest TPD total 4.8±2.9 vs. 7.7±2.8, p<0.05; TPDi 5.8±1.6 vs. 10.3 ± 2.1, p<0.05. Conclusion: In patients with typical chest pain and intact coronary arteries transient ischemia due to primary or secondary microvascular dysfunction could occur. Myocardial perfusion SPECT/CT might be a useful tool for risk stratification and management decision in these patients.

P066

Relationship between MDCT coronary angiography and SPECT myocardial perfusion imaging in patients with intermediate and significant coronary artery stenosis

K. W. Zavadovsky[1,2], M. O. Gulya[1,2], E. V. Grakova[1], Y. B. Lishmanov[1,2]; [1]Federal State Budgetary Institution «Research Institute for Cardiology» of Siberian Branch under the, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim. The aim of this study was to assess relationship between CT coronary angiography and SPECT myocardial perfusion imaging in patients with intermediate and significant coronary artery stenosis. Materials and Methods. We enrolled 70 consecutive patients (55 males and 15 females) aged 63.1±7.1 years who were referred for hybrid cardiac SPECT/CT. All patients underwent MDCT coronary angiography and myocardial perfusion imaging at rest and in combination with pharmacological adenosine stress test. Based on MDCT data, we analysed the presence of coronary artery stenosis, its degree (by minimal diameter), and segment involvement score. Based on SPECT data, we analysed summed stress score (SSS), summed rest score (SRS), summed difference score (SDS), total stress (TSE%) and total rest extents (TRE%) of perfusion defects and their difference (TED%), extent of fixed perfusion defect (EFix%), and extent of reversible perfusion defect (ERev%). Based on MDCT data, all patients were divided in three groups with nonsignificant coronary artery stenosis <40% (group I), intermediate coronary artery stenosis >40-<70% (group II), and coronary artery stenosis >70% (group III). Results. Except SRS and EFix%, SPECT indexes of myocardial perfusion statistically significantly differed between groups I, II and III. The incidence rates of reversible and mixed perfusion defects did not significantly differed between groups. Stable (fixed) perfusion defects were found significantly more often in patients of group III compared with group I. Normal myocardial perfusion was detected significantly more often in patients of groups I and II compared with patients who had stenosis >70%. Segment involvement score had weak and moderate correlation relationships with SSS (r=0.34; p=0.0015), TSE% (r=0.32; p=0.0026), SRS (r=0.30; p=0.009); SDS (r=0.42; p=0.0002), and ERev% (r=0.38; p=0.001). Conclusions. Scintigraphic indexes (SSS; TED%, ERev%) had the maximum power for differentiating the perfusion abnormalities in the presence of intermediate and significant coronary lesions in stable coronary artery disease patients. The study was supported by a grant from the Russian Science Foundation (№14-15-00178).

P067

Long-term Follow-up of Patients after Coronary Stent Implantation by Gated Myocardial Perfusion SPECT

E. Takács[1], L. Jorgov[1], Z. Varga[1], M. Janecskó[2], I. Szilvási[1]; [1]Semmelweis University, Dept. of Nuclear Medicine, Budapest, HUNGARY, [2]Semmelweis University, Dept. of Anaesthesiology and Intensive Care Unit, Budapest, HUNGARY.

Aim: Coronary artery disease is a progressive disease even after percutaneous coronary intervention (PCI). Ischemia detected by myocardial perfusion SPECT has been shown to predict future cardiac events regardless of patient symptomatology. Aim of our study was to evaluate the clinical usefulness of ECG-gated myocardial perfusion SPECT (GSPECT) in long-term follow-up of patients after coronary stent implantation. Patient and methods: 27 patients (4 females, 23 males) were followed for 3 to 9 years (mean 5,9±1,6 years) after coronary stent implantation. During this period all patients underwent at least two exercise/rest GSPECT using the one-day Tc99m-tetrofosmin protocol. Summed stress score (SSS), summed difference score (SDS), total perfusion deficit (TPD) and left ventricular ejection fraction (LVEF) were measured by using a semi-quantitative software (QPS/QGS, 20 segments model, scoring system). The changes of these parameters of the GSPECT were correlated to clinical data of patients including late revascularization procedures as well. Results: 14 out of 27 patients showed worsening of detected ischemia. The mean SDS value increased significantly from 3,1±1,3 to 7,5±1,8 (p<0,05). During the follow-up period no death or non-fatal myocardial infarction has occurred. Coronary angiography was recommended in 10 patients with severe ischemia or moderate ischemia and/or persistent angina (mean ΔTPD 7,1±1,9). Percutaneous revascularization was performed in 5 patients: coronary angiography showed restenosis in 2 cases, new stenosis on previously untreated coronary vessel occurred in 3 cases. CABG procedure was necessary in one patient with severe restenosis. No significant stenosis was found on angiography in 4 cases. Significant decrease in LEVF was found only in patients with SDS≥7. Conclusion: Myocardial perfusion GSPECT is useful for long-term follow-up and risk-stratification of patients after PCI indicating repeated revascularization procedures.

P068

Normal Myocardial Perfusion In Left Ventricle Inferior Wall Identified By Supine-Prone Stress-Only Gated Spect Myocardial Perfusion And Low Risk Of Coronary Events

V. López-Prior, I. Casáns-Tormo, R. Díaz-Expósito, A. Amr-Rey, J. Orozco-Cortés, H. Bowles-Antelo; NUCLEAR MEDICINE, HOSPITAL CLINICO UNIVERSITARIO, VALENCIA, SPAIN.

OBJECTIVE Stress-only GATED SPECT myocardial perfusion is an efficient method to establish the existence of normal myocardial perfusion in some patients, with reduced radiation exposure, time and cost, Obtanining supine and prone adquisitions is a very simple method to improve accuracy of image interpretation, especially in obese patients with suspected diaphragmatic attenuation. Our objective was to investigate the prognostic value of combined supine-prone images in the identification of normal myocardial perfusion by isolated left ventricular

inferior wall defect that dissapears from supine to prone. MATERIALS AND METHODS From a total of 65 consecutive patients with normal myocardial perfusion diagnosed by stress-only Gated SPECT, we retrospectively selected 18 of the 65 patients with normal myocardial perfusion in left ventricular inferior wall identified by reduction of hypoperfusion from supine to prone images, without other perfusion abnormalities. GSPECT was performed 1h after injection of a 99mTc-tracer (2 day-protocol, 20 mCi-70 kg), at the end of physical stress(S) in all cases. We have obtained visual and quantitative assessment (bull's eye) of myocardial segments perfusion, without attenuation correction, in supine and prone successive adquisitions. We obtained only in supine images left ventricular ejection fraction, end-diastolic and end-systolic volumes at post-S (SEF,SEDV,SESV) by QGS and wall thickening by visual assessment. All patients were followed for cardiac events (CE), considered as cardiac death, myocardial infarction and late (> 3 months after isotopic tests) myocardial revascularization. RESULTS The study group were 18 patients (17 m), mean age 64±10(48-82) y/o, mean body mass index (BMI) 29.4±4.5, (72% with BMI≥25), submitted to investigate possible myocardial ischemia, all of them with GSPECT after treadmill exercise test with Bruce protocol, mean MPHR (89.4±17.3%), no angor-no ST depression (11) angor-no ST (1) ST-no angor (6). In all these cases we found inferior wall perfusion hypoperfusion in supine adquisition that showed complete recovery in prone images, so inferior defects were attributed to diaphragmatic attenuation and the patients were identified as normal. Global and regional functional parameters were normal. Mean SEF(60.4±6.1%), SEDV(66.62±1.9 ml) and SESV(27.4±10.6 ml). After a mean follow-up of 31.6±14.6 months (10-48) any patient showed CE. CONCLUSION Combined supine and prone myocardial perfusion images is a simple, accurate and inexpensive method to improve diagnostic certainty of normal myocardial perfusion in patients with left ventricular inferior wall hypoperfusion attributed to diafragmatic attenuation with special benefit in obese men. This method can also identify patients with low risk of coronary events.

P069

Typical perfusion defects on myocardial perfusion SPECT in patients with left bundle branch block are related to myocardial wall motion but not to myocardial infarction or ECG characteristics

F. Hedeer, E. Ostenfeld, B. Hedén, M. Carlsson, H. Arheden, H. Engblom; Lund University, Lund, SWEDEN.

Introduction: Patients with left bundle branch block (LBBB) can have fixed septal wall perfusion defects on myocardial perfusion single-photon emission computed tomography (MPS), resembling myocardial infarction. Late gadolinium enhancement (LGE) cardiac magnetic resonance (CMR) imaging is considered to be the reference standard for *in vivo* assessment of infarction and for evaluation of myocardial function. The aim of this study was to investigate if myocardial infarction, electrocardiogram (ECG) characteristics and myocardial wall motion in patients with LBBB are related to perfusion pattern on MPS. **Methods:** Patients with complete LBBB undergoing both MPS and CMR were retrospectively included. Using MPS images the patients were grouped depending on if typical LBBB septal perfusion pattern was present or not. The CMR images were evaluated for myocardial wall motion and presence and location of myocardial fibrosis. ECGs were analyzed using recently suggested strict criteria for complete LBBB. **Results:** Twenty-four patients (nine females) with complete LBBB were included in the study. Fourteen patients had a typical LBBB septal perfusion pattern on MPS of which three had signs of infarction by CMR. Only in one case the location of the infarction could be considered the cause of the septal perfusion defects. No differences in ECG variables were seen between the LBBB patient groups with and without typical LBBB perfusion pattern on MPS (QRS duration 153±12 ms vs. 153±16 ms, p=1.0). LBBB-patients with LBBB perfusion pattern on MPS showed significantly more dyskinesia in the septal wall and significantly more hyperkinesia in the lateral wall compared to the LBBB-patients with normal septal perfusion pattern on MPS (p=0.011 and p=0.007, respectively). **Conclusion:** Differences in regional myocardial wall motion pattern can be a part of the explanation of why some patients with LBBB show perfusion defects in the septal wall on MPS without presence of underlying myocardial scar or fibrosis.

P070

The Logistics and Cost-Effectiveness of Performing Stress-Only Myocardial Perfusion Imaging (MPI) in a Busy Greek Nuclear Medicine Department

E. Kyrozi, A. Theodorakos, A. Iakovidou, A. Kalkinis, M. Koutelou; Onassis Cardiac Surgery Center, kallithea, GREECE.

Background: According to the European and American Guidelines for Myocardial Perfusion Imaging (MPI) rest SPECT images are not required when stress images are normal. The aim of this study is to evaluate the advantages of performing Stress-Only MPI protocol. **Method:** The study was carried out in the Nuclear Medicine Department of Onassis Cardiac Surgery Center. We analyzed data from a period of one calendar year (2015). With normal stress MPI, rest images provides no additional prognostic value and were therefore eliminated. The one-day protocol used a stress dose of 8-10 mCi Tc^{99m} Sestamibi and a rest dose of 18-20 mCi Tc^{99m} Sestamibi. **Results:** 3961 patients underwent MPI using Tc^{99m} Sestamibi , 887 of which (22.4%) performed a stress-only imaging protocol. The practice of omitting rest images has as a result the decrease of the test's duration (90 min compared to 2-3 hours) which is more convenient for the patient and staff and helps the logistics of the department. It also results in a lower radiation exposure to the patients 2.7mSv vs 9.3mSv (when both stress and rest imaging is performed). It is expected with the use of stress-only protocol a reduced occupational exposure to the staff of the nuclear medicine laboratory. In addition, this practice reduces the cost of the department as with the same number of vials we can examine more patients. **Conclusion:** Stress-only MPI provides only advantages. It helps the logistics of the department. Time saving, reduction of radiation exposure, and cost-effective examinations are the most significant benefits, without any compensation in the quality, the diagnostic accuracy and the prognostic value of the examination.

P071

Optimization physicals parameters for cardiac perfusion imaging

S. Alramlawy, M. Adel; Department of Critical Care medicine, Cairo University Hospitals, Faculty of Medicine, Cairo, EGYPT.

Objective myocardial perfusion imaging (MPI) has become an important tool and a substantial for diagnosis and management of heart disease. A new iterative reconstruction algorithm (flash 3D) has been recently proposed for (SPECT). The aim of work was to evaluate radiation exposure to practitioners and patients by reliance on reconstructions methods that aid in reducing the injected dose **Methods:** Forty-eight patients (30 M, 18F) who were referred to our department for MPI were randomly selected and divided into 3 groups: Group (1): contained two sub-groups, one scanned with full administrated dose (25±3.2 mCi) and half dose (10 ±2.5mci) Group (2): contained two sub-groups, one scanned with 32 projections per scan, the other with 16 projections per scan. Group (3): contained two sub-groups, one scanned at a time per projection of 20 s and the other scanned at 10 s per projection. The three groups were processed using 3D reconstruction algorithm(flash 3 D) (4 subsets, 13 iterations, FWHM=14 mm). Dose rate was recorded using a calibrated standard survey meter for all patients after dose administration. Besides, Dose calculations were also considered the time elapsed during staff exposure that included dose prepration, injection, patient imaging, and

release times.. Myocardial functional parameters such as Ejection Fraction (EF), End Diastole Volume (EDV), End Systole Volume (ESV) and Total Perfusion Defect (TPD) were compared for each group. **Results:** Qualitative assessments results from all groups showed which include (full dose (25±3.2mci) and half dose (10±2.5mci), one scanned with 32 projections per scan, the other with 16 projections per scan and a time per projection of 20 s and the other scanned at 10 s per projection Images were visually scored as very-good quality and sufficiently convergent and identical. Quantitative results using (3D) showed insignificant difference of the EF, EDV, ESV and TPD between the different groups. Dose rate reduced by 48%. when reducing to half dose (dose rate was 33±4.5 reduced to 14.8±3.6 along one meter from patient, also dose rate was reduced from 120±5.6 μSv/h to 67 ±3.9.6 μSv/h in patients' rest room) for that reason the effective dose 15.2 ± 2.4 was reduced to 7.1 ± 1.8 when using half protocols with 3D . **Conclusion:** New 3D enable reduction of dose administration or total acquisition time plays a significant role in staff exposure. Further investigations can be performed to assess these results on large patients cohort with further dose reduction.

P072

Cardiac Fusion Imaging (SPECT-CTCA) - better "Gate-Keeper" for Invasive Coronary Angiography

P. K. Pradhan, G. Sankar, S. Gambhir, N. K. Garg, A. Prashanth, A. K. Singh; SGPGIMS, Lucknow, INDIA.

Aim of the study: The aim of this study was to know whether fusion imaging (using both SPECT MPI and CTCA) is a better "gate-keeper" for segregating patients, with no prior history of coronary artery disease, who require further invasive evaluation than stand alone SPECT-MPI or CTCA. **Materials and methods:** Thirty one patients clinically diagnosed by cardiologists to have dilated cardiomyopathy (DCM) were included in this prospective study. They had no prior documented history of coronary artery disease (CAD). Initially they underwent pharmacological stress-rest SPECT-MPI using Tc-99m labelled sestamibi, using a dual head gamma camera (Infinia Hawkeye; GE healthcare). Low dose non contrast CT images were acquired after the SPECT images for the purpose of attenuation correction. Image analysis of SPECT images was done using commercially available software (EC toolbox; Xeleris workstation provided by G.E. Healthcare). Perfusion defects involving more than 20% of coronary artery territory were considered as significant. Of this only 28 patients underwent CTCA subsequently using 64-detector CT scanner (LightSpeed VCT; GE Healthcare). Coronary lesions were visually assessed for stenosis and those showing more than 50% stenosis were considered as significant. Fusion imaging was successfully done using CardIQ software (GE Healthcare). Only those patients who had matched perfusion defects to stenotic segments in fusion imaging were labelled as having CAD. **Results:** Significant perfusion defects (> 20%) were present in 22 of the 31 patients (71%). Mean total coronary artery calcium scoring was 291 Agatston score units (range: 0 - 2511; S.D: 641). Significant stenotic segments were seen in 51 segments (13% of all the segments analyzed). Significant stenosis (>50%) in one or more segments were present in 15 patients (54%). Only 10 patients showed significant perfusion defects which matched with the corresponding stenotic segments (36%) in the fusion imaging and only these patients were planned for invasive coronary angiography by the cardiologists. There was significant difference between the percentages of patients labelled to have CAD on the basis of SPECT-MPI, CTCA and that of fusion imaging (p value < 0.05). **Conclusion:** Fusion imaging may act as a better "gate-keeper", especially in patients with dilated cardiomyopathy, in segregating the patients requiring further invasive evaluation than stand alone SPECT-MPI or CTCA. Larger multicentric prospective studies and different study populations are required to validate these findings.

P073

Diagnostic performance of regadenoson vs dipyridamole in patients undergoing myocardial perfusion scintigraphy

M. Catalano, G. Annunziata, D. Scala, A. Sasso, R. Gottilla, V. Ippolito, I. Valenti; AORN, Naples, ITALY.

Aim: Regadenoson is a vasodilator agent that binds more selectively to the coronary A2a adenosine receptors than dipyridamole or adenosine. At present, there are no reported studies investigating the clinical utility of regadenoson as a vasodilator stress agent for myocardial perfusion scintigraphy (MPS) . Aim of this study is to evaluate whether dipyridamole and regadenoson are comparable in detection coronary artery disease(CAD) in patients (pts) undergoing to MPS. Materials and methods: 55 pts, 33 male and 22 female (mean age 65.6±11.6) underwent pharmacological test because of left bundle block or limitation to exercise test; 27 pts were stressed with dipyridamole and 28 patients with regadenoson because of asthma and severe chronic obstructive pulmonary disease (COPD) . Baseline characteristics were similar in both groups. 8 pts were affected with myocardial necrosis, 14 pts had prior coronary revascularization, 9 pts had history of myocardial infarction treated with percutaneous transluminal coronary angioplasty and 24 pts with suspected CAD because of chest pain or multiple coronary risk factors. Images were interpreted semi-quantitatively using a standard 17-segment model and a 5-point (0-4) scoring system. Global summed stress score, summed rest score and summed difference score were computed (Quantitative perfusion SPECT software QPS, version 2008; Cedars-Sinai Medical Center, Los Angeles, CA) The extent and severity of ischemia was defined as the difference between summed stress score and summed rest score. A summed difference score <6 was considered mild, 7 - 12 moderate and >12 severe. Results: In the group of pts stressed by dipridamole 13 scans were normal, a reversible or inducible myocardial perfusion abnormality was present in 11 pts , 2pts with severe ischemia, 6 pts with moderate ischemia and 3 pts with mild ischemia, 3 pts with fixed defects because of myocardial necrosis. In the group of pts stressed by regadenoson 13 pts had negative scans, 1 pt severe ischemia, 3 pts moderate ischemia, 7 pts mild ischemia and 5 pts were affected with myocardial infarction. We found omogeneus perfusion scores disease related in both group. No severe collateral effects and fatal or non-fatal cardiac events occurred in both groups too. Pts with scan positive for moderate or severe ischemia underwent coronary angiography that confirmed coronary vessels patency. Conclusions: Regadenoson and Dipyridamole are comparable as vasodilators for stress testing in pts with known or suspected CAD undergoing MPS, but Regadenoson is safe, well tolerated and accurate in pts affected with asthma and severe COPD.

P074

Quantitative Myocardial Perfusion Scintigraphy: a useful tool in the diagnosis, prognosis and risk stratification of patients undergoing investigation of chest pain

A. Oseni, L. Calovi Motschenbacher, E. Nowosinska, A. Haroon, K. Ranjan, H. Jan; Bart's Health NHS Trust, London, UNITED KINGDOM.

Objective: In England and Wales Coronary artery disease (CAD) is the most common cause of death. Despite advancements in modern medicine, CAD accounted for 15.4% of all male deaths in 2013. As a result, greater emphasis has been placed on accurate diagnosis, prognostication and risk stratification of patients who present with chest pain. Qualitative results from Myocardial Perfusion Scintigraphy (MPS) have been at the forefront of investigation of such patients, with CG95 NICE Guidelines recommending the use of functional imaging as first line. We evaluated whether semi-quantitative analysis of myocardial perfusion single computed tomography (SPECT) improves reliability of MPS results in the British population. **Method:** 200 patients underwent MPS with stress-rest protocol

between February and September 2014. Semi-quantitative data was extracted from these scans (ejection fraction and gated analysis) and correlated against patient symptoms, demographics, CAD risk factors and clinical pre-test probability scoring. Additionally, patients were followed up for one year and outcomes of further investigations and management recorded. **Results:** There was a positive correlation between low pre-test probability scores and normal MPS results both qualitative and quantitative. Patients with normal MPS results were more likely to have normal results from further investigation and no adverse outcome after 1 year ($p<0.001$). Patients with a high pre-test probability had worse MPS results ($p<0.05$). Poor MPS results were more commonly found in patients of Asian origin ($p<0.05$). **Conclusion:** Semi-quantitative MPS analysis is a good negative predictor for the diagnosis of CAD. The use of semi-quantitative analysis improves the diagnostic and prognostic value of MPS in the investigation of patients with chest pain. Patients of Asian origin demonstrated abnormal MPS results more frequently when compare to other ethnic subgroups.

P075

Performance of stress-induced ST changes during exercise stress test in relation to stress-induced myocardial ischemia as determined by myocardial perfusion single photon emission tomography: aspects on gender differences

S. Akil, B. Heden, O. Pahlm, M. Carlsson, H. Arheden, H. Engblom; Clinical Science, malmo, SWEDEN.

Background: Exercise stress test (EST) is usually the first method of choice when diagnosing stable ischemic heart disease. Myocardial perfusion SPECT (MPS) has been used as the reference standard for evaluation of amount as well as the presence of stress-induced ischemia, due to its high diagnostic accuracy. Studies relating EST findings to MPS findings, in a patient population with a specific focus on gender differences, are to a large extent lacking. **Aim:** To determine the diagnostic accuracy of stress-induced ST segment changes as a biomarker for stress-induced myocardial ischemia as assessed by myocardial perfusion single photon emission tomography (MPS), with a special focus on gender differences, in patients with suspected or established stable ishemic heart disease. **Methods:** 941 patients (474 females) with bicycle EST, performed in conjunction with MPS, were retrospectively included. An EST interpretation of stress-induced ST segment response alone and ST response in addition to other EST variables (blood pressure- and pulse response as well as exercise capacity) was done by an experienced physician and the findings were related to MPS findings. A significant decrease in regional perfusion on MPS during stress not seen at rest was considered to indicate stress-induced ischemia. **Results:** The positive predictive value (PPV) was 28% in the total patient population (13% females/42% males), when stress-induced ST segment changes were used to diagnose presence of stress-induced ischemia. The negative predictive value of a normal ST response was 90% in the total population (92% in females/86% in males). PPV increased when blood pressure- and pulse response as well as exercise capacity were added to the EST interpretation (PPV= 40% in total population; 23% females/54% males). **Conclusions:** There is a significant difference between females and males with regard to accuracy of ST segment changes in diagnosing stress-induced ischemia as determined by MPS. The accuracy is improved in both genders by considering other variables in the EST interpretation in addition to the ST response.

P076

Is stress-only supine and prone myocardial perfusion SPECT evaluation feasible? One-year follow-up study in patients with CZT gamma camera perfusion imaging

S. Piszczek, S. Osiecki, E. Witkowska-Patena, A. Mazurek, M. Dziuk; Military Institute of Medicine, Warsaw, POLAND.

Aim The goal of the study was to evaluate the utility of stress-only myocardial perfusion SPECT (MPS) performed with a dedicated cardiac CZT (Cadmium Zinc Telluride) gamma camera in discriminating patients with low or increased risk of adverse cardiac events during a one year follow-up period. **Methods** Supine and prone stress MPS imaging using CZT gamma camera was performed in 203 consecutive patients. Both exercise and pharmacological stress tests were carried out with 8-16 mCi ^{99m}Tc-sestamibi. The images were evaluated independently by 3 physicians experienced nuclear cardiology using a three-point scale: 1 - rest study unnecessary, 2 - rest study can be useful, 3 - rest study necessary. Patients were assessed after 12 months, using a questionnaire regarding their medical history during the follow-up period. **Results** The one-year follow-up was completed by 151/203 (74%) patients. 31/151 (21%) patients had a history of myocardial infarction and 46/151 (30%) patients underwent invasive coronary interventions prior to the study. In 125/151 (83%) patients none or mild perfusion abnormalities were observed (the evaluation results were: 1 point - 92 patients, 2 points - 33 patients). Of these, 18 patients (14%) underwent coronary angiography after MPS and 9 of them were subsequently referred for invasive coronary intervention (6 for percutaneous coronary intervention [PCI] and 3 for coronary artery bypass graft [CABG]). The remaining 9 (7%) patients received 1 (n=1) or 2 (n=8) points in course of evaluation. Severe perfusion abnormalities (more than 10% of left ventricle myocardium) were observed in 26/151 (17%) patients. In all of them a necessity of rest study was emphasized (all patients were given 3 points). Significantly higher number of invasive procedures was observed in this group. Coronary angiography was performed in 20 patients (77%), 13 of them (50%) were referred for invasive coronary interventions (7 patients for PCI and 6 patients for CABG). Another 2 patients were scheduled for a CABG procedure. No cardiac deaths were observed in the study group during follow-up. Rest imaging was performed in 82/151 (54%) patients according to a two day protocol. **Conclusion** The study showed that stress-only supine and prone MPS evaluation is feasible and safe in patients with suspected and diagnosed coronary artery disease. However, the minority of patients will require rest myocardial perfusion imaging.

P077

Comparison of hemodynamic effects and negative predictive value of normal adenosine gated myocardial perfusion scan with and without caffeine abstinence

N. Fatima[1], M. u. Zaman[2], A. Zaman[3], U. Zaman[3], R. Tahseen[3]; [1]Department of Nuclear Medicine, Dr Ziauddin Medical University, Karachi, PAKISTAN, [2]Dept. of Radiology, Aga Khan University Hospital,, Karachi, PAKISTAN, [3]Dow University of Health Scineces, Karachi, PAKISTAN.

Background: For vasodilator stress myocardial perfusion imaging (MPI) at least 12 hour caffeine is recommended as it attenuates cardiovascular hyperemic response of adenosine and dipyridamole. However, many published conflicting results have shown no significant effect upon perfusion abnormalities in MPI performed without caffeine abstinence. The aim of this study was to compare the hemodynamic changes and negative predictive value (NPV) of normal MPIs with adenosine stress performed with and without caffeine abstinence. **Material and Methods:** This was a prospective study which accrued 50 patients from May 2013 till September 2013 and followed till November 2014. These patients had a normal adenosine-gated-MPI with ^{99m}Tc-MIBI after 12 hour caffeine abstinence (No-caffeine). Next day, all patients had a repeat adenosine stress within 60 minutes after ingestion of a cup of coffee (about 80 mg of caffeine) followed by no MPI in 30 patients due to concern about radiation dose (Prior-caffeine adenosine No-MPI; Group A). Twenty patients opted for a repeat MPI (Prior-caffeine adenosine-MPI; Group B). Adenosine induced hemodynamic response and NPV of normal MPI with No-caffeine and Prior-caffeine protocols were compared. **Results:** The

mean age of the study cohort was 57 ± 09 years with a male to female ratio of 76:24% and mean body mass index (BMI) of 26.915 ± 4.121 Kg/m^2. Prevalence of hypertension, diabetes, dyslipidemia and positive family history was 76%, 20%, 22% and 17% respectively. Comparison of Group A with Group B revealed no significant difference in demographic parameters, hemodynamic or ECG parameters or left ventricular function parameters during adenosine intervention with Prior-caffeine and No-caffeine protocols. During follow no fatal MI was reported but 06 non-fatal MIs based upon history of short hospitalization for chest pain but without biochemical or ECG criteria for infarction (03/30 in Group A and 03/20 Group B). Event free survival (EFS) for fatal MI was 100% for both groups while EFS for non-fatal MI was 90% for Group A and 85% for Group B (non-significant p values). Kaplan Meier's survival plot also depicted non-significant EFS for non-fatal MI. **Conclusion:** This study did not find any significant attenuation effect upon adenosine induced hemodynamic response and similar negative predictive value of a normal GMPI in patients with and without caffeine abstinence. We assume that better designed prospective studies are required to validate findings of our study and provide justification for revision of guidelines about caffeine abstinence. **Key words:** Adenosine; Caffeine; Gated MPI; Negative predictive value; hyperemia

P078

Comparison of patient radiation doses in diagnostic and therapeutic cardiac imaging techniques

S. Alramlawy[1], **M. Khalil**[2], I. Maamoun[1], A. M. Hamed[3]; [1]Department of Critical Care medicine, Cairo University Hospitals, Faculty of Medicine, Cairo, EGYPT, [2]Department of Physics (Medical Biophysics), Faculty of Science, Helwan University, Cairo, EGYPT, [3]Department of Nuclear Medicine and Oncology, Ain Shams University Hospitals, Cairo, EGYPT.

Myocardial perfusion single photon emission computed tomography (SPECT), angiographic techniques based on x-ray computed tomographic (CT), and interventional cardiac procedures are different sources of radiation exposures to patients with coronary artery disease. It is always a good safety practice to avoid patient radiation dose if the diagnostic test wouldn't provide incremental diagnostic information. Therefore, it is critically important to understand the relative radiation risk of those diagnostic and/or therapeutic modalities. **Methods:** A retrospective analysis was performed on 165 patients with known or suspected coronary artery disease. They were consisted of 112 patients who underwent a two-day protocol Tc-99m sestamibi SPECT scans, 30 patients underwent CT angiography (12 using 64 slice CT and 18 subjects using 256 slice CT scanners), and 30 underwent interventional procedures. The later consisted of 12 patients who were referred to coronary angiography and occlusion assessment while 18 undergone percutaneous coronary intervention. Dose assessment of the myocardial perfusion SPECT was obtained using the ICRP dose coefficient. Dose estimate from CT were reported as CTDIvol using the conversion factor 0.016 mSv/mGy.cm. Dose estimates from Interventional procedures were obtained from protocol performed for each patient. Dose estimates for SPECT were derived using 0.01 mSv/MBq as combined (stress-rest) dose conversion factor. **Results.** Effective dose estimates (CTDI) revealed from CT was on average 32.0±10.5 mSv provided that the DLP was 1974.5±661.8 mGy.cm using mAs of 1467.1±385.5 and 120 kV tube voltage. Dose estimates from SPECT data was on average 13.5±1.7 mSv. Coronary catheterization showed effective dose levels of 4917±255 μGy.m^2 and 16064±6123 μGy.m^2 in diagnostic and therapeutic procedures respectively. These measures resulted in effective dose of 10.8± 3.79 mSv and 35.3 ±13.4 mSv respectively. The average time of fluoroscopy and cine-mode in diagnostic sessions was 4.2±1.8 min and 10.7±2.9 min respectively whereas in therapeutic ones were 17.3±7.1 min and 32.7±9.8 min respectively. Dose from 256 multi-slice CT was significantly higher than those produced from 64 slice CT (mean of 38.2 mSv vs. 21.4 mSv respectively, p<0.0001) **Conclusion:** Patient dose levels in cardiac imaging using radiological as well as nuclear techniques vary considerably with special concerns placed on therapeutic and multislice CT scanning procedures. A risk estimate based on an experimental models designed specifically for cardiac procedures would be the best approach to address the radiobiological dose-effect relationship. This will be potentially considered in future studies.

P079

Optimal Stress-rest Tracer Activity Ratio in Single-day Myocardial SPECT. A Phantom Simulation Study

C. Marcassa[1], M. Lecchi[2,3], C. Rodella[4], R. Mattheoud[5], R. Campini[6], O. Zoccarato[6]; [1]S. Maugeri Fnd, IRCCS, Veruno, ITALY, [2]Department of Health Sciences, University of Milan, Milan, ITALY, [3]Nuclear Medicine Unit, San Paolo Hospital, Milan, Milan, ITALY, [4]Spedali Civili Hospital, Brescia, ITALY, [5]Departments of Medical Physics and Nuclear Medicine, University Hospital, Novara, ITALY, [6]Nuclear Medicine Dept. S. Maugeri Fnd, IRCCS, Veruno, ITALY.

Background. In single-day stress-rest, myocardial perfusion SPECT studies a 1:3 tracer activity ratio is currently recommended, although 1:2 to 1:4 ratios have been also proposed. **Aim.** To define the optimal tracer activities ratio for a single-day stress-rest SPECT protocol. Methods. An anthropomorphic phantom of the chest, with inserts simulating lungs, liver, LV wall and LV chamber was used. The following acquisitions were obtained: 1) ***stress-equivalent***; with a tracer concentration equivalent to that obtained with an in-vivo stress study, using a low-dose approach. A solid insert filled with "cold" water was employed to simulate a transmural ischemia in septal location. 2) ***rest-equivalent***; simulating a 3h stress-rest time delay. The phantom's chambers were filled with tracer activities simulating the stress residual concentration corrected for a 3h physical and biological half-life (different for normal, ischemic and liver tissues) plus a rest-equivalent solution with a ratio to stress equal to 1:1, 1:1.5, 1:2, 1:2.5 and 1:3. Wide Beam Reconstruction (UltraSpect, ™) was used to reconstruct SPECT images; attenuation and scatter correction were also applied The defect contrast was calculated on the mid-ventricular short-axis slice best displaying the defect. Polar maps were scored by 3 independent observers using a 17-segments model; the septal-lateral ratio was also calculated. **Results.** From the stress-equivalent images to 1:1, 1:1.5, 1:2, 1:2.5 and 1:3 stress-rest activity ratio, respectively, the defect contrast reduced from 59.6% to 12.6%, 12.5%, 6.6%, 7.8%, and 8.7% ; the summed score reduced from 8 to 5, 2, 1, 1, and 1, respectively, and the septal-lateral ratio increased from 47% on stress-equivalent images to 73%, 76%, 82%, 83%, and 85%, respectively on rest-equivalent images. **Conclusions.** According to our simulation study, no clinically meaningful differences were observed from 1:2 to 1:3 stress-rest activity ratios. A 1:2 ratio is lower than that currently suggested by EANM Guidelines; this would imply a more favorable patients' and staff' radiation exposure. Clinical studies are required to confirm our experimental results

P081

Breast tissue attenuation in myocardial perfusion SPECT CT Imaging: Cardiac phantom study

F. BOGA[1], **F. CANBAZ**[2]; [1]Ondokuz Mayis University Hospital, Faculty of Physics, KURUPELIT / SAMSUN, TURKEY, [2]Ondokuz Mayis University Hospital, Faculty of Medicine, KURUPELIT / SAMSUN, TURKEY.

Aim: The aim of our study is to investigate the effect of breast tissue in different size and density on myocardial perfusion imaging(MPI) and to

evaluate the changes after CT attenuation correction (CTAC) using a modeled breast cardiac phantom. **Material and Method:** The breast models in our study were designed using 400, 700, 1000 and 1300 milliliters of balloons filled with water, oil and liquid soap to simulate the breast tissues of different size and density. The cardiac part of the phantom was filled with diluted water of 37 MBq (1 mCi) Tc-99m pertechnetate activity. The breast models were attached to cardiac phantom respectively. Using a double detector hybrid SPECT/CT system, imaging was performed with the parameters used in routine clinical settings of MPI (64x64 matrix; 20 second/ projection, total of 32 projections). We used Cedars Sinai QPS perfusion quantitative software (V.2009) in processing and data collection. We analyzed the images, semi-quantitatively, using 17 segment model through polar maps. The analyzing of data belonging to standard and CT attenuation correction results were carried out via SPSS (V22.0) statistical program by using Wilcoxon, Man-Whitney U, Kruskal-wallis tests on the base of myocardial segment, wall and level. **Results:** After CT attenuation correction, there were no significant differences (Δ) between the groups (p>0,05) regarding the density and size but among the left ventricular walls , but the highest mean difference values between standard and CTAC images were detected on septum. The mean differences for myocardial septum wall were: Δ= 18,2 ± 10,0; 20,4 ± 9,6; 18,2 ± 8,2 for oil, water and liquid soap groups, respectively; and Δ=19,1±10,8 , 19,0 ± 9,5, 19,6 ± 9,0 and 17,8 ± 8 were obtained for 400, 700, 1000 and 1300 volume groups, respectively. A heterogenic changing was seen on lateral wall {Δ=[(-0,7 ± 11,1) - (6,9 ± 14,4)]}, after CTAC. **Conclusion:** The results in our study support that a considerable improvement was seen on left ventricle septum after CT attenuation correction without depending on the size and density of breasts; but the physicians should be aware that, although without SPECT/CT misregistration, new perfusion defects can occur after CTAC , especially on the lateral myocardial wall .

P082

Value of Tc-99m MIBI myocardial perfusion scintigraphy in predicting non-critical coronary stenosis

B. Dirlik Serim[1], M. Yılmaztepe[2], E. Yigit[3], Z. Yigit[4], G. Durmus Altun[5]; [1]İstanbul University, Cardiology Institude, Nuclear Medicine Department, Istanbul, TURKEY, [2]Trakya University, Medical Faculty, Cardiology Department, Edirne, TURKEY, [3]Umraniye Train and Research Hospital, Internal Medicine Department, Istanbul, TURKEY, [4]İstanbul University, Cardiology Institude, Cardiology Depertment, Istanbul, TURKEY, [5]Trakya University, Medical Faculty, Nuclear Medicine Department, Edirne, TURKEY.

Aim: Coronary angiography of most of patients with unstable angina pectoris showed that one or more critical stenosis are found in the coronary arteries. However, studies have revealed some non-critical stenosis on angiography in this patient group. Some evidences are available about the mechanisms that cause ischemia of the resting; these are temporary thrombosis settlement on unstable non-critical stenotic plaque or coronary vasoconstriction. The aim of this study is to show the value of Tc99m MIBI myocardial perfusion scintigraphy (MPS) in predicting non-critical coronary stenosis. Material and method: Data of the patients referred to our department in order to determine the presence and localization of ischemia were examined. The images and reports of patients were analyzed retrospectively. The reports of lesions that seemed as viable tissue or infarct region were excluded. Ischemia quantitation analysis was made by visually with Cedars-Sinai polar map. Angiography results of the patients who were reported only as ischemia, achieved from hospital automation system. One hundred sixty nine patients with non-critical stenotic lesions were included in this study. Results: The study included 64 women, 105 men a total of 50 patients; 50 of them have normal MPS. Age was 60.4±10 years. The average number of 119 patients with defects in MPS was 5.03±3.7 and MPS was performed 37±44 days after angiography. The number non-critical stenosis was 29±18 as a result of angiography. The number of non-critical lesions according to vessels were; 45 of them was the only LAD stenosis,8 of them was the only CX and 9 of them were the only RCA stenosis;14 patients had on both LAD and Cx and 5 patients had on both RCA and Cx;,11 patients had on both LAD and RCA, 8 patients had on all LAD, Cx and RCA and in addition 3 patient had on LMCA. Stenosis was 43±14% at LAD, 41±12% at Cx and 44±15% at RCA. The diagnostic value of MPS predicting non-critical coronary stenosis were calculated as 80.8%; sensitivity and specificity were calculated as 90.9% and 78.1%. According to the calculations positive predictive value was 87.7% and negative predictive value was 83.3%. Conclusion: Predicting non critical stenosis with MPS may provide a clearer way to put forward the risk group. Active and effective intervention can contribute to the damage-free nad disease-free survival. Studies of large series of patients will highlight the value of MPS predicting non-critical stenotic patient group.

Need for standardization of ROI definition in planar cardiac I-123-MIBG imaging

C. Schmitt[1,2], C. Jungen[1,3], K. Okuda [4,5], Y. Kobayashi[1,2], A. Helberg[1,2], J. Mester[1,2], C. Meyer[1,3], K. Nakajima[4,6]; [1]UKE, Hamburg, GERMANY, [2]Department for Interventional and Diagnostic Radiology and Nuclear Medicine, Hamburg, GERMANY, [3]Department of Cardiology - Electrophysiology, University Heart Centre, University Medical Centre Hamburg-Eppendorf , Germany; DZHK (German Centre for Cardiovascular Research), partner site Hamburg/Kiel/Lübeck, Germany, Hamburg, GERMANY, [4]Kanazawa University, Kanazawa, JAPAN, [5]Department of Physics, Kanazawa Medical University, Kanazawa, JAPAN, [6]Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, GERMANY.

Background: Iodine-123-metaiodobenzylguanidine (MIBG) imaging has been established for risk assessment in patients with chronic heart failure or neurodegenerative diseases. Quantification of cardiac MIBG uptake using the heart-to-mediastinum ratio (HMR) is essential for the identification of pathologic loss of cardiac sympathetic nerve fibers.However, HMR is influenced by several technical factors, including the definition of region of interest (ROI). We aimed to investigate the comparability of different methods of ROI definition, to determine the inherent confidence interval of each method and to discuss the practical relevance of methodologiical uncertainties. **Methods and Results:** We retrospectively analyzed 32 planar images of 20 consecutive patients (63.5 years median; 2 females, 18 males) who were referred for MIBG imaging between January 2014 and October 2015 with cardiac arrhythmias (n=12) or with suspected neurodegenerative disease (n=8). Following intravenous application of 185 MBq (n=10) or 370 MBq (n=10) MIBG, patients underwent planar imaging at 15 minutes and 4 hours (n=12) or at 4 hours (n=8) only. The results of three different methods of ROI definition (manually during clinical routine (CLI), manually after simple standardization (STA) and semi-automated using a dedicated software (SAM)) were compared using Bland-Altman plots. Pairwise comparisons of HMR demonstrated significant mean differences (CLI vs STA 0.14, CLI vs SAM -0.22 and STA vs SAM -0.08, $p<0.05$, two sided t-test). Inter-method standard deviations (SD) were 0.17, 0.19 and 0.08 respectively). SDs from the comparison of CLI with the other methods were significantly higher than the SD from STA vs. SAM (chi^2 test, $p<0.05$). Intra-observer and inter-observer variabilities were

0.01 and -0.07 for STA and 0.01 and 0.01 for SAM, respectively. Considering a HMR of 1.60 as the lower limit of normal, and ±1.96*SD as the width of the 95% confidence interval, 13 of 32 (41%) for method STA and 5 of 32 (16%) for method SAM of the measured HMR values in our study could not be classified to normal or pathologic cardiac sympathetic innervation. **Conclusion:** Different methods of ROI definition result in different widths of a zone around the normal limit, where definitive rendering of the results to normal or pathologic innervation is not possible (gray zone). As MIBG imaging analysis and the calculation of HMR is crucial for risk classification of patients with chronic heart failure or neurodegenerative diseases, internal validation of evaluation methods, e.g. by using standardized clinical data sets, is strongly recommended.

P084

SPECT myocardial perfusion and sympathetic innervation in patients with hypertrophic cardiomyopathy

A. Ansheles, V. Sergienko; Russian Cardiology Research and Production Complex, Moscow, RUSSIAN FEDERATION.

Objective: to determine the characteristics of myocardial perfusion and sympathetic activity (SA) assessed by single-photon emission computed tomography (SPECT) in patients with hypertrophic cardiomyopathy (HCM). **Material and Methods:** The study included 36 patients with a confirmed diagnosis of HCM. All patients underwent clinical status assessment, Holter ECG monitoring, rest echocardiography. All patients, as well as a group of healthy volunteers (n=20) underwent myocardial perfusion SPECT with ^{99m}Tc-MIBI at rest and after bicycle exercise test, and myocardial neurotropic SPECT with ^{123}I-MIBG, performed in 15 min (early phase) and 4 hours (delayed phase) after MIBG administration. Perfusion abnormalities were evaluated using standard quantitative parameters: Summed Stress Score (SSS) and Summed Difference Score (transient ischemia index, SDS). Global SA abnormalities were assessed with delayed heart/mediastinum ratio (H/M_d) and MIBG Washout Rate in 4 hours (WR). Regional SA abnormalities were assessed using early Summed MIBG Score (SMS_e). **Results:** All myocardial SPECT parameters, both perfusion and neurotropic, significantly differed in HCM patients compared to the control group ($p<0.001$). According to perfusion SPECT, reliable transient myocardial ischemia (SDS>4) in the main group was detected in 33% of cases, while it was diffuse and had no connection with certain regions of coronary arteries. The volume of regional innervation defects (SMS_e) in HCM patients was significantly higher than the total volume of perfusion defects (SSS), amounting to 15 (11-17) and 9 (8-11) points, respectively ($p<0.001$). SMS_e and SSS had a positive correlation ($r=0.52$, $p=0.002$), but perfusion and innervation defects did not match in localization clearly. The severity of LV hypertrophy was a factor of more severe perfusion and innervation defects: we detected direct correlation between posterior LV wall thickness and LV cavity pressure gradient, measured by echocardiography ($r=0.31$, $p=0.07$), between LV mass index and SSS ($r=0.51$, $p<0.005$), WR ($r=0.51$, $p=0.002$), SMS_e ($r=0.34$, $p=0.03$). No influence of LV outflow tract obstruction on parameters of Holter ECG, stress-test, perfusion and neurotropic myocardial SPECT was shown. SMS_e was higher in HCM patients with arrhythmias ($p=0.046$), and lower in HCM patients with angina and cardialgias ($p=0.04$). More severe perfusion and innervation abnormalities were detected in patients with nondiagnostic exercise test result ($p<0.05$). **Conclusion:** Combination of myocardial neurotropic and perfusion SPECT has a certain diagnostic value in patients with HCM, since sympathetic innervation abnormalities is one of the earliest marker of myocardial damage.

P085

Cardiac SPECT Imaging with Iodine-123 MIBG in Heart Failure Patients Qualified for an Implantable Cardioverter Defibrillator

A. Teresinska, O. Wozniak, A. Maciag, J. Wnuk, A. Czerwiec, J. Jezierski, M. Madej, K. Biernacka; Institute of Cardiology, Warsaw, POLAND.

Introduction: The standard method of assessment of cardiac adrenergic nervous system with I-123 MIBG is semiquantification of MIBG uptake by calculating a heart-to-mediastinum ratio (H/R) in the planar anterior view. ***Purpose:*** The aim of this study was to determine the value of MIBG SPECT imaging in pts with post-infarction heart failure (IHF). ***Methods:*** We present a part of a single-center prospective study comprising consecutive patients with IHF qualified (on the basis of ESC Guidelines 2012) for undergoing implantation of ICD in the prevention of sudden cardiac death, i.e. pts with LVEF≤35%, NYHA class II-III, >40 d after infarction. Another inclusion criteria: age>50y, >3 mo from revascularization, signed informed consent. The 10-min-long planar studies were performed 15min and 3,5h after MIBG injection, and were followed by 30-min-long SPECT studies with dual-detector system and LEHR collimators. SPECT parameters: acquisition - 68 projections over 180°, 50 sec/projection, matrix 64x64; reconstruction - FBP with Butterworth filter, no scatter/attenuation correction. The image variables used in this analysis: late planar H/M and late SPECT summarized defect score (SDS; assessment in 17-segment model of the LV in a 5-step scale: 0-normal uptake, 4-lack of uptake). ***Results:*** Seventy-seven subjects were included (67 M): age 67±9y, weight 80±14kg, NYHA class 2.2±0.4, LVEF 26±9%, 17 (22%) of pts with diabetes mellitus; administered activity 9.3±1.1mCi. In 21/77 pts (27%, <18-38>) the assessment of SPECT studies was impossible because of very high lung uptake non-separating from LV walls. H/M values in this group were: 1.11-1.84 and the average (1.50±0.21) was lower than in the group of the others ($p=0.035$). In 56 pts submitted to planar and SPECT evaluation: H/M = 1.25-2.11 (av. 1.62±0.20), SDS = 8-52 (33±10), moderate correlation between H/M and SDS (-0,49). In 22 of those pts (22/77, i.e. 29% of all the pts), the assessment of SPECT studies was equivocal because of extracardiac uptake interferring with uptake in LV walls. Altogether, in 43/77 pts (56%, <45-67>), the SPECT quality was unacceptable or low. ***Conclusions:*** In pts with post-infarction HF qualified for implantation of ICD, with LVEF≤35%, NYHA class II-III and age>50y, the good-quality SPECT studies were achieved only in approximately half of cases. In relation to planar MIBG scintigraphy, SPECT can have additional prognostic value for improving selection of patients for ICD, but its usability is limited by frequent non-acceptable or borderline quality caused by high extracardiac MIBG uptake interferring with cardiac uptake.

Cardiac MIBG scintigraphy in predicting the effectiveness of interventional treatment of atrial fibrillation

Y. Saushkina[1], V. Saushkin[1], K. Zavadovskiy[1,2], I. Kisteneva[1], R. Batalov[1], I. Kostina[1,3], G. Romanov[1,3,4], Y. Lishmanov[1,2], S. Popov[1], R. Karpov[1], D. Ryzhkova[3], L. Maslov[1]; [1]RI Cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [3]Federal Almazov North-West Medical Research Centre, St. Petersburg, RUSSIAN FEDERATION, [4]S.M. Kirov Military Medical Academy, St. Petersburg, RUSSIAN FEDERATION.

Purpose. The aim of the study was to identify scintigraphic predictors of the effectiveness of interventional treatment of atrial fibrillation (AF). Methods and Materials. In this study were enrolled 35 patients with essential hypertension (EH) (the duration of EH 5-20 years): 17 patients with persistent AF and 18 patients with long-standing persistent AF. All

patients underwent single-photon emission computer tomography (SPECT) with 123I-metaiodbenzilguanidine (123I-MIBG) to evaluate cardiac sympathetic nervous system (SNS) activity before radiofrequency catheter ablation (RFCA). Evaluation of the effectiveness of RFCA was carried out after 12 months by means of twenty-four hour Holter monitoring. Results. Patients of both groups were divided into subgroups depending on the presence of recurrence of arrhythmia in a year after interventional treatment. In the group of patients with persistent AF, the arrhythmia recurrence 12 months after RFCA were detected in 7 people. In the group of patients with long-standing persistent AF, the arrhythmia recurrence 12 months after RFCA were detected in 8 people. By ROC analysis identified the main scintigraphic predictors of the effectiveness of interventional treatment of AF. Were investigated the preoperative scintigraphic characteristics of cardiac sympathetic activity for which subgroups with and without AF recurrence had significant differences. Optimal thresholds for predicting the effectiveness of RFCA in patients with persistent AF was ≥1,7 for delayed heart-to-mediastinum ratios (HMR) (0,991 area under the ROC curve; sensitivity 100%, specificity 71%). Optimal thresholds for predicting the effectiveness of RFCA in patients with long-standing persistent AF were ≥1,69 for early HMR (0,849 area under the ROC curve; sensitivity 100%, specificity 62%); ≥1,66 for delayed HMR (0,938 area under the ROC curve; sensitivity 94%, specificity 23%). Conclusion. Thus, cardiac MIBG scintigraphy can be used to predict high risk of recurrence of atrial fibrillation after radiofrequency catheter ablation. The study was supported by a grant from the Russian Science Foundation No 15-15-10016.

Cardiac MIBG scintigraphy in assessing the effectiveness of radiofrequency cardiac denervation

Y. Saushkina[1], V. Evtushenko[1], K. Smishlyaev[1], V. Saushkin[1], K. Zavadovskiy[1,2], I. Kostina[1,3], G. Romanov[1,3,4], Y. Lishmanov[1,2], A. Evtushenko[1], R. Karpov[1], L. Maslov[1], D. Ryzhkova[3]; [1]RI Cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [3]Federal Almazov North-West Medical Research Centre, St. Petersburg, RUSSIAN FEDERATION, [4]S.M. Kirov Military Medical Academy, St. Petersburg, RUSSIAN FEDERATION.

Purpose. The aim of the study was to evaluate the role of radionuclide imaging with 123I-metaiodbenzilguanidine (123I-MIBG) in assessing of the cardiac radiofrequency denervation effectiveness. Methods and Materials. In this study were enrolled 32 patients with mitral valve (MV) disease: 21 patients with long-standing persistent atrial fibrillation (AF), who was undergone MV surgery and the «Maze» procedure (Maze+ group) and 11 patients with sinus rhythm (SR) and with MV surgery without the «Maze» procedure (Maze- group). All patients underwent cardiac 123I-MIBG imaging prior and 10 days after surgery. In addition, we determined the levels of norepinephrine, metanephrine, normetanephrine in plasma, obtained intraoperatively from the coronary sinus (CS) and the ascending aorta (Ao) before and after the main stage of the surgery. All patients were intraoperatively intake of histological material (atrial appendage) to determine the distribution density of nerve endings in the myocardium. Results. In patients with AF the early and delayed heart-to-mediastinum ratios (HMR) prior surgery were significantly lower compared to patients with SR ($p<0.01$). The washout rate (WR) of 123I-MIBG prior surgery in patients with AF was greater compared to patients with SR ($p<0.01$). The HMR after surgery was significantly lower vs baseline in both groups (early HMR: 1,78±0,17 vs 1,56±0,19; $p<0,01$ and 2,12±0,25 vs 1,79±0,18; $p<0,01$; delayed HMR: 1,69±0,21 vs 1,47±0,19; $p<0,01$ and 2,0±0,22 vs 1,74±0,19; $p<0,01$). The WR after surgery was significantly increased vs baseline in both groups (27,3%±14,03% vs 35,0%±14,18%; $p<0,01$ and 17,1%±13,7% vs 31%±16,15%; $p<0,01$). After surgery sympathetic activity defect was increased only in the Maze+ group (12,7%±7,3% and 25,4%±8,5%; $p<0,01$). The correlations between the cardiac 123I-MIBG parameters and the levels of norepinephrine, metanephrine, normetanephrine in plasma were examined. Cardiac 123I-MIBG parameters had significant correlations with transcardiac gradients (CS-Ao) of the norepinephrine and normetanephrine. Cardiac 123I-MIBG parameters had significant correlations with the distribution density of nerve endings in the myocardium. Conclusions. Results of this study indicated that the more sympathetic innervation abnormality prior surgery was observed in patients with AF. In patients who had undergone MV surgery without the «Maze» procedure, there were no significant changes in sympathetic activity defect in the early stage. The MV surgery itself doesn't influence the regional cardiac sympathetic activity. The evaluation of the cardiac nervous activity using 123I-MIBG scintigraphy may be a promising tool to determine of effectiveness of the cardiac radiofrequency denervation. The study was supported by a grant from the Russian Science Foundation No 15-15-10016.

Myocardial scintigraphy with 123I MIBG in a patient with Parkinson's

G. Sadeck[1], N. Lavatori[1], I. Palazzo[1], M. Veras[1], M. Sabra[1], F. Correa[1], A. Cotrado[1], W. K. Aguiar[1], W. Ker[1], C. Andre[2], C. Tinoco[1]; [1]Hospital Pró-Cardíaco, Rio de Janeiro, BRAZIL, [2]Sinapse Reabilitação, Rio de Janeiro, BRAZIL.

The meta-iodo-benzyl-guanidine (MIBG) is an analog of guanethidine, and a false neurotransmitter that is captured by adrenergic neurons and resembles norepinephrine. Myocardial perfusion imaging with iodine-MIBG is a scintigraphic examination able to evaluate the cardiac sympathetic nervous system in physiological and pathophysiological conditions. The indications for the exam range from ischemic heart disease to congestive heart failure (CHF), diabetes mellitus (DM) and any other medical condition that culminates with cardiac denervation, such as Parkinson's disease. Case report: MR, 78, male, caucasian. Patient with vertigo when diagnosed with Parkinson's in 2011. The Patient underwent clinical treatment without remission, and his clinical picture of atypical parkinsonism suggested alternative mechanisms to nigrostriatal degeneration. The past medical history includes arterial hypertension , previous smoking, COPD. Medications in use included L-DOPA and others. The pacient had a previous brain scintigraphy demonstrating decreased presynaptic dopamine transport in the projection of the basal ganglia, more prominent in the right side. The scintigraphic images with I-123 MIBG showed functional impairment of the adrenergic nervous system of the heart with increased sympathetic tone. The pacient presented a cardiac washout of 91.70% (VN ≤ 27%), and early heart / mediastinum ratio of 1.19 (normal value ≥ 1.80) and late heart / mediastinum ratio of 1.01 (normal value ≥ 1.80). Conclusion: Parkinson's disease can cause not only a motor disorder, but also cardiovascular dysautonomia. Thus, based on this case, we conclude that the worsening in the clinical condition and in the evolution of PD is directly related to the level of cardiac denervation. In this context, the heart scintigraphic study is of great value in monitoring these patients

Comparison of FDG PET and aortic CT scan for the detection of aortitis in giant cell arteritis

M. Soussan[1], M. Hommada[1], S. Abad[2], R. Dhote[2], C. Larroche[2], O. Fain[3], A. Mekinian[3]; [1]APHP, Avicenne Hospital, department of Nuclear Medicine, Bobigny, FRANCE, [2]APHP, Avicenne Hospital, department of Internal Medicine, Bobigny, FRANCE, [3]APHP, Saint-Antoine Hospital, department of Internal Medicine, Paris, FRANCE.

Objectives: Positron emission tomography (PET) scan is described as a very sensitive tool to detect aortitis in giant cell arteritis (GCA). Unfortunately, there is no consensus regarding the preferred scoring method and studies evaluating FDG-PET do not systematically compare the results with aortic CT scan, that is currently the reference for aortitis assessment. Visual vascular uptake higher than liver uptake might be a more reliable criterion than vascular wall SUVmax, and resulted in high specificity in recent studies. The objectives are to assess the detection rate of aortitis in GCA patients with visual criteria and to compare the findings with aortic CT scan. **Methods:** Forty-six GCA patients (ACR criteria > 3, positive temporal artery biopsy in 28/46) who underwent FDG PET were included (initial staging 32/46, relapse 9/46, remission 5/46). Aortic CT scan was performed in 27/46, in an interval < 1 month with PET and without interim start of therapy. Criteria for LV inflammation were vascular uptake > liver uptake for PET, and aortic thickening > 3 mm for CT. The agreement between PET and CT was evaluated by kappa coefficient. **Results:** Aortitis was detected in 17/46 (38%) with PET, and in 11/27 (42%) with CT. Agreement was very good between PET and CT for the diagnosis of aortitis (kappa = 0.85). Vascular segment-based analysis showed excellent agreement for thoracic aorta (k=0.90), and abdominal aorta (k=0.91), but agreement was poor for supra-aortic vessels (k=0.35). PET was positive in 6/8 patients with biological relapse, and negative in 5/5 patients in remission. **Conclusions:** Frequency of aortitis in GCA patients with PET is around 40%, a figure closed to those found in the literature with CT scan. Agreement between PET and CT is very good for aortic involvement, but not for supra-aortic vessels. PET imaging is suitable for assessing GCA relapse.

Role of FDG PET/CT imaging in the measurements of inflammatory activity of atherosclerotic plaques in carotid artery

A. sinha, V. Sharma, S. kapur, S. Pillai; National University Hospital, singapore, SINGAPORE.

OBJECTIVE: Symptomatic carotid stenosis is associated with a 3-fold risk of early stroke recurrence compared to other stroke subtypes. FDG-PET/CT is exquisitely sensitive for detecting macrophage activity, an important source of cellular inflammation in vessel walls. More recently, we and others have shown that FDG-PET/CT enables highly precise, novel measurements of inflammatory activity of activity of atherosclerotic plaques in large and medium-sized arteries. Current carotid imaging techniques rely on estimating plaque-related lumen narrowing but do not evaluate intra-plaque inflammation, a key mediator of plaque rupture and thromboembolism. Using combined (18) F-fluorodeoxyglucose positron-emission tomography (FDG-PET)/computed tomography, we investigated the relation between inflammation-related FDG uptake and stroke recurrence in small group of the patients. METHODS: Consecutive patients with a recent stroke, symptomatic (since last one month) and ipsilateral carotid stenosis (≥50%) were included in this study. FDG uptake was quantified as mean standardized uptake values (SUVs). Patients were followed prospectively for stroke recurrence. RESULTS: Forty one patients were included. Three patients had stroke recurrence within 90 days. FDG uptake in ipsilateral carotid plaque was greater in patients with early recurrent stroke (mean SUV, 2.5; standard deviation [SD], 0.44 vs 1.58; SD, 0.32, p = 0.02). On life-table analysis, 90-day recurrence rates with mean SUV greater than a 2.14 threshold were 80% (95% confidence interval [CI], 41.8-99.2) versus 22.9% (95% CI, 12.3-40.3) with SUV ≤2.14 (log-rank, p < 0.0001). In a Cox regression model including age and degree of stenosis (50-69% or ≥70%), mean plaque FDG uptake was the only independent predictor of stroke recurrence (adjusted hazard ratio, 6.1; 95% CI, 1.3-28.8; p = 0.02). CONCLUSION: Inflammation in a previously stable carotid plaque is an important event that leads to local thrombosis and cerebral embolization. This phenomenon can be reliable imaged with F-18 FDG PET for better risk stratification and therapeutic strategizing in carotid stenosis.

P092

Comparison of tissue-to-background-ratio in major arterial vessels between 18F-fluorodeoxyglucose and 18F-fluoromethylcholine PET-CT - preliminary results of a pilot study

J. Jamsek, M. Grmek, S. Hawlina, **L. Lezaic**; Klinicni center Ljubljana, LJUBLJANA, SLOVENIA.

AIM. During the last decade, numerous studies have evaluated ^{18}F-FDG as a potential molecular marker for vulnerable atherosclerotic plaque identification using PET-CT. However, little attention was directed to other molecular markers of atherosclerotic inflammation, such as ^{18}F-fluoromethylcholine (^{18}F-FCH), which was shown in preclinical studies to accurately depict inflammation of the arterial wall. The aim of our pilot study was to directly compare ^{18}F-FDG and ^{18}F-FCH mean maximum tissue-to-backgorung ratio (mean TBR_{max}) in major arterial vessels to asses the suitability of ^{18}F-FCH as a molecular marker for vulnerable atherosclerotic plaque identification - preliminary results are presented. **MATERIALS AND METHODS.** We retrospectively evaluated ^{18}F-FDG and ^{18}F-FCH PET-CT examinations of 5 male patients (aged 76 years on average) who had had examinations with both PET tracers within one week, as part of a prostate cancer clinical trial. Imaging with both tracers was performed on a Siemens Biograph™ mCT PET-CT scanner: image acquisition started 60 min after administration of either ^{18}F-FDG (4 MBq/kg) or ^{18}F-FCH (2.5 MBq/kg). Following the EANM recommendations on PET imaging of atherosclerosis we measured mean TBR_{max} in the following great arterial vessels: ascending aorta (AscA), left and right common carotid arteries (LCC and RCC), thoracic aorta (TA), abdominal aorta (AA) and left and right common iliac arteries (LCI and RCI). We then compared the calculated mean TBR_{max} of the same anatomical segments using both tracers by performing a paired, two-tailed Student *t*-test (α = 0.05). **RESULTS.** Arterial vessel mean TBR_{max} for ^{18}F-FDG and ^{18}F-FCH in the AscA was 1.50 and 1.88 respectively (p = 0.013), in the LCC 1.57 and 1.76 (p = 0.173), in the RCC 1.52 and 1.46 (p = 0.849), in the TA 1.50 and 2.13 (p = 0.063), in the AA 1.68 and 2.15 (p = 0.234), in the LCI 1.44 and 1.67 (p = 0.226) and in the RCI 1.64 and 1.51 (p = 0.702). **CONCLUSION.** ^{18}F-FCH appears to be a viable alternative to ^{18}F-FDG in molecular imaging of arterial vessels, yielding comparable information on metabolic activity of the arterial wall in most anatomical vascular segments. For a more comprehensive analysis additional data as well as prospective studies comparing ^{18}F-FCH and ^{18}F-FDG are needed.

P093

Contribution Of Cardiac Scintigraphy With ^{99m}Tc-DPD In The Differential Diagnostic Of Cardiac Amyloidosis Subtypes; Anatomo -Pathological Correlation

A. Cobo Rodríguez, J. Gomez Hidalgo, J. Villanueva Curto, A. Sainz Esteban, M. Gonzalez Selma, M. Ruiz Gomez, M. Alonso Rodriguez, C. Gamazo Laherran, R. Olmos Garcia; Hospital Clinico Universitario de Valladolid, Valladolid, SPAIN.

OBJECTIVE: To assess the contribution of cardiac scintigraphy with ^{99m}Tc-3, 3-diphosphono-1,2-propanodicarboxylic acid (99mTc-DPD) in the diagnosis of different subtypes of cardiac amyloidosis (CA).

METHODS: We performed a prospective study in 11 patients (9 males and 2 females). The mean age was 73.6 (SD ± 8.1). Patients were specifically referred to our department for the performing of cardiac scintigraphy with ^{99m}Tc-DPD, in order to differentiate between monoclonal inmunoglobulin light chain amyloidosis (LC-CA) and transthyretin-related cardiac amyloidosis (ATTR-CA). Scintigraphy results were correlated with a biopsy (one of the patients refused the procedure). All patients underwent transesophageal echocardiography (TE) and 9 of them also cardiac MRI. Both TE and cardiac MRI were suggestive of infiltrative amyloid heart disease in all patients. We analysed each scan with a visual score from 0 to 3 to determine the existence and intensity of the radiotracer uptake in heart tissue. The lack of uptake was assessed as 0, less than the bone (adjacent rib) was assessed as 1, equal to bone as 2 and greater than the bone as 3. **RESULTS:** 5 out of 6 patients who showed a pattern 3 (myocardial uptake greater than bone) presented anti-transthyretin antibodies and / or positive immunohistochemistry for TTR-L. Patients with pattern 0-1 presented histological positivity for specific staining techniques (Congo Red and T-Thioflavine) but negative staining for anti-transthyretin antibodies and TTR immunohistochemistry. These findings corresponded to amyloid but not to the transthyretin-related one. **CONCLUSION:** Cardiac scintigraphy with 99mTc-DPD is a useful tool in the differential diagnosis between LC-CA and ATTR: scintigraphy with intense uptake of ^{99m}Tc-DPD would be indicative of ATTR, while a scan with no uptake rule it out.

P094

Application of the hybrid imaging methods in the diagnostics of patients suspicious for vascular graft infection

I. Kostadinova, A. Demirev; Medical University, Sofia, BULGARIA.

Although vascular graft infection is a rare complication, occurring in 2-6% of patients, it has a high rate of morbidity and mortality. The aim of the study was to evaluate the diagnostic value of "in vitro" labelled leucocytes, using SPECT-CT, in patients suspicious of vascular graft infection, determine the activity of the inflammatory process and compare obtained data with our first results from PET-CT application. We examined 25 patients (Pts), of whom 16 had aorto - bifemoral, 2-femoro - femoral, 2-axillo - femoral and 5-ileo - femoral bypass. Fourteen of the patients were still under the antibiotic therapy. We used labeled leucocytes with 99mTc-HMPAO and applied SPECT-CT. Results of all patients were verified microbiologically, surgically or by a follow-up. An index of accumulation (IA) was used for an evaluation of the activity of the infection process. IA was calculated as the activity of the suspected area divided by the activity of the contralateral area. Infection was ruled out when IA was below 1.1 (in 5 Pts), low grade activity was considered at IA of 1.1-1.3 (in 12 Pts) and active infection at IA above 1.3 (in 8 Pts). Use of CT, allowed for exact localization of the infectious process, differentiating infection along the vascular graft (in 13Pts) form infection in adjacent soft tissues (in 7 Pts). In 7/25 Pts, additional PET-CT with 18F-FDG was performed. The sensitivity with labeled leucocytes was 84.2%, specificity of 83.3% and accuracy of 83.9%. According to results from PET-CT examinations, no difference in the final diagnosis was found, in comparison between the two imaging modalities, with the exception of 4 out of 7 patients, in whom a larger area of the grafts had FDG uptake. The infected segments had SUVmax 6,3 and in those without infection- 3.45. We consider that the higher FDG uptake in the last was a result of a chronic inflammation or reaction to the synthetic graft material, but more studies are needed to confirm these hypotheses. For 30% of the patients, both modalities have contributed important additional information, which changed the therapy. In summary, we suggest that "in vitro" labeled leucocytes, using SPECT-CT is a more specific, with a possibility for the measurement of the activity of infection, but time consuming modality. Therefore in heavily ill patients or in those without leukocytosis, PET-CT is preferable.

Sensitivity and Specificity of Parathyroid SPECT/CT in Primary Hyperparathyroidism Detection in Relation to Parathormone and Calcium Levels

M. Trofimiuk-Müldner[1], A. Skalniak[2], L. Kluczyński[3], A. Zapendowska[4], A. Budek[4], M. Buziak-Bereza[1], A. Sowa-Staszczak[1], A. Hubalewska-Dydejczyk[2]; [1]Chair and Department of Endocrinology, Nuclear Medicine Unit, Jagiellonian University Medical College, Krakow, POLAND, [2]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, POLAND, [3]Department of Endocrinology, University Hospital in Krakow, Krakow, POLAND, [4]Department of Endocrinology, Nuclear Medicine Unit, University Hospital in Krakow, Krakow, POLAND.

Parathyroid scintigraphy and neck ultrasound are the main methods of primary hyperparathyroidism (PHP) imaging. The observed increasing frequencies of asymptomatic or oligosymptomatic PHP cases may increase the false negative imaging results rate. The aim of the study was to determine the level of PTH and calcium at which an enlarged parathyroid gland can be detected by parathyroid SPECT/CT. Material and methods. A retrospective analysis of 117 patients diagnosed with PHP (100 females and 17 males, aged 16-88 years, median age 62 years) was performed. In each patient parathyroid SPECT/CT after administration of 500 MBq of 99mTc-MIBI was conducted (Siemens Symbia T16). Serum calcium and parathormone (PTH) were measured in each patient, serum phosphate was estimated in 109 subjects. Statistical analysis was performed with Statistica 12 software. Results. Median serum calcium level was 2.77 mmol/L (LQ and UQ - 2.66 i 2.87 mmol/L respectively); median serum PTH level was 122.8 pg/mL (LQ and UQ - 97.2 i 191.9 pg/mL, respectively); median plasma phosphate was 0.84 pmol/L (LQ and UQ - 0.74 i 0.98 mmol/L, respectively). In 70 (59.8%) patients an enlarged parathyroid gland was detected with SPECT/CT, in the remaining 47 subjects results of radionuclide imaging were negative. There was a statistically significant difference in PTH levels (median 138.15 and 114.80 pg/mL, respectively, p=0.02) and serum calcium levels (median 2.74 and 2.67 mmol/L, p=0.0003) between patients with positive and negative parathyroid SPECT/CT. Serum phosphate levels did not differ significantly (median 0.83 and 0.85 mmol/L, respectively; p= 0.19). Receiver-operator curves (ROCs) were drawn to establish PTH and serum calcium cut-off levels for positive parathyroid SPECT/CT imaging. Sensitivity and specificity of parathyroid scintigraphy are 38% and 89.6%, respectively, for PTH cut-off level of 191.9 pg/mL, and 52% and 79% respectively for serum calcium cut-off level of 2.74 mmol/l. Conclusions. Limiting parathyroid SPECT/CT to patients with significantly increased PTH and/or serum calcium levels, particularly if surgical treatment is not considered, may decrease false negative imaging rates and allows to avoid unnecessary radiation exposure. More precise determination of PTH and calcium cut-off levels requires analysis of larger patients group data.

P096

The Diagnostic Effectiveness of ^{18}F-FCH PET/CT in Detecting Hyperfunctioning Parathyroid Lesions for Primary Hyperparathyroidism with indeterminate ^{99}mTc-sestamibi SPECT/CT and Thyroid Echography

R. Yen, W. CHiu, M. Wu, K. Chen, W. Yang; National Taiwan University Hospital, Taipei, TAIWAN.

Background: Hyperparathyroidism is a common endocrine disorder. Primary hyperparathyroidism is due to over-secretion of parathyroid hormone and subsequently hypercalcemia, hyperphosphatemia and osteoporosis with the prevalence of 1/500 in female and 1/2000 in male. Surgical approach is the major treatment modality for these. Pre-operative localization of hyperfunctioning glands may lead to minimally invasive surgery. The most commonly used imaging modality for this purpose is ^{99m}Tc-sestamibi (MIBI), and supplemented by ultrasonography (US) of the neck. However, the sensitivity and specificity is not satisfactory. Recently, some investigators reported cases of parathyroid adenoma discovered incidentally on choline PET images performed for prostate cancer. As a phospholipid analog, choline is integrated into newly synthesized membranes of proliferating cells by up-regulation of choline kinase. In addition, a previous study showed that the activity of phospholipid/Ca2+-dependent protein kinase was also higher in hyper-functioning parathyroid tissue than in atrophic parathyroid gland. Both mechanisms may be responsible for the uptake of choline tracers in hyper-functioning parathyroid tissue. The purpose of this prospective study was to evaluate the diagnostic effectiveness of ^{18}F-Fluorocholine (FCH) PET in detecting and localizing hyperfunctioning parathyroid lesions. **Materials and Methods:** ^{18}F-FCH PET/CT were performed for 9 patients with primary hyperparathyroidism and discordant/negative results on ^{99m}Tc-MIBI SPECT/CT and US. The diagnostic sensitivity of PET was evaluated according to pathological results and clinical outcome. **Results:** Table 1 lists the characteristics and serum parathyroid hormone levels of these patients (2 male and 7 female). Seven of them had parathyroid adenomas, 1 had adenomatous hyperplasia and 1 had hyperplasia for all 4 parathyroid glands. All patients showed normalization of serum PTH after operation. The diagnostic results of ^{18}F-FCH PET/CT, 99mTc-Sestamibi SPECT/CT and thyroid US are demonstrated in Table 2. PET only missed the case who had hyperplasia for all 4 parathyroid glands. The mean SUVmax of PET positive lesions was 4.6 ± 2.3 (range 2.8-9.9). The smallest PET positive lesion was less 100 mg (Fig. 1). Using clinical outcome as gold standard, ^{18}F-FCH PET/CT had 89% localization accuracy, while ^{99m}Tc-MIBI SPECT/CT showed 33.3% and thyroid echo showed 33.3% respectively. **Conclusion:** Our study demonstrates ^{18}F-FCH PET/CT is a sensitive and accurate diagnostic imaging tool in the localization of hyperfunctioning parathyroid lesions for patients with primary hyperparathyroidism and indeterminate 99mTc-MIBI SPECT/CT and thyroid US.

P097

Comparative efficacy of ^{18}F-Choline PET/CT, ^{99m}Tc Sestamibi imaging and neck ultrasonography for the preoperative localization of parathyroid adenoma in suspected cases of primary hyperparathyroidism

T. NTK, A. Sood, R. R. Kalathoorakath, R. Kumar, A. K. Reddy Gorla, B. R. Mittal, S. Bhadada, A. Behra; PGIMER, Chandigarh, INDIA.

Objective: To compare the diagnostic performance of ^{18}F-choline PET/CT (Choline PET), ^{99m}Tc sestamibi imaging (MIBI) and neck ultrasonography (USG) in the preoperative localization of parathyroid adenoma in patients with suspected primary hyperparathyroidism **Materials and methods:** A total of fifty-four patients with suspected primary hyperparathyroidism (PHPT) were included in this study. All the patients were evaluated using ^{18}F-Choline PET/CT, ^{99m}Tc-sestamibi (planar dual phase and SPECT/CT) and neck ultrasonography for the preoperative localization of parathyroid adenoma. Of the fifty-four patients, surgery was performed and final histology was available in twenty-four patients. Sensitivity, positive predictive value (PPV) and accuracy of these modalities were determined using histopathology as the reference standard. Also, correlation of histopathology with neck ultrasound, ^{99m}Tc-sestamibi imaging, ^{18}F-choline PET/CT and pre-operative serum iPTH was statistically analyzed. When statistically significant, cut off values were determined using ROC curves. **Results:** Mean age of the patient population was 49.5±15 years (Range: 27-72 years; 5 males, 19 females). All the patients showed uni-glandular involvement. Neck ultrasonography, ^{99m}Tc-sestamibi and ^{18}F-Choline PET/CT localized lesions in 16 (69.5%), 19 (79.1%) and 24 (100%) patients respectively. Choline PET was particularly useful in the accurate localization of ectopic lesions. Histopathology demonstrated adenoma in 23 out of 24 patients and remaining one detected by choline PET/CT had normal parathyroid tissue on histology, though patient had revealed clinical and biochemical improvement in postoperative follow up. Thus, sensitivity, PPV and accuracy were 71.4%, 93.7%, 69.6% for USG, 83.6%, 100%, 83.3% for MIBI imaging, and 100%, 95.8%, 95.8% for Choline PET respectively. Preoperative serum iPTH (PRE-PTH) levels showed no statistically significant correlation (P- 0.180) with USG. However, significant correlation was noted between PRE-PTH and MIBI imaging (P-0.023; for a cutoff of 149 pg/ml with 84.2% sensitivity and 80% specificity on ROC analysis). Good correlation (Pearson correlation coefficient- 0.748) was noted between histology and normalization of iPTH status, thereby suggesting that there was no residual hyperfunctioning parathyroid tissue post-surgery. **Conclusion:** ^{18}F-choline PET/CT imaging is a promising imaging modality with higher sensitivity and accuracy as compared to conventional imaging (USG and MIBI imaging), especially in patients with ectopic lesions. Further validation of the results in larger cohorts is warranted to establish the utility of this technique.

P098

Factors affecting the sensitivity of Tc-99m MIBI Parathyroid SPECT

M. Araz, D. Cayir, M. Erdoğan, B. Ucan, E. Cakal; Ankara Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, TURKEY.

AIM: The sensitivity of Tc-99m methoxyisobutylisonitrile (MIBI) SPECT is variable (43-96%). It has been reported that some mediactions, especially calcium channel blockers (CCB), have been reported to decrease the sensitivity of the study. However, literature is still lack of enough reliable data. In sthis study we aimed to investigate possible effect of coexisting thyroid dieases and regularly used medications on the sensitivity of Tc-99m MIBI parathyroid SPECT. **MATERIAL-METHOD:** 218 patients (190F,28M, mean age: 57±14) with primary hyperparathyroidism who had undergone thyroid-parathyroid USG and Tc-99m MIBI SPECT were retrospectively investigated. Patients were divided into two groups: 119patients (54,6%) who had a positive Tc-99m MIBI SPECT and 99 patients (45,4%) with a negative scan. The effect of sonographically detected thyroid diseases and use of CCB, beta blockers, Angiotensin converting Enzyme inhibitors (ACEI)/ angiotensin receptor blockers (ARB), oral antidiabetics, thyroid hormone preparates, nonsteroid antiinflammatory drugs (NSAID) and proton pump inhibitors (PPI) on the sensitivity of Tc-99m MIBI SPECT studies were investigated in two groups. **RESULTS:** Overall sensitivity, specificity, positive predictive value (PPV) and negative predictive value(NPV) of Tc-99m MIBI SPECT were calculated 89.6%, 92.5%, 94.1% and 86.9%, respectively. The sensitivity was low in NSAID users (75.6%), compared to non-users (96.5%). No such difference was detected for the other drug groups (Table 1). The comparison results of the patients with positive and negative Tc-99m MIBI SPECT study showed that the frequency of NSAID usage was significantly higher in the negative scan group ($p<0.001$). No significant difference was detected between two groups neither in terms of coexisting thyroid disease nor usage of other medications. In this context, the results of USG and Tc-99m MIBI SPECT were concordant (Table 2). First univariate and then multivarite logistic regression analysis were performed for possible variables indicative of the result of the scan. Only NSAID usage was in correlation with Tc-99m MIBI SPECT results (OR:0.262; CI: 0,128-0,538; p<0,001). **CONCLUSION:** It has been reported that CCB usage decreased sensitivity of Tc-99m MIBI SPECT. In this study, among various drug groups, only NSAID were found to affect Tc-99m MIBI SPECT results. Because COX-2 expression has been

reported be increased in hyperplastic and adenomatous parathyroid glands, we state that NSAID may decrease the sensitivity of Tc-99m MIBI SPECT via this pathway.

P099

Pediatric Solitary Thyroid Nodules on Tc-99m Thyroid scan and their correlation with Histopathological Examination

M. Siddique, A. Hassan, H. Bashir, M. Nawaz; Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore.Pakistan., Lahore, PAKISTAN.

Purpose: Although thyroid nodules are less frequent in paediatric population, but are more often malignant. Our aim was to evaluate the correlation between Tc-99m thyroid scan finding and histopathology of selected thyroid nodules in pediatric population. **Methods:** We retrospectively reviewed all pediatric patients who underwent thyroid scan for palpable thyroid swelling / deranged thyroid function tests at our center from 2007 to 2014. The scan findings were classified as diffuse goiter, Graves' disease and nodular goiter. Hot or cold nodules were assigned based on level of Tc-99m uptake. Cold nodules were further correlated with histopathological/ultrasound findings. **Results:** 227 cases with thyroid related signs and symptoms presented during the 8 years period. 177(78%) were females and 56(25%) were males. Mean age: 14.8 years (range= 1-18 years). 30 cases (13.2%) had nodular goitre on thyroid scan and the rest had diffuse goiter / hypothyroid / Graves' disease. Out of nodular glands, 23.3%(7/30) cases had toxic nodules. 76.7%(23/30) cases had cold nodules detected on thyroid scan; Out of 23 cases, 16 underwent ultrasound guided biopsy and seven were lost to follow up; Histopathological findings of fine needle aspiration cytology were categorized as Bethesda category I(n=0), 50% category II(n=8), category III(n=0), 18.75% category IV(n=3), 18.75% category V(n=3) and 12.50% category VI(n=2). Out of category II, three patients had thyroid cysts on further evaluation while five patients had follicular colloid nodule/hyperplasia. Among category IV and V, all six patients had papillary carcinoma (PTC) on subsequent total thyroidectomy. Of two cases with Bethesda category VI, there was one case each of PTC and medullary carcinoma of thyroid. Additionally, in two patients with unremarkable Tc-99m uptake pattern PTC was diagnosed on cervical nodal biopsy. **Conclusion:** According to our retrospective analysis, cold nodule on Tc-99m thyroid scan have a 50% chance of being malignant, therefore in the children with palpable thyroid nodules, an accurate multistep work-up is necessary.

P100

^{18}F fluorocholin PET/CT as a complementary tool to MIBI SPECT/ low dose CT for localisation of hyperproducing parathyroid tissue.

J. Kubinyi[1], M. Fialová[2], P. Libánsky[2], S. Adámek[2], D. Chroustová[1], V. Ptáčník[1], D. Zogala[1], P. Broulík[1]; [1]General University Hospital, Prague, CZECH REPUBLIC, [2]Motol Hospital, Prague, CZECH REPUBLIC.

AIM: Prove the utility of 18F-fluorocholine (FCH) PET/CT examination in the localization of hyper productive parathyroid tissue in cases of negative or equivocal finding with MIBI SPECT/low dose CT (MIBI) examination. Assess the accuracy of whole MIBI and FCH combining protocol when FCH is used only in negative and equivocal finding with MIBI. METHODS: During year 2014 and 2015 175 patients were examined in with MIBI (all) and 27 from them with FCH too because of localisation of hyperparathyroidism. Then the surgery was performed and scintigraphic localisation verified. All patients were with higher level of calcium and parathormone. Surgery, histology and normalisation of calcium and parathormone level were taken as confirmation of scintigraphic localisation of hyperproducing parathyroid tissue. MIBI - only SPECT/low dose CT with scanner Infinia/Hawkeye GE after injection of 700 MBq (70kg) MIBI. Scans early 5-10 minutes and late 120 - 150 minutes post injection. Tc - only SPECT with the same scanner after injection of 200 MBq pertechnetate (70 kg). In all patient evaluation of wash out and then 3D subtraction MIBI minus Tc. FCH - neck and thorax 10 - 20 minutes after injection of 100 - 120 MBq fluorocholine with scanner Discovery 690 f. GE (bet time 7 minutes). CT was performed in standard conditions with Iomeron as contrast agent. 20 patients with negative or equivocal findings in 99mTc-MIBI scan and clear evidence of hyperparathyroidism (high level of calcium and parathyroid hormone - PTH) were examined with FCH PET/CT. PET scan was obtained 10 - 20 minutes after intravenous injection of 80 - 100 MBq FCH. Extent of scanning was from scull base to diaphragm. Time for bed was prolonged to 7 minutes for thyroid region and 5 minutes for the rest of chest. RESULTS: RESULTS: All surgery examined glands were 539 in 175 patients. 18 patients had hyperplasia and 157 patients had adenoma/s. Overall sensitivity was 85% and specificity 96%, for adenomas only the sensitivity was 97%. Sensitivity for hyperplasia is low, only about 45%. SUMMARY: Combined protocol used FCH only in negative or equivocal finding with MIBI examination seems to be very promising tool for localisation of hyper productive parathyroid tissue with very good accuracy. FCH can find small lesions bordered with thyroid and perhaps MIBI non avid lesions. On the other hand, for clear finding with MIBI is no need for FCH examination.

P101

Glucose Metabolism of hepatic, muscular, and adipose tissues in obesity Before and after bariatric surgery

W. Yao, C. Wu; College of Medicine, National Cheng Kung University, TAINAN, TAIWAN.

Introduction: Obesity has been linked to insulin resistance, hypertension, dyslipidemia, type 2 diabetes, and cardiovascular disease. Recently, bariatric surgery has been proposed to improve insulin resistance and glucose metabolism in obese patients, partially independent of weight loss. The aim of this study is to evaluate how bariatric surgery modifies the glucose metabolism of the whole body and different tissues in obese patients using F-18 FDG PET/CT. **Subjects and Methods:** We enrolled 14 obese subjects, aged between 22 and 61 years old, with Fat% 33.3 to 66.8. Both dynamic and whole body F-18 FDG PET/CT were done before and 6 months after bariatric surgery. Amount of abdominal visceral and subcutaneous fat was measured from CT at umbilical level. Semiquantitation of glucose metabolism (SUV-bw and SUV-lean) was measured by placing ROIs in each organ (liver, psoas muscle, quadriceps muscle, subcutaneous fat, and visceral fat). Body composition with DXA, serum glucose and insulin levels were also measured. **Results:** Bariatric surgery significantly lowered body weight, mostly adipose tissue, insulin and glucose levels. Using body weight for SUV calculation (SUV-bw), the glucose uptakes were decreased in the liver and muscles, while remained unchanged in adipose tissues after surgery. However, using SUV-lean, the glucose uptake remained unchanged in the liver (1.75±0.35 vs 1.81±0.34) and the psoas muscle (0.50±0.13 vs 0.49±0.07), while increased in fat tissues, both in visceral fat (022±0.11 vs 0.31±0.12) and subcutaneous fat (0.13±0.03 vs 0.21±0.07). **Conclusion:** Bariatric surgery increased glucose uptake in the visceral fat and subcutaneous fat in obese subjects. The underlying mechanism needs further investigation. SUV-lean may be more appropriate than SUV-bw for quantifying tissue glucose metabolism in obesity studies with F-18 FDG PET/CT.

P102

Minimally invasive radioguided surgery of primary hyperparathyroidism

V. Dedek, M. Havel, M. Kolacek, M. Formanek; Faculty hospital, Ostrava - Poruba, CZECH REPUBLIC.

Introduction: minimally invasive radio-guided surgery (MIRS) is accepted technique in patients (pts) with ^{99m}Tc-MIBI positive scintigraphy in primary hyperparathyroidism (PHPT). **Aim:** the gamma detecting intraoperative probe (C-Trak) and assessment of its contribution in the successful removal of PT adenoma. **Materials:** 87 pts underwent MIRS (75 women, 12 men). **Methods:** Dual-phase MIBI-scintigraphy to confirm PT adenoma was performed by the „separate-day protocol". In the morning on the day of surgery we had administered i.v. 600 MBq ^{99m}Tc-MIBI and wrote in the report time interval to start operation (2,5 - 3 h). During MIRS surgeon was given auditory signals and digital counts (CPS-counts per second) to dissect the radioactive target tissue and placed upon record these facts: time of beginning and duration of MIRS, in vivo PT adenoma to thyroid ratio in CPS (A/T). We also estimated histological findings. **Results:** in 85/87 pts histological findings confirmed PT adenoma, once erroneously removed lymphatic node and in the second case papillary thyroid carcinoma. According to the surgeons the gamma probe detection was useful in 73/85 cases (86 %) and on the contrary the probe didn´t help them in 12/85 cases (14 %), but in the end PT adenomas were successfully removed. Out of the gamma probe successful cases A/T ratio were in 8/73 1,1-1,5, in 49/73 more than 1,5 and in the last 16/73 cases the ratios weren´t specified by surgeon. We analyzed the possible reasons of gamma probe failure (12 cases). In 2 of them MIRS started too early (100, resp. 120 min. after MIBI administration), in 4 cases weren´t MIBI uptake in scintigraphy significant, in the rest 6 cases we think about more factors: time to MIRS was too long (more than 240 min.), the sizes of PT adenomas were small (less than 1 cm), in two cases PT adenomas were ectopic (paraesophageal, resp. paravertebral). Duration of the operation in successful cases were 20-60 min in 72 pts and 70-160 min in 13 pts (included 7 cases of total thyroidectomia). **Conclusion:** In the PHPT pts MIRS is recommended technique in cases with high sestamibi uptake in dual-phase scintigraphy (included SPECT/CT). Our ORL surgeons were helped by gamma probe in 86 % out of the 85 PT adenoma dissections. In vivo A/T ratio was most often more than 1,5. We consider important to keep interval 2,5-3 h between sestamibi administration and MIRS. MIRS in the hands of experienced surgeon reduces time of surgery.

P103

Comparison of single-phase early SPECT/CT, dual-phase planar imaging with early SPECT and dual-phase planar imaging with early SPECT/CT Tc-99m Sestamibi Parathyroid Scintigraphy

JAVIER GÓMEZ HIDALGO, AMPARO COBO RODRÍGUEZ, **A. SAINZ-ESTEBAN**, CLAUDIA GAMAZO LAHERRÁN, JUAN GABRIEL VILLANUEVA CURTO, MARÍA ÁNGELES RUIZ GÓMEZ, MARÍA LUISA GONZÁLEZ SELMA, MERCEDES ALONSO RODRÍGUEZ, ROBERTO OLMOS GARCÍA; Nuclear Medicine Department. Hospital Clínico Universitario de Valladolid, VALLADOLID, SPAIN.

Aim: The purpose of our investigation was to directly compare diagnostic accuracies and confidences of various imaging protocols on same patients in the detection and localization of parathyroid adenomas. **Methods:** From January 2013 and December 2014 scintigraphy was performed on 337 patients with primary hyperparathyroidism. Of these, 45 had histologically proven single adenomas (40) or hyperplasias (5) and are the subject of this review. Planar imaging was performed at 15 min and 2 h after injection. Besides, SPECT/CT was performed after the early planar image. Three image sets (single-phase early SPECT/CT, dual-phase planar imaging with early SPECT and dual-phase planar imaging with early SPECT/CT) were reviewed for probability of adenoma on 5-point scale (1: definitely negative, 2: probably negative, 3: equivocal, 4: probably positive, and 5: definitely positive). Besides, the three image sets were also reviewed for adenoma localization at 7 possible sites. Each review was scored for location and certainty of focus by 2 reviewers. Surgical location served as the standard. **Results:** Dual-phase planar imaging with early SPECT/CT detected 38 pathological parathyroids (84.4%) and correctly localized 28 (62.2%). False negative corresponded to two hyperplasia and five single adenomas. Single-phase early SPECT/CT detected 34 pathological parathyroids (75.5%) and correctly localized 27 (60%). Dual-phase planar imaging with early SPECT detected 34 pathological parathyroids (75.5%) and correctly localized 26 (57.7%). False negative corresponded to three hyperplasia and nine single adenomas. Regarding the equivocal cases, dual-phase planar imaging with early SPECT and single-phase early SPECT/CT presented 6 equivocal cases, while dual-phase planar imaging with early SPECT/CT only 4. **Conclusion:** Dual-phase planar imaging with early SPECT/CT allows more accurate detection and localization of parathyroid adenomas than single-phase early SPECT/CT and dual-phase planar imaging with early SPECT. However, the correct detection and localization of multiglandular hiperplasia remains difficult.

P104

Towards harmonization in parathyroid scintigraphy in Finland

V. Tunninen[1], P. Varjo[1], T. Kauppinen[2]; [1]Satakunta Central Hospital, PORI, FINLAND, [2]Helsinki University Hospital, Helsinki, FINLAND.

AIM There is no consensus on how to perform parathyroid scintigraphy (PS), in terms of study method or acquisition techniques. This has led to a large variety of protocols worldwide, but also nationally. Finland has been working towards harmonization of PS since 2009, when a significant variability in PS protocols was revealed in our country. The aim of this follow-up study was to update the national status of in PS protocols. **MATERIALS AND METHODS** Our group published 2009 first results of national situation. All departments of nuclear medicine in Finland were now contacted in this study and the current status of PS methods and acquisition techniques were requested. **RESULTS** There are 25 departments of nuclear medicine in Finland. Current practices were received from all the departments which perform PS (n=19). There has been a significant change in the study methods used. Currently all hospitals use dual-isotope method using ^{123}I/^{99m}Tc-sestamibi as their primary method for PS (in comparison, 52,4% in 2009). ^{123}I activity ranged from 7,4 MBq to 30MBq (mean 18MBq), and iodine is given as an iv injection in all but one hospital (2009: 10-30MBq, 4 per os, 7 iv). ^{99m}Tc-sestamibi activity ranged from 400 MBq to 750MBq (mean 670MBq) (2009: 150-800MBq). The use of SPECT/CT acquisition technique has increased from 46% to 89,5% of hospitals using the dual-isotope method. At the same time, the use of planar imaging using the parallel-hole collimator has decreased from 100% to 47,4%, and with pinhole collimator from 46% to 36,8%. Additional acquisitions are performed in 16 of 19 hospitals (planar imaging with parallel-hole or with pinhole collimator). The late phase acquisition is still performed in 6 of 19 hospitals (all acquisition techniques are used). There still is variability in study protocols, but mainly in additional acquisitions and in the use of the late phase imaging. **CONCLUSION** Our follow-up study showed that the methods of PS have been harmonized significantly during the last seven years in Finland. We found two main reasons for this. First, 78,9% of hospitals have purchased new SPECT/CT equipment, so there is no instrumentational limits for using modern acquisition techniques. Second, we have been working actively in this field (research, lectures in national meetings, active discussion between professionals). However, there still is need for studies to optimize the PS protocols, to minimize the time required for the study, the patient discomfort and the total cost of the study.

P105

Hyperfunctioning parathyroid lesions with rapid 99mTc-Sestamibi washout: more common than usually thought

J. G. Santos, **M. R. Victor**, A. I. Santos; Hospital Garcia de Orta, E.P.E., Almada, PORTUGAL.

Aim: Parathyroid scintigraphy with 99mTc-Sestamibi (PTS) is widely used to pre-operatively localize hyperfunctioning parathyroid lesions (HPTL). However, the biokinetic behaviour of this radiopharmaceutical is known to be variable, potentially causing false negative exams. The purpose of this work is to evaluate the frequency of rapid 99mTc-Sestamibi wash-out in parathyroid glands. Materials and methods: We retrospectively analysed a group of 40 PTS positive for HPTL followed by surgical confirmation, performed on 37 patients. Scintigraphy protocol included both early and late planar images and early SPECT imaging. Thyroid scintigraphy with 99mTc-Pertechnetate (TS) was performed if the reporting physician felt it was necessary to properly interpret PTS. HPTL with slow washout of 99mTc-Sestamibi (SW) were diagnosed by delayed imaging. HPTL with rapid washout of 99mTc-Sestamibi (RW) were identified by one or both of the following criteria: radiopharmaceutical uptake posterior to the thyroid in early SPECT images; 99mTc-Sestamibi uptake with no corresponding 99mTc-Pertechnetate uptake. Data was categorized according to type of hyperparathyroidism (primary - 1HPTL vs secondary/tertiary - 2/3HPTL), number of hyperfunctioning parathyroid lesions (single gland vs multiple gland) and radiopharmaceutical washout (SW vs RW). The chi-squared test of homogeneity was used. Results: Forty PTS cases were identified, performed on 16 males (mean age=56 years;SD=18,7;min=13,max=87) and 24 females (mean age=64 years;SD=12,7;min=27,max=80). 1HPTL accounted for 23 cases (57,5%) and 2/3HPTL for the remaining 17 (42,5%). There was a total of 26 SW cases (65,0%) and 14 RW cases (35,0%). Among 1HPTL, RW was present in almost half the cases (47,8%), but for 2/3HPTL only 17,7% of cases presented RW. This difference seems statistically significant (p-value=0.0479). Single lesions accounted for 75,0% of cases and multiple ones for 25,0%. There was only one multiple lesion case in the 1HPTL group (4,4%), while in the 2/3HPTL group these were a slight majority (52,9%). Among single lesions, there was a large minority of RW (43,3%), but for multiple lesions only one case of RW was identified (10,0%). This difference was not statistically significant (p-value=0.0556). Diagnosis of RW was achieved by SPECT in 6 cases, comparison with TS and a combination of both methods in 4 cases each. Conclusion: This series supports the idea that HPTL with RW are common, representing more than a third of our sample. This is most significant when considering patients presenting with 1HPTL. Still, one case of 2/3HPTL with RW was identified. Early SPECT is very useful in identifying these lesions.

P106

Impact of resolution recovery for improvement of image quality in 123I/99mTc-MIBI parathyroid SPECT

M. VERSTRAETE, **Y. R. PETEGNIEF**, O. MOREL, C. UNGUREANU, G. LANDECY, L. COMAS, C. DROUET, H. Boulahdour; CHRU Jean Minjoz, BESANCON, FRANCE.

Introduction: The objectives of this study were to define a method for image reading of dual-isotope ^{99m}Tc -MIBI and ^{123}I- SPECT for the preoperative localization of parathyroid adenomas in the setting of primary hyperparathyroidism (PHPT) and to investigate the role of resolution recovery correction for iterative reconstruction. **Methods:** Twenty-eight consecutive patients who underwent imaging for PHPT over a 18-month period were retrospectively assessed. Visualisation of parathyroid adenomas in planar and SPECT dual-isotope studies was performed with subtraction of mean activity in thyroid gland on MIBI images to the mean thyroid activity on ^{123}I images. Thus, visual (K_1) and automatic (K_2) normalization coefficients were compared in planar and SPECT studies reconstructed with OSEM iterative reconstruction without (IR) and with collimator resolution correction (IRC). Neither scatter, nor attenuation correction were included in the reconstructions. Two readers rated planar and IR images and two readers rated IR and IRC images only. Images were graded on a 4-point scale : normal (0), probably normal (1), probably abnormal (2) and definitely abnormal (3) with respect to intensity and location of the lesion. Contrast of lesions was compared between IR and IRC data. The preoperative results were compared to intraoperative findings obtained for 17 parathyroid lesions. **Results:** Visual and automatic normalization coefficients for SPECT correlated well (K_2= 0.99 K_1+0.05, R^2= 0.78) except for 3 patients with larger K due to the presence of thyroid pathology. For the two readers referred for planar and IR studies, sensitivity (S) was 0,94 and 1. For SPECT studies, S varied from 0,87 to 0,88 for all readers. Two false negative results with IR were not correctly rated with IRC. Contrast of inferior lesions was better with IRC than IR (2.0 vs 1.6) whereas in upper quadrants, contrast of adenomas was limited after IRC (1.6) due to the presence of higher background. **Conclusion:** The role of planar imaging in dual-isotope PHPT imaging is always important. Image quality of IRC globally improved readers' confidence in subtracted MIBI SPECT interpretation, but didn't change classification of SPECT results.

P107

Preoperative Parathyroid Lesion Detection: The Success of Ultrasonography, Technetium Tc-99m Methoxyisobutylisonitrile Parathyroid Planar Scintigraphy and SPECT-CT

Ö. Özdemir Başer, B. T. Okudan, D. Köseoğlu, P. Arıcan, D. Berker; Ankara Numune Hospital, Ankara, TURKEY.

Purpose: Autonomous over-production of parathormon with hyperfunctioning parathyroid glands is the most frequent cause of hypercalcemia in outpatient populations. Despite the various methods are available for preoperative localization of parathyroid lesions, there is still no certain preoperative imaging algorithm to guide a surgical approach. We aimed to find out and compare the efficacy of ultrasonography (USG), technetium methoxyisobutylisonitrile (Tc-99m MIBI) parathyroid planar scintigraphy and SPECT-CT in detecting the localization of parathyroid adenomas in patients with primary hyperparathyroidism (PH). Methods: In this study we retrospectively analyzed 700 patients with hyperparathyroidism which referred parathyroid scintigraphy and SPECT/BT to our department from 2013 to 2015. Two hundred forty of 700 patients had neck surgery with definitive histologic reports. The 211 patients were included which exact localization of parathyroid pathologies obtained at the operation. Of these patients USG, planar Tc-99m MIBI and SPECT-CT imaging performed before surgery was available in 205 patients. USG was not done in only 3 of these patients. For scintigraphy, after 20 minutes injection of 555 MBq Tc-99m MIBI early planar imaging, after 180 minute planar and SPECT-CT imaging were obtained. Preoperative parathyroid imaging with USG, planar Tc-99m MIBI and SPECT-CT were evaluated and compared with operative findings. Results:Between the time period this study was conducted, 254 patients underwent surgery for PH, and the pathological results were present in 240 patients. The pathological examination showed that 224 (88.2%) patients had parathyroid adenoma, 5 (2%) patients had carcinoma and 11 (4.3%) patients had parathyroid hyperplasia. The analysis of 14 patients (5.5%) showed no parathyroid tissue. USG detected the localization of the parathyroid pathology correctly in 174 patients (84.9%), whereas SPECT-CT and planar Tc-99m MIBI imaging were correct in 165 (79.3%) and 130 (62.5%) patients, respectively. The positive predictive value of USG, SPECT and MIBI were 92.1% (174/189), 85.5% (130/146), and 89% (165/193) respectively. Conclusion: Surgical treatment can be planned in patients with hyperparathyroidism, because of its complications due to high levels of parathyroid hormone. In particular, minimally invasive surgery is preferred for single adenomas. Therefore, preoperative localization of adenoma is important. Although, this study showed us USG is better than scintigraphic imaging techniques to correctly localize the parathyroid adenomas, it could be dependent to re-evaluation of USG following the SPECT/CT.

P108

Procalcitonin in the detection of medullary thyroid carcinoma

J. Maffey-Steffan[1], R. Moncayo Nevada[1], A. Griesmacher[2], W. Prokop[2], I. Virgolini[1]; [1]Department of Nuclear Medicine, Innsbruck, AUSTRIA, [2]Department of Laboratory Medicine, Innsbruck, AUSTRIA.

Aim The aim of the present study was to investigate the usefulness of procalcitonin (PCT) as a diagnostic marker of medullary thyroid carcinoma (MTC). As the calcitonin (CT) radioimmunoassay (RIA) has relevant limits in the clinical praxis. **Methods** In 81 patients with multiple thyroid nodules CT and PCT were investigated in parallel. CT was measured by an Immuno Radiometric Test (Cisbio Assay) normal range: < 13 pg/ml and PCT was measured by ECLIA (Electro Chemi Luminescence Immuno Assay, Elecys BRAHMS PCT), normal range: < 0.1 ng/ml before surgery. **Results** In 72/81 patients in whom no MTC was found the PCT was equal or less than 0.06 ng/ml and the CT was < 13 pg/ml. In four patients with documented MTC the PCT and CT values were 0.4 ng/ml and 74.6 pg/ml, 3.36 ng/ml and 520 pg/ml (1:10), 4.72 ng/ml and 1160 (1:50) pg/ml, and 1.36 ng/ml and 370 (1:10) pg/ml, respectively. In one patient who was treated by chemotherapy PCT was 0.16 ng/ml and CT 11.3 pg/ml. In another patient treated by chemotherapy PCT was 3.44 ng/ml and CT was 400 pg/ml. In one patient with PCT of 0.07 ng/ml CT amounted to 16.6 pg/ml and in this patient a Ca2+-stimulation-test was positive. **Conclusion** Our data suggest that the determination of PCT is clinically useful as a quicker, cheaper and more practicable screening test than CT measurement in patients with nodular goiter to exclude MTC.

P109

Cost-effectiveness Analysis of Computed Tomography and Adrenal Scintigraphy in Primary Aldosteronism

C. Lu[1], R. Chang[2], R. Yen[1]; [1]National Taiwan University Hospital, Taipei, TAIWAN, [2]Graduate Institute of Health Care Organization Administration, National Taiwan University, Taipei, TAIWAN.

Background Primary aldosteronism (PA) is the most common cause of secondary hypertension. The two main causes of PA are aldosterone-producing adenoma, which could be cured by surgical intervention, and bilateral adrenal hyperplasia, which should be medical-treated. Computed tomography (CT) is the initial imaging approach for lateralization with wide variation of sensitivity. Adrenal scintigraphy has limited role in lateralization during early days due to resolution. With the SPECT/CT fusion imaging technique, the accuracy of adrenal scintigraphy is significant improved. This study aimed on the comparison of the accuracy, average cost and cost-effectiveness analysis of four imaging modalities for differentiating the etiology of PA, including CT, NP-59 planar, NP-59 SPECT and NP-59 SPECT/CT. **Methods** We retrospectively included 27 clinical-confirmed PA patients from TAIPAI database. All of them had CT, NP-59 adrenal scintigraphy (planar, SPECT and SPECT/CT) studies and pathology reports of adrenal lesion. The accuracy and average cost of these four imaging modalities were analyzed. By decision tree and setting effectiveness as diagnostic accuracy and diagnostic utility, cost-effectiveness were also analyzed. Sensitivity analysis was performed to determine the impact on the average cost while the variables changed. **Results** NP-59 SPECT/CT is the most accurate study among four imaging modalities, with borderline significance as compared with NP-59 planar and CT. NP-59 SPECT/CT bares the lowest average cost, and NP-59 planar bares the highest average cost. By setting diagnostic accuracy as the effectiveness, NP-59 SPECT/CT has the lowest cost-effectiveness ratio. If setting diagnostic utility as the effectiveness, NP-59 planar is considered an ineffectiveness study. In sensitivity analysis, if the sensitivity of NP-59 SPECT/CT decreases to 0%, the average cost of NP-59 SPECT/CT is still lower the average cost of CT. The average cost of NP-59 SPECT/CT is higher than the average cost of CT while the specificity of NP-59 SPECT/CT decreases to 59.5%. **Conclusion** Our study suggests that NP-59 SPECT/CT is the most accurate with the lowest average cost and the most cost-effective study among these four imaging modalities in differentiating the etiology of PA. It shows no significant impact on cost-effectiveness ratio as compared with CT while the sensitivity and specificity of NP-59 SPECT/CT changes. Aside from clinical concern, this result provides physicians consider the decision in another way to provide more effective management in PA.

P110

The role of preoperative imaging in localization of parathyroid adenoma - our experience

V. Militano, N. Seshadri, S. Vinjamuri; Royal Liverpool and Broadgreen University Hospital NHS Trust, Liverpool, UNITED KINGDOM.

Intoduction:Ultrasonography and 99mTc-MIBI scinitigraphy are well recognized imaging techniques for preoperative parathyroid lesion localization. The aim was to determine the accuracy of planar and SPECT-CT MIBI scintigraphy in the preoperative localization in patients of suspected primary hyperparathyroidism in our center and its comparison with ultrasonography. Materials and Methods:We retrospectively reviewed 118 patients, who underwent Technetium-99m sestamibi scintigraphy with planar and SPECT/CT imaging at Royal Liverpool University Hospital, with diagnosis of suspected primary hyperparathyroidism between July 2014 and June 2015. 62 patients had parathyroid surgery and 46 patients of these, also, underwent high-resolution ultrasonography prior to parathyroid surgery. The diagnostic accuracies of both these techniques were evaluated using surgical and histological findings as the reference standard. Results:Following surgery the histology showed 77% [48/62] solitary parathyroid Adenoma(PA) , 13%[8/62] parathyroid hyperplasia(PH), 5%[3/62] Dual parathyroid Adenoma(DPA) and 5%[3/62] normal parathyroid(NP).Of the 62 patients in whom histology was available planar imaging was true positive in 61%[38/62](33 PA, 1 DPA and 4 PH), true negative in 5%[3/62], false negative in 34%[21/62](16 PA, 4PH, 2DPA), false positive in 0% with a sensitivity of 64%, specificity of 100%, accuracy of 66%, PPV of 100% and NPV of 12.5%.Similarly SPECT/CT images was true positive in 74%[46/62](37 PA,6 PH, 3 DPA), true negative in 5%[3/62], false negative in 21%[13/62](11 PA, 2 PH) and false positive in 0% corresponding to a sensitivity of 78%, specificity of 100%, accuracy of 79% with a PPV of 100% and NPV of 18.75%.Likewise Ultrasonography was true positive in 48%[22/46](21 PA and 1 DPA), true negative in 4%[2/45], false negative in 48%[22/46](15 PA, 5 PH, 2 DPA) and false positive in 0% corresponding to a sensitivity of 50%, specificity of 100% with accuracy of 52% PPV of 100% and NPV of 8.3%.There was significant difference in the weight of the glands on histopathology with a mean weight of 413 mg(970-80) for FN vs 1175 mg(3430-120) for TP studies on MIBI scintigraphy.However there was no correlation on MIBI scintigraphy study between Serum Ca FN 2.8(3.2/2.61) vs TP 2.8(3.2/2.5) and PTH levels FN 10.5(19.1/4.3) and TP 13.7(89/6). Conclusion:SPECT/CT was superior to planar imaging with an accuracy of 66%(planar) vs 79%(SPECT/CT). MIBI scintigraphy is more accurate than US in localizing parathyroid lesions with the latter adding little incremental benefit in localizing. The accuracy of MIBI scintigraphy is inversely related to the weight of the parathyroid lesion. However there is no correlation with Serum Ca and PTH levels.

P111

Utility of sestamibi ^{99m}Tc-SPECT/CT in the localization of the pathological parathyroid gland before surgery compared with other conventional imaging techniques

M. OPORTO[1], C. SAMPOL[1], C. PEÑA[1], N. ORTA[1], M. TOSCANO[2], M. VILLAR[2], S. RUBI[1,3], J. MOLINA[1], F. CEPA[1]; [1]HOSPITAL UNIVERSITARIO SON ESPASES. NUCLEAR MEDICINE DEPARTMENT, PALMA DE MALLORCA, SPAIN, [2]HOSPITAL UNIVERSITARIO SON ESPASES. RADIOPHARMACY DEPARTMENT, PALMA DE MALLORCA, SPAIN, [3]INSTITUTO DE INVESTIGACION SANITARIA DE PALMA (IdISPa), Palma de mallorca, SPAIN.

Aim: To compare the capacity of Ecography, Planar scintigraphy dual-phase^{99m}Tc-sestamibi and SPECT/CT ^{99m}Tc-sestamibi in the localization of parathyroid adenomas in patients diagnosed with hyperparathyroidism before surgery. **Material and methods:** We retrospectively evaluated the pre-operative studies of 46p with primary (n=44) and secondary (n=2) hyperparathyroidism. Ecography was performed in 44p before or after the planar scintigraphy. Dual-phase ^{99m}Tc-sestamibi planar scintigraphy was carried out in 46p, acquiring SPECT/CT in 41p (early phase n=30 and delayed phase n=11). The adenoma's localization for the 3 studies was compared with operative findings, histology and intraoperative PTH blood test (basal, 5' and 10'). **Results:** Out of 46p included, median age 58.5 years, 37 female and 9 male, all with high suspicion of hyperparathyroidism, with mean for PTH and calcium of 174 pg/ml and 10.9 mg/dl respectively. The Ecography detected image suspicious of adenoma in 26/44p and was negative in 18/46p (sensitivity 59%). Early phase planar scintigraphy with ^{99m}Tc-sestamibi was positive in 22/46p, negative in 15/46p and unclear in 9/46p (sensitivity 47.8%), delayed phase planar scintigraphy with ^{99m}Tc-sestamibi was positive in 32/46p, negative in 7/46p and unclear in 7/46p (sensitivity 69.5%) and SPECT/CT ^{99m}Tc-sestamibi was positive in 39/41p and negative in 2/41p. Sensitivity for SPECT/CT^{99m}Tc-sestamibi was 95.1%.The accuracy for localizing pathologic parathyroid glands to the correct side of the neck was for ecography 25/44p (56.8%), Planar scintigraphy dual-phase^{99m}Tc-sestamibi 32/46p (69.5%) and SPECT/CT ^{99m}Tc-sestamibi 41/41p (100%), 15 in the right and 26 in the left side, 4 superior and 37 inferior. Ecography detected 5/16p ectopic adenoma (sensitivity 31.2%), planar scintigraphy dual-phase ^{99m}Tc-sestamibi 9/16p (sensitivity 56.2%), and SPECT/CT 16/16p (sensitivity 100%): 9 in the anterior cervical region, 4 retrotracheal, 1 paraesophageal and 2 prevertebral. Out of 46p, 36p went to radioguided surgery and 10p to conventional surgery. The average intraoperative basal PTH was 202.3 pg/ml, 5' PTH 160.5 and 10' PTH 91.6. A total of 50 parathyroid glands were removed with a final diagnosis of parathyroid tissue and only 1p had unclear histology. A total of 41p (89.1%) were biochemically cured, 36/36p with radioguided surgery and 5/10p with conventional surgery. **Conclusion:** SPECT/CT ^{99m}Tc-sestamibi it is high recommended as a first-line imaging in patients diagnosed with hyperparathyroidism before surgery. It is superior to ecography and planar imaging for a more specific localization of the pathological gland and for the detection of ectopic adenoma, providing additional topographic information, which is crucial in order to achive radioguided surgery success.

P112

The Relationship Between Disease Severity and Quantitative Parameters Derived From Tc-99m MIBI SPECT Images in Primary Hyperparathyroidism

D. Cayir, **M. Araz**, A. Yalcindag, E. Cakal; Ankara Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, TURKEY.

AIM: Tc-99m methoxyisobutylisonitrile (MIBI) parathyroid SPECT is the method of choice in detecting parathyroid pathology in primary hyperparathyroidism. It has been previously reported that there was a relation between retantion index (RI) and parathyroid washout parameters derived from parathyroid scintigraphy and serum intact parathormone (PTH) levels, size of the tumor and oxyphilic cell content. In this study, a possible correlation between multiple scintigraphic quantitative indices and clinical, laboratory and radiological data was investigated in a large population. **MATERIAL-METHOD:** 93 patients (14M, 79F, mean age: 59.61 ±13.55) were involved. They had been preoperatively investigated by Thyroid-parathyroid USG and Tc-99m MIBI SPECT and both imaging modalities revealed a single parathyroid adenoma. Histopathological confirmation of a parathyroid adenoma was made by single sided parathyroidectomy. Region of interests (ROI) of equal pixel numbers were drawn around the parathyroid adenoma (PT), neighbouring thyroid tissue (T) and background (BG) in early and late planar images and isocontour ROI were drawn around the adenoma in SPECT images (Figure 1 and 2). Following background activity correction, early and late PT, PT/T,PT-T, PT washout [(Early T-Late T)/Late T], RI [(Late PT/T - Early PT/T) X100 / Early PT/T] were calculated. The relationship between these parameters and serum PTH, Ca, P, urinary Ca levels, weight of the adenoma and urinary ultrasonography findings were investigated. **RESULTS:** Pearson correlation analysis revealed that there was a statistically significant relationship between the weight of the adenoma and serum PTH and Ca levels. Among the scintigraphic parameters, Early PT-T was correlated with serum CA levels and RI was correlated with serum PTH levels ($p<0.05$). When patients were divided into two groups, the patients who have findings of nephrolithiasis shown by Urinary USG and the patients who don't, the results of student's t test revealed that Early and Late PT values were significantly higher in the group with nephrolitiasis compared to the patients with no signs of nephrolitiasis. **CONCLUSION:** In this study, we state that some parameters derived from Tc-99m MIBI parathyroid SPECT study can be indicative of disease severity

The Utility of Rapid Parathyroid Hormone Radioimmunoassay in the Surgical Management of Hyperparathyroidism

J. Koutsikos[1], G. Angelidis[1], K. Kalogeropoulou[1], M. Vogiatzis[1], E. Ilia[1], A. Evagelatou[2], A. Velidaki[2], N. Dimakopoulos[1]; [1]Nuclear Medicine Dept., Army Share Fund Hospital (417 NIMTS), ATHENS, GREECE, [2]Nuclear Medicine Dept., Laiko General Hospital of Athens, ATHENS, GREECE.

INTRODUCTION: Primary hyperparathyroidism is a common disease caused by single or multiple parathyroid lesions. If treatment is necessary, surgery is the commonly used procedure. Before operation, hypercalcemia and elevated PTH levels must be observed. Most failures in parathyroidectomies are associated with the inability to identify a multiglandular disease or an ectopic location. Intraoperative PTH measurement (i-PTH) aims to ensure parathyroidectomy success, as the half-life of PTH is approximately 5 min. In our institution, we use an immunoradiometric assay (ELSA-PTH, CISBIO, France) for PTH measurement. The standard PTH assay in the analyzer has an 18 hrs +/- 2 incubation time, not suitable for (rapid) i-PTH measurement. Furthermore, in the literature, the methodology of radioimmunoassays is seldom used today because of lengthy turnaround time and poor diagnostic utility. However, a rapid ELSA-PTH procedure characterized by 30 min incubation time is recommended by the manufacturers. The aim of our study was to define a possible diagnostic utility of rapid ELSA-PTH procedure, compared to standard method. METHODS: Twenty-eight plasma samples were collected from patients with suspected hyperparathyroidism in our hospital. The samples were analyzed according to both standard and rapid methodology. Findings were assessed by simple linear regression analysis. RESULTS: The mean PTH level using the rapid procedure was 170,3 nm/l (range 21.8 - 1153.4), while using the standard method was 125,2 (range 13.8 - 771.8). Higher PTH values were measured in 24/28 samples

with the rapid method. Significant coefficient correlation was found between the values measured with the two methods (r=0.988, p<0.0005). There was no normal measurement based on one of the two methodologies performed corresponding to an abnormal value, when the same sample was analyzed according to the other procedure. CONCLUSION: Our findings support the diagnostic value of rapid PTH radioimmunoassay methodology, suggesting a favourable clinical utility in the intraoperative setting given its short incubation time. Under a well-designed protocol, this procedure can lead to a close co-operation between the operating surgeon and the specialized laboratory staff, placing the nuclear medicine department at the immediate disposal of the surgical team.

A Convenient Low Iodine Diet for Preparation of Radioiodine rhTSH Scanning in Korean Patients

M. Lee[1], Y. Ryu[2], I. Hyun[1]; [1]Inha University Hospital, Incheon, KOREA, REPUBLIC OF, [2]Gangnam Severance Hospital, Seoul, KOREA, REPUBLIC OF.

Introduction: A stringent LID for 2 weeks has been recommended in Korean patient with DTC prior to DxWBS. The reason is that the dietary iodine intake in Korea is higher than all other countries except for Japan and Canada. Seaweeds take up over 70% of the dietary iodine intake in Korea. Considering it, we make an hypothesis that the body iodine pool may be sufficiently depleted by seaweeds restriction. Based on this concept, we proposed a new protocol; a simplified LID protocol (seaweeds restrictio only) for the patients with preparing DxWBS by using rhTSH. We want to evaluate the efficacy of this compromised plan and compare it with conventional protocol by using spot urine analysis. Material & Methods: Total 72 papillary thyroid cancer patients (53 females, 19 males) preparing for follow-up DxWBS with rhTSH were enrolled. In order to assess the impact of 2 weeks stringent LID (LID1) on urinary iodine excretion during the preparation of RAIT, morning spot urine specimen was obtained on the final day of LID1 from each patient and the urine iodine excretion (UIE1) was checked to evaluate the efficacy of LID1. For rhTSH DxWBS, they contributed morning spot urine 8 days (LID2) and 10 days (LID3) after a simplified LID prior to DxWBS; on the day of first and second rhTSH injections. The urine iodine excretion on LID2 (UIE2) and LID3 (UIE3) were also evaluated. Results: The median value of UIE after LID1 was 12.80μg/L. The median value of UIE after LID2 was 111.38μg/L . There was no significant difference in the median UIE values between gender. The median UIE value of LID3 and LID2 was not significantly different. The frequencies of excellent and good iodine deficiency did not differ between 8 and 10days simplified LID. However, the median UIE value of LID1 was significantly lower than that of LID2 and LID3. Conclusion: A simplified LID protocol is acceptable to achieve an optimal level of body iodine depletion for rhTSH DxWBS.

Liver function assessed by 99mTc mebrofenin hepatobiliary scintigraphy to evaluate the gain of hepatic functional mass after portal vein stenosis preconditioning of living donor liver in swine

P. BRIGE[1], G. HERY[2], G. BAUDIN[3], C. BUFFAT[1], A. ARCHIER[4], A. MOYON[5], A. COPPOLA[1], J. HARDWIGSEN[6], Y. LE TREUT[6], E. GUEDJ[4], B. GUILLET[5], V. VIDAL[7], G. GORINCOUR[8], P. ROLLAND[1], E. GREGOIRE[9]; [1]CERIMED_ LIIE / Aix-Marseille university, Marseille, FRANCE, [2]Department of general pediatric surgery and liver transplantation, Hopital Timone, Marseille, FRANCE, [3]Department of diagnostic and interventional medical imaging, Hopital l'Archet 2, Nice, FRANCE, [4]CERIMED_ Nuclear medicine / Aix-Marseille university, Marseille, FRANCE, [5]CERIMED / Aix-Marseille university, Marseille, FRANCE, [6]Aix-Marseille University/ Department of General surgery and liver transplantation, Hôpital Timone, Marseille, FRANCE, [7]CERIMED_ LIIE / Aix-Marseille university/ Department of diagnostic and interventional Imaging, Hôpital Timone, Marseille, FRANCE, [8]CERIMED_ LIIE / Aix-Marseille university/ Department of pediatric diagnostic and Interventional Imaging, Hôpital Timone, Marseille, FRANCE, [9]CERIMED_ LIIE / Aix-Marseille university/ Department of general surgery and liver transplantation, Hôpital Timone, Marseille, FRANCE.

In order to reduce the morbi-mortality risk for the donor in living donor liver transplantation (LDLT), we previously identified 20% left portal vein (LPV) stenosis as the effective preconditioning to induce cell proliferation in the contralateral lobe without the downstream ipsilateral atrophy. We report, here, the pathways involved in the first hours after the preconditioning and investigate the changes in liver volume and function. Fourteen pigs entered this study. Five of them were used to study the genetic, cellular and molecular mechanisms set up in the early hours after the establishment of our preconditioning. Nine pigs were equally divided into 3 groups: sham operated animals, 20% LPV stenosis and 100% LPV stenosis. Volumetric scanner and 99mTc-Mebrofenin hepatobiliary scintigraphy were performed before and 14 days after preconditioning in order to study morphological and functional changes in the liver. We demonstrated that liver regeneration triggered by 20% LPV stenosis in the contralateral lobe involves TNF-alpha, IL-6 and NOS2, by means of STAT3 and HGF. We confirmed that our preconditioning was responsible for an increase in the total liver volume. Finally, we demonstrated that this volumetric gain was associated with an increase in of hepatic functional capacity.

P116

Fatty meal substitute vs Intravenous CCK for hepatobiliary imaging, a large case volume retrospective analysis

C. Sinsabaugh, M. Tann; Indiana University School of Medicine, Indianapolis, IN, UNITED STATES.

Since the advent of functional hepatobiliary imaging, there has been continued debate over the appropriate assessment of gall bladder ejection fraction. The mainstay for induction ofgallbladder contraction continues to be intravenous infusion of CCK analogue. Multiple studies have been conducted to assess oral alternatives to intravenous CCK analogues, although these studies are typically limited to relatively few imaging studies on relatively healthy individuals. Our institution made a concerted switch to performing functional hepatobiliary imaging with the use of a liquid, high fat content meal replacement supplement in February 2014. After 17 months of imaging was performed using this protocol, a retrospective analysis was performed of 463 examinations conducted with the use of a high fat content meal replacement supplement. Additional retrospective analysis was performed of 1384 biliary examinations conducted using our institutions' standard protocol with intravenous CCK. Comparison of the two agents' histogram data was performed, which yielded a right skewed, bell-shaped data set with a high fat content meal replacement including a mean ejection fraction of 73% with a standard deviation of 19%. The intravenous CCK data set revealed a non-normalized, random distribution of ejection fractions with a mean ejection fraction of 55% and a standard deviation of 30%. Using the widely agreed upon cut-off of 34% for an abnormal gall bladder ejection fraction, 28.6% of IV CCK examinations resulted in an abnormal gall bladder ejection fraction vs. 9.7% with the use of an oral, fatty meal supplement. This data set suggests that the use of a fatty meal supplement may generate a more normalized sample of ejection fractions that one might expect in a population and that the currently agreed upon 34% cut-off for abnormal gall bladder ejection fractions may be too

low. Continued analysis of this data set and further evaluation of the patients contained there-in, including final disposition of therapy (i.e. surgery vs. no surgery) and outcomes could help provide further elucidation of the most appropriate methods and use of functional hepatobiliary imaging.

P117

The utility of oro-pharyngeal-esophageal scintigraphy (OPES) to assess instrumental deglutition function in patients with idiopathic inflammatory myopathies (IIM): short-term results of an ongoing prospective study

G. Puccini[1], E. Tardelli[1], E. Fiasconaro[1], S. Barsotti[2], F. Guidoccio[1], M. Gennaro[1], S. Margotti[1], B. Dell'Anno[1], R. Neri[3], M. Grosso[1], D. Volterrani[1]; [1]Regional centre of nuclear medicine, PISA, ITALY, [2]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa,, PISA, ITALY, [3]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, PISA, ITALY.

Background Dysphagia represents a major burden in IIM patients. OPES is a safe, reliable and repeatable technique, which allow a semi-quantitative scoring of oropharyngeal (OP) and esophageal (E) involvement. **Aim:** To report the initial results of prevalence of upper gastrointestinal abnormalities in IIM patients using OPES and the correlation of abnormalities detected by OPES with disease activity and dysphagia. **Patients and Methods** Since 2014 to 2016, we enrolled 32 IIM patients (M:F=4:28; 12 dermatomyositis, 18 polymyositis, 2 inclusion body myositis; mean age: 61±12.6 years). Each patient underwent a disease activity evaluation: physician's and patients' visual analogue scale (phVAS and ptVAS), health quality assessment questionnaire, manual muscle test 8 (MMT8) and serum creatine kinase. Dysphagia was assessed by the "MD Anderson dysphagia inventory" (MDADI), which classifies dysphagia as not present, mild, moderate, severe and total disability. Dysphagia parameters, assessed by OPES after 10 ml liquid (L) and semi-solid (SS) bolus labelled with 99mTechnetium-nanocolloid, were: pre-deglutition penetration, aspiration, OP and E transit time (OPETT) and retention index (RI). OP-RI was classifiable by a 4 grade scale: no retention (<8% of the swallowed bolus), mild (9-20%), moderate (21-40%) and severe retention (>40%), while E-RI was classifiable by a 3 grade scale: no retention (< 20%), mild (20-45%) and severe retention (>45%). **Results** According to MDADI score, 11 patients (35%) presented no dysphagia, 13 (41%) mild, 5 (15%) moderate and 3 (9%) severe disability. OPES showed a normal OPETT and absence of pre-deglutition penetration in all patients. RI were altered in almost all patients, and, both after L and SS bolus, RI was altered in 25 patients. In the 10 patients with no dysphagia symptoms, IR alterations for L and SS bolus were detected respectively in 9 and 7 patients. Correlations with statistical significance between disease activity parameters and MDADI index were found for phVAS and ptVAS (p=0.032 and p=0.017) and MMT8 (p=0.014), while E-RI correlated with MMT8 (p=0.007). Moreover, 14 patients presented uncoordinated movement at proximal and medium esophagus and 2 patients presented SL bolus inhalation. **Conclusions** Dysphagia represents a major disabling feature in 64% of IIM patients and is associated with disease activity. OPES could allows to identify subclinical involvement in almost all patients examined, even if no symptoms were reported. Greater sample size and, above all, prospective clinical follow-up will clarify the clinical meanings of the alterations detected by OPES and their prognostic value.

P118

Value of ^{75}SeHCAT in the diagnosis of bile acid malabsorption in Crohn´s disease with chronic diarrhoea

L. Mena Bares, F. Maza Muret, E. Carmona Asenjo, E. Moreno Ortega, V. Guiote Moreno, E. Iglesias Flores, V. García Sánchez, J. Benítez Cantero, J. Vallejo Casas; Hospital Universitario Reina Sofía, Córdoba, SPAIN.

Aim: The objective of this study is to analyze the utility of ^{75}SeHCAT in patients with Crohn´s disease and chronic diarrhoea with suspected bile acid malabsorption (BAM), and to assess whether there is a relationship between the malabsorption degree and the presence of ileal resection. **Material and Methods:** We analyzed retrospectively 31 patients with Crohn´s disease and chronic diarrhoea with and without ileal resection during the period between August 2015-April 2016. In all patients an inflammatory process was previously discarded. No patients had received treatment with bile acid sequestrants (Cholestyramine) before the study. We perform the test after the ingestion of a ^{75}SeHCAT capsule (0,37 MBq) prior fasting the night before. Three hours later an initial gamma measurement is taken from a large field of view gamma camera, equipped with high sensitivity and parallel-hole collimator. Abdominal retained activity was measured in anterior and posterior views for 5 minutes. Room background is also measured for 5 minutes before and after the patient has been scanned. Seven day measurements were compared with 3 hours activity to calculate the abdominal retention percentage. BAM was diagnosed when retention was <10% at seventh day. **Results:** We studied 16 women and 15 men with mean age of 43 years old. 24/31 patients had undergone ileal resection (ranged from 2 to 80 cm, average= 27,87 cm). 96,8% of patients demonstrated abnormal values of ^{75}SeHCAT scan defined as < 10% abdominal retention of ^{75}SeHCAT after seven days. 24/24 patients with ileal resection and 6/7 patients without resection had BAM. 92% of patients with ileal resection had severe malabsorption and 8% moderate malabsorption. 72% of patients without resection had severe malabsorption, 14% moderate malabsorption and 14% had normal retention. We performed linear regression analysis and we found no significant association between ^{75}SeHCAT retention and performing surgery or not, type or length of resection. **Conclusions:** ^{75}SeHCAT is an useful procedure for diagnosing BAM in patients with Crohn´s disease and chronic diarrhea, with and without ileal resection. There was no significant association between ^{75}SeHCAT retention and performing surgery or not, type or length of resection.

P119

Gastric Emptying at 2 Hours and 4 Hours: Sensitivity Depends on Severity of Delayed Gastric Emptying

P. Magnone, J. Fletcher, J. M. Wo, M. Tann; Indiana University, Indianapolis, IN, UNITED STATES.

Purpose. Gastric emptying (GE) scintigraphy has been recognized as the gold standard for the assessment of gastric motility. Imaging guidelines have been established concerning how to acquire images for evaluation of delayed gastric emptying (DGE) over a 4 hour period, and additional studies have suggested shortening this time period to 2 hours for many patients. However, the severity of DGE correctly or incorrectly identified at the 2 hour period has not been evaluated. We sought to determine how well the 2 hour criteria set by Bonta et al identified patients with different severities of DGE. Additionally, we sought to determine if the Bonta criteria were optimum for our patient population. **Methods.** We collected GE data on 900 patients over a 10 month period. After excluding patients aged 12 years or younger, patients with prior gastric surgery, and incomplete studies, 703 patients remained (ages 13-86, 185 males, 518 females). We calculated the sensitivity, specificity, accuracy, and percentage of exams that would be shortened with different cutoff values in addition to the Bonta criteria (35% and 55%). We then determined the severity of DGE in these patients by the amount of activity remaining at 4 hours (mild: >10% and <= 20%; moderate: >20% and <=35%; severe: >35%). **Results.** 166 patients (23.6%) demonstrated DGE at 4 hours (70 mild, 30 moderate, 66 severe). Using the Bonta criteria resulted in 86.8% sensitivity, 89.6% specificity, 89.0% accuracy, and 74.7% of exams that could be terminated after 2 hours. However, we found that using cutoffs of 30% and 60% resulted in 90.4% sensitivity, 91.4% specificity, 91.2% accuracy, and 61.5% of exams that could be terminated after 2 hours. Using either

criteria resulted in excellent sensitivity for moderate or severe DGE but relatively poor sensitivity for mild DGE. **Conclusion.** The 2 hour Bonta criteria performed fairly well, but not as well as reported elsewhere. However, this performance was primarily due to poor performance with mild DGE, while sensitivity with moderate or severe DGE was quite good. Given these results, we recommend close collaboration with referring gastroenterologists before instituting a change in the GE protocol, as treatment may vary depending on severity of DGE. While terminating some exams at 2 hours instead of 4 hours will result in some false positives and false negatives, the severity of DGE correctly or incorrectly identified at 2 hours may influence whether or not such a change in protocol is acceptable.

P120

Assessment of spleen size-function relationships by technetium-99m-heat altered red blood cells scintigraphy in cirrhotic patients

G. Arsos[1], S. Georga[1], L. Kirkineska[2], D. Katsampoukas[1], E. Moralidis[1], A. Siozopoulos[3], T. Vasiliadis[2]; [1]3rd Dept of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Hospital, THESSALONIKI, GREECE, [2]3rd Internal Medicine Clinic, Aristotle University of Thessaloniki Medical School, Papageorgiou Hospital, THESSALONIKI, GREECE, [3]Department of Anatomy, Demokrition University of Thrace Medical School, ALEXANDROUPOLIS, GREECE.

Background and aim : Cirrhosis may be associated with splenic hypofunction (hyposplenism) despite the commonly seen splenomegaly in patients with portal hypertension. Radionuclide studies using image quantitation or kinetic, non-imaging, analysis, are best suited for splenic function assessment and with the recent advent of the hybrid imaging, for successful splenic size determination. In this frame, functional splenic volume (FSV) as the percentage of an amount of heat-altered red blood cells labelled with technetium-99m (Tc-99m-hRBC) trapped in the spleen (% uptake) divided by the spleen volume is considered a reliable index of splenic function. In order to explore the splenic size-function relationship across disease stages, we calculated FSV in a number of cirrhotic patients submitted to Tc-99m-hRBC scanning for splenic function assessment. **Patients and methods** : Thirty (33.3% F) adult cirrhotic patients (47% on stage A, 53% on stages B-C according to Child-Turcotte-Pugh), aged 61.4±10.7 years were evaluated. Autologous Tc-99m-hRBC were in vitro prepared and dynamic, static and combined tomographic single photon emission computed tomography and CT (SPECT/CT) scans were obtained for up 2 hours post-injection. After splenic Tc-99m-hRBC uptake assessment from SPECT imaging and previous phantom-based calibration and splenic volume from CT slices using the interactive OSIRISX MD software, FSV was calculated. Between-variable differences and correlations were assessed by Mann-Whitney test and linear or non-linear regression analysis respectively. **Results** : Medians of splenic volume (ml), splenic uptake (%) and FSV (%/ml) for the stages A and B-C patients were 278 vs 686, p=0.07; 47 vs 55, p=0.07 and 0.16 vs 0.07, p=0.272 respectively. Splenic volume showed a moderate positive correlation with splenic uptake ($r = 0.640$, $p<0.005$) but a strong inverse correlation with SFV ($r = 0.945$, $p<0.0001$). **Conclusions** : In cirrhotic patients disease progression is accompanied by both splenic enlargement and Tc-99m-hRBC uptake increase. However, slenic function as expressed by the functional splenic volume is seriously suppressed.

P121

^{99m}Tc-Mebrofenin (HIDA) SPECT-CT: New Tricks for an Old Test? A Pictorial Review

S. Soares, N. Mulholland, N. Gulliver, B. Corcoran, A. Eccles, G. Vivian; King's College Hospital, London, UNITED KINGDOM.

Introduction: Advances in dynamic CT and MRCP liver imaging has resulted in dynamic ^{99m}Tc-trimethylbromo-iminodiacetic acid (*TBIDA*, *mebrofenin*) or HIDA cholescintigraphy being used less frequently in the investigation of hepato-biliary disorders. There have been anecdotal reports of the use of SPECT and SPECT-CT in the management of patients with trauma to the biliary tree. We aim to highlight the role of HIDA SPECT-CT in diagnosing hepatobiliary leak. Methods: We present the protocols and results of the dedicated HIDA SPECT-CT protocol in a single institution with a tertiary service liver transplant unit. Results: HIDA SPECT-CT is now considered a first line investigation. Between April 2015 and April 2016 we performed 27 examinations on patients suspected of having a biliary leak. Dynamic 60 minute supine examinations followed by SPECT-CT (low dose CT for AC and localization) were performed on a Siemens Symbia 16T or a Phillips Skylight followed by supine slide transfer to the Symbia for SPECT-CT. Tomography was performed before 60 min if a leak was seen on the dynamic images. Delayed static images were performed if no leak was seen. Discussion: The majority of patients were referred for iatrogenic leak but patients were also examined after liver sepsis and blunt trauma. 14 patients were shown to have a biliary leak.Two patients were found to have a very rare condition of broncho-biliary fistula. In one sequential studies were used to assess therapy, including microembolisation with glue particles. These are discussed in further detail as case studies. Reference: Hepatobiliary scintigraphy with SPET in the diagnosis of bronchobiliary fistula due to a hydatid cyst. Hell J Nucl Med 2015; 18(2): 160-162

P122

30 Minutes or 60 Minutes: Which is Optimal for the Assessment of Rapid Gastric Emptying

P. Magnone, J. Fletcher, J. M. Wo, M. Tann; Indiana University, Indianapolis, IN, UNITED STATES.

Purpose. Gastric emptying scintigraphy has been recognized as the gold standard for assessment of gastric motility. Imaging guidelines have been established concerning how best to acquire images for evaluation of delayed gastric emptying, however there is still some confusion concerning how best to detect rapid gastric emptying as both may show similar overlapping symptoms. We compared the sensitivity of measurement of gastric emptying at 30 minutes and 60 minutes post-prandial to determine which measurement time showed a higher detection rate. **Methods.** We collected gastric emptying data on 900 patients over a 10 month period. After excluding patients aged 12 year or younger, patients with prior gastric surgery, and studies with incomplete data, 622 patients remained (ages 13-86, 160 males, 462 females). The percentage of activity remaining in the stomach at 30 minutes and 60 minutes post-prandial was evaluated to determine how many patients met criteria for rapid gastric emptying (less than 70% remaining at 30 minutes or less than 30% remaining at 60 minutes). **Results.** A total of 152 patients (24 .4%) demonstrated rapid gastric emptying, including 114 patients at 30 minutes only, 3 patients at 60 minutes only, and 35 patients at both 30 and 60 minutes. Thus, the 30 minute time point identified 149/152 (98%) patients with rapid gastric emptying, and the addition of the 60 minute time point resulted in the identification of an additional 3 patients with rapid gastric emptying. Comparatively, the 60 minute time point identified 38/152 (25%) patients with rapid gastric emptying. **Conclusion.** If the purpose of imaging at 30 minutes or 60 minutes post-prandial is to identify patients with rapid gastric emptying, then the 60 minute post-prandial time point is a less useful time point as it is significantly less sensitive and may be replaced by using the 30 minute time point alone.

P123

The Clinical Utility of ^{99m} Technetium Red Blood Cell Scintigraphy in the Diagnosis of Gastrointestinal Haemorrhage: A Retrospective Study Between 2009 to 2016

A. Saviatto, D. Marin Ferrer, J. Marroquin Galvez, E. Martinez Albero, M. Tabuenca Mateo, A. Gomez Grande, P. Pilkington Woll, A. Hernandez Martin, P. Sarandeses Fernandez, S. Ruiz Solis, J. Estenoz Alfaro; University Hospital 12 de Octubre, Madrid, SPAIN.

OBJETIVE: The aim of the present study was to evaluate the 99m-Technetium labelled red blood cell scintigraphy (RBCS) utility for detection and localization of gastrointestinal bleeding (GIB).MATERIALS AND METHODS: A retrospective review of 156 patients, mean age of 68.7 years (16-88), 65 females, who underwent a RBCS for the evaluation of GIB at our institution from 2009-2016. RBC were labelled with 740-925 MBq of 99m-Tc by the modified in vivo method. The patients were referred to the Nuclear Medicine Department for the following reasons: chronic anemia (63), rectorragia (27), melena (51), haematochezia (10), occult blood stool (3) and hematemesis (2). Additionally, 137 patients underwent colonoscopy, 126 gastroscopy, 42 capsule endoscopy and 3 arteriography. The findings of all these techniques were correlated, and treatments analyzed on those patients that tested positive for GIB. We have conducted a clinical follow up during a minimum three month period with all patients. RESULTS: We detected 40/156 (25.6%) patients with active GIB as follows: 13/40 (32.5%) tested positive with RBCS and also with some of the other techniques; 18/40 (45%) tested positive only for RBCS and the remaining 9/40 (22.5%) patients positive with the other techniques and negative for RCBS. The correct location of the bleeding site was identified in 11/40 (27.5%) patients: 6/11 (54.5%) were positive for RBCS and positive with some other technique; 3/11 (27.2%) positive with the other techniques and negative for RBCS, and the remaining 2/11 (18.1%) were positive only with the RBCS.On the 63 patients diagnosed of chronic anemia, haemorrhage was detected in only 9 (14.3%) of them. However, the other 93 patients which showed signs of haemorrhage, an active GIB was detected in 31 (33.3%).The bleeding sources were located in the colon (3), small intestine (14) and stomach (1). Out of 40 patients with evidence of GIB, 14 underwent conservative treatment, 5 surgical, 9 argon plasma coagulation, 2 octreotide, 2 embolization, 7 died and 1 patient requested voluntary discharge. In the 116 patients tested negative for GIB there were neither death nor signs of bleeding detected in the following 3 months.CONCLUSION: RBCS is an effective imaging modality for detecting and localizing active GIB, and it is complementary to other techniques. RBCS proved to be specially successful for detecting the bleeding location in the small intestine, on the other hand, it was less accurate when used on patients with chronic anemia.

Is It Advisable To Perform A High Dose SPECT-CT For Minimally Invasive Radioguided Parathyroidectomy?

M. Milá; Hospital Universitari Germans Trias i Pujol, Badalona, SPAIN.

AIM OF THE STUDY: SPECT-CT hybrid imaging has proved to offer advantages over planar acquisition in the diagnosis and anatomic location of hyperfunctioning parathyroid glands in patients with primary hyperparathyroidism (HPT). The aim of this study was to evaluate the feasibility of preoperative Sestamibi SPECT-CT before minimally invasive radioguided parathyroidectomy (MIRP). **METHODS:** From 2013 to 2015, consecutive patients with primary HPT and positive Sestamibi SPECT/CT who underwent MIRP were included in this observational study. Planar and SPECT/CT acquisition were performed after ^{99m}Tc-Sestamibi injection (740 MBq). Diagnostic SPECT/CT (2- slice SPECT-CT, Siemens Symbia T2) was acquired 20 or 120 minutes after injection according to the findings on the planar scintigraphy. Acquisition parameters were: CT (70 mAs -care dose 4D-, 130 kV, 3 mm, 2x 2,5 mm), SPECT (128X128 matrix, 180° rotation, 32 frames, 15 s/frame). Radioguided surgery was planned according to SPECT/CT findings. MIRP consisted of a unilateral cervical exploration through minimal incision followed by radioguided and macroscopic identification of pathological parathyroid tissue. Surgical time and postsurgical morbidity were evaluated. **RESULTS:** Thirty four patients with primary HPT and positive Sestamibi SPECT/CT underwent surgery by MIRP (8 males; age mean 68 years, range 41-88): 31 glands were orthotopic and 3 ectopic. Pathology was consistent with parathyroid adenoma (n= 30) or hyperplastic gland (n=4). The average operating time was 42 min (range 20-80), the longest time for ectopic lesions. Surgery was successful in all patients with short-term income, less than 24 hours, without postoperative complications or remarkable late events. **CONCLUSION:** Preoperative diagnostic SPECT/CT is advisable for MIRP because it provides useful anatomic information which improves surgical outcome avoiding bilateral neck exploration and with a short surgical time.

P125

Intraoperative Radioguided Localization Of Non Palpable Lung Lesion Or Difficult Surgical Site

M. D. Danús Laínez[1], J. Fuertes Manuel[1], M. Martin Domenech[1], M. Mendoza Pares[1], J. Garcia Bennett[1], D. Rodriguez Martinez[2], P. Rodriguez Taboada[2], G. Rosado[2], E. Baeta[1]; [1]Hospital Universitario Sant Joan de Reus, Reus, SPAIN, [2]Hospital Universitario Juan XXIII, Tarragona, SPAIN.

Objective Description of the technique used in the localization of nonpalpable lung lesion or difficult surgical site and our experience.**Material and methods** Radioguided technique intraoperative detection of nonpalpable lesions or difficult pulmonary localization was performed in 20 patients, removing a total amount of 22 lesions. The average age was 64.2 years (range 17-84 years), 13 men and 7 women. The technique was performed a few hours before surgery by injecting 0,5mCi Tc99m macroaggregated albumin as a tracer, with posterior scintigraphic control, performing CT-guided (with or without fluoroscopy) marking, and gamma-detecting probe (thoracoscopic or not), during the surgical procedure. The types of lesions studied were 14 pulmonary nodules and 8 pulmonary lesions with ground-glass opacity. **Results** 21 of the 22 lesions studied (95.45%) were successfully located. The lesion not initially detected was localizated by palpation. The types of excised lesions were 8 adenocarcinomas of colorectal origin (36.36%), 3 lung adenocarcinomas (13.6%), 3 atypical adenomatous hyperplasia (13.6%), 2 no mucinous bronchoalveolar adenocarcinomas (9.09%), 2 hamartomas (9.09%), 1 melanoma (4.5%), 1 necrotic nodule (4.5%), 1 lung squamous carcinoma (4.5%), and 1 emphysema (4.5%, the failure detection with subsequent detection of lung adenocarcinoma by palpation). Regarding the type of surgery, there have been 14 thoracotomies and 6 videothoracoscopies (after the acquisition of thoracoscopic probe). **Conclusions** The intraoperative radioguided localization of nonpalpable lung lesions or difficult surgical site is a reliable technique. It allows accurate and fast location of lesions, with minimization of aggression in surgical approaches in most cases (Performing videothoracoscopy instead of thoracotomy VATS).The learning curve of this technique is affordable after a few patients.

P126

Usefulness Of Radioguided Surgery By Intraoperative Scintigraphy In Patients With Primary Hyperparathyroidism And Not Conclusive Previous Scintigraphy

J. OROZCO-CORTÉS[1], R. DÍAZ-EXPÓSITO, Sr.[1], I. CASÁNS-TORMO[1], H. BOWLES-ANTELO[1], V. LÓPEZ-PRIOR[1], A. AMR-REY[1], A. ALMARCHA-GIMENO[2], R. JOVER-BARGUES[3], N. CASSINELLO-FERNÁNDEZ[3], J. ORTEGA-SERRANO[3]; [1]NUCLEAR MEDICINE SERVICE. HOSPITAL CLÍNICO UNIVERSITARIO DE VALENCIA, VALENCIA, SPAIN, [2]RADIOPHARMACY UNIT. NUCLEAR MEDICINE SERVICE. HOSPITAL CLÍNICO UNIVERSITARIO DE VALENCIA, VALENCIA, SPAIN, [3]SURGERY SERVICE. HOSPITAL CLÍNICO UNIVERSITARIO DE VALENCIA, VALENCIA, SPAIN.

INTRODUCTION We analyse the usefulness of the intraoperative scintigraphy(IS) in patients diagnosed with primary hyperparathyroidism, who were treated by minimally invasive parathyroidectomy(MIP), and presented a not conclusive previous parathyroid scintigraphy(PS). MATERIAL AND METHODS 30 patients(20 women), age 60+11(29-79 y/o), with PS performed with 99mTc-MIBI(20 mCi-70 kg) and double phase protocole(Philips Brightview gammacamera). In 20 patients, the PS was considered unclear and in 10 negative for the presence of parathyroid adenoma (PA). In 18/30(60%) cases, SPECT was performed. 19/30 patients presented morphological studies(sonography, CT and/or MR). 10 patients had thyrod disease. The value of pre and postoperative PTH was determined. MIP was performed using IS with a portable gammacamera Sentinella®, after administration of 99mTc-MIBI(5 mCi). We performed initial images 20min after radiotracer administration, and after identification of the suspicious lesions, in vivo and ex vivo images of the removed piece as well as the surgical bed. Finally, it was performed later pathological confirmation. RESULTS After remove the lesion, in 25/30(83.3%), the anatomopathological result was PA, in 3/30(10%) parathyroid hyperplasia, 2(thyroiditis,thyroid nodule). In the 16/20 cases with unclear PS, the IS was coincident with the previous PS, in the localization of the possible lesion. In 12 of these 16 cases(75%) the surgical localization was coincident,(finally PA in 10) and in 4/16(25%) not(finally PA in 3). In the 10 patients with negative PS, 3(30%) had a negative IS, although in those 3 cases, the removed piece was a PA(false negatives). The IS found a possible PA in 7 of these 10(70%) patients. In 12/18(66.6%) cases with suggestive PA in SPECT,in 9(75%) the localization was coincident in relation with the IS. 12/19 patients with morphological study were suggestive of PA and the PS was coincident with a possible PA in 8/12(66.6%). 7/8(87.5%) cases were finally PA. Globally, when we analyzed the 25 patients who finally had a PA, the IS provided information for the localization and removal in 18 (72%). The mean value of preoperative PTH was 248.8 and the postoperative was 66.2. CONCLUSIONS When we perform MIP in patients with primary hyperparathyroidism and negative or unclear previous scintigraphy, the IS provided valuable information for the final localization of the PA in the majority of patients. There was a high probability to find a PA, when there was a coincident diagnostic between the morphological studies and PS. There was a high concordance between the PA localization with SPECT and IS.

P127

Use of SPECT/CT lymphoscintigraphy in the management of chylous ascites

M. PRPIC, M. Franceschi, Z. Kusic; University Hospital Centre Sestre Milosrdnice, ZAGREB, CROATIA.

Introduction: Chylous ascites (CA) is characterized as accumulation of chyle containing lymphatic fluid within the peritoneal cavity. CA is usually secondary to disruption of the lymphatic duct derangement to cisterna chyle. CA has various causes, as follows: trauma (including surgery), miscellaneous disorders and idiopathic. Lymphoscintigraphy is noninvasive method for evaluation of lymphatic drainage. The aim our study is to elucidate the contribution of SPECT/CT in diagnosis and management of CA. Case report. A 34 years old lady, presents with one week history of distended abdomen, without upper or lower extremity swelling or dyspnea. She had mild abdominal pain with agitation and vertigo. She had cesarean section two months and laparoscopic extirpation of retroperitoneal right ovarian cyst 3 years before onset a symptoms. Lymphoscintigraphy was suggested after computed tomography (CT), ultrasound and abdominal paracentesis examinations. Whole body and additional static images was performed in differential time intervals (immediately, 20 min, 4h and 24h) after subcutaneous injections of 37 MBq 99mTc-nanocolloid between the 1th and 2nd dorsal interdigital spaces of both feet. Scintigraphic images showed accumulation of radiopharmaceutical in abdominal space and lymphatic leakage around right iliac lymphatic vessel, especially in SPECT/CT images after 24h. Discussion. CA is peritoneal lymphatic leakage. Determination of leakage localization is not always accurate and depends on functional status of lymphatic vessels and amount of lymphatic leak. The potential clinical problem could be a pain as a results of distension of the peritoneum, suggestive of an acute abdomen. Conclusion. The additional use SPECT/CT can increase the sensitivity and specificity instead planar lymphoscintigraphy. Thus, it can provide better anatomical localization of lymphatic leakage and direct surgical management . Hence, according to our presented case SPECT/CT improves the noninvasive assessment of determination lymphatic leakage, especially in the case of damaged lymphatic vessels.

P128

Value of Radioguided Surgery in an Osteoid Osteoma case

M. Solá[1], M. Minoves[1], P. Bassa[1], S. Mas[2], M. Fraile[1]; [1]CETIR-ERESA, Barcelona, SPAIN, [2]COT Clínica Sagrada Familia, Barcelona, SPAIN.

Osteoma osteoid is the third most frequent benign tumor in bone, and accounts for the 10% of the cases. Osteoid osteoma shows a high prevalence in children and young adults, and is usually found in long bones. The most common localizations are the femur and the tibia which, when considered together, correspond to more than 50% of the cases. Bone scan is the most common procedure to confirm when osteoid osteoma is suspected, thus giving also a guide for the tomographic selective study, CT or MR, in order to exactly determine size of the nidus. Preferred definitive treatment of choice consists in percutaneous excision of the lesion by means of CT-guided radiofrequency. However, this procedure is not always available and percutaneous en-bloc resection is still a valid option for the orthopedic surgeon. We present the case of a 17-year-old female patient with symptoms and imaging procedures consistent with osteoid osteoma in her left tibia, which was excised by radioguided surgery after performing a bone scan. Intraoperative x-ray and subsequent pathological definitive exam both confirmed the final diagnosis. Implementation and advantages of radiosurgery location in this kind of benign lesions are discussed.

Emphasizing the pivotal role of F 18 FDG PET CT as an effective tool in evaluation of patients with pyrexia of unknown origin(PUO) in Indian population

A. JAYKANTH, S. SHELLEY, E. INDIRANI, K. SHILPA, J. AVANI; APOLLO HOSPITALS, CHENNAI, INDIA.

Aim: In a densely populated country like India, in the background of ever increasing air and water pollution and lack of proper sanitation, people are more prone to recurrent microbial infections. Changing dietary habits, sedentary life style, use of tobacco, smoking, alcohol consumption and in era of foods with abundant preservatives and chemicals, the incidence of malignancy is becoming high. Patients presenting with PUO have become a challenging task for physicians to diagnose and treat. F18 FDG PET CT is being done as a last resort imaging in the workup of patients with PUO. F18 FDG PET CT has the advantage of being a one stop shop with high sensitivity and high negative predictive value to diagnose, exclude various causes of PUO and guides in further management by showing the appropriate metabolically active site to do biopsy. Objective of this study is to emphasize the pivotal role of F18 FDG PET CT as an effective tool in evaluation and management of patients with PUO. **Materials and Method:** A total of 42 patients (23 males, 19 females) with PUO who underwent F 18 FDG PET CT were studied prospectively during a period of 1 year. These patients were subsequently worked up and followed till final tissue diagnosis was confirmed. **Result:** Final diagnoses were categorised as infective and non-infective. 74% of patients had features of infective etiology and 26% had features of non-infective etiology. Tuberculosis was the predominant cause of infective etiology(90%) with various spectrum of presentation and rest were foci of microbial abscesses(10%). Non-infective causes include lymphomas/ haematological malignancies(80%), vasculitis(10%), sarcoidosis(2%), carcinoma lung (3%), thyroiditis(2%), IgG4 related disease(2%) and cholecystitis(1%). **Conclusion:** In this study, we found more than 90% sensitivity and 60% specificity of PET CT findings in correlation with final tissue diagnosis. Almost 100% negative predictive value in excluding occult malignancy and infective foci. In an endemic country like India, various spectrum of presentation of tuberculosis was illustrated by F18 FDG PET CT which had significant impact on the further management. Hence F18 FDG PET CT can be an efficient, noninvasive technique for evaluation, management and follow up of patients with PUO with high sensitivity and high negative predictive value reducing the overall cost of hospitalization.

P130

FDG PET/CT in Tuberculosis: when and why?

D. Grigolato, M. Del Rizzo, M. Cucca, L. Locantore, M. Zuffante, E. Concia, M. Ferdeghini; Azienda Ospedaliera di Verona, VERONA, ITALY.

AIM: to assess the utility of functional imaging in the evaluation of patients with suspected tuberculosis (TB) and in monitoring therapy. Method: we retrospectively reviewed 88 patients (28 female, 60 male, age range 19 -78 years) who came in our department for diagnosing, staging and assessing therapy in TB between the beginning of 2014 to March 2016. Diagnosis of TB was based either on histology or microbiological assessment in 78 patients, on typical morphological features of TB in CT and improvement on antimycobacterial treatment in 10 patients. All scans were carried out on the 16-slice Gemini Big Bore TOF (Philips). Results: FDG PET/CT was performed in 42 patients for diagnostic purpose (48%), in 25 patients with previous history of TB (29%), in 10 patients during therapy (11%) and in 11 patients after treatment (12%). FDG PET/CT was positive in 74 patients and negative in 14 (all true negative). Among positive PET/CT, TB were found in 54 patients (73%): in 24 patients with suspicious TB (SUVmax range 1.7-26.2), in 15 patients with previous history of TB (SUVmax range 1.6-13.5), in 9 patients during therapy (SUVmax range 2.8-11.5) and in 6 patients after therapy (SUVmax range 1.5-5.7). FDG PET/CT identified 14 patients with exclusively lung involvement (SUV max range 1.5-10.9), 10 patients with extrapulmonary localizations and 30 patients with involvement of both sites. The most affected regions/organs were: lungs in 44 patients (bilateral in 35) and SUVmax range 1.5-19.9, lymph nodes in 36 patients with SUVmax range 2.7-20.4 (88% mediastinal nodes, 58% laterocervical nodes, 47% retroperitoneal nodes, 19% axillary nodes, 13% other basins), visceral organs in 11 patients, bone in three cases. In the remaining 20 patients with positive scans (23%), TB were ruled out after biopsy. There were four patients with tumors and 16 patients with infections (10 cases with pulmonary involvements and 5 patients with lymphoadenopathy). Conclusions: metabolic imaging is valuable in the diagnostic work-up of patients with TB in patients with probable or confirmed TB to check disease activity, extension and monitoring response to therapy; it is appropriate in case of previous history of TB infection to distinguish latent from active TB. It can not differentiate tumors from TB but it guided biopsy and assisted to early diagnosis.

P131

Dual Time Point FDG PET/CT Imaging in Prosthetic Heart Valve Endocarditis

A. M. Scholtens[1], L. E. Swart[2], H. J. Verberne[3], R. P. J. Budde[2], M. G. E. H. Lam[4]; [1]Meander Medical Center, Amersfoort, NETHERLANDS, [2]Erasmus Medical Center, Rotterdam, NETHERLANDS, [3]Amsterdam Medical Center, Amsterdam, NETHERLANDS, [4]University Medical Center, Utrecht, NETHERLANDS.

Purpose: ^{18}F-fluorodeoxyglucose positron emission tomography combined with computed tomography (FDG PET/CT) has been of increasing interest and clinical impact in the diagnostic workup of prosthetic heart valve endocarditis (PVE). Although some reports advocate later imaging times to improve the diagnostic accuracy for PVE, the optimal delay between FDG administration and image acquisition time has not been established yet. In this study, we compared standard and late FDG PET/CT images in patients under suspicion of PVE. ***Materials and Methods:*** Fourteen scans in 13 patients referred for FDG PET/CT for suspicion of PVE were performed at standard (60 min post injection) and late (150 min post injection) time points. Images were scored based on visual interpretation (PVE vs. no PVE) and semi-quantitatively with SUVmax and Target-to-Background Ratio (TBR, defined as [SUVmax valve/SUVmean blood pool]). Visual and semi-quantitative scores were compared for both time points. The imaging findings were related to the final diagnosis, based on surgical findings in all cases of infection (n=6) and unremarkable follow up after clinically rejected diagnosis of endocarditis in all others (n=8). ***Results:*** Compared to the standard time, TBR was higher in late images, mostly due to diminished activity in the blood pool (SUVmax standard 3.77 ± 1.06 vs. late 4.30 ± 1.64, TBR standard 2.55 ± 0.93 vs. late 4.27 ± 1.89, P=0.0001). Late images were more prone to false positive interpretation for both visual and semi-quantitative analyses. Visual analysis of the early images yielded 1 false negative and 1 false positive result. On the late images, no scans were false negative but 5 scans were false positive. ROC-analysis of the TBR showed a larger area under the curve for early measurements (0.87) compared to late measurements (0.79), though not significantly so (P=0.22). ***Conclusion:*** Late FDG PET/CT imaging for PVE seems to have a propensity for false positive results. Therefore late imaging should be interpreted with caution.

P132

Efficacy of 99mTc-UBI 29-41 scintigraphy in diagnosis of peri-prosthesis spinal infection

S. Fatima, S. T. Butt, N. Ahmed, M. Faheem; Nuclear Medicine , Oncology & Radiothearpy Institute (NORI), Islamabad, PAKISTAN.

Spinal surgery is associated with significant risks. Although several technical and operative improvements for surgical treatment of spinal problems especially the use of orthopaedic implants have recently been introduced. Infection rates after spinal surgery currently remain relatively high. In particular, postoperative spinal infection, is one of the most

serious complications after spinal surgery, is observed in up to 1% to 6% of all patients. The rate of implant associated infections is reported as high as 10% in various studies. Currently MRI is most reliable technique for diagnosing spinal infection however, prosthetic insertion may leads to false positive results. Objective: The purpose of the study was to evaluate the efficacy of Tc99-UBI for diagnosing vertebral prosthetic infection in comparison with MRI. Methods . All patients underwent UBI scans and contrast enhanced MRI. The scans were interpreted in a blind and independent fashion by 2 experienced observers. The final diagnosis was obtained with the histopathologic study or a microbiologic culture or with the clinical findings after a follow-up of at least 6 months. The sensitivity, specificity, positive and negative predictive values, and the positive and negative probability ratio were determined, always using a 95% confidence interval (CI). The concordance with the kappa index was determined. Results Fifteen patients with suspected post-prosthetic spinal infection were included; 9 males and 6 females, with a mean age of 50 years (SD = 16). Nine patients had a history if spinal infiltrations. The number of patients with a positive scan was 20. The sensitivity for detecting prosthetic infection was 100% (CI: 0.901-1) and the specificity was 86.5% (CI: 0.647-0.865). The positive predictive value was 0.95, and the negative predictive value was 1 (CI: 0.739-1). The intra- and interobserver kappa value was 1. Conclusion The UBI scan showed 100% sensitivity and 86% specificity for peri-prosthesis spinal infections. Although the role of this method in the diagnostic protocol of the patient with suspected post-implant spinal infection has not yet been defined We found a high diagnostic accuracy for ^{99m}Tc-UBI [29-41] scintigraphy in suspected orthopedic implants infections . Therefore, ^{99m}Tc-UBI [29-41] scintigraphy might be potentially recommended as a safe and promising imaging modality in these settings. However, further studies on larger number of patients and different pathologies are still needed.

P133

Qualitative and semiquantitative [^{18}F]FDG-PET/CT analysis in patients with IE: a strategy to enhance specificity?

r. boni[1], s. margotti[1], m. sollini[2], r. doria[3], u. conti[4], f. menichetti[3], e. lazzeri[1], p. erba[1]; [1]Centro Regionale di Medicina Nucleare, Pisa, ITALY, [2]Umanitas University, Milano, ITALY, [3]U.O. Malattie Infettive, Pisa, ITALY, [4]U.O. Cardiologia 2, Pisa, ITALY.

AIM:The recent 2015 ESC Guideline for the diagnosis and management of infectious endocarditis (IE) included molecular imaging procedures such as radiolabeled leukocytes and [^{18}F]FDG-PET/CT as major criteria to establish the diagnosis of IE. Whereas in case of radiolabeled leukocytes the criteria for definig positive and negative scan are well established, in case of [^{18}F]FDG-PET/CT there is still unanimous consensus of the criteria that define a positive scan. MATERIALS AND METHODS: In this work prospectively evaluated a series of 76 patients (M:F=50:26, mean age 67±16 years, median age 72 years, range 18-88) that performed [^{18}F]FDG-PET/CT for suspected IE between January 2013 and January 2016 in our center to define which the pattern of uptake and the semiquantitative parameters (SUVmax,valve/liver, valve/lung and valve/mediastinum uptake ratio) with the highest diagnostic accuracy for diagnosis IE. Patients with permanent cardiac devices were excluded. PET/CT results were correlated with transthoracic (TTE) or transesophageal (TEE) echocardiography, blood culture, the Duke criteria. The new ESC criteria were also evaluated. RESULTS: globally PET/CT was true positive in 26/27 and false negative in 1/27 cases (96% sensitivity, 97% NPV, 75% specificity and 68% PPV). A focal pattern of uptake was found 15/26 patients with confirmed IE (mean SUVmax=5.29±1.8, median SUVmax=5.5) and only 2/49 patients without IE whereas a diffuse pattern of uptake was found in 11 patients with confirmed IE (mean SUVmax=8.1±3.5, median SUVmax=7.6) and in 10 negative scans (mean SUVmax=4.1±1.1, median SUVmax=3.3). No significant differences between the valve/liver ratio uptake and the valve/mediastinum uptake ratio were found between positive and negative patients with either focal or diffuse pattern of uptake. Interesting, in presence of diffuse valve uptake both SUVmax and the valve/lung uptake ratio were significantly higher in patients with a final diagnosis of IE, including the group of patients under antimicrobial treatment (>90%). PET/CT confirmed its ability to identify extracardiac sites of [^{18}F]FDG uptake in presence of septic embolism (35%) and in patients with other diseases (vasculitis, vascular prosthesis infections, mediastinitis and cancer, particularly in patients with IE sustained by Streptococcus Gallolyticus). CONCLUSIONS: Our results confirmed the role of [^{18}F]FDG PET/CT in patients with IE to confirm or reject the diagnosis as well as in identifying septic embolic sites or alternative causes of infection/inflammation. The pattern of [^{18}F]FDG uptake more specific for valve infection in this series is a focal uptake or a diffuse uptake with a SUVmax>5 and a valve/lung ratio >8.

P134

The Value Of FDG PET/CT In The Diagnosis Of Aortic Stent Graft Infections

D. Zogala, V. Ptacnik, D. Rucka, V. Cerny, P. Varejka, J. Trnka, J. Kubinyi; General Teaching Hospital in Prague, Prague, CZECH REPUBLIC.

AIM: Endovascular aortic repair with stent graft (SG) insertion is a method of choice for the treatment of growing aortic aneurysm or dissection. FDG PET/CT is a recognized method for the diagnosis of infected surgical vascular grafts, but the literature evidence on its use in suspected stent graft infection (SGI) is scarce. Our aim was to analyse the value of FDG PET/CT in the diagnosis of SGI. MATERIALS AND METHODS: Two experienced nuclear medicine physicians have independently retrospectively analysed 11 FDG PET/CT examinations in 10 patients (8 males, 64 ± 10 years) referred with clinical suspicion of SGI between 2012-2016. The images were evaluated and scored visually (the pattern: diffuse, focal or inhomogeneous; the intensity of uptake: visual grading scale comparing the level of FDG uptake in the area of SG with accumulation in healthy liver parenchyma) and semiquantitatively (SUVmax in the area of SG, target-to-background ratio (TBR) comparing SUVmax in SG with average SUV of blood pool in the inferior vena cava). The SGI was defined as the presence of focal hyperactivity in the area of SG and eventually in adjacent tissues with the intensity exceeding the activity of the liver parenchyma. The CT images (mostly not dedicated vascular protocol) of PET/CT were independently assessed by one radiologist (blinded to PET). All images were evaluated in randomized and blinded manner. The clinical judgment of two angiologists based on thorough review of all available unblinded data in subsequent follow-up was used as a reference (the results of PET/CT were not taken in concern). The discrepancies between researchers were solved by confrontation and consent. RESULTS: 6/11 (55%) cases were interpreted as SGI by clinical review. FDG PET/CT correctly diagnosed SGI in 5/6 (83%) cases and yielded sensitivity of 83% and specificity of 80%. Mean SUVmax and TBR (average ± SD) were 8.4 ± 3,5 and 5.7 ± 1,6 resp. in the group of patients with true SGI and 4.6 ± 1,1 and 2.7 ± 0.5 resp. in true negative cases. Analysis of CT images resulted in sensitivity of 83% and specificity of 80% and was concordant with PET in 9/11 (82%) cases. CONCLUSION: In our limited patient group FDG PET/CT with visual assessment correctly identified 83% of cases of SGI and might be useful diagnostic tool in this clinical setting.

The role of 18F-FDG PET/CT in patients with suspected infective endocarditis and echocardiographic inconclusive findings

C. E. Popescu[1], S. Capitanio[1], R. Sara[1], M. Milella[1], S. Fiorino[1], B. De Chiara[2], A. Moreo[2], C. Giannattasio[2], C. Rossetti[1]; [1]Nuclear Medicine

Department, Niguarda Hospital, Milan, ITALY, [2]"De Gasperis" Cardiovascular Department, Niguarda Hospital, Milan, ITALY.

AIM: The diagnosis of infective endocarditis (IE) can be difficult to make and in most institutions, the final diagnosis is established using the modified Duke criteria. The latest European Society of Cardiology guidelines have introduced nuclear imaging as a diagnostic test in patients with suspected IE. Compared to radiolabelled white blood cell imaging, the PET has the advantage of having a better spatial resolution and to have significantly lower acquisition times. The purpose of this preliminary study was to evaluate the role of 18F-FDG PET/CT in patients with suspected IE and echocardiography not conclusive. MATERIALS AND METHODS: Twenty-one patients (mean age 58 ± 16 years) hospitalized with suspected IE in our hospital from December 2013 to January 2016, underwent 18F-FDG PET/CT in the presence of echocardiographic findings doubts or inconclusive. PET/CT scan results were correlated with transthoracic or transesophageal echocardiography, blood cultures, and the Duke criteria. RESULTS: 10 (47, 6%) patients presented native valves, 8 (38%) had prosthetic valves after surgery (> 6 months) and 3 (14.4%) had cardiac implantable electronic device (CIED). Nine patients (43%) had positive blood cultures, 17 (81%) had hyperpyrexia and 18 (85.7%) performed the PET/CT scan during the antibiotic therapy. All patients with certain diagnosis had fever and 4 had positive blood cultures.The 18F-FDG PET/CT scan was positive in 5/21 (23.8%) patients. In 4 of these, PET/CT scan has allowed the diagnosis of definite endocarditis according to the modified Duke criteria. Among the 16 patients with negative results, the negativity of 18F-FDG PET/CT has ruled out the diagnosis of IE in 14 cases. None of the patients excluded from the diagnosis of endocarditis subsequently underwent surgery or died in follow-up (median 8 months, minimum one month, maximum 37 months). CONCLUSIONS: Our experience confirms the value of 18F-FDG PET/CT in the diagnosis of patients with suspected infectious endocarditis. Especially, for those cases where echocardiography is not conclusive, nuclear medicine proves a crucial role to conclude diagnostic procedure.

P136

PET/MR for evaluation of hepatic inflammation in patients with chronic hepatitis C virus infection

N. S. Nielsen, H. H. Johannesen, A. E. Hansen, E. Fallentin, J. Löfgren, M. S. Kjær, M. R. Clausen, A. Kjær, S. D. Nielsen, B. M. Fischer; University Hospital of Copenhagen/Rigshospitalet, Copenhagen, DENMARK.

AIM Chronic hepatitis C (CHC) infection is associated with systemic as well as hepatic inflammation, the latter contributing to the development of fibrosis, cirrhosis and hepatocellular carcinoma (HCC). Recently, direct-acting antiviral (DAA) agents have been introduced for treatment of CHC, resulting in sustained virological response (SVR) in the majority of patients. This pilot study examines the use of FDG PET/MR for evaluation of hepatic inflammation in patients with CHC, before and after treatment with DAA. **MATERIALS AND METHODS** The study is a substudy to a prospective study evaluating coagulation and inflammation in patients with CHC. FDG-PET/MR (Siemens Biograph mMR) was performed prior to and after DAA therapy. PET/MR included PET acquisition 60 and 90 min after FDG-injection, DIXON for AC, T2 and DWI (10 b-values between 0-700 s/mm^2). Three VOI of each 12-15 cm^3 were placed in the liver parenchyma, avoiding larger vessels. The following parameters were extracted: SUV_{mean60}, SUV_{mean90}, ADC_{total}, Perfusion Fraction (PF) and ADC_{slow} (perfusion free). Furthermore, HCV viral load, ALT and CRP was measured. Level of fibrosis was determined using transient elastography. **RESULTS** Ten patients completed PET/MR before and after DAA. Four patients had cirrhosis. Average HCV viral load prior to therapy was $1.7*10^6$ IU/ml(SD $1.2*10^6$). All patients obtained SVR. Average (SD) ALT decreased from 103(92) U/l to 22(12) U/l, p=0.02. CRP was within the normal range and did not change significantly during therapy. Prior to therapy average SUV_{mean60} and SUV_{mean90} was 1.9(0.2) respectively 1.7(0.3). The ratio $SUV_{mean90}/SUV_{mean60}$ was 0.9 (0.1). Neither changed significantly during therapy, nor did ADC_{total} or ADC_{slow} (1017(55) and 1013(91) s/mm^2 respectively). PF increased from average 207(40) to 259(58) s/mm^2, p=0.001. There was a trend towards higher SUV and lower PF in patients with cirrhosis. Plotting changes in the ratio $SUV_{mean90}/SUV_{mean60}$ against changes in PF suggests a correlation between the two parameters. **CONCLUSION** PET/MR in patients with CHC infection is feasible. In this study, all participants achieved SVR, and ALT decreased. Isolating PF on DWI-MR, an effect of therapy was found. However, all other PET/MR parameters including FDG-uptake were unchanged. A correlation between changes in FDG-uptake and PF is suggested, underlining that FDG-uptake is not only dependent on the presence of inflammatory cells, but also on perfusion. Whether or not PET/MR could be a useful tool to separate changes in FDG-uptake caused by changes in perfusion from changes in the number of inflammatory or malignant cells should be explored in future studies.

The Role Of FDG-PET/CT In Infectious Processes

M. CORTES-ROMERA[1], E. LLINARES-TELLO[1], A. SABATE-LLOBERA[1], M. SANTIN-CEREZALES[2], L. RODRÍGUEZ-BEL[1], L. GRÀCIA-SÁNCHEZ[1], J. ROBLES-BARBA[1], F. MARTÍNEZ-TORRENTS[3], J. VERCHER-CONEJERO[1], J. MESTRES-MARTÍ[1], C. GÁMEZ-CENZANO[1]; [1]PET UNIT NUCLEAR MEDICINE. IDI. HOSPITAL U BELLVITGE-IDIBELL, L-HOSPITALET DE LLOBREGAT (BARCELONA)., SPAIN, [2]DEPARTMENT OF INFECTOLOGY/INTERNAL MEDICINE. HOSPITAL U BELLVITGE-IDIBELL, L-HOSPITALET DE LLOBREGAT (BARCELONA)., SPAIN, [3]DEPARTMENT OF RADIOLOGY. HOSPITAL U BELLVITGE-IDIBELL, L-HOSPITALET DE LLOBREGAT (BARCELONA)., SPAIN.

AIM: To assess the utility of 18F-FDG-PET/CT in identifying the origin of infectious processes. MATERIAL AND METHODS: Fifty-one patients with suspected infectious processes were included in this study from 2011 to 2015. They were 18 women (36 %) and 33 men (64 %), with a mean age of 63 years (range 15-87). Patients were classified in 7 different groups according to the clinical suspicion: vascular graft infection (19), tuberculosis (9), renal or hepatic cyst infection in polycystic disease (7), abdominal or chest infection with lymph nodes (7), bacteraemia or sepsis of unknown origin (5), postoperative (3) and spinal infection (1). All patients underwent a whole body PET/CT at 60-120 minutes after intravenous administration of 3.7 MBq/Kg FDG. Nine patients were under antibiotics (including tuberculosis drugs). The results were compared with the final diagnosis based on the histopathology, microbiological assays, trans-thoracic echocardiography, morphological techniques, clinical and/or imaging follow-up after antibiotic treatment. Results were categorized as true-positive when abnormal 18F-FDG uptake was confirmed as infection. Normal test results were true-negative when no infectious process was confirmed or spontaneous remission. Accuracy, sensitivity, specificity, positive and negative predictive values were calculated. RESULTS: Forty-two out of 51 patients had a positive PET scan (82 %). In 38 of them (90%), PET/CT helped in identifying the cause of infectious processes (90 %) and these were classified in: abdominal infection (hepatic cyst in 4, hepatic and pelvic abscesses in 2), vascular or endovascular infection (endocarditis 3, mycotic aortic aneurysm 1, aortic prosthesis 4, catheter 1, pacemaker 1, femoro-popliteal bypass 1and aorto-femoral bypass 2), spinal infection (2), postoperative infection (costocondritis 1, chronic osteomyelitis 1), mycobacterial (M) infection (tuberculosis 13, atypical M 1) and miscellanea (1). In the remaining 4 positive scans (9%), PET/CT helped to confirm the final diagnosis as an inflammatory process: sarcoidosis, choledocholithiasis, aortic aneurism and postoperative changes. A negative PET scan was seen in 9/51 patients (18%), 2 of them during the course of antibiotic therapy due to

bacteraemia and were considered as false-negative. PET/CT contributed to the final diagnosis in 82% of the patients (42/51). Accuracy, sensitivity, specificity, positive and negative predictive values were 88%, 95%, 63%, 90% and 77%, respectively. CONCLUSION: FDG-PET/CT helped to identify the potential origin of the infection in 90% of patients with positive scans. Globally FDG-PET/CT contributed to the final diagnosis in 82% of the patients, but clinical scenario must be considered for a correct interpretation of the findings.

P138

Contribution of ^{18}F-FDG PET-CT in diagnostic work-up of patients with fever of unknown origin.

M. Lavalle[1], P. Castaldi[1], M. Lorusso[1], R. Manna[2], A. Giordano[1]; [1]Institute of Nuclear Medicine, Università Cattolica Sacro Cuore, Rome, ITALY, [2]Institute of Internal Medicine, Università Cattolica Sacro Cuore, Rome, ITALY.

Aim. Fever of unknown origin (FUO) represents a challenge not only for the internists but also for other specialists due to time and resources consumed in its diagnosis and management. Despite recent advances in diagnostic techniques, an algorithm covering all possible causes of FUO does not exist and a final diagnosis can not be made in up to 50% of cases. Recently, the use of ^{18}F-FDG PET/CT in the evaluation of patients with FUO is increasing. Aim of our study is to evaluate the diagnostic value of ^{18}F-FDG-PET/CT in FUO and its place in the diagnostic algorithm of these patients. **Materials and methods.** All patients who underwent ^{18}F-FDG-PET/CT because of FUO from 2008 to 2015 were enrolled in this retrospective observational study. PET/CT results were compared with the final diagnosis, which was established by additional procedures including histopathology, microbiological or serologic test, and clinical follow-up for more than 6 months. PET/CT results were definite "contributory to final diagnosis" when capable to correctly lead to further diagnostic investigations and the final cause of fever was identified or when a normal finding excluded other cause of FUO. **Results.** Seventy-six patients (54 ± 21years, 34 women, 42 male) were retrospectively evaluated. Final diagnosis was made in 72/76 patients (95%), including non-infectious inflammatory disease (53%), malignant disease (17%), infectious disease (12%), and miscellaneous disease (13%). No diagnosis was reached in 4 patients. PET/CT was "contributory to the final diagnosis" in 60% patients (n=43), correctly leading to further diagnostic investigations and to the final diagnosis in 36 patients (large vessel vasculitis, neoplasms and infectious diseases) and excluding other cause in 7 patients. PET/CT was non "contributory to the final diagnosis" in 40% (n=29) of patients, resulting positive in 12 patients and negative in 7 patients. **Conclusion.** Our study supports the data that ^{18}F-FDG PET/CT may be a useful diagnostic tool for the diagnosis of FUO guiding for further diagnostic investigations.

P139

Efficacy Of Radiological Methods In Diagnosing Diabetic Foot Infection

M. Zorkaltsev, V. Zavadovskaia, A. Kurazhov, V. Udodov, M. Zamyshevkaia, O. Kilina, E. Grigoriev; Siberian State Medical University, TOMSK, RUSSIAN FEDERATION.

Purpose: to compare the effectiveness of radiological methods for the establishment of osteomyelitis (OM) in the diabetic foot (DF). **Materials and methods:** In 211 patients (105 male (49.8%), 106 female (50.2%); mean age 56.8±14.2) with DF suspected OM were performed: X-ray (n=83), CT (n=83), ^{67}Ga-scintigraphy (n=47), ^{201}Tl-scintigraphy (n=40), WBC-scintigraphy (n=41), three-phase scintigraphy (n=83) and MRI (n=42). Study was performed by using Apollo Villa Sistemi Medicali (x-ray), Toshiba Xpress GX (CT), Philips BrightView (SPECT) and Siemens MAGNETOM ESSENZA 1.5T (MRI). **Results:** Values of sensitivity, specificity and accuracy of X-ray and CT were 78.2%, 28.6%, 61.4% and 77.8%, 57.1%, 70.7% respectively. Low specificity of X-ray and CT was principally due to false positive results (FP) in Charcot foot. Also it should be noted poor visualization of soft tissues. Values of sensitivity, specificity and accuracy of ^{67}Ga-scintigraphy, ^{201}Tl-scintigraphy, WBC-scintigraphy, three-phase scintigraphy were 96.6%, 72.2%, 87.2%; 87.5%, 66.7%, 75.0%; 95.8%, 64.7%, 82.9% and 91.5%, 50.0%, 79.5% respectively. FP results of scintigraphy were caused by difficulty in determining the localization of the pathological accumulation of radiotracer due to the low resolution of the method. Values of sensitivity, specificity and accuracy of MRI were 90,9%, 80,0%, 85.7%. The specificity of MRI decreased due to the complexity of the differential diagnosis of bone marrow edema and inflammatory infiltration. **Conclusion:** Among the available methods of radiological diagnosis of osteomyelitis in the diabetic foot, priority is given MRI. However, we must remember the presence of FP results in neuropathic form of DF.

P140

Role of 18 F-FDG PET-CT in documenting the disease burden in Tubercular meningitis

S. GAMBHIR, M. RAVINA, N. KUMAR, M. DIXIT, S. C. KHERUKA, K. RANGAN, J. S. KALITA, U. K. MISHRA; S.G.P.G.I.M.S, Lucknow, INDIA.

AIM: The authors demonstrate the potential of F-18 Fluorodeoxyglucose Positron emission tomography (PET)/Computerized tomography (CT) and magnetic resonance imaging (MRI) at disease onset and its complementary role along with MRI in elucidating the brain involvement. This may have a possible role in planning duration of treatment in scenario of TB resurgence and reported increase in multi-drug resistance (MDR) and extensively drug resistant (XDR) tuberculosis (TB) in patients with past history of TB. Materials and methods: 10 patients with definite Tubercular Meningitis (TBM), based on clinical, CT/MRI scan and CSF criteria were prospectively studied and subjected to whole body 18F FDG PET CT imaging and MRI. ^{18}F-FDGPET/CT results were independently reviewed and results were compared with MRI brain and other conventional imaging modalities (Ultrasound abdomen and Chest -X-Ray). The severity of TBM was graded into stage I to III meningitis. Results: There were 10 patients with TBM whose median age was 27 (range, 14-55) years and the median duration of illness was 4 (range, 0.5- 8.0) months. Two patients were in stage I; 6 in stage II; and two in stage III meningitis. ^{18}F-FDG PET/CT confirmed the cranial MRI findings in 07 patients, revealed additional brain lesion in 01 and did not detect the existing MRI lesions in 02 patients. ^{18}F-FDG PET/CT however detected additional lesions in vertebrae, spinal cord, lymph nodes in comparison to the conventional imaging. Conclusion: ^{18} F-FDG PET/CT is complementary to conventional imaging modalities in documenting upfront disease burden in diagnosed cases of tuberculosis with further ramifications in long term management of these patients. Keywords: 18 F - FDGPET; Tubercular meningitis; stage; MRI; disease burden

P141

The Clinical Contributions of SPECT/CT in 99mTc-HMPAO-Labelled Leukocyte Scintigraphy For Bone Prosthesis Infections

T. Sengoz[1], O. Yaylali[1], D. Yuksel[1], F. Demirkan[2], O. Uluyol[1]; [1]pamukkale university,Faculty of Medicine, Department of Nuclear Medicine, denizli, TURKEY, [2]pamukkale university,Faculty of Medicine, Department of Orthopedics, denizli, TURKEY.

Introduction: White blood cell scanning with 99mTc-hexamethylpropylene amine oxime (HMPAO) has proven a highly sensitive and specific imaging method in the diagnosis and follow-up of patients with suspected prothesis infection. The aim of this retrospective study was to evaluate the usefulness

of SPECT-CT performed simultaneously using a hybrid imaging device of prothesis infections. **Methods:** 99mTc-HMPAO scintigraphy was performed on 37 patients (11 men and 26 women; age range 38-84 years; mean age ±SD, 65.7±5.6 years old) . Planar scans were acquired 2., 4. and 24. h after injection. SPECT/CT was obtained 4 h after tracer injection, using a dual-head hybrid gama camera coupled with a low-power x-ray tube (Philips Brightview XCT; Ohio, Cleveland, USA). In all patients, scintigraphic results were matched with the results of surgery or cultures and clinical follow-up. **Results:** Seventeen (45,9 %) out of 37 patients were prothesis infection and 20 (54,1 %) out of 37 patients were non-infectious prothesis pathologies (9 aseptik loosening (45 %), 11 prosthesis secondary degenerative changes (55 %)) with Tc 99m-HMPAO scintigraphy and SPECT/CT. The Tc 99m-HMPAO scintigraphy was true-positive for infection in 16 of 37 patients and true-negative in 20 of 37 patients. There was no infection in a patient considered as infectious disease by scintigraphic evaluation (false positive). SPECT/CT provided an accurate anatomic localization of all positive foci. With regard to the final diagnosis, SPECT/CT added a significant clinical contribution in 22 of 37 patients (59,4 %). There was no clinical contributions with SPECT/CT in 15 of 37 patients (40,6 %). SPECT/CT provided accurate anatomic localization and differentiated soft-tissue from bone involvement in 17 of 22 patients. Any pathological activity uptake was not detected on SPECT/CT images in 5 patients who were only mild activity uptake showed in static scintigraphic images. Thus, false positive results were prevented by addition of SPECT/CT. SPECT/CT was usefull for differentiating soft tissue from bone tissue in patients with suspected prosthesis infection. SPECT/CT was contributed the localization of osteomyelitis in patients with structural alterations after traumatic process. **Conclusion:** Our results indicate that SPECT/CT performed using a hybrid device can improve imaging with 99mTc-HMPAO-labeled leukocyte scintigraphy in patients with suspected osteomyelitis by providing accurate anatomic localization and precise definition of the extent of infection.**KeyWords:** 99mTc-HMPAO-labeled leukocyte scintigraphy; prosthesis infection ; SPECT; SPECT/CT

P142

Role of ^{18}F-FDG PET CT in detecting active disease and in management of patients with Takayasu arteritis

G. Sankar, S. Gambhir, A. K. Singh, A. Prashanth; SGPGIMS, Lucknow, INDIA.

Aim and objective: Takayasu arteritis (TA) is a systemic large vessel vasculitis involving aorta and its main branches. Serum inflammatory biochemical markers and angiography are the main investigations in diagnosis and follow up. ^{18}F-fluorodeoxyglucose (FDG) is a glucose analogue and its uptake is noted in both malignancies as well as in inflammatory conditions. Aim of this study was to see if FDG can be used as a bio-marker in detecting active inflammatory lesions in TA patients and its role in management of these patients. **Material and Methods:** Whole body FDG PET-CT scan was done in 17 known or suspected case of TA over a period of two years (2013-2015) in this retrospective study. Serum inflammatory markers (ESR & CRP) work up was done prior to PET/CT. Semi-quantitative parameter, SUVmax, was calculated in all the active lesions. Correlation between inflammatory markers and SUVmax was also calculated and a p value <0.05 was considered significant. PET scan report leading to any change in the management was asked from the treating immunologists and was obtained only in 10 patients. Rest of the patients are yet to follow up. **Results:** A total of 17 including 15 females (88%) and 2 males (12%) were studied. The mean age of the patients was 29.9 years (range: 16-52). Twelve patients were already on steroid therapy prior to the PET-CT scan (71%). Four patients had prior angioplasty and stenting done at least in one major vessel (24%). Mean ESR value in patients having active lesions was 57.62 mm/hr (range: 25-100) and in others was 18 mm/hr (range: 8-26). CRP was done only in 14 patients. Mean CRP level was 2.46 mg/L (range: 0.26-16.6). A total of 28 active lesions were detected in the FDG PET-CT scan. The mean SUVmax of these lesions was 3.03 (range: 1.4-5.9). There was significant correlation between SUVmax and ESR (p value: 0.01) as well as between SUVmax and CRP (p value: 0.01). FDG PET-CT scan lead to change in management in 7 out of the 10 patients who were followed up post PET-CT scan (70%). The most common change was addition of methotextrate or azathioprine in addition to steroids. **Conclusion:** SUVmax can be used as a bio-marker and shows significant co-relation with both ESR and CRP levels. FDG PET/CT scan can lead to change in management in TA patients. However larger prospective studies are required to validate these findings.

P143

Quantification of Ga67 in Necrotising Otitis Externa

D. O. Hall, L. Armstrong, A. Demmery, J. Kabala; UH Bristol NHS FT, Bristol, UNITED KINGDOM.

Aim: Necrotising Otitis Externa (NOE) is a rare but serious infection of the external ear and skull base. Clinical assessment is not always sufficient to diagnose the condition, or monitor the progress of disease and effect of treatment, so imaging is used, including MRI, CT and nuclear medicine bone and Gallium scans. Imaging however may remain abnormal even after the infection has subsided; for example nuclear medicine bone scans often show increased uptake in the healing phase of the disease. Gallium-67 citrate is a sensitive measure of the development and progress of the disease, and promises to be an early measure of disease response, as uptake should reduce as the infectious process resolves. This study was carried out to define a practical protocol for calculation of disease activity in NOE using Ga67 SPECT/CT, and to determine cut-offs to detect active disease and to decide whether disease has resolved. Materials and Methods: 22 patients had 33 SPECT/CT scans on a Symbia T16. 150 MBq Ga-67 Citrate was injected i.v., with imaging at 24 hours from injection. Studies were acquired on the Symbia T16 SPECT/CT scanner, Medium Energy Low Penetration (MELP) collimator, 128X128 matrix, no zoom, pixel size 4.8mm, 128 projections, 20s per projection. CT was acquired at 130kV, 120mAs with Automatic Exposure Control (Siemens Caredose). Ratios of abnormal to normal side and abnormal side to cervical spine were calculated using Siemens MI Apps Volumetric Analysis. 12 studies had active disease, 12 were normal, and 9 were equivocal. Cut-offs were determined using ROC analysis with the web-based utility Cutoff Finder [1]. Results: Results were calculated using both methods, i.e. ratios of abnormal to normal side and abnormal side to cervical spine. Inter-operator variability was significantly poorer for ratios of abnormal side to cervical spine than abnormal to normal side. Uptake in active disease was significantly higher than in equivocal or normal studies. For ratios of abnormal to normal sides, ratios of <1.215 were normal, 1.215-1.375 was equivocal, and >1.375 were abnormal, with sensitivity and specificity >95%. The use of these limits is demonstrated in patients who had repeated studies to monitor treatment. Conclusion: A practical method has been demonstrated for quantification of uptake of Ga67 SPECT/CT in NOE. Reference: 1. Budczies J, Klauschen F, Sinn BV, Gyorffy B, Schmitt WD, et al. Nuclear imaging and infective endocarditis: the diagnostic role of 99mTc-HMPAO-Labeled Leukocyte SPECT/CT in patients with inconclusive echocardiographic exam

C. E. Popescu[1], S. Capitanio[1], R. Sara[1], M. Milella[1], S. Fiorino[1], B. De Chiara[2], A. Moreo[2], C. Giannattasio[2], C. Rossetti[1]; [1]Nuclear Medicine Department, Niguarda Hospital, Milan, ITALY, [2]"De Gasperis" Cardiovascular Department, Niguarda Hospital, Milan, ITALY.

AIM: The diagnosis of infective endocarditis (IE) may be particularly challenging. The so-called modified Duke criteria, recommended for diagnostic classification, can be improved through functional imaging procedures. Compared to PET, scintigraphy with labeled leukocytes has the advantage of having a better specificity, especially in patients with chronic inflammatory states and previous cardiac surgery. The purpose of this preliminary study was to evaluate the role of 99mTc-HMPAO-Labeled Leukocyte SPECT/CT in patients with suspected IE and echocardiography not conclusive. MATERIALS AND METHODS: We assessed the value of 99mTc-HMPAO - Labeled Leukocyte scintigraphy including SPECT/CT acquisitions in 13 patients (mean age 50 ± 25 years) hospitalized in our hospital from March 2013 to November 2015, with suspected diagnosis of IE in the presence of echocardiographic findings doubts or inconclusive. 99mTc-HMPAO - Labeled Leukocyte scintigraphy results were correlated with transthoracic or transesophageal echocardiography, blood cultures, and the Duke criteria. RESULTS: 5 patients (38.5%) had native valves, 5 (38.5%) had prosthetic valves and 3 (23%) cardiac implantable electronic device (CIED). 8 (61.5%) patients presented positive blood cultures, 11 (84.6%) had hyperpyrexia, and 12 (92.3%) patients performed the exam during the antibiotic therapy. In 6 patients it was confirmed the diagnosis of definite endocarditis according to the modified Duke criteria. Scintigraphy was true-positive in 3 of 6 patients (23%) and had an important role to conclude the diagnosis, representing in 2 cases, the major criterion, along with positive blood culture results. In one case it was the minor criterion and was able to identify an extracardiac uptake indicating septic embolism. In 7 of the 10 patients with negative scintigraphy scan, was excluded the diagnosis of endocarditis. None of them had evidence of infected endocarditis in follow-up (mean duration 24 months, minimum 3 months, maximum 37 months). CONCLUSION: This study, even if having a limited number of cases, supports the use of 99mTc-HMPAO- Labeled Leukocyte scintigraphy in patients with high clinical suspicion of IE but inconclusive echocardiographic findings to confirm the diagnosis in unclear circumstances or to detect sites of septic embolism.

P145

Diagnostic Value of Fluorine-18 Fluorodeoxyglucose Positron Emission Tomography/computed Tomography In Fever of Unknown Origin

L. Kang, Y. Huo, R. Wang; Peking University First Hospital, Beijing, CHINA.

Objective: Fever of unknown origin (FUO) is a challenging problem in diagnosis in clinic. The diagnostic value of ^{18}F-FDG in malignant tumors has been well accepted. However, the differential diagnostic value of FDG PET/CT among tumors, infection and non-infectious inflammation still needs to be elucidated. This study is to evaluate the diagnostic value of ^{18}F-FDG PET/CT in FUO. **Methods:** We analyzed the records of 51 patients with FUO (32 men and 19 women; mean age of 54-year-old with a range between 3- and 81-year-old) retrospectively. All patients were examined by ^{18}F-FDG PET/CT and the results were compared to the final diagnosis established by additional procedures including pathology, laboratory examination and clinical follow-up for more than 3 months. The maximum of standard uptake value (SUVmax) in tumors and benign lesions was compared. T test was used for statistical analysis. **Results:** Final diagnosis were established for 48 patients, including 31 patients with infectious diseases, 9 with malignancies, and 8 with non-infectious inflammatory diseases. By FDG PET alone, the true positive (TP), false positive (FP), false negative (FN) and true negative (TN) rate was 52.9%, 27.5%, 17.6% and 2.0%, respectively. By FDG PET/CT, TP, FP, FN and TN rate was 70.6%, 27.5%, 2.0% and 0%, respectively. PET/CT had a sensitivity of 97.3% (36/37), a specificity of 0% (0/14) and an accuracy of 70.6% (36/51) in FUO, especially a high sensitivity and accuracy of 100% (9/9) in malignant tumor. Moreover, SUVmax in tumor was significant higher than that in infection (3.7±2.7 vs 7.7±3.5, P=0.001, t=3.6) and might be useful in differential diagnosis. **Conclusions:** ^{18}F-FDG PET/CT is a valuable imaging tool for the identification of the etiology in patients with FUO. It is helpful for locating the lesion, especially in the diagnosis of FUO cases with potential malignant lesions.

P146

Abdominal Tuberculosis in a low-incidence Country: a single-center experience on 13 patients investigated with 18F-FDG PET/CT

L. Zanoni[1], V. Ambrosini[1], G. Vandi[2], G. Martelli[2], M. Tadolini[2], S. Brocchi[3], J. Morigi[1], P. Viale[2], M. Zompatori[3], S. Fanti[1]; [1]Nuclear Medicine, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [2]Infectious Diseases, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [3]Radiology, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY.

AIM: To assess the role of 18F-FDG PET/CT in the diagnosis of abdominal tuberculosis (ATB). **MATERIALS AND METHODS:** Clinical records, contrast-enhanced-CT and 18F-FDG PET/CT findings of patients diagnosed with ATB between January2013 and January2016 at the Infectious-Diseases-Unit were retrospectively analyzed. Abnormal CT and PET/CT findings were independently documented, anatomically categorized and compared. **RESULTS:** A total of 289 pts were diagnosed with TB. 23/289 had ATB. 13/23 pts underwent 18F-FDG PET/CT (12 before, 1 immediately after diagnosis) and were included in the analysis. Clinical characteristics (13 pts): 7 women, 6 men; median age 39 years (range 25-72). 12 foreigners, 1 Italian. All pts had no past history of TB. 2 HIV+; 11 seronegative. Common symptoms were: loss of body weight (12), abdominal pain (10), night sweats (7), fever (6); ascites (5), diarrhea (1). Clinical requests for imaging were: differential diagnosis between cancer and TB (4 pts); suspect of cancer (2), lymphoma (2) or TB (3) (n/a: 3). Abdominal nodes were identified in 12 pts (CT performed better in 1/12 and showed typical enlarged necrotic nodes with hypo-attenuating centers and hyper-attenuating enhancing rims in 7 cases; FDG uptake varied from faint/diffuse to intense/focal up to SUVmax 15,8). Peritoneal involvement (11 pts; 2 detected only by CT) markedly accumulated FDG (SUVmax: mean 9,6; median: 9,2; range 5,2-13,9) mimicking peritoneal carcinosis; in all cases, CT revealed smooth thickening and strong contrast-enhancement of the parietal peritoneum and ascites (UH: mean 21; median 21; range 10-253). Gastrointestinal-tract was affected in 3 pts (high PET metabolism and, in 1 case, typical ileocecal thickening on CT). Liver was involved in 1 pt (both PET and CT positive). Spleen involvement was detected in 1 case by CT but not clinically confirmed. Extra-abdominal localizations were depicted in lung in 5 pts (3/5 only CT positive), and other regions (i.e. intrathoracic nodes, pleural effusion/deposits, muscle) in 10 pts (2 only PET positive). Overall PET identified 44 affected regions whereas CT 46. Half of the population presented with disseminated disease (>10 lesions). PET report hypothesized malignancy rather than ATB in the majority of pts (6), correctly suspected infection in 3 cases, remained indeterminate in 4. Based on PET findings, focused biopsy led to bacteriological TB confirmation in 10/13 pts (77%) and histological confirmation in 3/13. **CONCLUSION:** PET seems to play an important role in ATB diagnosis, identifying the involved sites for focused biopsy. Larger studies are needed to confirm our observations.

P147

Brief experience of the clinical utility of three phase F-18 NaF bone PET for evaluation infected prosthesis

Y. Jeong, S. Choi, J. Jeong, H. Son, H. Yoon, D. Kang; Dong-A University Hospital, Busan, KOREA, REPUBLIC OF.

Purpose: Because F-18 NaF has a rapid kinetics than Tc-99m MDP, F-18 NaF bone PET has many advantages which are clear bone image, short imaging time and ability to quantify bone turn over. However, the usefulness of three phase NaF bone PET to diagnosis bone infection is not well known. In this study, we studied the clinical usefulness of three phase bone PET with F-18 NaF to identify the presence of prosthesis infection of joint. Materials and Methods: Five patients who presented symptoms suggesting infection of joint prosthesis after joint replacement surgery of knee (n=4) or hip (n=1) were enrolled. All patients performed three phase Tc-99m MDP bone scan and F-18 NaF bone PET on the same day. Three patients performed 3-time point PET acquisition (perfusion, blood pool and delayed images). Other two patients underwent F-18 NaF bone PET examinations as following protocol. First, list mode image was obtained for 20 min after injection of F-18 NaF. The list mode data was reconstructed into dynamic curve for 20 min, perfusion and blood pool images. Second, delayed static bone phase scanning was performed at around 60 min after injection of radiotracer. Ten normal controls who underwent joint replace surgery without symptom were also recruited for. Three volume of interest were drawn on artery, muscle, bone marrow and two different site of bone in patients and normal control. Results: Of five patients, infection of joint prosthesis was confirmed in 4 subjects. Non-infected joint prosthesis was revealed in another one patient and symptom of the patient gradually subsided with symptomatic treatment. As the patients with infected prosthesis, one patient without infection showed increased uptake in the peri-prosthesis area in delayed image. But pattern of tracer uptake was relatively even in patient with non-infected prosthesis. Time-activity curve for 20 min showed markedly different curve pattern between the patients with and without infected prosthesis.Conclusion: This preliminary data suggested that F-18 NaF bone PET showed clearer three phase images which helped to identify the site and extent of disease. Adding of dynamic curve could improve diagnostic accuracy.

Use of Ultra-Portable Ultrasound to Improve IV Access for Nuclear Medicine Dose Administration

M. I. Knopp, C. Odom, K. Binzel, C. L. Wright, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

Aim: IV access with no extravasation is essential for safe, precise and quantitative nuclear medicine imaging. As many procedures are performed on an outpatient basis for co-morbid patients with challenged venous access, optimal needle placement remains a top priority. Unfortunately, extravasations, though mostly minor, regularly occur. The miniaturization of ultrasound systems reached a new breakthrough with the clinical release of a smart device (tablet or phone) micro-USB attachable ultrasound transducer. We introduced and assessed the feasibility of such a device concept in nuclear medicine. **Materials and Methods:** An ultraportable, Android app-based FDA approved ultrasound system (Lumify, Philips) was purchased to explore innovative uses in nuclear medicine. The app runs on current generation tablets and smartphones. It installs like any app with a scan ready start up screen. For venous access imaging a linear array probe was used that also enables flow Doppler overlay on the morphologic image. Via settings, many characteristics can be customized including the setup of DICOM / network destinations that support direct upload to PACS via Wifi. Local storage of images and videos is supported as well as expected features for annotation or measurements. Overall operation is intuitive, fast and scaled to the size of display device. The app is fully integrated so that additional display casting options via Wifi are supported, enabling instantaneous sharing on a remote display. **Results:** Once the probe is attached to the smart device, it is immediately usable making it extremely practical from fitting readily into a lab coat pocket to be ready for use. Most nuclear medicine technologists are not familiar with the use of ultrasound to find and place IV needles, but can be readily trained. The ability to cast images on PC/TV screens in the injection environment was found extremely helpful and convenient for training. While our prospective IV access performance collection is still ongoing, the clinical impact appears to evolve favorably and the operator, especially less IV experienced young professionals rate the availability of the system to be very helpful. One aspect that remains an inconvenience is that ultrasound gel remains necessary for coupling to the skin. Image quality consistently rated as excellent and operability as fully compatible within the nuclear medicine environment. **Conclusion:** Using ultrasound to improve IV access in nuclear medicine is considered inconvenient, inefficient, expensive and clunky. Ultra-portable, smart device-based probe technology overcomes these limitations. We observed very favorable acceptance and access quality improvements.

Value 18F FDG PET CT in the assessment of Erdheim Chester disease

P. Gykiere[1], P. Ardies[2], G. Serry[1], H. Everaert[2], B. Van den Broeck[1]; [1]University Hospital Ghent, Ghent, BELGIUM, [2]University Hospital Brussels, Brussels, BELGIUM.

Objective: Erdheim-Chester disease (ECD) is a rare non-Langerhans form of histiocytosis of unknown etiology (1). ECD is a systemic disease and can present with a wide array of clinical manifestations involving many different organs, including the skeleton, central nervous system (CNS), cardiovascular system, kidneys, lungs and skin (1, 2). Because of this variable clinical presentation, diagnosis of ECD is often challenging. The aim of this study was to evaluate the use of FDG PET/CT in the assessment of the extent of the disease. Methods:We retrospectively reviewed PET/CT scans of 6 histological confirmed cases of ECD performed in two university hospitals between 2010 -2016. Results: After reassessment, the most common characteristic in our series (83%) is hypermetabolic skeletal involvement showing bilateral and symmetrical cortical FDG-avid osteosclerosis of the diaphyseal and metaphyseal regions in the long bones (typically sparing the epiphysis). Also, cardiovascular involvement with hypermetabolic sheathing of the aorta, retroperitoneal and perirenal involvement ("hairy kidney on CT") was frequently observed (both 66%). In addition although less frequently, in some patients there was augmented activity in the lungs, adrenals, sinuses and CNS. These results correlate well with the known distribution of clinical manifestations of ECD (1, 3). Conclusion: Since ECD is a multisystemic disease, we found that whole-body FDG-PET scanning was able to depict the extent and activity of the ECD lesions. This is important because the clinical prognosis is dictated by the degree of organ involvement, especially the CNS (2). Secondly, PET/CT could help guide a safe and appropriate site of biopsy for definitive diagnosis. References: 1. Erdheim-Chester disease. Campochiaro C, Tomelleri A, Cavalli G, Berti A, et al. Bone SPECT for the evaluation of condylar growth: comparison between different standardization methods

M. Silva[1], P. Gil[1], R. Silva[1,2], J. Isidoro[1], A. Albuquerque[1], F. Álban[1], P. Lapa[1], G. Costa[1], J. Pedroso de Lima[1,2]; [1]Centro Hospitalar da

Universidade de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saude, Coimbra, PORTUGAL.

Aim: Hyperplasia of the mandibular condyle is a complex deformity of the mandible that may lead to important functional and aesthetic problems. Bone single photon emission computed tomography (SPECT) is an essential tool for assessing mandibular condylar uptake as a surrogate for mandibular growth. This study aimed to compare two different SPECT methods for the quantification of condylar uptake. Material and Methods: Eight patients (2 males and 6 females; 18-26 years of age, mean age:23.5±2.8 years) who performed ^{99m}Tc-MDP bone scans for indications not involving the skull, were asked to have an additional SPECT that included the mandibular condyles, with a source of known activity above the skull, included within the field of view (external standard). For each patient three dimensional (3D) regions of interest (ROIs) were drawn over both condyles, the clivus (internal standard) and the external standard. Maximum and total pixel values within the 3D ROIs were recorded and used to develop normal values for both quantification methods (average±2 standard deviations, 95% confidence interval). One hundred and thirty-eight bone SPECTs were performed for the assessment of mandibular condylar uptake (95 patients; 35 males and 60 females, 17-38 years of age, mean age:21.0±4.1 years). Condylar uptake was determined using both standards in all scans. Statistical analysis was performed using IBM© SPSS© Statistics, version 22. Results: Normal ranges were determined for the condylar uptake using both internal and external standards. All patients were classified as having normal or hyperplasic condyles, according to both internal and external standards and the normal values previously defined. A statistically significant correlation was found between the normal/hyperplasic classification using both methods (Pearson Chi-square < 0.05). Also, statistically significant correlations were found between internal and external condylar uptake in the right ($p<0.01$, r^2: 0.459) and left clivus ($p<0.01$, r^2: 0.255). Discussion: ^{99m}Tc-MDP bone SPECT provides a quantitative technique for assessing mandibular condylar uptake as a reflection of mandibular growth. However, several quantification methods can be used. In this study local normal ranges were determined for the condylar uptake using both internal and external standards and statistically significant correlations were found between them. We predict that the external standard may have significant advantages; however this thesis needs to be further evaluated.

P151

Is there anno 2016 still a role for quantitative salivary gland scintigraphy in suspected Sjögren Syndrome?

P. Kaldeway, E. ten Borg, E. M. W. van de Garde, J. B. A. Habraken, J. Lavalaye, M. M. C. van Buul; St. Antonius hospital, Nieuwegein, NETHERLANDS.

Purpose: Aim of this study is to evaluate the diagnostic value of semi quantitative parameters in salivary gland scintigraphy (SGS) in the diagnostic work-up in Sjögren's Syndrome (SS) using the AECC as gold standard. **Patients and methods:** Tc-99m pertechnetate-SGS was performed in 110 patients with suspected Sjögren's Syndrome. Uptake ratios (UR) and excretion fractions (EF) for all parotid and submandibular salivary glands were calculated. Patients were divided in SS-positive, SS-negative and SS-unequivocal groups based upon the AECC criteria, ocular and oral symptoms, Schirmer's test, labial biopsy and anti-SSA or anti-SSB antibodies. SGS semi quantitative parameters were compared per group and cut-off values were defined. **Results:** Ninety-six women (87%) and 14 men(13%) with a mean age of 51 years (range 18-77 years) were included. All patients underwent SGS, labial biopsy, Schirmer's test and antibody test (anti-SS-A and anti-SS-B). Twenty-four patients were SS-positive, 56 patients SS-negative and 30 SS-unequivocal. UR of the parotid glands did not differ between SS-positive and SS-negative groups (3.4 and 3.9, respectively), while UR of the submandibular glands were significantly lower in SS-positive patients (2.7 versus 3.5). EF in both parotid and submandibular glands was significantly higher in SS-negative compared to SS-positive patients: parotid 44% and 56% respectively, submandibular 36% and 49%. Based upon a cut-off value of 2.0 for UR and 20% for EF, sensitivity, specificity, PPV and NPV were 0.67, 0.86, 86%, and 67%, respectively. Out of the 30 SS-unequivocal patients, 15 had a positive SGS and the other 15 were SGS negative. In both, there was no correlation with the results of AECC criteria IV (histopathology) and VI (antibodies). In these cases, the SGS result was decisive. Conclusions: Quantitative salivary gland scintigraphy is still a valuable tool in the diagnostic management of patients with suspected Sjögren's syndrome, especially in those in which the non-scintigraphic AECC criteria are not conclusive. The straightforward quantitative analysis of salivary gland scintigraphy used in this study can be implemented in any nuclear medicine department.

P152

Functional Recovery Of Patients With Secondary Lymphedema Treated With Lymphatic Venous Anastomoses And Lymph Node Transfer, Monitoring By Isotopic Lymphography. Value Of SPECT/CT

M. L. Lozano Murgas, L. Reguera Berenguer, J. Ardila Manjarres, A. Rotger Regí, J. Orcajo Rincon, C. Duran Barquero, R. Pascual Pérez, J. Lasso Vázquez, C. Pinilla Martínez, J. Alonso Farto; Hospital General Universitario Gregorio Marañon, Madrid, SPAIN.

AIM The aim of this cross-sectional descriptive study was to assess the functional recovery of lymphatic flow in patients with secondary lymphedema treated with microsurgical techniques (lymphatico-venous anastomosis and vascularized lymph node transfer) by isotopic lymphography. In addition, we wanted to evaluate the added value of single photon emission computed tomography/computed tomography (SPECT/CT) in medium term follow up of these patients treated with microsurgical techniques. **MATERIAL AND METHODS** A total of 16 consecutive patients (14 females; mean age 54 years, range 41-76) were studied. Eleven patients were operated with lymphatico-venous anastomosis (LVA) and 5 with vascularized lymph node transfer (VLNT). After injection of ^{99m}Tc-nanocolloid (about 96 MBq per limb) conventional lymphoscintigraphy was performed to obtain early (average 28 min) and late (2 h) images of both upper or lower limb according to the patient´s condition (16 upper limbs and 16 lower limb). SPECT/CT delayed images were acquired in 8 inguinal and axillary regions respectively. **RESULTS** In 50% (8/16) of cases, lymphatic flow was restored, five of them had been treated with LVA and three with VLNT. Of these, 75% (6/8) showed lymph node appearance. In 2 of the remaining patients, additionally, radiopharmaceutical dermal backflow was improved. From a total of 124 lymph nodes identified (upper limb, n=52; lower limb, n=72), 73,4% (91/124) were detected by conventional lymphoscintigraphy and 100% (124/124) by SPECT/CT. Therefore SPECT/CT provided 26,6% additional diagnostic information compared to planar lymphoscintigraphy, in the following anatomic sites: 8 axillary, 1 supraclavicular fossa, 4 infraclavicular fossa, 2 mid-arm, 1 right scapula, 1 elbow, 8 inguinal, 6 iliac and 2 para-aortic nodes. In cases undergoing LVA, 67,7% (84/124) of lymph nodes were detected while 32,3% were detected (40/124) after VLNT. **CONCLUSION** Our results, although preliminary, suggest an increase of lymph node recovery by ALV compared to VLNT microsurgical technique. SPECT/CT is complementary to conventional lymphoscintigraphy providing additional information regarding exact anatomic localization and improving the identification of lymph nodes.

P153

Evaluation of serum 25 Hydroxy vitamin D levels in patients with Diabetes Mellitus

A. S. ZISSIMOPOULOS[1], C. Tsigalou[2], D. Papazoglou[3], N. Papanas[4], O. Zissimopoulou[1], A. Pistola[1], M. Lambropoulou[5]; [1]Nuclear Medicine

Dept Democritus University of Thrace, Alexandroupolis, GREECE, [2]Biopathology Lab Democritus University of Thrace, Alexandroupolis, GREECE, [3]Diabetes Center- Second Department of Internal Medicine Dept Democritus University of Thrace, Alexandroupolis, GREECE, [4]Diabetes Center- Second Department of Internal Medicine Democritus University of Thrace, Alexandroupolis, GREECE, [5]Lab Histology-Embryology Democritus University of Thrace, Alexandroupolis, GREECE.

Introduction: Vitamin D deficiency is a condition of increasing prevalence worldwide. Diabetes mellitus (DM) is related to vitamin D levels. In recent studies there is association with vitamin D deficiency and the risk of developing diabetes and diabetes complications. Aim: The aim of this study is to evaluate the serum levels of 25 hydroxy- vitamin D [25(OH) D] in patients with type 2 diabetes mellitus. Patients and method: We study 108 patients (66 male and 42 female) aged between 43 and 70 years old (median age of 58±12 years) with type 2 diabetes mellitus with or without diabetes complications. All were in follow up at the University Hospital of Evros. In all patient's blood samples were taken for (25-OH-D) determination. After centrifugation the serum was collected and kept refrigerated at -70 ° C. The vitamin D status was measured by radioimmunoassay (RIA) method with I^{125}[25(OH)D] kits Diasorin at in- vitro laboratory of Nuclear Medicine Dept. University Hospital of Evros, Democritus University of Thrace. Also we studied 40 healthy individuals (blood donors) as control group. Statistical analysis: Statistical analysis was performed by the x^2- test (student test) and statistical significance was considered to be $p < 0.005$. Results: Diabetes mellitus patients had lower levels of 25(OH)D than controls ($p < 0.005$).In 62 patients with severe complications of the disease, the levels of [25(OH)D] were significantly low 0-20 ng/mL ($p < 0.005$), in 28 patients with mild complications of the disease the levels were 20-40 ng/mL (hypovitaminosis) and the rest 18 with no complications, had levels of [25(OH)D] > 40 ng/mL($p < 0.005$). Conclusions: Diabetes mellitus patients had lower levels of 25(OH)-D than controls. Patients with severe complications of the disease had significantly low levels than the others. Vitamin D deficiency may be a risk factor for DM. Clinical trials with vitamin D supplementation are needed.

^{99m}Tc-HDP Bone scintigraphy and ^{18}F-sodiumfluoride PET/CT in primary staging of patients with prostate cancer

A. M. Burgers[1], M. Wondergem[1,2], R. J. J. Knol[1], I. J. de Jong[2], J. Pruim[2,3], F. M. Van der Zant[1]; [1]Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS, [2]University Medical Center Groningen, Groningen, NETHERLANDS, [3]Stellenbosch University, Tygerberg Hospital, Stellenbosch, SOUTH AFRICA.

Introduction/Aim Correct staging of patients with prostate cancer is important for treatment planning and prognosis. In patients with high-risk primary prostate cancer bone scintigraphy with ^{99m}Tc-phosphonates (BS) is performed for detection of bone metastases. Due to the high rate of inconclusive BSs, new imaging techniques for bone metastases are being evaluated. Recent studies show better performance of ^{18}F-sodiumfluoride PET/CT (NaF-PET/CT) compared to BS. The aim of this study is to evaluate the performance of both BS and NaF-PET/CT in primary staging of patients with prostate cancer. **Methods** Two cohorts were studied. The first , restrospective cohort consisted of patients who received a BS from January 2011 till December 2011 with a clinical follow-up of at least 18 months. The second, prospective cohort contained patients who received a NaF-PET/CT from January 2014 till October 2015 and had a follow-up of at least 6 months (6-28 months). The follow-up period was used as the reference standard and consisted of clinical, biochemical and radiological follow-up. **Results** Fifty-nine patients underwent NaF-PET/CT whereas 122 patients underwent BS. On a patient basis sensitivity of 97-100% and 88-96% and a specificity of 96-100% and 72-100% was found for detection of bone metastases with NaF-PET/CT and BS respectively. The combination of NaF-PET with low-dose CT resulted in detection of extra-skeletal metastases in a large number of patients (lymphadenopathy in 47% and pulmonary metastases in 3%), even in 8 patients (14%) without bone metastases. In comparison to bone scintigraphy, NaF-PET/CT yielded less equivocal results requiring further evaluation (3% vs 22%). **Conclusion** NaF-PET/CT is an excellent tool for detection of bone metastases in patients with prostate cancer. Due to the combination of PET and low-dose CT the interpretation of foci with increased tracer-uptake is highly specific. Moreover, extra-skeletal metastases are found frequently on the low-dose CT.

P155

Simplifying the role of Lymphoscintigraphy for the assessment of lymphedema

D. Shivdasani; P D Hinduja Hospital, Mumbai, INDIA.

Introduction: Lymphedema is an under treated condition, causing swelling of the extremities. Misdiagnosis and/or delayed diagnosis are common. Lymphoscinitgraphy is a specific radio-isotope technique to detect lymphatic causes of limb swelling from other causes like obesity, venous disease and hypoalbuminemia. Materials and Methods: Total of 113 patients (age 2-86y, mean 41.7y), 59 females , 54 males were referred to our Nuclear Medicine department for lymphoscintigraphy . One patient was excluded in view of intravascular tracer injection. 34 patients were referred to rule out chyle leak. 78 patients were referred for the evaluation of limb edema of which 75 patients had only lower limb edema, two children both 2 years of age were referred to rule out primary lymphedema and one patient suffered from upper limb edema following trauma. Lymphoscintigraphy was performed in all patients by intradermal injection of 0.1-0.2ml of 500microcuries of filtered Tc -99m sulphur colloid in the first web space. Whole body imaging was carried out 10-30 minutes post injection, followed by a second image at 1 hour and a delayed image (3-4 hours after injection) post- exercise of the injected limbs. Lymphatic obstruction was defined as absence of visualization of any tracer activity in regional(inguinal or axillary) nodes upto 4 hours post injection. Asymmetric delayed visualization of comparatively fewer nodes with either presence of dermal backflow or visualization of nodes of the deeper drainage system was defined as lymphatic dysfunction. Results: 32% patients referred to our center for evaluation of lymphedema had normal scans. 19% had lymphatic obstruction of which 11 scans were unilateral and 4 scans were bilateral. 36% patients with unilateral obstruction also demonstrated lymphatic dysfunction in the contra lateral asymptomatic limb. Lymphatic dysfunction was seen in 49% of which 30 patients had unilateral and 8 patients had bilateral dysfunction. Dysfunction in the form of dermal backflow was seen in 79% patients and 8 patients had visualization of deeper nodes either popliteal (n=6) or epitrochlear (n=2). 18% with dysfunction demonstrated both dermal backflow and abnormal nodes on their scans. Conclusion: The diagnostic utility of lymphoscintigraphy depends upon technical performance and accurate image interpretation. Our data reflects its simple, visual and qualitative interpretation using well defined criteria for classifying scans as normal, lymphatic obstruction or dysfunction. We suggest it can serve as a specific tool for differentiating lymphedema from other causes of limb swelling.

P156

^{111}Indium-DTPA-Scintigraphy Including SPECT-CT Can be Extreme Helpfull in Solving Intrathecal Drug Delivery Failures. An Analysis of 15 Cases

A. Fröberg[1], E. Delhaas[2], F. Huygen[2], B. Harhangi[3], A. van der Lugt[1], J. F. Verzijlbergen[1]; [1]Erasmus MC, Department of Radiology & Nuclear

Medicine, ROTTERDAM, NETHERLANDS, [2]Erasmus MC, Department of Pain Treatment, ROTTERDAM, NETHERLANDS, [3]Erasmus MC, Department of Neurosurgery, ROTTERDAM, NETHERLANDS.

Aim: To assess the diagnostic potential of ^{111}Indium-DTPA-scintigraphy including SPECT-CT in patients suffering intrathecal baclofen (ITB) delivery failures. **Materials and Methods:** Our hospital is a referral center for ITB troubleshooting and for years ^{111}Indium-DTPA-scintigraphy has been one of the diagnostic tools in challenging cases. In the last two years we extended the standard planar investigations with Single Photon Emission Tomography in combination with computed tomography (SPECT/CT). The pumps are filled with a mixture of baclofen and ^{111}Indium-DTPA and both planar and SPECT/CT imaging of spine and head was performed at 24, 48, 72 and if warranted also at 96 hours and/or 8 days. Until now 15 consecutive patients referred for ^{111}Indium-DTPA-scintigraphy because of treatment failure had this extended procedure. Images were correlated with available radiographic examinations (like CT after intrathecal contrast administration and MRI) and clinical symptoms. **Results:** Though sometimes suffering from severe muscle spasms (because of delivery failure) all patients were able to complete the imaging procedure successfully. In 13 patients the cause of delivery failure could be demonstrated (hereby disapproving the assumption of tolerance for the intrathecal baclofen treatment). Discovered problems were (partial) catheter or spinal canal obstructions and CSF-leakage. Therapeutic interventions resulted in improvement of the symptoms in the majority of the patients. **Conclusion:** ^{111}Indium-DTPA-scintigraphy including SPECT-CT can be very helpful in the clarification of intrathecal baclofen delivery failures. This imaging technique can have a strong impact on the choice of treatment of these failures, thereby improving the quality of life of these patients enormously.

P157

The usefulness of salivary glands scintigraphy in the diagnostics of Sjögren's syndrome

D. BEN SELLEM, T. BEN GHACHEM, B. DHAOUADI, L. ZAABAR, B. LETAIEF, M. F. BEN SLIMENE; University of Tunis El Manar, Faculty of Medicine of Tunis, Salah Azaiez Institute, Department of Nuclear Medicine, Tunis, TUNISIA.

Aim: Sjogren's Syndrome (SS) is an autoimmune disease characterized by dryness of the mouth and eyes, defining the dry syndrome. SS can consequently be complicated by infections of the eyes, breathing passages, and mouth. The diagnostic confirmation is based on biopsy of the accessory salivary glands, and incidentally on the salivary glands scintigraphy that is not a routine test. The aim of this study was to demonstrate the contribution of salivary gland scintigraphy in SS suggested clinically without histological evidence. **Materials and methods:** This is a retrospective study of 167 patients (148 women, 19 men), collected over a period of 7 years. The average age was 47 ± 13.95 years (14 to 82). All these patients had a dry syndrome suggested clinically and were sent to our department for salivary glands scintigraphy. The protocol included dynamic acquisition contemporary to the injection of 74-111 MBq Technetium-99m Sodium Pertechnetate and up to 40 minutes. Activity-time curves were plotted after making regions of interest on the parotid and submandibular glands. **Results:** Salivary glands scintigraphy was positive in 137 cases (82 %). Involvement was bilateral in 98 cases (58.7 %). The hypofunctioning interested both parotid and submandibular glands in 95 cases (56.9 %), only the parotid glands in 55 cases (32.9 %) and only the submandibular glands in 17 cases (10.2 %). **Conclusion:** Salivary glands scintigraphy is a simple, physiological and non-invasive test that evaluates salivary gland function. It plays an important role in the diagnosis of SS, 82 % of our cases, especially when salivary biopsy is unrealizable or remains equivocal.

P158

Use of workplace based assessment tools in nuclear medicine

K. Makhdomi; Aga Khan University Hospital, Nairobi, Kenya, Nairobi, KENYA.

OBJECTIVES: To document the introduction of two workplace based assessment tools in Nuclear Medicine for a Radiology residency program, and to assess its impact and resident feedback. METHODS: Two workplace based assessment tools, the direct observation of procedural skills (Rad-DOPS) and Mini Image Interpretation exercise (Mini-IPX) were modified from those used by RCR, and implemented in the Nuclear Medicine Section during the rotation of Radiology residents. Each resident underwent one assessment each with these two tools during their monthly rotations in Nuclear Medicine. The feedback provided was documented, including the opinions of the residents regarding the process. The subsequent assessments of the residents were compared with their previous ones and evidence of any change in performance noted based on comments from previous assessments. A total of twelve residents were involved over a one year period. RESULTS: The results revealed general acceptance of these tools by the residents as part of their workplace based assessment. Objective evidence of improvement in performance was noted in ten of the twelve residents, based on the feedback from the serial assessments. CONCLUSION: The study documents the utility of the workplace based assessment tools in the formative assessment of residents in Nuclear Medicine, and also their acceptance by the residents.

P159

Scintigraphic assessment of the Indium 111-DTPA transit in patients with an intrathecal baclofen delivery system

A. SHER[1], M. DINOMAIS[2], F. FREMONDIERE[2], I. RICHARD[2], P. MENEI[3], O. COUTURIER[1], F. LACOEUILLE[1]; [1]Department of Nuclear Medicine, University of Angers, Angers, FRANCE, [2]Department of Physical Medicine and Rehabilitation, University of Angers, Angers, FRANCE, [3]Department of Neurosurgery, University of Angers, France, Angers, FRANCE.

Introduction: In case of increased spasticity in patients with intrathecal baclofen infusion system, a resistance to treatment, an intercurrent disease and a mechanical or non-mechanical device malfunction should be considered. The aim of this work was to study the interest of Indium 111-DTPA scintigraphy combined with SPECT/CT in case of suspected malfunctioning of the intrathecal baclofen delivery system. **Patients and Methods:** Seven scintigraphic examinations were performed in 6 patients (4 men and 2 women, age min 27 years, max 73 years). A median dose of 30 MBq (min18MBq, max 35MBq) of Indium 111-DTPA was injected into the pump reservoir without interrupting the delivery of baclofen. Static and SPECT/CT images were acquired at different times until 7 days after injection. **Results:** Three cases of catheter (n = 2) or pump (n = 1) malfunction, 2 cases of abnormal distribution in the cerebrospinal fluid and one normal appearance were observed in scintigraphy and confirmed by clinical follow-up and operating data. SPECT/CT helped localize and identify the cause of the dysfunction. The calculation of the theoretical arrival time of the radiotracer, which depends on the flow of baclofen, appeared necessary to adjust the acquisition times. **Conclusion:** Indium 111-DTPA scintigraphy combined with SPECT/CT could be usefull for the understanding and management of spasticity recurrences in patients with intrathecal baclofen pumps.

P160

Positioning for positron emission tomography/ computed tomography in public hospitals in Nigeria

A. T. Orunmuyi[1], Y. A. Onimode[1], K. S. Adedapo[2], I. A. Lawal[3], J. E. Ejeh[4], B. O. A. Osifo[5]; [1]Nuclear Medicine Centre and Radiation Oncology

Department, University College Hospital (UCH) and College of Medicine, Ibadan, Ibadan, NIGERIA, [2]Nuclear Medicine Centre and Chemical Pathology Department, University College Hospital (UCH) and College of Medicine, Ibadan, Ibadan, NIGERIA, [3]Radiopharmacy Unit, Nuclear Medicine Centre, University College Hospital (UCH) Ibadan, Ibadan, NIGERIA, [4]Medical Physics Unit, Nuclear Medicine Centre, University College Hospital (UCH) Ibadan, Ibadan, NIGERIA, [5]Nuclear Medicine Centre, University College Hospital (UCH) Ibadan, Ibadan, NIGERIA.

Background: The importance of positron emission tomography/computed tomography (PET/CT) in diagnosis and choice of cancer treatment strategy in Nigeria is unknown. Presently, medical tourism is the only source of PET/CT imaging in Nigeria. Since the establishment of Nigeria's first Nuclear Medicine centre in 2006, the centre has provided short-lived radionuclide scans and therapies daily to patients from all over the country. Developing a vision for PET/CT is critical to the introduction of a public PET/CT service in Nigeria. The aim is not to replace existing technical reports for developing countries. It is directed at establishing a formal reference for the Nuclear Medicine Institution in Nigeria with the objective to catalyse a framework for public PET/CT services in Nigeria. Materials and Methods: Primary data from Nigeria's first nuclear medicine centre was compared with country statistics from the International Agency for Research on Cancer (IARC). References were made to PET/CT experiences from South Africa and Egypt. The results are a descriptive epidemiology of cancers, nuclear medicine referrals, challenges and recommendations based on the experience of the authors towards a vision for PET/CT services in Nigeria. Conclusion: Gathering evidence for sustainable and cost-effective provision of public PET/CT services in Nigeria is a major contribution to the development of Nuclear Medicine in the country. Education and training of regulators, oncologists and other clinicians on new PET/CT tracers particularly more tumour specific and generator based Ga68-PSMA and Ga-68 DOTATATE/DOTATOC may be crucial to the initial realisation of the Nigeria PET/CT Vision. We welcome a private initiative to commission a cyclotron in Lagos, Nigeria as this will undoubtedly enhance the growth of Nuclear Medicine.

Green way

I. Marikova, L. Cerna, L. Baierova; Prague Medical Care Department s.r.o., Prague, CZECH REPUBLIC.

Structure: Presentation of common project of the Ministry of Defence of Czech Republic and Military University Hospital Prague. Nuclear medicine department is participating on this project. The project Geen way is determined primarily for soldiers, military veterans, police officers, firemen or people from areas endangered by war. Aim: The aim is to show the usage of nuclear medicine in military health service in conditions of closely specialized Medical department of Military Hospital. Material and methods: Presentation is based on case interpretations of typical patients integrated in project of „Green way". Results and conclusion: Relatively small and often discussed medical discipline as the nuclear medicine may be used in environment of military hospital. Multidisciplinar cooperation is possible in conditions of civil and military health service as well and everything is dependend of mutual cooperation of civil and military medical doctors.

P162
Assessment of thyroid uptake in dynamic salivary gland studies correlated with diagnostic ultrasound findings in patients with connective tissue diseases

A. Renda Alcalde, Jr., F. S. Zelaya Reinquet, Jr., D. M. Ruiz Hernández, M. A. Castrillón Sánchez, C. Castillo Berrio, F. J. Loira Bamio, L. M. Campos Villarino, J. M. Nogueiras Alonso, A. M. Lopez Lopez, R. Guitián Iglesias; EOXI-VIGO-Hospital Meixoeiro, VIGO, SPAIN.

Salivary gland scintigraphy(SGS) is useful to assess the uptake and excretion of radiotracer in the major salivary glands(MSG). It is widely used in the diagnosis of xerostomia. In the standard technique, the thyroid gland(TG) is included in FOV. AIM: To determine the value of thyroid uptake pattern as an additional contribution to SGS tests at our departament and correlating it with ultrasonographic(US)findings in patients with connective tissue diseases. MATERIAL AND METHODS: Retrospective review of 95SGS performed at our centre among a period of 14 months (January/2015-February/2016), in patients with connective tissue diseases, mainly Sjögren's Syndrome. All the SGS were performed in fasting patient, after administering 5-10mCi(185-370Mbq) of 99mTc-O4. Dynamic scintigraphy was performed within the first 20 minutes post injection. Lemon juice stimulation was delivered at 10 minutes and the study ended with projections of the anterior and lateral views. In all test the thyroid gland was included in the FOV. To interpret the tests, we assessing the salivary incorporation and secretion in dynamic phase, as well as overall uptake, in the planar images. In addition, we classified thyroid uptake according to the following patterns: P1-high-uptake, P2-low-uptake, P3-normal uptake, and correlating them with US findings. RESULTS: We reviewed a total of 95studies(95s), 89woman-6men; mean age 55, 78s(82%) with salivary gland malfunction. 52s(54.7%) revealed thyroid uptake alteration (TUA) and 43s(45.3%) normal uptake. Of the total, only 26s(27.4%) had additional cervical US. Subsequently, the studies were classified according to three thyroid uptake patterns: Pattern 1: 32s(33.7%), Pattern 2: 20s(45.3%) and Pattern 3: 43s(45.3%). P1-high uptake 32s, which 7 US: 4 nodules, 1 thyroiditis, 2 normal. P2-low uptake 20s, which 9 US: 4 nodules, 3 thyroiditis, 1 normal, 1absence because of surgery. P3-normal uptake 43s, which 10 US: 3 nodules, 5 normal, 1non assessable, 1 glandular atrophy. CONCLUSION: The assessment of thyroid gland visualized in SGS let us detecting unknow pathology. It is posible that we had over stimated the number of P1 in our sample which was of 32s(33.7%) mainly due to the significant amount of impair SGS 78s(82%). Althought our review has a small sample size, we observed a good correlation between altered thyroid uptake and US findings (81.25%).

P163
The role of the three phase bone scintigraphy in the evaluation of the patients with idiopatic carpal tunnel syndrome

M. Ceber[1], **E. Sahin**[2], B. Topcu[3], R. Alp[4]; [1]Namik Kemal University Hospital, Department of Plastic, Reconstructive and Aesthetic Surgery, Tekirdağ, TURKEY, [2]Namik Kemal University Hospital, Department of Nuclear Medicine, Tekirdağ, TURKEY, [3]Namik Kemal University Hospital, Department of Biostatistics, Tekirdağ, TURKEY, [4]Namik Kemal University Hospital, Department of Neurology, Tekirdağ, TURKEY.

Purpose/Introduction: Considering the anatomy of the carpal tunnel, the median nerve carries main sympathetic supply of the hand. Although sympathetic autonomic innervation of bones is an intriguing topic, its effects in the carpal bones in patients with carpal tunnel syndrome (CTS) is unknown. In this preliminary study, we aimed to investigate blood supply disorders and its effects in the wrist bones in patients with idiopathic CTS with the three-phase bone scintigraphy. **Subjects & methods:** A total of 90 hands (75 affected and 15 non-affected hands) in fourty-five patients (age range: 29-65 years old, gender: 15 male, 30 female) with idiopatic CTS were analysed in the study.To analyse the changes in blood supply to the bones of the wrist, three-phase bone scintigraphy with 99mTc-MDP was applied to patients before surgical

treatment. Perfusion,blood-pool,delayed images were evaluated quantitatively-qualitatively in three-phase bone scintigraphy. Bone scintigraphy values for non-affected hands were used as controls for comparison with affected hands. **Results:** In patients with unilateral CTS, it was observed in all phases of increased radiopharmaceutical uptake in three-phase bone scintigraphy in affected carpal bones regions. There were a statistical significance for delayed phase related areas when compared to the non-affected hand and affected hand quantitatively in patients with unilateral CTS (p=0,071). However, it was observed no significant difference in radiopharmaceutical uptake in all phases and there were not statistical significance for delayed phase related areas when compared to the each of two affected hand quantitatively (p=0,000), in patients with bilateral CTS. **Discussion/Conclusion:** We believe that three-phase bone scintigraphy is a useful technique for the demonstration of the evolving circulatory disorders and its effects in the wrist bones in patients with unilateral CTS.**Key words:** Carpal Tunnel Syndrome; Radionuclide Imaging; Median Nerve; Wrist

Radiosynoviorthesis in hemophilic arthropathy: Positive blood pool imaging on pretherapeutic bone scintigraphy is not a predictor of treatment success

A. Sabet[1], A. C. Strauss[2], J. Schmolders[2], R. Bornemann[2], A. Sabet[3], J. Oldenburg[2], P. H. Pennekamp[2], H. J. Biersack[2], S. Ezziddin[1]; [1]Saarland University, Homburg, GERMANY, [2]University of Bonn, Bonn, GERMANY, [3]University of California, Riverside, CA, UNITED STATES.

Purpose: Increased articular ^{99m}Tc-MDP uptake on blood pool imaging (BPI) of patients with rheumatologic conditions is indicative of active infilammatory changes and has been suggested as a strong predictor of response to radiosynoviorthesis (RSO). In this study we aimed to assess the value of pretreatment BPI positivity (i.e. scintigraphically apparent hyperaemia) for successful RSO in hemophilic arthropathy. **Methods:** 34 male patients with painful hemophilic arthropathy underwent RSO after failure of conservative treatment. Treated joints were comprised by the knee in 8, elbow in 5, and ankle in 21 patients. Pretreatment triple-phase bone scintigraphy showed hyperemic joints (positive BPI) in 17 patients, whereas 17 patients had no increased tracer uptake on BPI. Response to RSO was evaluated 6 months post-treatment measuring changes in intensity of arthralgia according to the visual analogue scale (VAS), bleeding frequency, and range of motion. The association of hyperemia (positive BPI) and treatment outcome was examined using nonparametric tests for independent samples. **Results:** Evident pain relief occurred in 26 patients (76.5 %) and the mean VAS decreased from 7.7 ±0.1 to 4.6 ±0.5 ($p<0.001$). The joint bleeding frequency (hemarthrosis) decreased from 4.5 ±0.6 to 2.1 ±0.4 during the first 6 months after RSO ($p<0.001$). According to both parameters (pain relief and bleeding frequency) patients benefited similarly from RSO regardless of pretreatment BPI: Arthralgia (p=0.312) and frequency of hemarthrosis (p=0.396). No significant improvement was observed for range of motion, but it was significantly more restrained in hyperemic joints both before (p=0.036) and after treatment (p=0.022). **Conclusions:** Hemophilic arthropathy can be effectively treated with RSO regardless of pretherapeutic BPI. Patients with no scintigraphically detectable articular hyperemia may have similar (outstanding) outcomes and should thus not be discarded from treatment.

P165

Hepatic HMDP tracer uptake on bone scintigraphy: report of two cases

A. Ezzine[1,2], R. Sfar[1], S. Melki[1,2], H. Boudriga[1], M. Nouira[1,2], M. Ben Fredj[1,2], K. Chatti[1], S. Ajmi[1], M. Guezguez[1]; [1]Nuclear medicine department, Sousse, TUNISIA., Sousse, TUNISIA, [2]LR 12Es02, Faculty of Medecine Sousse, University of Sousse, Sousse, TUNISIA.

Aim: Hepatic uptake of hydroxyl-methyl-diphosphonate labeled to 99mTc (^{99m}Tc-HMDP) is an accidental and unusual findings with multiple mechanisms. The purpose of this paper is to report two cases of abnormal hepatic accumulation and to discuss their pathophysiology.Materials and methods: We report the cases of two patients who were referred to our nuclear medicine department in order to search a bone infection site. The first patient was a newborn baby of 26 days old, who presented a limitation on the mobilization of the left hip evolving with fever. Laboratory tests showed elevated CRP and positive blood culture for Klebsiella. Ultrasound of the left hip was normal. The second case was a patient aged 16, suffering from a major beta thalassemia, hospitalized for red blood cell transfusion. Both patients underwent planar bone scan with acquisition of static tissue phase images followed by a whole body scan two hours after the injection of 10 MBq/kg of 99mTc-HMDP. Results: The initial bone scintigraphy did not find any suggestive sign of infectious bone location, but there was a diffuse hepatic uptake of ^{99m}Tc-HMDP despite a normal quality control of the preparation. Complementary exploration revealed a very high ferritin levels for both patients. For the first patient, a scintigraphic control after three months showed a normal bone scintigraphy with the normalization of the hepatic uptake correlated with a normal ferritin levels. For the second patient, a repeat bone scan performed three weeks later showed a better skeletal uptake with the persistence of an abnormal renal and hepatic radiotracer accumulation. It also showed the presence of bone uptake foci that can be related to infectious site. Conclusion: Knowledge of ^{99m}Tc-HMDP hepatic uptake mechanisms in bone scans, improves the interpretation of the examination. In this context, obtaining a relevant medical history can clarify incidental soft-tissue findings.

P166

Three phase bone scintigraphy in diagnosing stress fractures

M. Somai, I. Yeddes, I. Meddeb, K. Limam, A. Mhiri, I. Slim, M. F. Ben Slimene; institut Salah Azaiez, Tunis, TUNISIA.

Introduction : Stress fractures are an uncommon but important source of pain and disability in young. It is caused by sustained and submaximal physical activity. It is frequent among athlete. The diagnosis is suspected in case of a progressive onset of bone pain, that contrasts with the poverty of physical examination and radiographic signs. In such case, triple phase scintigraphy finds all its importance, it allows to detect metabolic changes few days after the begining of this symptoms. **Methods** This was a retrospective study of 27 patients who were suspected to have a stress fracture. Standard radiography was noncontributory. These patients were referred to the departement of nuclear medicine for a bone scintigraphy. This exam has included 3 phases: an angiographic phase , applied immediately after injection of 555 to 740mBq Hydroxy - Methylene Diphosphonates-Tc^{99m} (Tc^{99m} - HMDP) , a tissue phase after 5 minutes of injection and a bone phase, on average 2 hours after . During these three phases, the acquisitions of images were focused on the painful area, taking both right and left sides. The late time also included a full-body scan in search of other bone alterations. **Results** Among these 27 patients, 52% were females. The average age was 31 years [13-67]. They had all initially been seen because of a progressive onset of a mechanical bone pain of the lower limb that is unresponsive to analgesics. 9 patients were athletes.All the patients had benefited standard radiographs of the painful area that has not objectified any abnormalities. Two patients underwent magnetic resonance imaging (MRI), that has showed signs for stress fracture. The triple phase Bone scintigraphy confirmed the diagnosis of stress fracture in 13 cases. It has objectified signs of periostitis in 5 cases. Scintigraphy was negative in 6 cases and it was inconclusive in three cases. In one case MRI has showed stress fracture signs that were not identified in bone scintigraphy. These fractures interested the lower limb especially the tibia followed by metatarsal bones. **Conclusion** Because it demonstrates subtle changes in bone uptake before changes are seen on conventional radiographs and high cost of MRI, the triple phase bone

scintigraphy is the choice procedure to diagnosis stress fracture. This exam is highly recommended in order to achieve early diagnosis, especially that the improvement of instrumentation has enhanced very significantly its diagnostic performance.

P167

Quantitative surgical criteria of bone scintigraphy in patients during hip arthroplasty

P. Korol[1,2], M. Tkachenko[2], V. Bondar[1]; [1]Kiev's Clinical City Hospital #12, Kiev, UKRAINE, [2]A.A. Bohomolets National Medical University, Kiev, UKRAINE.

Aim. Define the quantitative surgical criteria using bone scintigraphy in patient with deforming osteoarthrosis during hip arthroplasty. Material and methods. Retrospective descriptive study (2005 - 2015): 468 patients with hip arthroplasty were imaged by a standard method of whole body bone scan. Intestinal uptake was observed visually 3 hours after the intravenous administration of 740 MBq 99mTc MDP. A whole body bone scan; anterior, posterior, oblique spot views of the hip joint region were obtained. Results. All patients were divided into three groups. The first group included 169 (36 %) patients who at bone scintigraphy the percentage accumulation of radiopharmaceuticals in the projection of the affected joint to 10% - 110%, and in the projection of the proximal femur 5% - 50%, relative to symmetric parts. The second group included 187 (40 %) patients whose accumulation rate indicator in the projection of the affected joint complex was 110% - 180%, and in the projection of the proximal femur 50% - 100%. The third group consisted of 112 (24 %) patients with accumulation indicator in the projection of the affected joint set of more than 180%, and in the projection of the proximal femur over 100%. In patients of first group on postoperative imaging in projection of the paraprosthetic area of joint percent accumulations of the indicator was equal 5 % - 65 %, in projections the proximal area of hip consisted 5 % - 20 %, to symmetrical area of the study. In patients second group - percent accumulations of the indicator in projections of the paraprosthetic area of joint was is 160 %- 250 %, in projection the proximal area of hip consisted 55 % - 120 %. In patients third group in projection of the paraprosthetic area of joint was is 215 % - 380 %, in projection the proximal area of hip consisted 90 % - 200 %. In 67 (22 %) patients two and three diagnostic groups were diagnosed with postoperative complications operated hip (inflammation, sprains). Conclusion. For avoiding the postoperative complications during hip arthroplasty, percent of the accumulation of the indicator on diagnostic imaging, in projections hip jount with osteoarthrosis, must be within 10 % - 110 %. The percent of the accumulation of the indicator in projections of proximal area of hip must be consisting 5 % - 50 %, to symmetrical area of the study.

P168

Basal glucose metabolism in skeletal muscles measured by FDG-PET as a non-activated muscular activity: preliminary result

I. Chun[1], H. Park[2], S. Baik[1], K. Ahn[2], D. Lee[2], J. Park[2]; [1]Kangwon National University, School of Medicine, Chuncheon-Si, KOREA, REPUBLIC OF, [2]Kangwon National University Hospital, Chuncheon-Si, KOREA, REPUBLIC OF.

Purpose/Introduction: ^{18}F-fluorodeoxyglucose (FDG) is an analogue of glucose which is one of important energy substrates for most cells including cancerous, inflammatory, neuronal cells, and so it has been widely used in positron emission tomography (PET) imaging for evaluation of oncologic, neurologic, and sometimes inflammatory diseases. Recently, it was reported FDG-PET could detect activated muscles which might be related with musculoskeletal diseases. However, it is not clear what degree of radioactivity within muscles on FDG-PET is closely related with activated muscles. Herein we tried to estimate glucose metabolism in the non-activated skeletal muscles by FDG-PET and to extract a threshold value of muscular glucose metabolism to distinguish activated muscles from non-activated ones. Subjects & Methods: Health screen-purpose FDG-PET images in seven healthy male subjects (age=37.42.3y, range=33-39y) were retrospectively reviewed. Each PET emission scan was obtained about 1 hour after intravenous injection of ^{18}F-FDG (370.618.3MBq) and then non-contrast CT scan was obtained for attenuation correction. A muscular volume of interest (VOI) was obtained by manual delineation of paraspinal back muscles on the non-contrast CT image and it was copied on FDG-PET image to extract mean (SUV_{mean}) and standard deviation (SUV_{sd}) of standardized uptake value. Normal distribution was assumed in all SUV data and the normal distribution of non-activated muscular SUV was obtained by applying kernel density estimation (KDE). Results: Averaged SUV of seven subjects were 0.756, 0.186, 1.128, and 1.313 for SUV_{mean}, SUV_{sd}, $SUV_{mean+2sd}$, $SUV_{mean+3sd}$, respectively. On the other hand, predicted SUVs were 0.747, 0.165, 1.077, 1.242, respectively after kernel density estimation. Discussion/Conclusion: SUV_{mean} of 1.242 is the threshold value that can distinguish basal muscular glucose metabolism from activated one for 99.6% significance. This result can be a used as a reference for evaluation of muscular function by FDG-PET in various musculoskeletal diseases.

P169

Evaluation of of the results of PTH, Vitamin D and Calcium in Osteoporosis

R. Alimanovic-Alagic[1,2], **R. Alimanovic-Alagic**[1]; [1]University Clinical Centre Sarajevo, sarajevo, BOSNIA AND HERZEGOVINA, [2]Clinic for Nuclear Medicine,University Clinical Center of Sarajevo, Sarajevo, BOSNIA AND HERZEGOVINA.

Objective(s): Osteoporosis is a serious, life-threatening disease in both men and women. Vitamin D deficiency can contribute to bone loss from decreased vitamin D-mediated intestinal calcium absorption and resultant secondary hyperparathyroidism (HPTH). The parathyroid glands control of calcium and phosphorus in the blood and they do this by making a hormone called parathyroid hormone (PTH). Material and Methods: As a part of the investigational project 873 participans were examined of the University Clinical Center of Sarajevo and Public Medical Care Institution, Canton Sarajevo, age 20 to 80 during 6 months. For each patient we did personal history, age, medications, BMI, family history. We established presence of vitamin D deficiency, calcium levels, high level PTH, DXA higher than -2.5 SD. Results: In investigated group of 873 patients. The frequency of occurrence of osteoporosis is most common 44% between the ages of 40-59 years. Elevated levels of PTH at 64% patients, the patients have a vitamin D deficiency 77% and low-normal calcium levels 69 %. Analysis of BMI obesity 52% as a potential factor for osteoporosis. Conclusion(s): Vitamin D deficiency is associated with increased parathyroid hormone (PTH) and also associated with low bone mineral density in patients who have diagnosed osteoporosis. Nutrition and BMI affect the metabolism and osteoporosis. Vitamin D and calcium supplementation reduces the risk of hip fractures and other peripheral fractures.

P170

Persistent muscular uptakes of rhabdomyolysis in ^{99m}Tc-HMDP scintigraphy after normalization of creatinine kinase levels

F. Hives, F. Demailly, F. Vandici, S. Hiroual, A. Besson, R. Hassad Ben Ticha, **G. Collet**; CH Valenciennes, Valenciennes, FRANCE.

AIM: Many causes can be suspected with a muscular uptake in bone scan. Rhabdomyolysis is a classic cause of muscular uptake in bone scan. Usually, creatinine kinase (CK) blood dosage and clinical examination are sufficient to confirm rhabdomyolysis. There is no evidence in literature of persistent muscular uptake in bone scan after normalization rate of CK. MATERIALS AND METHODS: A 85 year-old patient was admitted for rhabdomyolysis (CK: 25559 U/L, normal < 145 U/L) in a context of repeated falls. The rhabdomyolysis was complicated of acute kidney injury, hyponatremia and hypokalemia. Also, patient presented inflammatory syndrome, consequence of endocarditis and spondylodiscitis at staphylococcus aureus well treated by cefotaxime - ornidazole then clindamycin - levofloxacin. During hospitalization, CK level decreased, and was normal after nine days (CK: 70 U/L). We performed a ^{99m}Tc-HMDP scintigraphy to research signs of hip prosthesis infection, the same day as normalization of CK dosage. RESULTS: ^{99m}Tc-HMDP scintigraphy found muscles uptakes: right pectoralis major, gluteus maximus, sartorius, adductors, tibialis anterior, and bilateral sacred insertion of gluteus maximus. It found no pathologic uptake in contact with prosthesis. Laboratory tests days after bone scan showed no elevated CK levels. CONCLUSION: This case showed muscular uptake in bone scan and normal CK blood test level, because of a delay between normalize CK blood test level and disappearance of muscular uptake in bone scan. A negative CK blood test is not sufficient to eliminate a rhabdomyolysis as a cause of muscular uptake in bone scan. Clinical history is essential in the evaluation of muscular uptake.

P171

Value of ^{18}F-NaF PET/CT imaging in the assessment of Gorham-Stout disease activity

G. Z. Papadakis[1], C. Millo[2], U. Bagci[3], N. J. Patronas[1], M. T. Collins[4]; [1]Department of Radiology & Imaging Sciences, Clinical Center (CC), National Institutes of Health (NIH), Bethesda, MD, UNITED STATES, [2]Division of Nuclear Medicine, Clinical Center, National Institutes of Health (NIH), Bethesda, MD, UNITED STATES, [3]Center for Research in Computer Vision (CRCV), Electrical and Computer Science Department, University of Central Florida (UCF), Orlando, FL, UNITED STATES, [4]Craniofacial and Skeletal Diseases Branch, National Institutes of Dental and Craniofacial Research, Bethesda, MD, UNITED STATES.

AIM: To assess the application of ^{18}F-NaF PET/CT imaging in monitoring the activity of Gorham Stout disease (Vanishing Bone Disease). PATIENT AND METHODS: A 44 year-old male diagnosed with Gorham Stout disease underwent whole body PET/CT scan after intravenous administration of 3.29 mCi ^{18}F-NaF. PET acquisition commenced 65 minutes post injection, while a non-contrast low dose CT scan was performed for attenuation correction and co-registration. Maximum Standardized Uptake Values (SUVmax) were normalized to body weight and were obtained from Time-of-Flight (TOF) PET images. The patient had presented with worsening pain and movement limitation in the right shoulder joint, while CT and MRI scans of the chest revealed absence of the largest portion of the right scapular body with preservation only of the scapular spine. RESULTS: The remnant upper portion of the affected right scapula showed markedly increased ^{18}F-NaF uptake (SUVmax:27.3) compared to the corresponding portion of the unaffected left scapula. Furthermore, multiple foci of intensely increased ^{18}F-NaF activity were observed on the right posterior ribs, associated with areas of incipient bone resorption seen on CT scan. CONCLUSION: ^{18}F-NaF is a PET agent which is deposited on bone tissue via ^{18}F-ions exchange with hydroxyl (OH-)-ions on the surface of the hydroxyapatite matrix leading to formation of fluoroapatite. ^{18}F-NaF bone uptake and retention reflects osseous blood flow and bone remodeling. At the same time, Gorham-Stout disease is characterized by proliferation of endothelial-lined vessels in bone, and by progressive replacement of bone with fibrous tissue. These underlying processes which are present in Gorham Stout disease result in increasing the bone surface exposed to blood flow providing high availability of binding sites for ^{18}F-NaF. This data suggests ^{18}F-NaF as the optimal bone-seeking PET-radiopharmaceutical to assess Gorham Stout Disease activity as well as monitor treatment response.

P-15 – Monday, October 17, 2016, 16:00 - 16:30, Poster Exhibition Hall
Conventional & Specialised Nuclear Medicine: Paediatrics

Detecting More Reliable Time Period for the Calculation of Relative Renal Function in Assessing Response to Pyeloplasty in Children with Hydronephrosis

N. C. M. Gulaldi, N. Altun Yologlu, S. Ozyurt; Department of Nuclear Medicine, Dr. Sami Ulus Maternity and Children's Health and Diseases Training and Research Hospital, ANKARA, TURKEY.

Aim: The aim of the study is to evaluate 60-90 seconds period or 90-120 seconds period compared to 60-120 seconds period using 99mTc-MAG3 for the calculation of relative renal function for assessment of better prediction of surgery effect in hydronephrotic kidneys in pediatric patients. As a hypothesis, if one time period would better delineate relative kidney function correlated with other parameters such as residual activity and size of the pelvis, these could be used as to avoid any early collecting system activity within the ROIs. Methods: Twenty children (8 female, 12 male) (1 month-17 years of age mean=50±15,3 months) diagnosed as unilateral hydronephrosis because of narrowing in uretheropelvic junction level were included into the study. Dynamic renal scintigraphies using 99mTc-MAG3 were done before and after open pyeloplasty to all patients. Post-operative MAG3 scans were performed 292,7±39,7 days after pyeloplasty. Relative renal functions were calculated from the frames summed between 60-120 seconds, 60-90 seconds and 90-120 seconds images to evaluate any difference or comparative advantage between them. Background corrected ROIs drawn over kidneys were used and counts/pixel values within those ROIs were noted for each period. Results: Paired t-tests were used to compare results of counts/pixel values between the time periods. A p-value <0.05 was considered statistically significant for the difference. Relative kidney functions did not differ statistically (p>0,05) with regard to ROIs drawn for different time periods between 1-2 minutes. Pre-op and post-op relative kidney functions were in accordance with size of the kidneys and overall kidney functions in 17 patients. Three patients showed deteriorating relative function in spite of better diuretic response after pyeloplasty. However those patients also did not show statistically significant difference in correlation calculated for 3 time periods (p>0,05). Conclusions: Hydronephrosis in children requires 99mTc-MAG3 to be used for the scintigraphy in detecting kidney functions. However rapid excretion of the tracer may sometimes be cumbersome for the interpretation of the studies. In this study we showed that several time periods could be used before 2 minutes of the study to calculate relative renal function and this chosen period should be the same for the calculation in serial studies. We suggest using relative kidney function with the excretion parameters of the kidneys when deciding the operation or detecting the effect of surgical procedure.

P173

Interest of the renal dynamic scintigraphy with MAG3 in exploration of infant hydronephrosis About 70 cases

S. Touil, H. Aschawa, Y. Shimi, F. M'hamdi, H. Bendaoud, J. Benouhoud, A. Guensi; Faculty of Medicine and Pharmacy, Nuclear medicine service, Ibn Rochd University Hospital Center, Casablanca, MOROCCO.

Renal scintigraphy using 99mTc-MAG3 with diuresis has an important role in the exploration of hydronephrosis in infants. This non-invasive and low-radiating exploration allows both to specify the quality of drainage and the separate evaluating renal function. We report, through this work, a retrospective descriptive study including 70 patients referred for scintigraphic exploration of their hydronephrosis or uretero-hydronephrosis between January 2012 and March 2014. The renal dynamic scintigraphy using 99mTc-MAG3 (RDS) and diuresis test of furosemide F + 20 protocol was performed in all patients, supplemented by static acquisitions post-micturition and verticalisation. The interpretation takes into account the semi-quantitative and qualitative parameters of isotopic renogram obtained after treatment of dynamic sequential images. Of the 70 cases studied (11 F/59 M), the mean age was 5.44 months, with a range of 2-24 months. Data from the scintigraphic exploration with 99mTc-MAG3 allowed to classify our patients into three groups. Group I: absence of drainage alteration, with preserved function (group Ia) in (30%) and without preserved function (group Ib) in (4.3%) of patients. Group II: presence of altered drainage, with functional conservation (group IIa) in (38.6%) and without functional conservation (group IIb) in (11.4%) patients. Group III: represented by an equivocal response (comprising 15.7% of cases). Renal dynamic scintigraphy with MAG3 (radiotracer of choice, particularly in neonates and infants) and furosemide test F + 20 (protocol allowing sufficient diuresis) has, through this study, judged the quality of permeability ureteropelvic and specifying the relative contribution of each kidney in global function. Such information remains crucial to guide the surgeon to choose between a surgical or endoscopic therapy or no treatment and close monitoring well codified. Currently, it is recognized that any restriction on urinary excretion, which untreated, cause renal injury and that surgery should only be considered if the function is altered. So, this exploration occupies a specific place in the care decision in the hydronephrosis infant.

P174

Agreement Between Renal Lenght Measurements by Planar DMSA Scintigraphy and Ultrasonography

V. Marković, A. Barić, V. Čapkun, A. Punda, D. Eterović, A. Pranić-Kragić, A. Marović, A. Arapović; University Hospital Split, Split, CROATIA.

AIM: Renal lenght measurements (RLM) are considered as a surrogate measure for kidney function. Measurement by ultrasonography (US) is accepted as a standard procedure in nephrourological practice, while the role of planar Tc-99m-DMSA scintigraphy is underestimated and neglected. The purpose of this study is to compare RLM by these two methods and to examine if there is agreement between them? MATERIAL AND METHODS: This was a retrospective study of 43 patients (83 kidneys), 25 females and 18 males with a median age of 3,67 years (range: 3 months to 51 years) with various nephrourological pathologies, and who had RLM by both methods. Agreement between RLM by US and posterior DMSA scintigraphy were evaluated by Pearson's correlation, Wilcoxon test and Bland-Altman Plot analysis. RESULTS: Median value of right kidney lenght measurements (KLM) by US was 75 mm (min-max:43-124 mm) and by DMSA scintigraphy 75 mm (43-128 mm) ($z=0.747$; $p=0.455$). Pearson correlation coefficient $r= 0.922$ ($p<0.001$). Median value of left KLM by US was 84 mm (45-124 mm) and by DMSA scintigraphy 79 mm (47-142 mm) ($z=0.023$; $p=0.455$). Pearson correlation coefficient $r= 0.907$ ($p<0.001$). Average value of differences between measurements by these two methods for right kidneys lenghts was 0,983 ±15 mm with 95% limit of agreement from -15 to17 mm. Average value of differences between measurements by these two methods for left kidneys lenghts was 1.41 ±10.3 mm with 95% limit of agreement from -21.6 to19 mm. Differences of measurements were tested by one sample t-test with test value zero for the average bias. We did not find average bias neither for right kidneys ($t=0,971$; $p=0,337$) nor for left kidneys ($t=0,689$; $p=0,945$). We also made linear regression analysis where the independent variable was average and dependent variable was differences of measurements for each kidney separately by these two methods (proportional bias). We didn't find proportional bias niether for right kidneys ($p=0,966$) nor for left kidneys ($p=0,476$). After this results we put all measurements for right and left kidneys together and made same analysis. Average value of differences between measurements by these two methods for left and right kidney lenghts together was 0,756±9.26 mm with 95% limit of agreement from -18 to18.2 mm. There was not average bias ($p=0,941$) and proportional bias ($p=0,573$). CONCLUSION: RLM on posterior planar scintigraphy with Tc-99m-DMSA are in agreement with ultrasound measurements and we recommend it to be a routine procedure.

P175

^{99m}Tc-DMSA scan in assessing acute pyelonephritis

S. E. Bouyoucef, M. Habbeche, s. Rahabi, A. Khelifa, D. mouas, I. Kellou; CHU Bab El Oued, Algiers, ALGERIA.

Introduction Acute pyelonephritis (AP) is a potentially organ- and/or life-threatening infection that often leads to renal scarring. The diagnosis is based on clinical symptoms including fever and biological findings of bacteriuria (>100 000 bacterias/ml). ^{99m}Tc-DMSA scan has a good negative predictive of value in case of febrile urinary tract infection Objective Assessing the role of ^{99m}Tc-DMSA scan in acute pyelonephritis in children and defining the clinical, biological and morphological predictif factors for a positif ^{99m}Tc-DMSA Patients and methods : 192 children aged from 1 year to 16 years have been referred to the department for suspicion of AP after one or more episode of febrile urinary tract infection. All children presented fever above 38° and bacteriuria (>100 000 bacterias/ml). Those children with obstructive uropathy were excluded. Each child underwent two ^{99m}Tc-DMSA scan, the first within the 10 days following the onset acute episode of urinary tract infection and the second 6 months later. Both ^{99m}Tc-DMSA scan were reported by two experienced nuclear physicians and compared to the findings of ultrasonography, urethrocystoscopy and complete biological inflammatory tests. Results: 110 girls and 82 boys have had urinary tract infection with a causal agent of E. Coli (94.79%). Abdominal US were normal. Initial ^{99m}Tc-DMSA scans were positive in 102 patients (53.13%). 6 months after, the second ^{99m}Tc-DMSA scans showed a persistence of cortical DMSA abnormalities in 45 children (45/102). Those cortical abnormalities were reported as kidney scar post pyelonephritis. Among those children with a scar, 21 have had VUR identified by urethrocystoscopy. 57 patients among the 102 with a positive first ^{99m}Tc-DMSA scan have had a negative second ^{99m}Tc-DMSA scan 6 months later with only 11 VUR seen on urethrocystoscopy. After statistical analysis, VUR was found as a strong predictive value for renal scar ($p=0.004$) meanwhile the female sex is at the limit value of predicting kidney scar ($P=0.06$). The age, the temperature, and inflammatory factors and even the grade of VUR were not predictive for kidney scars ($P=0.05$). Conclusion: The VUR was present in more than 25% patients with febrile urinary tract infection. The VUR has a good predictive value for kidney scars meanwhile age, temperature, and biological inflammatory parameters and even the grade of VUR were not predictive for kidney scars ($P=0.05$). ^{99m}Tc-DMSA scan was very useful for better management of the AP and permitted a targeting the populations of children who have highest risk of developing kidney post infection complications.

Accuracy of 18F-FDG PET/CT versus bone marrow biopsy in assessing bone marrow involvement in paediatric Hodgkin's Lymphoma. Accuracy in a multicenter series of 156 patients

a. cistaro[1], l. cassalia[2], c. ferrara[3], m. bianchi[4], f. fagioli[4], g. bisi[4], m. pillon[5], a. zanella[6], p. zucchetta[6], m. burei[7], l. evangelista[7], c. ferrari[8], C. Altini[9], T.

Perillo[9], n. quartuccio[10]; [1]centro PET IRMET, torino, ITALY, [2]università di messina, messina, ITALY, [3]ospedale Umberto I, siracusa, ITALY, [4]università di torino, torino, ITALY, [5]ocoematologia pediatrica A.O.Padova, padova, ITALY, [6]università di padova, padova, ITALY, [7]IOV, padova, ITALY, [8]università di bari, bari, ITALY, [9]Università di Bari, Bari, ITALY, [10]università di manchester, manchester, UNITED KINGDOM.

Objectives. To assess the utility of F-18-fluoro-2-deoxy-D-glucose (18F-FDG) positron emission tomography/computed tomography (PET/CT) in assessing bone marrow involvement (BMI) compared to bone marrow biopsy (BMB) in newly diagnosed pediatric Hodgkin's lymphoma (HL). **Materials and Methods.** 171 pediatric patients (range 5-18 years) with HL were retrieved from the hospital database of 6 different nuclear medicine departments. The patients were referred for completion of staging and evaluation of bone marrow involvement and underwent a baseline 18F-FDG PET/CT. The diagnostic distribution for stage disease at the time of the PET/CT exam was: stage I = 9 pts; stage II = 77 pts; stage III = 47 pts; stage IV = 38 pts. 18F-FDG PET/CT scans were performed in all the patients within 10 days from BMB, performed in the iliac crest. **Results.** Out of 171 cases, 8 patients had positive BMB. Among these 8 pts, 6 had evidence of lymphomatous involvement on PET/CT , one showed a pattern of diffuse and disomogeneous 18F-FDG distribution and the other one resulted PET/CT negative. In 131 of the remainder 163 patients presenting with negative BMB, PET/CT resulted negative (80.3%) , positive in 19 patients (11.7%) (stage II=1, stage III= 2, stage IV= 16) and doubtful in 13 cases (8%) disomogeneus 18F-FDG distribution (stage II= 6, stage III= 6, stage IV=1). In 16/19 patients with positive PET/CT and negative BMB bone marrow involvement was confirmed by MRI, bone scan or CT images. The remaining 3 pts (stage III=1, stage IV=2) resulted to be false negative at BMB and true positive at PET/CT. The doubtful 18F-FDG PET/CT cases (uptake with diffuse and heterogeneous pattern of distribution) could be considered as functional bone marrow activation or as expression of bone marrow involvement. In our experience, if we had considered this FDG PET pattern as negative, the overall sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of 18F-FDG PET/CT for BMI detection would have been, respectively, 91.6%, 98.6%, 76%, 98.6%. On the contrary, considering the imaging pattern as positive, the overall sensitivity, specificity, PPV and NPV would have changed in 95.8%, 89.1%, 58.9%, 99.2%, respectively. **Conclusions** 18F-FDG PET/CT shows a good agreement with BMB results in early and advanced stages disease. Further data are warranted to confirm whether BMB should be omitted in patients with negative or positive PET/CT scan and reserved exclusively for patients with doubtful 18F-FDG uptake in bone marrow.

P177

18FDG PET-CT in the diagnosis of GIT Graft versus Host Disease (GvHD) in Children

M. Seng, **N. Kisiel**, E. Turner, K. London, P. Shaw, T. O´Loughlan, R. Howman-Giles; The Childrens Hospital at Westmead, Sydney, AUSTRALIA.

Background: Gastrointestinal tract graft-versus-host disease (GIT-GvHD) is a common and potentially life threatening complication after allogenic hematopoietic stem-cell transplantation. GIT-GvHD has been related to poor response to treatment and higher mortality. The diagnosis maybe difficult and may require endoscopy/biopsy. These procedures are invasive and morbid in patients who are already medically compromised. ^{18}F-FDG PET/CT may be able to stratify patients who require endoscopy and biopsy. **Aims:** To evaluate the performance of ^{18}F-FDG PET/CT in differentiating no or mild disease compared to moderate or severe disease in pediatric patients with suspected GIT-GvHD. **Methods:** Paediatric patients referred for ^{18}F-FDG PET/CT with suspected GIT-GvHD were reviewed. Clinical follow-up, endoscopy and biopsy findings were correlated with ^{18}F-FDG PET/CT. Regional SUV parameters were extracted by placing ROIs around stomach, duodenum, distal ileum, caecum, ascending colon, transverse colon, descending colon, recto-sigmoid colon and rectum. Regional, and average large and small bowel SUV data were statistically compared between patients with no or mild GIT-GvHD versus moderate to severe disease. **Results:** 47 scans in 35 patients were analysed (age range 6months to 18years; 36 with no or mild GvHD and 11 with moderate to severe disease). Transverse colon SUVmax was significantly higher in the moderate to severe group compared to no or mild disease (Mann-Whitney-U $p<0.05$). There was a non-significant trend for average large bowel SUVmax to be higher in the moderate to severe group than the no or mild disease group (mean SUVmax 2.83 compared to 2.03, $p=0.07$). **Conclusion:** Large bowel ^{18}F-FDG PET/CT may be higher in patients with moderate to severe GIT-GvHD, and transverse colon SUVmax could have the ability to differentiate children with no or mild GvHD from those with moderate to severe disease and allow triaging of patients who would be more likely to benefit from more proceeding to more invasive endoscopy and biopsy.

P178

F^{18} FDG PET/CT Pitfalls and Artifacts in Paediatric Malignancies

A. A. Nawwar, M. Abu Gabal, A. Tawakol, H. Moustafa; Faculty of medicine, Cairo University, Cairo, EGYPT.

Paediatric malignancies have been on the rise over the last decade and early detection and accurate follow-up is key for better prognosis. F18-FDG PET/CT used requires consideration of particular challenges that are common to paediatrics but uncommon to adults, such as cooperation, fasting, intravenous access and sedation. Also, normal distribution of F18-FDG in "children" differs than adults'. Aim: Determine the prevalence, location and appearance of the non-tumoural F18-FDG focal uptakes (potential pitfalls) and various artifacts in pediatric malignancies. Methods: Over 2 years, 253pediatric patients of both genders and various primary malignancies underwent F18-FDG PET/CT at CCHE using the standardized protocol for the hospital. Scans were prospectively reviewed by 2nuclear medicine physicians. Detailed clinical history was obtained. Visual and quantitative image analyses were done. Pitfalls and artifacts were characterized into physiological uptakes, technical artifacts, benign lesions and therapy-related artifacts. Results: When the patients were examined on lesion-based analysis, 1098 pitfall and artifact sites were encountered. Physiological uptake was the highest (75.9%) followed by technical artifacts (15.8%), benign lesions (3.1%) and finally, therapy-related artifacts (5.3%). The commonest site of physiological uptake was the head and neck (279 sites); the nasopharynx (29%) with mean SUV max of 6.4 ± 1.1. It was noted in our study that uptake in brown adipose tissue was significantly higher in the >5 age group (P=0.01) which opposes to Park et al's results that state that BAT detection rate was higher with younger age (7.94% vs. 0.73%). Respiratory movement was the commonest technical artifact (24.2%). Bone marrow and splenic hyperplasia were the commonest therapy-related pitfall (61.2%), average SUV max of 1.4 ± 0.6. Benign lymph nodal uptake was found in 36.7% with mean SUV max 1.9 ± 0.5, representing the commonest benign lesion encountered. Conclusion: The prevalence of pitfalls and artifacts in pediatric PET/CT are high, mainly attributed to various physiological uptakes followed by misregistration, mainly due to failure of patients of such age group to hold their breath (respiratory motion). Many of the normal variants in children are similar to adults' but nevertheless unique, such as uptake in lymphatic tissue. It is vital to know the incidence of such pitfalls and artifacts, in order to avoid misinterpretation; for better prognosis. Therefore, correlation with clinical history is crucial alongside experienced nuclear medicine physicians. The CT component also provides vital information; localization and accuracy. Also, relaxed, child-oriented environment, and staff experienced in paediatric venipuncture and management are important.

P179

Correlation Between the Number of Acute Pyelonephritis Episodes and the Presence and Severity of Renal Scarring, Evaluated by ^{99m}Tc-DMSA Scintigraphy

J. RODRIGUEZ ALBAN; CHUC, Coimbra, PORTUGAL.

Aim: To evaluate the correlation between the number of acute pyelonephritis (APN) episodes and the presence and severity of renal scarring, evaluated by renal scintigraphy with dimercapto-succinic acid labelled with ^{99m}Tc (^{99m}Tc-DMSA). **Material and Methods:** We reviewed the clinical charts of 950 children with history of APN, submitted to renal ^{99m}T-DMSA scintigraphy in our department, between September-1995 and July-2014. The minimum interval between the APN and the scintigraphy was, at least, 6 months. We selected only the cases with positive uroculture and with a recent ultrasound study. Then, we created 2 groups concerning the number of APN episodes (Group-1: 1; Group-2: >1). The renal scans were divided into 3 groups according to the number of scars ($DMSA_0$:0; $DMSA_1$:1; $DMSA_2$:2, $DMSA_3$: ≥3) and into 2 groups according to the absence/presence of functional impairment, considering an asymmetry of 20% or more in the differential renal function (DRF) (Group-A:<20% ; Group-B: ≥20%). Cases with doubtful results on the scintigraphy were excluded. **Results:** We selected 135 studies [59 boys (43.7%) and 76 girl (56.3%); age: 2.8±3.6], 99 from Group-1 (73.3%) and 36 from Group-2 (26.7%). Concerning the scintigraphy, 77 did not show any abnormality ($DMSA_0$) and 58 revealed scars ($DMSA_1$: 26; $DMSA_2$: 20; $DMSA_3$: 12). A hundred and sixteen cases (86%) had an asymmetry of DRF<20% (Group-A) and in 19 (14%) the asymmetry was ≥20% (Group B). We found a strong statistical correlation between the number of APN episodes and the number of scars (p=0.000) and functional impairment (p=0.000). In Group-1, 27 (27.3%) patients had at least 1 scar and 7 (7%) had already a significant function loss. Among the 58 children with renal scar, only 17 (23.9%) showed ultrasonographic changes consistent with scars. *Escherichia Coli was t*he pathogenic agent isolated in the majority of the cases. **Conclusions:** Our results point towards a positive correlation between the number of APN episodes and the presence and severity of renal scarring. Children with one APN episode are less likely to develop renal scars than children with more episodes. Our study also confirms the low sensitivity of renal ultrasound in scar detection, with a sensitivity of only 29.3%.

P180

Congenital Ureteropelvic Junction Obstruction: which renographic parameter is used by the surgeon for deciding about surgery?

A. I. Santos[1,2], M. Bernardo[1,3], P. Calhau[1,3], G. Costa[4], G. Mimoso[4], A. Vaz-Silva[5], M. Knoblich[5], I. Conde[6], I. Vieira[1], M. T. Neto[5,2], A. Piepsz[7]; [1]Hospital Garcia de Orta, E.P.E., Almada, PORTUGAL, [2]Nova Medical School - Faculdade de Ciências Médicas de Lisboa, Lisboa, PORTUGAL, [3]Faculdade de Medicina de Lisboa, Lisboa, PORTUGAL, [4]Centro Hospitalar e Universitário de Coimbra, E.P.E., Coimbra, PORTUGAL, [5]Hospital Dona Estefânia - Centro Hospitalar Lisboa Central, E.P.E., Lisboa, PORTUGAL, [6]Quadrantes - Grupo Joaquim Chaves, Miraflores, PORTUGAL, [7]CHU St Pierre – Université Libre de Bruxelles, Bruxelles, BELGIUM.

Aim: In congenital hydronephrosis it is not consensual which renographic parameters influence more the clinicians for their surgical decision. The present study aims to evaluate the differences on renogram parameters between two groups of children, one operated immediately after a first renogram and another with two or more renograms performed before surgery. Population and methods: Retrospective analysis of a series of 38 children with unilateral congenital hydronephrosis submitted to pyeloplasty, 21 immediately after a first diuretic renogram (median age and interquartile range - 1.6[1.3;5.6]months) [Group 1] and 17 after a follow-up period in which 2 to 4 diuretic renograms were performed (median age and interquartile range - 2.6[1.9;5.6]months) [Group 2]. There was one horseshoe kidney on each group and there were no children with single kidneys. For the kidney with pyeloureteral obstruction, differential renal function (DRF) and normalized residual activity at post-micturition image (NORAPM) on the first performed renogram were compared between the two groups, using T-Student test for DRF and the Mann-Whitney Test for NORAPM. For the 17 children on Group 2, these same parameters were compared between the first and the last pre-operative renogram, using the Sign Test for DRF and the paired Samples t-Test for NORAPM. The presence of visually determined delayed cortical transit (CT) of the radiopharmaceutical was also analysed in the same groups. Results: No statistical significant difference was found for the initial DRF between the two groups (p= 0.16). There was a statistical significant difference for initial NORAPM between these same groups (p<0.001). For Group 2, considering the comparison between the first and the last pre-operative renogram, there were no statistical significant differences for none of these parameters (p=0.21 for DRF, and p=0.16 for NORAPM). The initial CT was delayed in the majority of children in both groups (17/21 operated after the first exam, and 11/17 scheduled for follow-up). Five of the children in Group 2, which had initial normal CT, presented delayed CT on the last pre-operative study. Conclusion: In this study, compromised kidney drainage seems to have been the most influential parameter for our clinicians to decide to perform the surgical procedure.

P181

Can the new renal imaging agent L -ethylenedicysteine replace MAG 3 in children dynamic scintigraphy?

M. C. Fornito, S. Russo, A. Ruggeri, D. Familiari, R. A. Balzano; Nuclear Medicine Department - ARNAS GARIBALDI, Catania, ITALY.

AIM: Search for the ideal radiopharmaceutical to measure ERPF is still underwaying. 99mTc-mercaptoacetyltriglycine (MAG3), the agent of choice, is not the perfect replacement for 131I-Orthoiodohippurate (OIH). 99mTc-ethylene dicysteine (EC), a metabolite of ethylene cysteine dimer (ECD), is a new technetium-labelled renal tubular function tracer alternative to OIH, with imaging qualities similar to 99mTc-MAG3. Preclinical and clinical studies in adult volunteers and patient showed that 99mTc-EC is a good tubular agent as well as 99m-TcMAG3. Only few studies with 99mTc-ED have been done in the paediatric population and all have used it as cortical agent for static scintigraphy. The aim of this study is to demonstrate the potential usefulness of ^{99m}Tc- EC in paediatriac dynamic renal scintigraphy. **MATERIALS AND METHODS** 55 children (ranging 0.2-5 years) with various kidney disorders underwent conventional dynamic scintigraphy after intravenous injection of 99mTc-EC (EAMN paediatric guidelines). The most frequent disorders were ipo-displasya, pyelo-ureteral stenosis, megaureter, vescico-ureteral reflux, and obstructive nephropathy.Furosemide was administrated in case of excretory disorders. No adverse effects were noted. Quality control (radiochemical purity and stability) was performed immediately at the preparation and after 2, 3,4 and 5 hours. **RESULT** ^{99m}Tc-EC provided high-quality images similar to ^{99m}Tc-MAG3, even in newborns (2 or 3 months), with a low/negligible extra-renal clearance and high kidney-to-background ratio similar to DMSA. These properties allow good delineation of the kidneys and the detection of renal parenchymal lesions.. The lower liver and intestinal activity respect to 99mTc-MAG3, makes 99mTc-EC particularly attractive because the possibility of a clear delineation of right kidney from liver can affect the interpretation of the study, particularly in newborn babies. Tc-99m EC shows a good renal uptake in the smallest babies (8/12 weeks) comparable to that of the older children as well as the renogram shape and the diuretic time of response. These favorable characteristics depend on the significantly lower plasma protein-bound fraction (30%) and the lowest red blood cell binding (5.7%) The labelling procedure is easy, radiochemical purity is high (99.8%) and the complex is stable in the quality controls up to 5 hours or more. **CONCLUSION** Our experience showed that ^{99m}Tc-EC

has excellent imaging characteristics similar to ^{99m}Tc-MAG3 and excretion properties similar to OIH. Despite its use is not currently recommended in leaflet for children dynamic studies, our experience showed the radiopharmaceutical safety and that it can be used routinely to evaluate paediatric patients, particularly newborns, for the easier interpretation of the renogram.

P182

The levels of serum 25 Hydroxy vitamin D in pediatric patients with Bronchial Asthma

A. S. ZISSIMOPOULOS[1], A. Tsalkidis[2], E. Maziotis[3], E. Parashakis[2], O. Zissimopoulou[1], D. Benti[3], A. Pistola[1], C. Christofis[4]; [1]Nuclear Medicine Dept Democritus University of Thrace, Alexandroupolis, GREECE, [2]Pediatrics Clinic Democritus University of Thrace, Alexandroupolis, GREECE, [3]Molecular Biology and Genetics School Democritus University of Thrace, Alexandroupolis, GREECE, [4]Department of Anaesthesiology Democritus University of Thrace, Alexandroupolis, GREECE.

Introduction: Bronchial asthma is a serious childhood disease which can cause discomfort in young patients and may have severe effects in their later life. The control of the aggravating factors of bronchial asthma may lead to the discovery of better treatments that will relief the young patients. Aim: The aim of this study is to evaluate the serum levels of 25 hydroxy- vitamin D [25(OH)D] of children patients and to correlate them with the severity of the disease's symptoms, in order to modify the pharmaceutical treatment which will improve the patient's condition. Patients and method: 85 pediatric patients (44 boys and 41 girls) was studied aged between 3 and 13 years old (median age of 8±3 years old). The most of them (62) were patients of the University Pediatrics Clinic of the University Hospital of Evros and the rest were patients of other pediatricians. All of the children had bronchial asthma because of different reasoning (mostly due to allergic reasoning and other lung diseases).In all children blood samples were taken and after centrifugation the serum was collected and kept refrigerated at -70 ° C. The vitamin D status was measured by radioimmunoassay (RIA) method with I^{125}[25(OH)D] kits Diasorin at in- vitro laboratory of Nuclear Medicine Dept. University Hospital of Evros, Democritus University of Thrace. Statistical analysis: Statistical analysis was performed by the x^2- test (student test) and statistical significance was considered to be $p < 0.005$. Results: In 52 patients with severe symptoms of the disease, the levels of [25(OH)D] were significantly low 0-20 ng/mL (0-50 nmol/L), in 21 patients with mild symptoms of the disease the levels were 20-40 ng/mL (50-100 nmol/L) (hypovitaminosis) and the rest with no symptoms, had levels of [25(OH)D] > 40 ng/mL (>100 nmol/L) Conclusions: According to our results it is concluded that a statistically significant number of children who have vitamin D deficiency show severe symptoms of asthma($p < 0.005$). Pediatric patients with mild asthma have hypovitaminosis ($p < 0.005$). While pediatric patients with adequate vitamin D levels had no symptoms. The levels of serum vitamin D is statistically significantly associated with the severity of the symptoms of asthma. It is possible to administer vitamin D supplements in pediatric patients with bronchial asthma in order to cause a reduction in the severity of disease symptoms. Clinical trials with vitamin D supplementation are needed.

P183

A Single Center's 5 Year Experience Regarding Relative Renal Function in Children, 99mTc DTPA versus 99mTc DMSA

I. C. Grierosu, Sr.[1,2], M. Starcea[3,2], M. Munteanu[3], R. Russu[3], I. Pasarica[2], A. Statescu[1], M. M. Gutu[1,2], C. Stefanescu[1,2]; [1]Emergency Clinical Hospital Sf. Spiridon, Iasi, ROMANIA, [2]Faculty of Medicine, UMF Gr. T. Popa, Iasi, ROMANIA, [3]Emergency Children Clinical Hospital Sf. Maria, Iasi, ROMANIA.

Aim: The study was realized in the single Nuclear Medicine Department, who deserves the entire North-East region of Romania. Materials and methods: This is a retrospective study on five years period of time (2011-2015), with 69 cases of congenital hydronephrosis who undergoes both scintigraphic methods: 99mTc DTPA and 99mTc DMSA. We took into the consideration only 46 cases for which there was one day difference between the two methods. 99mTc DTPA dynamic scintigraphy with diuretic administration was performed to determine the type of obstruction and to calculate the relative renal function (RRF). 99mTc DMSA static scintigraphy was realized in cases with history of urinary infection to localize the scars and to measure the RRF. Results: Related to the age we classified them in: group A (under 3 years old) = 17 cases (36.96 %) and B (3-16 years) = 29 cases. The main diagnostics were: congenital ureteropelvic junction obstruction, vesicoureteral reflux, megaureter uni- or bilaterally and renoureteral duplication. In relation with the severity of the disease, meaning degree of hydronephrosis (HN) and degree of vesicoureteral reflux (VUR) we found: group 1 (HN and VUR < IV) = 26 cases (56.52 %) and group 2 (HN and VUR > IV) = 20 cases. The RRF for left kidney with 99mTc DTPA was compared with the same kidney with 99mTc DMSA using Pearson correlation factor (r). We found a strong positive correlation for both groups of age: $rA = 0.947$ (with $p < 0.00001$) and $rB = 0.9789$. High correlation with minimum differences were mentioned also in others two groups, classified after the disease severity: $r1 = 0.9909$ and $r2 = 0.9446$ ($p < 0.00001$). We notice a difference higher than 10 % for RRF between two kidneys: in 21 cases (45.66 %) with 99mTc DMSA and 18 cases (39.13 %) with 99mTc DTPA. Conclusion: The minor difference of RRF mentioned until 3 years old was, most probably, in relation with the maturation of kidneys. Also the minimum difference noticed in the cases of hydronephrosis and vesicoureteral reflux with degree higher then IV was related with urinary stasis in the pielocaliceal system. We conclude that when a scintigraphy with 99mTc DMSA is done for a patient in order to characterize renal parenchyma, the relative renal function can be taken into the consideration.

P184

Predictives factors of positive discharge perchlorate test in new born with congenital hypothyroidism

A. LEGENDRE, Jr., G. PETYT, G. COLLET, G. LION, B. Dimitri, F. SEMAH, H. LAHOUSSE; CHRU de Lille, LILLE, FRANCE.

AIM : Performing a perchlorate discharge test (PDT) in diagnostic of congenital hypothyroidism is not so easy between duration of the test and succed to have perchlorate. MATERIEL AND METHOD : We evaluated retrospectively 48 new born under one month who had PDT after thyroid scintigraphy with 123 iodine in CHRU of Lille between 2004 and 2014. We analized four pre test variables: sex, TSH on Guthrie test, thyroid area and iodine fixation rate. Then we analized 3 of these variables in 3 under groups depending of percent of decreasing of iodine rate after PDT : negative inferior to 15%, positive shared itself in two groups 15-50% and superior to 50%. RESULTS : Thyroid area is the only pre variable test wich is statistically higher $p<0,0001$ (Wilcoxon two-sample Test) when PDT is positive. Bigger is thyroid area more test has chance to be positive. Under 514 mm^2 all tests are negative and beyond 960 mm^2 all tests are positive. Thyroid area can help to well isolate 40% of patients. Sex, TSH on Guthrie test and 123 iodine fixation rate are not predictive on positive PDT. Furthermore, sex is not different between 3 under groups but different between negative and positive superior 50% PDT with more girls when test PDT is positive. TSH on Guthrie test is not statistically different between 3 under groups of PDT for $p= 0,0573$. Thyroid area is statistically higher in positive group than negative group $p= 0,02$, but not different between two positive group $p=0,11$. CONCLUSION : Thyroid area is correlate with positive PDT but not enough to not perform PDT. We can't discriminate only with thyroid area PDT positive with 15-50 percent of decreasing than beyond 50 percent. We will continue to perform PDT.

P185

Lesion detectability in neuroblastoma children by mIBG planar images: could it be partially related to the display performances and the diagnostic expertise?

M. Castellani, A. Lorenzoni, R. Luksch, C. Cavatorta, M. Lualdi, S. Meroni, F. Crippa; Fondazione IRCCS Istituto Nazionale Tumori, MILAN, ITALY.

Aim To test the diagnostic variability related respectively to display monitor performances and medical expertise in a Nuclear Medicine Unit. Materials and Methods Between mIBG scans performed in children (2m-8y old) with neuroblastoma, 78 planar mIBG images with different levels in difficulty of interpretation were selected by a senior Nuclear Medicine Physician (NMP). 26 images presented 3 uptake areas, 26 more than 3 and 26 no uptake areas, respectively. All images were blindly evaluated, during two different sessions, by the senior-NMP and a junior-NMP with a lower level of expertise using three models of color displays from NEC Company with different calibrated luminance values and display functions, DICOM or not. For each of the 234 evaluations, the observers were asked to complete a record form, stating the presence or the absence of uptake areas and their location and to grade the difficulty of interpretation of the images. The agreement coefficient Kc from Cohen Kappa statistic was computed in order to evaluate the reproducibility in identifying the presence of uptake areas between monitors and within/between observers; the correctness in the interpretation of the images was evaluated with respect to senior evaluation. Results Regarding the between-monitor agreement, a high reproducibility was found for the senior-NMP ($Kc \geq 0.80$), whereas lower values were found for the junior-NMP (range 0.60-0.78). Preliminary results for the DICOM display with the highest luminance show the lowest values of misclassified case for the junior-NMP with respect to the senior evaluation with 8% and 7% mistake rate in the two reading sessions. The number of misclassified cases increases when using the not-DICOM display with the lowest luminance, with a percentage of misclassified cases of 6% for senior-NMP, and of 24% and 21% for junior-NMP, in the two reading sessions, respectively. Conclusion A proper DICOM display function and a high contrast ratio seem to facilitate the detection of low uptake areas thus optimizing the diagnostic information that can be obtained from mIBG scintigraphic images. Our preliminary results confirm the importance of display settings in the medical decision process even when images with poor spatial resolution were considered as in nuclear medicine examinations.

P186

SPECT and SPECT-TC increase the sensitivity of 123I-mIBG for the evaluation of primitive tumour and soft tissue-lymph nodal lesions in patients on treatment for neuroblastoma.

M. Castellani, R. Luksch, M. Testoni, G. Aliberti, M. Maccauro, C. Zanette, D. Mansi, A. Lorenzoni, F. Crippa; Fondazione IRCCS ISTITUTO NAZIONALE TUMORI, MILAN, ITALY.

Aims To investigate if I-123-MIBG SPECT/ SPECT/TC, prospectively performed at diagnosis and during therapy in neuroblastoma, has superior sensitivity than standard acquisition not only for the bone metastases, but also for assessing the primary tumour and for detecting the recurrences in the so-called soft tissue(ST) lesions : regional or distant lymph-nodes and viscera (liver, lung, skin, CNS) . Method From January 2011 to April 2016, 94 neuroblastoma patients consecutively underwent MIBG scan study. 33 pts were 2- 18 months old; 32pts were 19-59 months;18 pts 5-18 year old;11 pts>18 year old. 22/33 pts less than 18 months old were excluded from the present study due the lack of SPECT/SPECT-TC (SPECT) in adding to the standard MIBG (S-MIBG) acquisition (planar static or WB)). The remaining 72 evaluable patients were studied with a total of 247 scans (range 1-13, median 4) . The SPECT acquisition was in most cases centred to the abdomen +/- thorax +/- skull. Co-registered SPECT/ CT consisted in CT low-dose acquisition (80 kVp, 33 mAs) with attenuation correction. SPECT was compared with S-MIBG results and confirmed by not co-registered TC or MR. Results At diagnosis SPECT recognized the Primitive Tumour in 67/69 (97%) vs S-MIBG in 63/69 pts (91%): The FN S-MIBG vs VP SPECT were 4 pts with respectively dominant photopaenia of T, the retro vesical or cervical site, the intense lumbar bone uptake. In the case of retrovesical tumor, SPECT confirmed the clinical suspect of neuroblastoma due to the opsomyoclono ataxia syndrome . SPECT identified 26/28 (92%) of the regional loco-regional lymph-nodal lesions vs 11/28 (39%) of the S-MIBG ; 17/20 vs 8/20 of mediastinal lesions, 9/10 vs 6/10 of left supraclavicular lesions and 5/7 vs 3/7 of the cervical nodes. Liver lesions were identified in 4 babies <12 m old with lesions more than 1 cm . Skin lesions were seen in 3/3 cases. During the follow-up , SPECT showed in the cases S-MIBG negative the persistence of disease (or relapse) in soft tissue disease in 4 patients, in 2 patients in CNS and in 2 pts in spine (BM thin spots). In conclusion: In our experience SPECT/SPECT-TC significantly raised the MIBG sensitivity in the diagnosis of soft tissue lesions, so far considered as near silent in S-MIBG.

P187

Value of MIBG scan in the diagnosis & initial staging in patients with neuroblastoma

A. SELLEM, W. ELAJMI, K. TRABELSI, H. HAMMAMI; MILITARY HOSPITAL, TUNIS, TUNISIA.

Introduction and purpose Neuroblastoma (NBL) is the commonest extra-cranial solid tumor in children. The purpose of this study was to evaluate the usefulness in a clinical setting of iodine-123-metaiodobenzylguanidine (123I-MIBG) scintigraphy in patients with neuroblastoma as detected by a mass screening survey. **Methods** Fifty patients provisionally diagnosed by clinical and imaging criteria to have neuroblastoma were included. Each patient had imaging by ultrasound, CT and/or MRI. **Results** The age of patients ranged from 2 months to 11 years with a mean of 32.9 months. They were 33 boys and 17 girls. In all cases, 123I-MIBG whole body images was performed and revealed 14 (28%) patients had normal iodine-123 MIBG scans, and histology showed a malignancy other than a neural crest tumour. The remaining 36 patients (72%) showed abnormal iodine-123 MIBG scans. The location of the primary site was retroperitoneal in 63.8 % of cases, thoracic in 16.6 %, pelvic in 11.1 % and 8.3 % in cervical. 16 of the 36 patients had metastasis : 9 (25%) with bone metastasis, 2 (5.5%) with liver metastasis, 2 (5.5%) with liver and bone metastasis, and 3 (8.3%) with both bone and lymph nodes metastasis. **Conclusion** 123I-MIBG scintigraphy has an excellent ability to discriminate between neuroblastoma and other small round cell paediatric tumours and it is a powerful tool for initial staging which is crucial for effective management.

P188

FDG PET/CT Versus I-131 MIBG in Neuroblastoma Osseous Infiltrates

M. A. Abdelwahab[1], M. H. Kotb[1], H. Mostafa[2], W. M. Omar[1], H. Elsayd[1], M. Fawzy[1]; [1]National Cancer Institute, Cairo, EGYPT, [2]NEMROCK, Cairo University., Cairo, EGYPT.

Purpose: To compare diagnostic performance of 18F-FDG PET/CT & I-131 MIBG in neuroblastoma (NB) osseous lesions. **Patients and methods:** Comparative study with 63 pathologically proved NB patients who were referred to Nuclear Medicine department, Children's Cancer Hospital, Egypt (CCHE) from Oct., 2009 till Jan. 2014, their age ranged from 2 to 156 months, with male to female ratio 1.4:1 & dominating high risk category (~65.1 %). They underwent paired F-18 FDG PET/CT and

I-131 MIBG scans (with maximum 2 weeks interval) using standard techniques and results of all scans were correlated to bone marrow biopsy, and follow up clinico-radiological data. **Results:** On lesion based analysis of neuroblastoma bone metastases, statistically significant higher sensitivity was seen with 18F-FDG PET/CT (73.1%) compared to 55.2 % for I-131 MIBG (***p- Value=0.03)***. Higher yet comparable specificity of 100% was seen with I-131 MIBG compared to 92.5% for 18F-FDG PET/CT (p-value=0.95). **CONCLUSION:** 18F-FDG PET/CT seems to have an added value in detection of NB osseous infiltrates with considerable specificity, compared to I-131 MIBG, yet further larger scale studies are needed.

P189

True Whole-Body versus Standard 18F-FDG PET/CT Acquisition for Staging Pediatric Lymphoma

E. Etchebehere[1], **A. E. Brito**[2], C. Mosci[2], A. Santos[1], S. Aguiar[3], L. Cristofani[1], A. Vicente[1], V. Buccheri[4], J. Soares Junior[4], P. Lymphoma Group[5], T. Pascual[5]; [1]Sirio Libanes Hospital, Sao Paulo, BRAZIL, [2]University of Campinas, Campinas, BRAZIL, [3]Centro Infantil Domingos A. Boldrini, Campinas, BRAZIL, [4]University of Sao Paulo, Sao Paulo, BRAZIL, [5]INTERNATIONAL ATOMIC ENERGY AGENCY, Vienna, AUSTRIA.

Introduction: The role of 18F-FDG PET/CT in lymphoma staging is well established mainly in the adult population. Standard (eyes to thighs) 18F-FDG PET/CT acquisition is performed when staging lymphomas in adults, but guidelines recommend true whole-body acquisition in children. However, this acquisition is time consuming, increases radiation exposure and is not cost-effective especially as it requires sedation. These disadvantages limit the use of 18F-FDG PET/CT in developing countries. Objectives. This study aimed to evaluate the clinical impact of performing true whole-body versus standard (eyes to thighs) 18F-FDG PET/CT for pediatric lymphoma staging in developing countries. MethodologyTrue whole-body 18F-FDG PET/CT acquisitions were performed for staging patients with histological diagnosis of Hodgkin´s (HL) or Non-Hodgkin´s lymphoma (NHL). Inclusion criteria consisted of patients between 0-18 (inclusive) years of age at the time of the baseline scan. Patients that were pregnant, lactating, had prior radiation therapy, prior chemotherapy and/or prior history of cancer were excluded. 18F-FDG PET/CT acquisition parameters and administered doses were performed according to SNM or EANM guidelines. True whole-body (vertex to feet) acquisitions were performed with a minimum of 2 min per-bed position for torso and 1 min per-bed position for extremities, in 3D MODE. CT parameters were: 80 - 120 kVp; dose modulation (mAs); iterative reconstruction; 2.5 - 4.0 mm slices. The true whole-body 18F-FDG PET/CT images for each patient were compared to a standard (eyes to thighs) acquisition. The clinical impact among the two were evaluated. Results: True whole-body 18F-FDG PET/CT acquisitions were performed in 19 patients (15 males), mean age=10±4 years-old, 12 HL. Four patients (21%) (1 HL and 3 NHL) had metastases outside the eyes-to thighs field-of-view, although none of them had disease only in the arms or legs. Since these patients also had multiple extranodal sites (bone, pleura, lung and peritoneum) within the eyes-to thighs field-of-view, management was not altered based on the lower limb results. Conclusion: Staging of pediatric lymphoma with a true whole-body 18F-FDG PET/CT acquisition protocol does not seem necessary as there is no clinical impact in patient management. A standard 18F-FDG PET/CT acquisition may be sufficient. Exceptions may be in bone lymphomas, although these cases correspond to a minority of patients and must be analyzed individually. Standard 18F-FDG PET/CT reduces examination time, the need for sedation, radiation exposure and is therefore more cost-effective in the pediatric population. These results will optimize the use of 18F-FDG PET/CT imaging in developing countries.

P190

The Role of ^{123}I-mIBG Scintigraphy in Kinsbourne Syndrome

D. BEN SELLEM, L. ZAABAR, B. DHAOUADI, B. LETAIEF, M. F. BEN SLIMENE; University of Tunis El Manar, Faculty of Medicine of Tunis, Salah Azaiez Institute, Department of Nuclear Medicine, Tunis, TUNISIA.

Aim: Kinsbourne syndrome or opsoclonus-myoclonus syndrome is very rare. It is characterized by opsoclonus (fast, multidirectional, conjugate eye movements), a jerky ataxia sometimes with a myoclonic component, marked irritability and/or sleep disturbance. It may be associated with occult neuroblastoma. MIBG scintigraphy is needed then. The aim of this study is to demonstrate the contribution of the ^{123}I-mIBG scintigraphy in the detection of neuroblastoma in the case of Kinsbourne syndrome. **Materials and methods:** Five girls and 2 boys aged from 10 months to 10 years (median 6 years) presenting Kinsbourne syndrome with increased serum neuron-specific enolase, were addressed to our department for ^{123}I-mIBG scintigraphy to search a neuroblastoma. Static acquisitions and fused images with SPECT/CT hybrid gamma-camera, equipped with low-energy collimators, were acquired 24 hours post injection of ^{123}I-mIBG. **Results:** In four cases, ^{123}I-mIBG scintigraphy not objectified abdominal or ectopic neuroblastoma. In the fifth case, the SPECT/CT demonstrated a left paravertebral focus of moderate uptake at D11 level, evoking a thoracic neuroblastoma. In the sixth case, the SPECT imaging showed a left posterior focal hot spot concluding to adrenal neuroblastoma. In the last case, the ^{123}I-mIBG scintigraphy has objectified asymmetric uptake depending on the right adrenal gland without anatomical correlation, compatible with poorly differentiated right adrenal neuroblastoma. **Conclusion:** Kinsbourne syndrome is exceptional. The mIBG scintigraphy allows the search for an underlying neuroblastoma, changing so prognosis and therapeutic managment of this syndrome.

Comparison of cigarette and ecigarette smoking to alveolocapillary membrane by dynamic ventilation scintigraphy

S. Barna[1], I. Garai[1], D. Rózsa[2], J. Varga[3], A. Fodor[4], M. Szilasi[4], L. Galuska[3]; [1]ScanoMed Ltd, University of Debrecen, Debrecen, HUNGARY, [2]BBS Nanotechnology Ltd, Debrecen, HUNGARY, [3]Dept. of Nuclear Medicine, University of Debrecen, Debrecen, HUNGARY, [4]Dept. of Pulmonology, University of Debrecen, Debrecen, HUNGARY.

Aims: Dynamic ventilation scintigraphy (DIT) has proved to be a suitable method for the staging and follow up of the damages of alveolo-capillary membrane (ACM) system of the lungs. The e-cigarette is a new smoking device producing vapor from nicotine solution. Here we present the first comparative DIT results of e-cigarette users, who returned for one week to the usual cigarette smoking. **Patients:** We included 13 healthy man volunteers (age 20-40) in the study, who regularly used e-cigarette, containing 10 or more mg nicotine/mL concentration fluid.. **Methods:** First we acquired a baseline DIT study, calculating the separate clearance half time ($CT_{1/2}$) values of the lungs, and performed respiration tests (FVC, FEV1, PEF, FEV1/FVC) as well as measured CO and COHg concentrations from exhaled air at e-cigarette use. Then we asked the volunteers to return to traditional cigarette smoking for a week's period. After that we repeated the above-mentioned tests, and statistically compared the results, using paired t-test for normally distributed variables, and Wilcoxon's test for the rest. **Results:** There was no significant change in the results of respiration tests, except for the exhaled CO and COHg levels, which were significantly higher at cigarette use ($p<0.01$), and increased in every case (CO: from a median value of 2 to 15 ppm;

COHg: from a median value of 1.0 to 3.0%). The DIT $CT_{1/2}$ times were lower at traditional cigarette smoking compared with e-cigarette use in every case ($p<0.0001$): from 69.3±13.8 min decreased by 31.1±11.0 min), on average to 55.0% of the base value (95% confidence interval: 44.4 - 65.6 %). **Conclusion:** We first compared at the same persons the direct effect of traditional smoking vs. e-cigarette upon the lung ACM. Our results confirmed the known toxic (especially CO) effect of traditional cigarette smoking causing persistent alveolitis. The normal $CT_{1/2}$ values at e-cigarette use prove that it has no similar effect, there is no sign of alveolitis. So it could be recommended for heavy smokers who are unable to stop smoking, to switch to e-cigarette use, which is more tolerable for the lungs, for the ACM.

P192

Importance of V/P SPECT in Diagnosing COPD and Pulmonary Comorbidities

M. Bajc[1], Y. Chen[2], X. Li[3], C. Wang[4], H. Huang[5], A. Lindqvist[6], X. He[7], X. He[7]; [1]University Hospital Lund, LUND, SWEDEN, [2]Changzheng Hospital, Shanghai,, CHINA, [3]Hua Dong Hospital Shanghai,, Shanghai, CHINA, [4]Xin qiao Hospital Chongqing, Chongqing, CHINA, [5]Changzheng Hospital Shanghai, Shanghai, CHINA, [6]Helsinki University Hospital, Helsinki, FINLAND, [7]Suzhou University Affiliated Tumor Hospital, Wuxi,, Wuxi, CHINA.

Objective: To assess the degree of obstructivity in COPD patients and identify pulmonary comorbidities. Methods: 66 stable patients with a clinical diagnosis of COPD were included in this prospective, multicentre study. They were classified according to GOLD criteria, spirometry, and symptom evaluation. Ventilation and perfusion tomography (V/P SPECT) was performed and interpreted according to European Nuclear Medicine guidelines. Obstructivity was evaluated blindly and semi-quantitatively using V/P SPECT[1]. Results: Two patients showed no obstructivity with spirometry or V/P SPECT. However, V/P SPECT demonstrated pulmonary embolism (PE) in one and signs suggestive of tumour in the other. Mild obstructivity in V/P SPECT was found in 2 patients: both showed signs of suspected tumour and one chronic PE and emphysema. Among 23 patients with moderate obstructivity in V/P SPECT (post-bronchodilation FEV% 63+/-18% and FEV1 63+/-15% of predicted), 17 patients had emphysema (74%), 14 PE (61%), 6 left heart failure (LHF) (26%), 5 of whom also had both LHF and PE, and finally 7 (31%) had parenchymal changes. Thirty-nine patients had severe obstructivity in V/P SPECT (post-bronchodilation FEV% 47+/-10% and FEV1 39+/-11% of predicted) and emphysema was present in 38 (97%), 11 had LHF (28%), 2 had PE (5%) and 4 demonstrated other parenchymal changes (11%) in V/P SPECT. Conclusions: To our knowledge this is the first time that a prospective study has been conducted on COPD patients which focusses on pulmonary comorbidities using V/P SPECT. Most importantly V/P SPECT is not contraindicated in the diagnostic evaluation in COPD patients and can even grade its severity. Emphysema was a frequent finding and always present in patients with severe COPD. Regardless of the severity of COPD, V/P SPECT was able to demonstrate PE, LHF and other parenchymal changes difficult to see on planar images.These findings may explain the variety of complex patient symptoms and heterogeneity of the disease. V/P SPECT might play an important prognostic tool in COPD patients and have an impact on patient treatment. [1]Bajc et al, Ann. Nucl. Med. 2015; 29: 91.

P193

V/Q SPECT/CT findings of residual emboli and lung diffusion impairment after surgical embolectomy compared to thrombolysis in acute pulmonary embolism

J. Mortensen, P. Lehnert, J. Kjærgaard, P. S. Olsen, C. J. H. Møller, J. Carlsen; Rigshospitalet, COPENHAGEN, DENMARK.

Aim: To investigate the long-term amount of residual emboli and pulmonary diffusion impairment after acute high- and intermediate-risk pulmonary embolism (PE) treated with surgical embolectomy and thrombolysis. Methods: Prospective follow-up of a retrospective cohort treated between 1998 and 2014 at Rigshospitalet. Follow-up evaluation at least 3 months after the acute PE included ^{81m}kr ventilation / ^{99m}Tc-MAA perfusion SPECT/CT and lung function tests of CO diffusion capacity. Results: A total of 136 patients (high-risk: 64; intermediate-risk pulmonary embolism: 72) were included, 80 were eligible for clinical follow-up, while 40 had deceased. Median clinical follow-up time was 31 months. For high risk PE patients, V/Q mismatch was found in 31% of cases treated with surgical embolectomy compared to 76% of cases treated with thrombolysis ($p=0.01$): The following no. of V/Q. mismatch defects was detected in the two patient groups: 1-3 segments in 3 and 12 patients, resp.; 4-6 segments in 0 and 3 patients, resp.; and 7-10 segments in 1 from each group. Pulmonary diffusion impairment was identified in 31% cases treated with surgical embolectomy and in 71% cases treated with thrombolysis ($p=0.02$). In the intermediate-risk PE patients, no difference in V/Q mismatch (5/11 vs. 18/35, $p= 0.73$) or in diffusion capacity impairment (6/11 vs. 8/35, $p=0.07$) was found. Conclusions: Surgical embolectomy for acute high-risk PE seems to result in less residual PE and lung diffusion impairment when compared to treatment with thrombolysis. In intermediate-risk PE patients no difference was seen.

P194

Quantitative ventilation/perfusion SPECT - Initial experience

S. Carmona, J. G. Santos, A. Prata, J. A. Sequeira, M. R. Victor, A. I. Santos; Hospital Garcia de Orta, ALMADA, PORTUGAL.

Ventilation/perfusion SPECT scintigraphy (V/P SPECT) is presently the gold standard technique to perform ventilation/perfusion scintigraphy. Some authors defend that the determination of the perfusion percentage affected by pulmonary embolism (PE) can be an important adjuvant to decide pulmonary embolism treatment. But how easy is it to perform quantitative ventilation/perfusion SPECT? Aim: To analyse interobserver reproducibility in ventilation/perfusion SPECT, regarding the quantification of perfusion impairment, in pulmonary embolism. Materials and methods: We analysed 30 V/P SPECT performed in 30 patients (7 men and 23 women), median age and interquartile range 64[43;70] years. 28 patients were referred for PE diagnosis and 2 patients had already an angio CT confirming PE. Each study was analysed independently by 4 Nuclear Medicine specialists. PE quantification was made by counting segments or sub-segments of ventilation/perfusion mismatches compatible with PE, according to the method proposed on literature (Bajc M. et al). A sub-segmental defect was attributed 1 point, and a segmental defect 2 points (both lungs comprising 18 points). Mismatch defects were expressed as mismatch points, and after division by 36 gave the percentage of the lung that was embolized. Intraclass Correlation Coefficient was used for assessment of multiple raters agreement on the percentage of embolized lung. Non parametric tests for paired samples (Wilcoxon and sign tests), were used to evaluate the difference of embolized lung percentage for each observers pair. Results: For the 30 exams, the total mismatch points considered in both lungs and the number of exams with no mismatch defects were, for observer 1: 59 mismatch points and 5 (17%) exams with no defects; for observer 2: 86 mismatch points and 2 (7%) exams with no defects; for observer 3: 69 mismatch points and 7 (23%) exams with no defects; for observer 4: 62 mismatch points and 4 (13%) exams with no defects. The interobserver agreement, regarding the percentage of embolized lung was moderate (ICC = 0,43). For each pair of observers, regarding the percentage of embolized lung, there was only a statistically significant difference between observers 1 vs 2 (p=0,033) and 2 vs 4 (p=0,024). Conclusion: Although quantitative ventilation/perfusion scintigraphy is a powerful tool to evaluate the extent of perfusion affected by PE, care must be taken performing this technique. Our

initial experience revealed a moderate interobserver concordance quantifying perfusion mismatch defects in ventilation/perfusion scintigraphy, leading us to conclude that an initial learning process is needed to standardize the quantification results.

P195

Added value of low-dose CT coupled to Ventilation /Perfusion SPECT in acute pulmonary embolism

W. Amouri, F. Hamza, I. Jardak, F. Kallel, S. Charfeddine, F. Guermazi; Habib Bourguiba hospital, sfax, TUNISIA.

Introduction: There is increasing evidence of the improved accuracy of single photon emission CT (SPECT) and SPECT combined with low-dose CT (SPECT/CT) compared to planar Ventilation/Perfusion (V/Q)lung scintigraphy for the diagnosis of pulmonary embolism (PE). In this work, we aim to compare V/Q SPECT with perfusion SPECT/CT scan and to assess the additional information provided by this hybrid technique for accurate diagnosis of PE. Materials and Methods: In a retrospective study, 22 patients (13 men and 9 women with mean age of 54 years) were referred for suspicion of PE. 2 days protocol was conducted on Symbia T6 gamma camera. The first day, perfusion SPECT acquisition was performed after injection of 185 MBq 99mTc-labelled macro aggregated human albumin (99m Tc-MAA), followed by low dose CT acquisition without contrast iodine injection. The second day, ventilation SPECT was acquired after inhalation of 99mTc-labelled Technegas. The reconstructed images were interpreted according to the EANM criteria (2009). Correlations between V-SPECT and CT were studied. PE is diagnosed when there is more than one sub segment showing a V/Q mismatch representing an anatomic lung unit. Results: According to the criteria of the EANM, PE was excluded in 9 cases and confirmed in 12 patients. One case (4.5%) was classified no conclusive given the presence of one subsegment mismatch on both V/Q and Perfusion SPECT/CT. The concordance rate between clinical probability and scintigraphic results was of 68%. The comparison of Perfusion SPECT/CT and V/Q SPECT showed a concordance in 100% of cases. CT allowed however a better anatomical localization of perfusion defects, as well as a best characterization of abnormalities related to non-embolic etiologies such as pneumonia lesion, pleural effusion and calcification, COPD and recognized pulmonary infarction. Conclusion: This study demonstrates that Perfusion SPECT/CT obtained with hybrid camera could be used for PE diagnosis with performances similar to V/Q SPECT. In addition, SPECT/CT improves test specificity by identifying non-embolic etiologies and allows accurate localization of perfusion defects.

P196

Continuous acquisition mode gives comparable images to step-and-shoot in lung perfusion SPECT

P. C. Holdgaard; Nuclear Medicine Dept., Vejle Sygehus, Vejle, DENMARK.

AIM: EANM guidelines recommend a 5 minute lung perfusion SPECT. Step-and-shoot mode (SS) acquisitions increase scan time by >3 minutes compared with continuous mode (CONT) where data is acquired during detector motion. If image quality is comparable it would give the possibility to reduce camera time or acquire longer and improve image quality with 60 %. We have previously made a thorough phantom study and found CONT equivalent to SS in cold lesions, but should be evaluated in the patient setting prior to clinical implementation. MATERIALS AND METHODS: Twenty two consecutive patients suspected for lung embolism were scanned first with SS and immediately after with CONT. Both SPECTs were acquired with 5 minutes sampling time (60 projections of 10 seconds), dual-head, LEAP collimator and 128 matrix, and OSEM reconstructions (30 iterations and 2 subsets) made with resolution recovery and scatter correction. Prior to the perfusion study, all patients had a Technegas® ventilation study. The two SPECT modes were compared side by side for each patient by a nuclear medicine physician. Number of perfusion defects, localisation and difference between the two modes were recorded. RESULTS: There were 7 patients with lobar and/or several segmental perfusions defects, 7 with one sub-segmental or non-segmental defects and 8 with normal perfusion. All defects seen in SS were also seen in CONT and no new defects were introduced. It was visually observed that CONT acquisitions were slightly less homogenous, but had slightly greater contrast between defects and normal perfused areas compared with SS. The minor visual difference was considered negligible in a clinical setting, especially compared with the lower count ventilation studies. CONCLUSION: The distribution of defects is the same in CONT and SS acquisitions in lung perfusion SPECT. This gives the possibility to reduce scan time or improve image quality with CONT. If ventilation is also acquired with CONT, a total of 6-7 minutes can be saved. It is also possible to reduce doses if the perfusion/ventilation count ratio is still adequate.

P197

Comparison between V/Q Lung Scintigraphy and Computed Tomography Pulmonary Angiography in the Diagnosis of pulmonary embolism

D. A. M. Hassanin, Maryam Qaw, Sara Abdulwahab ,Jenan Al-Awami; South Egypt Cancer Institute, Assiut, EGYPT.

Abstract : Pulmonary embolism is a disease characterized by a blockage of the pulmonary artery . It can be diagnosed using ventilation/perfusion scintigraphy (V/Q) or using CT pulmonary angiography (CTPA). The aim of our study was to compare between the properties of V/Q and CTPA and to propose when to perform each. **Method:** A questionnaire was published to a total of 150 radiologists, nuclear medicine technologists and physicians. And the results were compared with research papers comparing between V/Q and CTPA. **Results:** 74% of the sample said that V/Q is more effective in diagnosing PE and 53% said that CTPA is more.63% said that CTPA is more available and widely used. 62% said that CTPA used more in emergency cases. 59% said that CTPA is more accurate with less mistake ratio and 41% said that V/Q is more. 77% said that in V/Q patients will have less radiation exposure than CTPA. 66% said that CTPA gives more quick results than V/Q. 64% that CTPA may cause allergic reaction, complications or side effects. 37% said that CTPA is sufficient alone to diagnose PE, 17% said that V/Q is sufficient alone and 45% said that both can be sufficient alone. **Conclusion:** V/Q will provide accepted diagnostic results for PE with low radiation dose and no side effects. CTPA with similar diagnostic results in a shorter procedure time but a higher radiation dose and a probability of some side effects. In general both CTPA and V/Q provide results with satisfactory sensitivity and accuracy, so exclusion or inclusion of PE will be better using the combination of these two tests. **Keywords :** Pulmonary embolism, ventilation/perfusion scintigraphy (V/Q), CT pulmonary angiography (CTPA).

P198

Diagnosing PE with V/P SPECT in the presence of COPD

A. Nasr, M. Bajc; Clinical Physiology and Nuclear Medicine, Lund, SWEDEN.

Background: The presence of Chronic Obstructive Lung Disease (COPD) is generally considered as a contraindication to perform lung scintigraphy in patients suspected for pulmonary embolism (PE). These facts were based on planar imaging technique and mainly Xenon gas was

used for the ventilation study. Tomographic technique (SPECT) for ventilation/perfusion scintigraphy, make detecting of PE possible even in the very obstructive patients. This is through use of the smallest aerosol-Technegas with very good periphery penetration. Aim: To determine the diagnostic value of VP SPECT in detecting PE in the presence of COPD. **Methods and materials:** We retrospectively analysed 1485 consecutive patients referred to V/P SPECT during a one year period. 1274 (86%) of those patients were referred for suspected pulmonary embolism (PE). The number of segments and sub-segments indicating PE typical mismatch were counted and expressed in percentage of the total lung parenchyma. Furthermore, areas with ventilation abnormalities were recognized which allowed the degree of total lung malfunction to be estimated. In the report to the clinicians the extent of PE was given as well as other sign of ventilation disturbances. These were described and interpreted in accordance with EANM Guidelines. **Results:** Among 1274 patients included in this study, 353 patients (28%) were detected with PE. More than a half of the patients (55%) showed signs of airway obstruction (from the sign of uneven ventilation to deposition of Technegas in small and large airways as well as areas of absent ventilation, mild-severe). Among the 353 patients with PE, 90 patients were also diagnosed as obstructive. In the group of obstructive patients, majority (87%) had small PE, <25%, of the total pulmonary perfusion, 10 patients (11%) had medium size PE (<50 %) and 2 (2%) had extensive PE (>50%).All examinations in patients with both PE and COPD were diagnostic even in the most severe grade of obstruction which was identified in 28% of these patients. **Conclusion:** COPD is not a contraindication to use pulmonary ventilation/perfusion tomography for PE diagnosis even in the most severe grade of COPD. All studies were diagnostic. The method is applicable to all patients and could explain patient symptoms.

P199

Inclusion of SPECT-CT in Assessment of Chronic Thromboembolic Pulmonary Hypertension

B. PEREZ LOPEZ, F. GOMEZ-CAMINERO LOPEZ, P. GARCIA-TALAVERA SAN MIGUEL, R. RUANO PEREZ, M. E. MARTIN GOMEZ, L. G. DIAZ GONZALEZ, E. MARTIN GOMEZ, M. P. TAMAYO ALONSO; HOSPITAL UNIVERSITARIO CLINICO DE SALAMANCA, SALAMANCA, SPAIN.

Objetive: To stablish the role of pulmonary perfusion SPECT-CT in patients with suspicion of chronic thromboembolic pulmonary hypertension as a complement to ventilation/perfusion scintigraphy. **Methods:** Chronic thromboembolic pulmonary hypertension has an incidence of 4% after suffering an acute pulmonary thromboembolism. It is caused by incomplete resolution of the thromboemlism that produces increased pulmonary vascular resistance. We reviewed all patients derived to our departament with clinical suspicion of chronic thromboembolic pulmonary hypertension. Pulmonary perfusion SPECT-CT was performed depending on health status. Ventilation scintigraphy with Technetium-labeled (Tc-99m) - DTPA and perfusion scintigraphy and perfusion SPECT-CT with Technetium-labeled (Tc-99m) - MAA were performed to all patients. Acute pulmonary tromboembolism at the moment of the studio was exclusion criteria. **Results:** 27 patients were analysed, 10 were men and 17 women, with average age of 71 years old. 67% of them were derived with known pulmonary hypertension and 33% without pulmonary hypertension diagnosis. Combining ventilation/perfusion scintigraphy and perfusion SPECT-CT, 18.52% of patients presented positive result for chronic thromboembolic pulmonary hypertension, 74% showed normal perfusion, and just 7.4% were not conclusive. Perfusion defects found in positive studios were mainly localized in left upper lobe. **Conclusion:** Pulmonary perfusion SPECT-CT is a very important tool that shows complementary information to ventilation/perfusion scintigraphy and allows to localize and define better perfusion defects. SPECT-CT is useful in diagnosis, follow-up and treatment response of chronic thromboembolic pulmonary hypertension. SPECT-CT should be performed when chronic thromboembolic pulmonary hypertension is suspected.

Serum Thyroglobulin Concentration as a Predictive Factor for Nodule Size and Malignancy in Patients with Thyroid Nodules

S. Gaberscek[1,2], S. Kukman[3], A. Biček[1], A. Oblak[1], E. Pirnat[1], K. Zaletel[1]; [1]Department of Nuclear Medicine, University Medical Centre Ljubljana, LJUBLJANA, SLOVENIA, [2]Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA, [3]Faculty of Medicine, University of Ljubljana, LJUBLJANA, SLOVENIA.

AIM. According to latest guidelines, measurement of serum thyroglobulin (Tg) concentration in the diagnostics of thyroid nodules is not recommended. In some studies, serum Tg concentration was associated with the nodule size. In papillary thyroid cancer, serum Tg concentration has no significant predictive value. In follicular and Hürthle-cell neoplasms, however, preoperative serum Tg concentration was reported either as a poor or as a useful predictor of thyroid malignancy. Therefore, our aim was to establish the value of Tg measurement in our patients with thyroid nodules. MATERIALS AND METHODS. In this retrospective study we reviewed medical records of all patients who were first diagnosed with thyroid nodules between May 2014 and December 2015 at our thyroid department. In all patients, a volume of thyroid nodules was measured by ultrasound (US), and a serum concentration of Tg was measured. In patients with thyroid nodules, which were larger than 1 cm and not active on thyroid scintigraphy, US-guided fine-needle aspiration biopsy (FNAB) was performed. The cytology report was categorized as suspicious or unsuspicious. Patients with cytology report suspicious for papillary thyroid cancer were not included in the study. RESULTS. Out of 801 consecutive patients with thyroid nodules (603 women and 198 men), 107 patients with the Tg concentration above 100 ng/mL had significantly higher volume of thyroid nodules than 694 patients with the Tg concentration below 100 ng/mL (median (range), 11.1 (0.02-95.5) and 1.1 (0.003-84.7) mL, respectively, p=0.006). We found a significantly positive correlation between the serum Tg concentration and the volume of thyroid nodules (R=0.469, p<0.001). Out of 413 patients with cytology reports, 41 patients with thyroid nodules suspicious for follicular and Hürthle cell neoplasm had significantly higher Tg concentration than 372 patients with unsuspicious thyroid nodules (median (range), 65.0 (7.0-34,650.0) and 23.5 (0.0-6,248) ng/mL, respectively, p=0.001). When applying a cut-off level of 200 ng/mL, the sensitivity and the specificity of the serum Tg concentration as a predictor for the suspicious or unsuspicious cytology report were 27% and 93%, respectively. Furthermore, the positive and the negative predictive values for the serum Tg concentration as a predictor were 32% and 91%, respectively. CONCLUSIONS. In our patients with thyroid nodules, serum concentration of Tg turned out to be a useful predictive factor of nodule size and malignancy. With more than 90% negative predictive value, a serum Tg concentration below 200 ng/mL was able to predict unsuspicious cytology report.

Association of established hypothyroidism associated genetic variants with Hashimoto's thyroiditis

A. Baric[1], L. Brcic[2], S. Gracan[1], V. Torlak Lovric[1], I. Gunjaca[2], M. Simunac[1], M. Boban[2], T. Zemunik[2], O. Polasek[3], M. Barbalic[2], A. Punda[1], V. Boraska Perica[2]; [1]Department of Nuclear Medicine, University Hospital Split, Split, CROATIA, [2]Department of Medical Biology, University of Split, School of Medicine, Split, CROATIA,

[3]Department of Epidemiology, University of Split, School of Medicine, Split, CROATIA.

Aim: Hashimoto's thyroiditis (HT) is a chronic autoimmune disease of the thyroid gland, with 8 times higher incidence in women. It is the most common cause of hypothyroidism. Recently, two genome-wide association analyses showed association of several genetic variants with hypothyroidism. Since HT and hypothyroidism are closely related, the main aim of this study was to explore the association of established hypothyroidism single nucleotide polymorphisms (SNPs) with HT. Materials and methods: The case-control dataset included 200 HT cases and 304 controls. Diagnosis of HT cases was based on clinical examination, measurement of thyroid antibodies (TgAb, TPOAb), hormones (TSH and FT4) and ultrasound examination. We genotyped and analysed 11 known hypothyroidism associated genetic variants. Case-control association analysis was performed in order to test each SNP for the association with HT using logistic regression model. Additionally, each SNP was tested for the association with thyroid related quantitative traits (TPOAb levels, TgAb levels and thyroid gland volume) in HT cases only using linear regression. Power of the study was calculated using Quanto and all association analyses were performed using Plink and R statistical software. Results: We identified two genetic variants nominally associated with HT: rs3184504 in SH2B3 gene (P=0.0135, OR=0.74, 95% CI=0.57-0.95) and rs4704397 in PDE8B gene (P=0.0383, OR=1.32, 95% CI=1.01-1.74). The SH2B3 genetic variant also showed nominal association with TPOAb levels (P=0.0163, β=-0.46, SE=0.19) and rs4979402 inside DFNB31 gene was nominally associated with TgAb levels (P=0.0443, β=0.41, SE=0.2). There were no significant associations with thyroid gland volume. Conclusion: Our findings suggest that SH2B3 and PDE8B genetic variants are associated with HT. SH2B3 gene has previously been associated with susceptibility to several autoimmune diseases, whereas PDE8B has been associated with TSH levels and suggested to modulate thyroid physiology that may influence the manifestation of thyroid disease. Identified loci are novel and biologically plausible candidates for HT development and represent good basis for further exploration of HT susceptibility.

P202

Color Flow Doppler Sonography In Patients With Amiodarone-Induced Thyrotoxicosis

G. Horvatic Herceg, I. Bracic, S. Kusacic-Kuna; Clinical Department of Nuclear Medicine and Radiation Protection, University Hospital Center Zagreb, Zagreb, CROATIA.

It is well known that excess of iodine intake may alter thyroid function, presented as amiodarone-induced hypothyroidism (AIH) which is more frequent in iodine sufficient areas or amiodarone-induced thyrotoxicosis (AIT) which occurs more frequently in areas with low iodine intake. AIT may arise from iodine-induced excessive thyroid hormone synthesis in patients with underlying functional thyroid autonomy (type 1) or destructive thyroiditis in apparently normal thyroid glands with release of hormones (type 2). Also, mixed forms characterized by coexistence of these two phenomena exist. Distinguishing thyrotoxicosis types 1 and 2 is important to plan therapy. AIT type 1 usually responds to thionamides and potassium perchlorate, while type 2 responds to glucocorticoids. Aim: To evaluate the utility of color-flow Doppler sonography (CFDS) in the differential diagnosis of AIT. 94 patients (pts) on chronic amiodarone treatment (6 months-2 years) were included in this study. All patients (m: 60, f: 34, mean age 53 y) were on long-term therapy with amiodarone at maintenance doses ranging from 200 to 400 mg daily. The mean value of urinary iodine excretion was 423.5 μg/l (min. 256.9 μg/l, max. 592.1 μg/l). AIH was found in 28% and AIT in 31% of pts. In 29 hyperthyreotic pts with nodular or diffuse goiter, 21 (72%) had CFDS increased glandular vascularity diagnostic for type 1 AIT and in 8 pts (28%) glandular vascularity was absent (type 2 AIT) (p<0.0001). 2-h I-131 uptake (RAIU) in 28 pts was low (range 2.09-5.6%) and in 1 pt was normal (11.4%). There were no patients with elevated RAIU. In the group of 21 pts with AIT type 1, nodular changes were found in 15 cases and diffuse changes in 6. In all pts with type 2 we have found diffuse changes of echostructure. Tc 99-m thyroid scans in all pts showed very low or absent uptake, consistent with either thyroiditis or blockade of uptake by iodine excess. Conclusion: CFDS can accurately distinguish between type 1 and type 2 AIT, but is not always concordant with the thyroid RAIU. Low uptake is of no differential value. Identification of the different subtypes of AIT helps to choose the appropriate therapy.

Methimazole Treatment Influences Thyroid Vascularity in Patients with Graves' disease

K. Zaletel[1], P. Klavžar[2], A. Kisovar[2], S. Gaberšček[1,2]; [1]University Medical Centre Ljubljana, Department of Nuclear Medicine, Ljubljana, SLOVENIA, [2]University of Ljubljana, Faculty of Medicine, Ljubljana, SLOVENIA.

OBJECTIVES. In untreated Graves' disease (GD), significantly increased thyroid vascularity most likely reflects the action of thyroid stimulating autoantibodies (TSAb). Since less data is available on thyroid vascularity during the treatment of hyperthyroidism, our aim was to evaluate the effect of methimazole on thyroid blood flow in GD patients. METHODS. In our prospective clinical study, which was performed between November 2014 and November 2015, we enrolled 23 consecutive newly diagnosed hyperthyroid patients with GD (19 females and 4 males), aged between 26 and 78 years (mean, 50.7±13.9 years). All patients were prescribed with initial dose of methimazole between 20-40 mg per day, which was reduced to 10 mg per day during the follow-up. Before as well as 7 weeks, 4 months and 7 months after initiation of treatment we determined thyroid function and TSAb. We measured thyroid volume and the peak systolic velocity (PSV) at the level of intrathyroid arteries. We compared the measurements during the treatment and determined correlations. RESULTS. Before treatment, patients had TSH 0.008±0.0004 mU/L, fT_4 48.68±18.73 pmol/L, fT_3 21.68±8.08 pmol/L and TSAb 7.58 pmol/L (range, 2-60 pmol/L). Thyroid volume was 20.52±9.43 mL and PSV was 18.77±4.84 cm/s. During treatment with methimazole, initial PSV significantly decreased to 13.38±2.01 cm/s at 7-week follow-up (p<0.001), to 12.00±1.94 cm/s at 4-month follow-up (p<0.001), reaching 10.43±0.77 cm/s by the 7-month follow-up (p<0.001). Before treatment, a significant correlation between PSV and TSAb was confirmed (R=0.608, p=0.002), whereas no correlation with thyroid hormones was found. During the follow-up, no correlation with TSH, thyroid hormones or TSAb was found until the final evaluation when the laboratory tests showed TSH 2.49±3.30 mU/L, fT_4 14.36 ±3.35 pmol/L, fT_3 5.56±2.68 pmol/L and TSAb 2.50 pmol/L (range, 0.0-45.19 pmol/L). CONCLUSIONS. Our findings indicate that during treatment of GD patients with methimazole thyroid vascularity significantly decreases. Therefore, estimation of thyroid vascularity represents an additional useful tool to estimate the progress of treatment.

Lycopene for Renal Ischemia Reperfusion Injury: Scintigraphic, Histopathologic and Biochemical Evaluation

M. SADIC[1], H. I. ATILGAN[2], A. AYDIN[3], G. KOCA[1], M. KORKMAZ[1], T. KARAKAN[1], H. SURER[1], P. BORCEK[4]; [1]Ministry

of Health Ankara Training and Research Hospital, ANKARA, TURKEY, [2]Kahramanmaras Necip Fazil City Hospital, Kahramanmaras, TURKEY, [3]Sanliurfa Mehmet Akif Inan Training and Research Hospital, Sanliurfa, TURKEY, [4]Baskent University, Faculty of Medicine, ANKARA, TURKEY.

OBJECTIVE: Medical protection of kidney against ischemia reperfusion injury is very important. Many agents were used for the protection of ischemia reperfusion renal tissue injury.We aimed to evaluate the radioprotective effect of lycopene on the kidney in ischemia reperfusion injury with histopathological, biochemical and scintigraphic parameters. **METHODS:** Twenty one Wistar male albino rats were divided in three groups as lycopene, control and sham group. In lycopene group, lycopene was started 3 days before right renal ischemia reperfusion injury and continued for 15 days. In the control group, right renal ischemia reperfusion injury was applied with no medication. In the sham group, which neither right renal ischemia reperfusion injury nor medication were applied. On 15th day, all rats were sacrified after DMSA scintigraphies were taken. Histopathological, biochemical and scintigraphic evaluations were made. **RESULTS:** The histopathological score was lower in the lycopene group. In biochemical analysis, MPO level was lower in the lycopene group than in the control group, but not statistically significant. The MDA and nitrite levels were lower in the lycopene group than in the control group. The postoperative mean Tc-99m DMSA uptake values were 44.82 ± 1.84 in the lycopene group, 38.92 ± 1.17 in the control group and 50.21 ± 1.35 in the sham group. DMSA uptake values were higher in lycopene group than in control group. **CONCLUSION:** Lycopene seems to be an effective agent for protection of the kidney in ischemia reperfusion injury as demonstrated by the histopathological, biochemical and scintigraphic parameters.

P205

Calculation of percent cardiac output to kidneys by implementation of Rutland-Patlak plot on initial part of renogram

S. BEATOVIC[1], M. Jankovic[2], D. Sobic Saranovic[1], E. Jaksic[1], M. Blagic[3], V. Antic[3], V. Artiko[1]; [1]University of Belgrade Faculty of Medicine, Center for Nuclear Medicine, Clinical Center of Serbia, BELGRADE, SERBIA, [2]University of Belgrade Faculty of Electrical Engineering, BELGRADE, SERBIA, [3]Center for Nuclear Medicine, Clinical Center of Serbia, BELGRADE, SERBIA.

The aims of this study were a) to evaluate whether renal blood flow (RBF) could be accurately estimated by the analysis of vascular transit of Tc-99m MAG3 by the use of the Rutland-Patlak (RP) analysis and b) to determine the sensitivity of this technique in assessing perfusion of native and transplanted kidney. **Subjects and Method:** Investigation was carried out in 54 subjects: 20 healthy potential kidney donors (Group A, control group), 20 patients with well-functioning t kidney transplant (Group B) and 14 patients with transplanted kidney and suspicion on acute graft rejection (Group C). 74 kidneys were analyzed in total. Dynamic scintigraphy was done 22 minutes after injection of 370 MBq Tc-99m MAG3. For the first 40 seconds two frames per second were recorded. Regions of interest were outlined over left ventricle, right lung and kidneys. Lung region serves to eliminate lung activity in posterior view of left ventricle. For transplanted kidney, regions are outlined over kidney and abdominal aorta. RBF was estimated from a derived first pass activity plateau in renal region of interest as the difference between maximal slopes of renal and arterial TA curves. RBF was generated in units of percentage cardiac output (CO). **Results:** In group A, mean values of RBF were 18.28%±3.65% CO for both kidneys and 9.14%±2.15% CO for one kidney. Transplant blood flow (TBF) in group B was 13.99% ±2.29% CO. This was 53% higher than one kidney RBF and 23% lower than global RBF in group A. TBF in group C was 6.11%±2.27% CO. It was 66% lower than in group A and 56% lower than in group B. Statistical difference between A/C and B/C was significant ($p<0.005$). There was no overlapping between groups C and B: the highest value in group C of 7.93% CO was lower than the lowest value in group B (9.62% CO). **Conclusion:** Fractional RBF, derived from the first-pass activity plateau as upslope ratio of kidney curve and arterial curve is sensitive method for quantifying renal perfusion. Method is independent of time interval between arterial and kidney time-activity curves. In healthy individuals physiological values of RBF were obtained. Well functioning transplants receive a fraction of CO similar to that delivered to two normal kidneys. Flow to rejecting allograft is significantly reduced.

P206

Predictive value of cortical transit time on MAG3 for the need of surgery in antenatally detected unilateral hydronephrosis due to ureteropelvic junction stenosis

J. Lee[1], **S. Jeong**[1], S. Lee[1], M. Cho[1], J. Jeong[1], J. Ha[2], S. Lee[1], S. Chung[1]; [1]Kyungpook National University School of Medicine, Daegu, KOREA, REPUBLIC OF, [2]Chosun University Hospital, Daegu, KOREA, REPUBLIC OF.

Background and purpose: Unilateral ureteropelvic junction (UPJ) stenosis is the most common prenatally detected disease leading to hydronephrosis. The aim of management is to preserve renal function by selecting the children who require early surgical intervention from those for whom watchful waiting may be appropriate because of spontaneous resolution without a significant loss of renal function. Some studies showed that cortical transit time (CTT) could successfully predict functional deterioration in children with UPJ stenosis. We assessed the impact of initial CTT on Technetium-99m mercaptoacetyltriglycerine (MAG3) diuretic renogram for the need for surgery in children with antenatally detected unilateral hydronephrosis due to UPJ stenosis. Materials and Methods: We retrospectively reviewed the medical records of 33 antenatally detected unilateral hydronephrosis (anteroposterior diameter (APD) > 10mm) due to UPJ stenosis patients who managed at our institution between 2006 and 2014. Delayed CTT was defined by absence of activity in the subcortical structures within 3 minutes of tracer injection on MAG3 diuretic renogram. This study analyzed and compared the initial level of society of fetal urology (SFU) grade, APD, spilt renal function (SRF), drainage pattern on diuretic renogram, and CTT with the need for surgery. Results: Of the 33 children, 16 were classified as the delayed CTT group and 17 were placed in the normal CTT group. During follow-up period (31.8 months), the surgery was performed in 75.0% (12/16) of delayed CTT group and in 5.9% (1/17) of normal CTT group ($p < 0.001$). Multivariate analysis showed that delayed CTT on initial MAG3 scan and APD on initial ultrasonography were independent predictive factors of the need for surgery. Conclusion: CTT on initial MAG3 scan was found to be a predictive factor of the need for surgery in children with antenatally detected unilateral hydronephrosis due to UPJ stenosis. Our findings indicate that CTT should be considered a priority in the management of congenital unilateral hydronephrosis due to UPJ stenosis.

Correlation of quantitative indices of basal renal transplant scintigraphy with same day and 1-week graft function

B. Yazici, A. Oral, A. Akgün; Ege University Medical Faculty, Department of Nuclear Medicine, Izmir, TURKEY.

Aim: The aim of this study was to evaluate the correlation of quantitative indices of renal transplant scintigraphy (RTS) performed 2-days after transplantation with same day and 1-week post-operative serum creatinine (sCr) and estimated glomerular filtration rate (eGFR) levels.

Materials and Methods: A total of 221 patients (110 female, 111 male, mean-age 45.5) underwent kidney transplantation at Ege University Medical Faculty between October 2011 and January 2016 and to whom RTS with Tc-99m DTPA was performed within 2-days after transplantation were analyzed retrospectively. Hilson's perfusion index (HI), time between peak perfusion of graft and iliac artery (ΔP), peak-to-plateau ratio (P:Pl), ratio of peak graft perfusion to peak iliac artery (P:A), T½ of graft washout (GW½), peak perfusion to peak uptake ratio (P:U) and Graft Index (GI= $\Delta PxAxPl)/(PxU_3)$ were obtained. A 1-week sCr of >2.5mg/dl and eGFR of <30ml/min and decreasing of sCr ratio <30% and increasing eGFR ratio <50% in one week were considered to be abnormal. Spearman's coefficient of correlation, Mann-Whitney U tests and receiver-operating characteristic (ROC) curve analysis were used for statistical analysis. *P*<0.01 was accepted significant. **Results:** Graft index had the strongest correlation with same day and 1-week sCr and eGFR (*r*=0.54 for same day sCr, *r*=-0.58 for same day eGFR, *r*=0.70 for 1-week sCr and *r*=-0,69 for 1-week eGFR). Correlation coefficient of other indices with same day sCr/eGFR were <0.40 and 1-week sCr/eGFR were <0.50. In predicting 1-week graft function, all indices were significant (*P*<0.01). Using the ROC curve analysis, the most accurate index was GI in predicting 1-week sCR of >2.5 mg/dl (AUC=0.88) and eGFR of <30 ml/min (AUC=0.87) and for prediction of decreasing sCr ratio of <30% (AUC=0.76) and increasing eGFR ratio of <50% (AUC=0.75) in one week. In predicting 1-week sCR of >2.5mg/dl and eGFR of <30ml/min, the AUC of other indices were <0.80. For prediction of decreasing sCr ratio of <30% and increasing eGFR ratio of <50% in one week, the AUC of other indices were <0.70. **Conclusion:** Assessing of the parameters of ΔP, A, Pl, P and 3rd minutes uptake (U_3) with the formula of GI increased the accuracy of RTS. Among the quantitative indices of basal RTS, GI had the best correlation with graft function. In addition, correlation of GI with 1-week graft function was better than its correlation with same day graft function. We considered that GI could be used as quantitative definition of graft function for RTS.

P208

Comprehensive Assessment Of Renal Function In Patients With Type 1 Diabetes Mellitus According To Dynamic Renal Scintigraphy And Doppler Ultrasound Of Renal Arteries

V. Zavadovskaia, A. Kurazhov, M. Zorkaltsev, A. Merinov, T. Saprina; Siberian State Medical University, Tomsk, RUSSIAN FEDERATION.

Aim. To study renal function in patients with type 1 diabetes mellitus used to dynamic renal scintigraphy and doppler ultrasound of renal arteries. **Material and methods.** The study based on 83 patients with type 1 diabetes mellitus (T1DM) (52 male, 31 female, aged from 18 to 56 years). According identified stage of diabetic nephropathy (DN) patients were assigned into 3 subgroups: subgroup 1 included DN patients with normoalbuminuria (NAU) (n=27, 32.5%); subgroup 2 consisted of patients with microalbuminuria (MAU) (n=35, 42.2%); and subgroup 3 included DN patients with proteinuria (PU) (n=21, 25.3%). Comparison group consisted of 15 patients with essential hypertension; control group consisted of 30 healthy volunteers. Cystatin C level was measured in all groups. **Results.** The analysis of clinical and laboratory data demonstrated that the values of cystatin C in control and comparison groups were significantly higher than the corresponding values in T1DM group (p=0.007 and p=0.027, respectively). The cystatin C level was significantly higher in MAU and PU subgroups compared NAU subgroup (p=0.02 and p=0.003, respectively). Analysis of duplex Doppler ultrasonography of renal arteries showed a statistically significant increase in the resistivity index (RI) at level of segmental renal arteries in both kidneys in T1DM group compared control group (p=0.001 for right kidneys, and p=0.03 for left kidneys). Intragroup analysis demonstrated a significant decrease in Vmin in PU subgroup compared NAU and MAU subgroups (p=0.006 and p=0.04, respectively). Disease duration caused a statistically significant Vmin reduction and RI increase in T1DM patients (p=0.01). Glomerular filtration rate (GFR) increasing on dynamic renal scintigraphy data were reviled in all groups. Intragroup comparison revealed a significant increase in Tmax and T½ in PU subgroup compared with NAU subgroup (p=0.01). An increase in the duration of T1DM was significantly associated with a decrease in GFR (p=0.03). **Conclusion.** Leading radiological signs of renal dysfunction in patients with type 1 diabetes mellitus were resistivity index increase on duplex Doppler ultrasonography data and decreasing of glomerular filtration on dynamic renal scintigraphy data. Besides Cystatin C level duplex Doppler ultrasonography and renal scintigraphy data seems available tools for assessment of renal function in T1DM patients.

P209

The Protective Effect of Lycopene on Kidney against Experimentally Induced Unilateral Ureteral Obstruction

H. I. ATILGAN[1], A. AYDIN[2], M. SADIC[3], M. KORKMAZ[3], T. KARAKAN[3], E. Ogus[3], P. Borcek[4], G. KOCA[3]; [1]Kahramanmaras Necip Fazil City Hospital, Kahramanmaras, TURKEY, [2]Sanliurfa Mehmet Akif Inan Training and Research Hospital, Sanliurfa, TURKEY, [3]Ministry of Health Ankara Training and Research Hospital, ANKARA, TURKEY, [4]Baskent University, Faculty of Medicine, ANKARA, TURKEY.

Purpose: To investigate the possible protective effect of lycopene on kidney after unilateral ureteral obstruction. **Methods**: Twenty one Wistar albino rats were divided into 3 groups. In lycopene group, lycopene was administered 2 days before left ureteral ligation and was continued for 15 days. In control group, left ureteral ligation was applied with no medication. In sham group, a midline incision was made to abdomen and then closed. Histopathological, biochemical and scintigraphic evaluations were made. **Results**: Microscopic score was 50.56 ± 34.32 in lycopene, 97.22 ± 39.14 in control and 28.33 ± 12.58 in sham group. Microscopic score was lower in lycopene group than control group (p=0.033). In biochemical analysis, mean value of MPO, MDA and nitrite levels were 0.05 ± 0.03, 4.64 ± 1.49 and 0.06 ± 0.01 respectively in lycopene group, 0.10 ± 0.03, 8.37 ± 3.31 and 0.14± 0.09 in control group and 0.04 ± 0.01, 18.76 ± 9.30 and 0.05 ± 0.01 in sham group. MPO, MDA and nitrite levels were lower in lycopene group than in control group (p=0.033, p=0.007 and p < 0.001, respectively). Postoperative mean Tc-99m DMSA uptake values of left kidneys were 6.26 ± 5.17 in lycopene, 2.09 ± 1.03 in control and 49.17 ± 1.37 in sham group. There was no statistically significant difference between lycopene and control groups in respect of postoperative DMSA uptake values (p=0.063). **Conclusion**: Lycopene is effective for the protection of kidney after ureteral obstruction as shown by microscopic parameters and decreased reactive oxygen species.

Feasibility and advantages of ^{99m}Tc-DTPA dynamic SPECT renogram combined with a SPECT/CT session

M. Spiliotopoulou[1], E. Papachristou[2], P. Kalidonis[3], A. Fotopoulos[4], T. Spyridonidis[1], **D. J. Apostolopoulos**[1]; [1]University of Patras, Medical School, Department of Nuclear Medicine, Patras, GREECE, [2]University of Patras, Medical School, Department of Nephrology, Patras, GREECE, [3]University of Patras, Medical School, Department of Urology, Patras, GREECE, [4]University of Ioannina, Medical School, Department of Nuclear Medicine, Ioannina, GREECE.

Aim: This study addressed the feasibility and the advantages of ^{99m}Tc-DTPA SPECT renogram combined with SPECT/CT for attenuation correction and correlation of functional with anatomical data. *Method*: 20

patients aged 38-77 y.o. were examined. The imaging protocol included: Day 1: Conventional planar renogram with 74-111 MBq of ^{99m}Tc-DTPA for 30-40 min (lasix was given at 20 min) followed by 74-111 MBq of ^{99m}Tc-DMSA administration and SPECT/CT imaging (Infinia hawkey-4, GE Helthcare) 3 hrs post-injection. Day 3: Dynamic SPECT (D-SPECT) renogram after injection of 222-370 MBq of ^{99m}Tc-DTPA (no lasix was given), immediately followed by a SPECT/CT session (VG hawkey, GE Helthcare). GFR was calculated at the same day by the clearance method with blood samples taken at 2 and 4 hrs post-injection. D-SPECT was performed as follows: Consecutive SPECT sessions were acquired over 360^0 arc with continuous acquisition mode, 140±30% KeV energy window, on 64x64 matrix, 2 sec/frame (SPECT time=1 min) for the first 8 min and 4-8 sec/frame afterwards. A total of 14 SPECT groups was acquired for 26 min. CT-derived maps were used for attenuation compensation of D-SPECT data [D-SPECT(AC)], while CT slices were fused with SPECT images. Renal activity was measured in the whole kidney volume by ROIs manually drawn on consecutive transaxial CT slices which were then copied on each of the 14 SPECT series. The reference method for split renal function measurement was ^{99m}Tc-DMSA SPECT/CT. *Results*: a) D-SPECT(AC) images were of good quality. b) 26-min renographic curves obtained by planar renogram were quite similar in shape to those created by D-SPECT(AC). c) Spilt renal function calculation by D-SPECT(AC) correlated perfectly (r=0.98) with the reference method, whereas planar renogram was less accurate (r=0.87). Planar-SPECT inconsistencies were often in case of ectopic kidneys (n=2) and marked size differences between the two kidneys (n=12). d) Anatomic information provided by contrast-unenhanced CT (calcium-containing calculi, parenchymal cysts, renal pelvis and ureter dilation, etc) offered an integrated structural-functional view valuable for the final diagnosis. e) D-SPECT(AC) kidney uptake at 2-3 min as a fraction of injected dose correlated better with reference GFR (r=0.87) than that estimated by the Gates method (r=0.73). *Conclusion*: 3-D ^{99m}Tc-DTPA renogram corrected for attenuation and fused with CT images is feasible with conventional gamma-cameras incorporated into hybrid SPECT/CT systems. It allows accurate split renal function measurement, is enriched by useful anatomical information and can be used for closer approximation of GFR compared with Gates method.

P211

Scintigraphic evaluation of renal protective effects of trimetazidine

Z. V. Vesnina[1,2], E. O. Vershinina[1], Y. B. Lishmanov[1,2]; [1]Institute of Cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Introduction. One of the adverse effects of the x-ray angiography and endovascular procedures can be contrast-induced kidney dysfunction. In this connection, it requires the use of therapeutic approaches and pharmacological agents having high nephroprotective efficiency during radiocontrast procedures. **Aim**. Scintigraphic evaluation of the renoprotective efficacy of trimetazidine in patients undergone endovascular revascularization (ER) of the myocardium. **Material and methods**. The study included 48 patients with ischemic heart disease (42 men and 6 women, mean age 56.98 ± 1.40 years) who underwent ER (stenting of the coronary arteries). All patients were randomized into 2 groups: patients (20 men) who took trimetazidine before angiographic procedures (group I), and patients (28 men) who underwent ER without nephroprotection (group II). Dynamic radionuclide renoscintigraphy with 99m Tc - DTPA were performed before and 2-3 days after the ER with the calculation of the parameters of filtration and excretory renal functions. **Results**. Patients of Group II after ER had the negative dynamics of renal filtration function parameters. Thus, there has been a significant decrease in the mean value of the total GFR, mainly by reducing the filtration activity of the left kidney. In patients of this group we observed a significant increase of radiopharmaceutical clearance half- time from the renal pelvis system (RPS), from the parenchyma of both kidneys and decrease of cortical delay index of the left kidney. In the group of patients treated with trimetazidine (group I), mean values of parameters of filtration activity of the kidneys did not significantly change compared with the baseline (before ER) data. Compared to the filtration activity, in Group I adverse changes in the processes of renal excretion were observed frequently. However, in patients of Group I average changes of scintigraphic parameters that reflect the evacuation function of the kidney parenchyma and RPS were insignificant. **Conclusion**. It is shown that trimetazidine prevents contrast-induced renal dysfunction in patients undergone coronary procedures. Key words: contrast-induced renal dysfunction, trimetazidine, radionuclide renoscintigraphy. Funding This work was supported by a grant from the Russian Science Foundation (№ 14-15-00178).

Glomerular Filtration Rate Measurement by Means of the Slope-Intercept Method - Do We Really Need the Standard Solution?

M. Silva[1], R. Silva[1,2], J. Isidoro[1], P. Gil[1], A. P. Moreira[1,2], P. Lapa[1], G. Costa[1], J. Pedroso de Lima[1,2]; [1]Centro Hospitalar da Universidade de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saude, Coimbra, PORTUGAL.

AIM: Glomerular filtration rate (GFR) is an accepted measure of renal function. It is routinely assessed using tracers that are cleared exclusively by glomerular filtration, the most common being ^{99m}Tc-diethylenetriaminepentaacetic acid (^{99m}Tc-DTPA). For all routine clinical purposes GFR can be satisfactorily estimated using 2 blood samples taken from the latter of the 2 exponential components of the plasma clearance curve (slope-intercept method). Although simpler than inulin infusion or the multiple blood samples technique, it is still labour intensive and involves the preparation of a standard solution (SS). The SS may, however, be discarded if the high accuracy and precision of the well counter guarantee a robust activity to counts ratio. In this study we mean to compare the classic slopeintercept method with a simplified version, that disregards the SS. MATERIAL AND METHODS: Twenty-eight consecutive patients (18 males and 15 females, 18-87 years of age, mean age: 57.0 ±18.9 years), referred to our department between January and April 2016 for GFR measurement, were included. The GFR was estimated, after the injection of 114.3±6.3 MBq, according to the British Nuclear Medicine Society guidelines. Additionally, the well counter's (CAPINTEC© CAPTUS3000©) activity to counts ratio was calculated and used to estimate the GFR without the SS for all patients. Statistical analysis was performed using IBM © SPSS © Statistics, version 22. RESULTS: On average, the GFR calculated without the SS was 1.04±1.47 ml/min higher than the conventional method (65.32±24.88 ml/min vs 64.28±24.57 ml/min, respectively). A statistically significant correlation was found between both methods (Pearson r:0.998, $p<0.01$). CONCLUSION: In this study the GFR calculated with and without the SS solution were nearly identical and very strongly correlated, calling into question the need for a SS solution and opening the possibility of simplifying the technique.

P213

Comparison Of 99m Tc Ethyelene Dicysteine And 99m Tc Dimercaptosuccinic Acid Scintigraphy For The Evaluation Of Renal Cortical Scarring And Differential Function In Patients With Urinary Tract Infections

A. Dharmalingam; Seth G.S Medical College and KEM Hospital, Mumbai-4000012, INDIA.

COMPARISON OF 99m-Tc ETHYELENE DICYSTEINE AND 99 m-Tc DIMERCAPTOSUCCINIC ACID SCINTIGRAPHY FOR THE EVALUATION OF RENAL CORTICAL SCARRING AND

DIFFERENTIAL FUNCTION IN PATIENTS WITH URINARY TRACT INFECTIONSDr.D.Anitha, Dr.Shwetal Ghule Pawar, Dr.G.H.TilveSeth G.S. Medical College and K.E.M Hospital, Mumbai-400 012, IndiaAIM OF THE STUDY: The aim of this study was to assess the ability of Tc-99m Ethyelene Dicysteine (EC) scintigraphy to detect renal cortical scarring over Tc-99m Dimercaptosuccinic Acid(DMSA) and also to compare the difference between the renal split function obtained by both the radiopharmaceuticals in patients with urinary tract infections.MATERIALS AND METHODS45 patients (age range of 15 days-12 years) presented with features of urinary tract infections with the kidneys located in the normal position were included in this study. The two studies, i.e Tc-99m DMSA and Tc-99m EC scintigraphy as per the EANM guidelines, were performed on two separate days within an interval of 10 days of each other.Tc99m EC images were acquired in 128×128 matrix after administering activity of 3.7MBq/kg of body weight(minimum of 37 MBq) and Tc-99m DMSA study was acquired in both the 128×128 and 256×256 matrices after administering activity of 1.85 MBq/kg (15 MBq). The images of the 2-3 minutes of the dynamic study of the EC study were summed and compared with that of DMSA scan using same matrix size. The presence and the distribution of the scars in the upper, middle and lower poles were compared in 128×128 matrix of both the studies and was confirmed on 256×256 matrix images of DMSA study as gold standard. The split function values were calculated with Tc-99m EC were compared with Tc-99m DMSA. Both studies were performed on the same gamma camera, and reviewed by a single nuclear medicine physician to eliminate bias due to technical factors or inter-observer variability. RESULTS:In the detection of cortical scars EC showed a positive predictive value was 100%, negative predictive value was 93.71%, sensitivity was 92.48% and specificity was 100% as compared with Tc99m DMSA as the gold standard. Differential function of both the kidneys calculated by using Tc-99m EC was found concordant with that of Tc-99m DMSA which is the gold standard.CONCLUSION: This study indicates that EC is comparable with DMSA in evaluating the cortical defects and differential function. By doing a single scan, there are added advantages of lower cost, convenience and low radiation exposure to the patient.

P214
^{99m}Tc-DMSA scan in child's uropathies

S. E. Bouyoucef, A. Khelifa, S. Rahabi, M. Habbeche, E. Atia, K. Chentli; CHU Bab El Oued, Algiers, ALGERIA.

Objective: To determine the role of ^{99m}Tc-DMSA scan when reporting the ^{99m}Tc-EC renogram in children with uropathy. **Materiel and methods:** It is a retrospective study done between January and March 2016 with a total of 200 children with uropathy who underwent in a two days protocol a ^{99m}Tc-EC renogram and a ^{99m}Tc-DMSA scan. 131 boys and 69 girls aged from 20 days to 15 years (average age of 4,47years) with uropathy were all referred in nuclear medicine for assessment of function and the drainage. Pyelo-ureteral junction (PUJ), mega ureter and vesico-ureteral reflux (VUR) were the most common indications. The injected activities for dynamic F0 ^{99m}Tc-EC scan were (20-90MBq) and for static ^{99m}Tc-DMSA(20-74MBq). For each kidney, the results of ^{99m}Tc-DMSA scan were compared to those of ^{99m}Tc-EC renogram before writting the final reporting. Both EC renogram and DMSA scan were reported separately by two experienced nuclear physicians. **Results**: 253 kidneys have had normal renograms, 115 kidneys have had abnormal renograms and 32 kidneys were not functioning. 275 kidneys have had a normal DMSA scan and 125 kidneys and abnormal DMSA scan. Among the 125 abnormal DMSA scans, 49 were seen in kidneys with abnormal ^{99m}Tc-EC renogram including an impaired drainage (49/115). In other hand, the 253 kidneys with normal ^{99m}Tc-EC renogram presented 76 abnormal DMSA scans (76/253). Those abnormal DMSA scans with normal EC renograms, were seen essentially in VUR followed by PUJ. DMSA scan confirmed the also the cases of non functioning kidneys and revealed additional morphological abnormalities such horse kidney. **Conclusion**: The ^{99m}Tc-DMSA scan is essential when assessing an uropathy in children and allows better follow up and contribute for adapting a better management of the disease.

P215
Normalized residual activity: diagnosis of kidneys obstruction

D. BEN SELLEM, B. LETAIEF, B. DHAOUADI, L. ZAABAR, M. F. BEN SLIMENE; University of Tunis El Manar, Faculty of Medicine of Tunis, Salah Azaiez Institute, Department of Nuclear Medicine, Tunis, TUNISIA.

Aim: Normalized residual activity (NORA) is a parameter proposed for the estimation of renal emptying during renography with ^{99m}Tc-MercaptoAcetyltriGlycine (^{99m}Tc-MAG3) or ^{99m}Tc-Diethylene Triamine Pentaacetic Acid (^{99m}Tc-DTPA) on dilated kidneys. This parameter allows, in many cases, the differentiation between simple dilatation urinary tract requiring simple monitoring and obstruction whose treatment is surgical. The aim of this study was to evaluate the value of NORA in the diagnosis of obstructive dilated kidneys. **Materials and methods**: This is a retrospective study of 300 patients referred to our department to evaluate kidney obstruction. Dynamic data acquisition was started at the moment of injection of a maximal activity of 100 MBq, adapted to body-surface. The patient was in the supine position and the collimator is posteriorly positioned. Furosemide was injected at 20 minutes (F+20). Data were processed in order to generate renogram curves. When the curves were suggestive of obstruction, delayed acquisition of dynamic images was performed to evaluate late emptying and to calculate the NORA. A total of 330 NORA was calculated. NORA is considered normal if its value is lower or equal to 1, abnormal if superior to 2 and equivocal if between 1 and 2. **Results**: The NORA was normal in 63.94 % of cases (211/330), abnormal in 12.12 % of cases (40/330) and equivocal in 23.94 % of cases (79/330). The NORA has allowed a good classification of the obstruction in 76% of cases, thus guiding referring clinicians in their therapeutic decision. **Conclusion**: Evaluation of renal emptying is crucial in the exploration of dilated kidneys. In fact, obstruction is managed surgically; while absence of obstruction needs a medical follow up. NORA is a simple parameter for the estimation of renal emptying during renography. In our study, it allowed the diagnosis of obstruction under the dilated renal tract in 12.12 % of cases and guided the therapeutic decision of clinicians in 76% of cases. Any suggestive signs of obstruction on renal curves must indicate delayed images in order to calculate the NORA.

P216
Comparison of Methods for Estimating Glomerular Filtration Rate in Head and Neck Cancer Patients Treated with Cisplatin

L. Lindberg, B. Kristensen, B. Zerahn; Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Herlev Hospital, Herlev, DENMARK.

Introduction: Cisplatin is a chemotherapeutic agent widely used in the treatment of various solid tumours. Cisplatin induces nephrotoxicity in a dose-dependent manner and may lead to long-term reduction of kidney function. Subsequently, determination of glomerular filtration rate (GFR) is used to monitor potential kidney damage during treatment. ^{51}Cr-EDTA clearance (CrCl) is the clinical gold standard for determination of GFR. However, estimation of GFR from plasma creatinine applying different equations is widely used owing to the simplicity of the method. This study aimed to compare CrCl with two commonly used algorithms for estimating GFR (eGFR) from plasma creatinine. *Materials and Methods:* Retrospective single center study of 94 head and neck cancer patients

treated with cisplatin at a maximum cumulated dose of 420 mg. CrCl was performed once before, during, and after treatment. CrCl was performed according to the principles of one sample clearance a.m. Broechner-Mortensen. Plasma creatinine was measured six times, concurrently. eGFR was assessed from plasma creatinine applying the Cockcroft-Gault (CG) equation that includes weight, and the Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) equation. Agreement between the methods was assessed applying the statistical methods of Bland and Altman. A predefined limit of variation between CrCl and eGFR of 14% was applied in order to decide whether eGFR derived from the two equations would be useful in a clinical setting. *Results*: Comparison of CrCl and $eGFR_{CKD}$ revealed a positive slope of the linear regression line, suggesting proportional bias ($p < 0.001$). No systematic bias was found between CrCl and $eGFR_{CG}$. Concerning the precision of each equation, 49 (54%) and 43 (47%) observations exceeded the clinically acceptable limit of variation for $eGFR_{CKD}$ and $eGFR_{CG}$, respectively. Weight changes ranged from -17.0 kg to 4.7 kg. Median weight change was -0.6 kg/week, significantly different from zero ($p < 0.001$). *Conclusion:* Estimated GFR_{CKD} cannot sufficiently replace CrCl in the assessment of GFR in head and neck cancer patients during treatment with cisplatin. If CrCl is unavailable, then weight-corrected $eGFR_{CG}$ is the better choice (probably due to its ability to compensate for changes in bodyweight during treatment) provided proper attention to the large variation between methods.

P217

Low level of GFR at baseline renal scan can predict postoperative 1 year function regardless of BMI

J. Ha[1], A. Chong[1], S. Jeong[2]; [1]Chosun University Hospital, Gwangju, KOREA, REPUBLIC OF, [2]Kyungpook National University Hospital, Daegu, KOREA, REPUBLIC OF.

Introduction On previous research of our group, we found low level of GFR at baseline renal scan could predict abnormal Cr level at postoperative 1 years follow-up. In that study, patient's factor of body weight and height showed difference between normal and abnormal groups of serum Cr(reference 1). The aim of this study was to find out whether body weight, height, or BMI affect the relationship between baseline GFR and function of transplanted kidney. **Materials and Methods** Baseline Tc-99m DTPA scan (within 8 days after transplantation) of 86 patients were analyzed retrospectively. Serum creatinine (Cr) levels at the timing of postoperative 1 year , GFR of renal scan, height, weight, and BMI at the timing of renal scan were also analyzed. P<0.05 was considered as significant. **Results** Baseline GFR correlates with serum Cr level at the timing of postoperative 1 year. Among clinical variables, height and weight showed difference between groups (serum Cr>1.5 or not at the timing of postop 1 year). However, partial correlation analysis showed significant correlation between baseline GFR and serum Cr level of postop 1 year with covariates of BMI, height and weight. Cut-off value of baseline GFR to predict anormal serum Cr level at postop 1year were 65.6 ml/min (sen 90.5% and spe 52.4%). **Conclusion**Lower GFR of baseline renal scan could predict abnormal Cr of postoperative 1 year follow-up regardless of patients BMI, height and weight.

Comparison of Single Sample and Two Sample Methods for Measuring Glomerular Filtration Rate (GFR) Using Tc99m DTPA Plasma Clearance Method

N. R. AKEPATI; JAWAHARLAL INSTITUTE OF POST GRADUATE MEDICAL EDUCATION AND RESEARCH, Pondicherry, INDIA.

AIM: The study aimed to assess the level of agreement between GFR values obtained with single plasma sample method (SPSM) and two plasma sample method (TPSM) using plasma sampling technique. MATERIALS AND METHODS: Consecutive subjects referred to our department for GFR measurement between the period June 2014 to March 2016 were included in thr study. 1 mCi of Tc-99m DTPA was injected intravenously to each subject and venous blood samples were withdrawn at approximately 60 and 180 minutes. Plasma was separated and counted after 24 hours. GFR was measured using Russel's two plasma sample technique formula (60 and 180 minutes samples) and single sample technique formula (180 minutes). GFR values obtained with SPSM and TPSM were normalised for body surface area and were expressed as median and interquartile range (IQ) Agreement between GFR values obtained with SPSM and TPSM was measured with Wilcoxon Signed Rank Test. Strength of agreement between SPSM and TPSM was carried out using Bland Altman analysis. P value less than 0.05 was considered significant. Results: 209 subjects (113 males, 96 females) with mean age of 41.28 years (SD 13.15 years, range 18-65 years) were included in the study. Out of 209 subjects, 70 were voluntary kidney donors, and 28 were transplant recipients. Chronic kidney disease patients with TPSM GFR values less than 30 ml/min were not included in the study. Mean GFR values for TPSM and SPSM were found to be 74.75 ml/min (IQ range-36.09) and 78.31 ml/min (IQ range-49.13) respectively. Wilcoxon Signed Rank Test showed no significant difference between median values of TPSM and SPSM values. On Bland-Altman analysis, GFR values calculated by SPSM were concordant with TPSM (Gold standard) in 95% confidence interval (average±1.96 SD). Conclusion: GFR values obtained with SPSM correlates well with TPSM in subjects with measured GFR values more than 30 ml/min. SPSM is a more convenient method since it involves a single blood sample and can be used in subjects who are expected to have GFR more than 30 ml/min.

P219

Diuretic Renography is a Gold Standard Method for Radiological Diagnosis of Urinary Obstruction: Optimal Timing of Diuresis injection

H. M. Gad[1], A. Elgendy[2], S. Mansour[1], H. Abdelkader[2]; [1]Urology and nephrology center- Mansoura University, al mansura, EGYPT, [2]Biophysics Department- Faculty of Science, al mansura, EGYPT.

Diuresis renography is widely accepted as a useful test for investigating the dilated urinary tract, evaluation of kidney function & urinary drainage and discriminating between obstructed and non-obstructed systems.The test achieve popularity because of its simplicity and noninvasiveness. Purpose: The aim of this study is to assess the optimum timing of furosemide injection in diuretic renography to gain the most accurate diagnosis. Patients and Methods: One hundred patients with suspected urinary obstruction due to presence of hydronephrosis underwent F+10 min diuretic renography. Forty patients gave no response to diuresis, diagnosed as obstructed kidneys however twenty patients showed delayed excretion but improved in response to diuresis and diagnosed as non obstructed kidneys. The remaining forty patients showed equivocal response to dieresis were enrolled in this study and underwent F-15 min .The results were classified into obstructed and non-obstructed according to images, T½ and curves of renogram after F-15 min diuretic renography. Results: The Results obtained for one hundred patients by F+10 min protocol showed that forty were obstructed and twenty were non-obstructed with sensitivity 60% , however the remaining forty patients with equivocal response to diuresis underwent F-15 min diuretic renography with thirty-one patients were proved to be obstructed and the other nine were non obstructed with sensitivity 100%. Obstruction was found in 71 out of 100 patients with mean ± SD T½ values 31.39 min ± 10.63. The mean kidney split function was 43.7% ± 2.6. Twenty nine patients were non-obstructed with mean ± SD T½ values 9.76 min ±3.31 min and there mean kidney split function was 45.59%± 3.34 %. As regard the forty patients with equivocal response to diuresis at F+10 min; thirty one patients were proved to be obstructed by F-15 min study with mean ± SD T½ values 29.77 min ± 8

which was 16.63 min ± 2.28 by F+10 min (p=.001), however the other nine patients were proved to be non-obstructed with mean ± SD T½ values 12.89 min ±3.22 min in F-15 min study and it was 24.89 ± 10.8 min in F+ 10 min (p=.01). A p value less than .05 was considered significant. Conclusion: The optimum timing of diuretic injection is 15 min prior to renography study with the exact T½min and so F-15 min renal scintigraphy can be considered as the most sensitive method for diagnosing urinary obstruction and can be taken as a gold standard in this matter.

P220

Tc-99m DMSA Absolute renal uptake: Is it a reliable quantitative parameter to assess the degree of renal impairment in patients with chronic kidney disease

H. Nasr[1,2], H. Farghaly[3,2], A. Al Qarni[2], A. Kheder[2]; [1]Nuclear Medicine Department, Cairo University, Cairo, EGYPT, [2]Radiology Department, Prince Sultan Military Medical City, Riyadh, SAUDI ARABIA, [3]Nuclear Medicine Unit-Clinical Oncology Department, Assiut University, Assiut, EGYPT.

Objectives: To determine the accuracy of Tc-99m DMSA absolute renal uptake (ARU) in assessment of the severity of chronic kidney disease (CKD) in comparison to Cr-51 EDTA GFR. Methods: We retrospectively analyzed 66 patients with CKD (mean age 62.8±15.07, 35 males and 31 females). All patients had Tc-99m DMSA renal scans, Cr-51 EDTA GFR and serum creatinine, all three studies performed within less than 6 months period (mean 30.69±63.06 days) and within less than 1 month in 86% of patients. Total (left + right) DMSA ARU was calculated using posterior view images performed after 3 hours of Tc-99m DMSA injection. For purpose of attenuation correction the depth of the kidneys was estimated using Tonnensen equation. Stages of CKD were based on GFR values according to KDOQI guidelines. Patients were classified into 3 groups; Group 1: GFR ≥ 60 (13 pt.), Group 2: GFR 30-59 (30 pt.) and group 3: GFR < 30 (23 pt.). The mean total ARU was compared between groups using ANOVA with post Hoc test. Pearson's correlation was performed between ARU, GFR and creatinine. Equation to estimate the GFR from the ARU was generated using regression analysis. Results: There was significant differences between the study subgroups as regards the mean ARU (group 1=41.4±10.8, group 2=19.7±5.7, group 3=7.9±4.2; p<0.001) as well as for creatinine (group 1=89.1±25.9 , group 2=132.1±39.9, group 3=242.8±109.3) with p values between all groups <0.001 except for creatinine between group 1 and group 2 (p=0.072). The GFR for the entire study group was better correlated to the ARU than to creatinine (r=0.914 vs. r=-0.713). The correlation of GFR with ARU in patients with GFR ≥40 ml/min was better than with creatinine (r=0.827 vs. r=-0.423), however in patients with GFR <40 ml/min correlation of GFR was comparable for both ARU and creatinine (r=0.716 vs. r=-0.708). The equation for rough GFR estimation from ARU was: GFR =14.11+1.40 ARU. Conclusions: The ARU is well correlated to Cr-51 ETDA GFR and can be considered a reliable and more sensitive indicator than serum creatinine to detect renal impairment specially in early stages of CKD during which serum creatinine is relatively low and is not well correlated to GFR values.

P221

Evaluation of 99mTC DMSA's efficiency as a radiopharmaceutical in dynamic renal scans

i. M. A. abd-elfadil, Sr., Heba M Fahmy1, Hossam M Yassin2, Islam M Muhamed1,Samar E Mohamed1, Shimaa S Hassan1 1: Biophysics; science, cairo, EGYPT.

Background: Dynamic and static renal scanning are considered the routine techniques for the preoperative, postoperative and follow-up evaluation of renal functions. In dynamic renal Tc-99m diethylenetriamine pentaacetic acid (DTPA) is much used and give information about the renal blood-flow and excretory function. Tc-99m dimercaptosuccinic acid (DMSA) is employed for static renal imaging and can show also the renal cortical structure. ***Aim of work:*** The purpose of this work was to evaluate whether DMSA can be utilized as a radiopharmaeutical in dynamic renal scans. The aim extends also to compare the results obtained from DMSA with those obtained with DTPA scans. ***Materials and methods:*** A total of 47 subjects (patients and normal kidney function cases) that had 99mTc-DMSA and 99mTc-DTPA dynamic scintigraphies using the same protocol. ***Results:*** Estimation of the total GFR from 99mTc-DTPA and 99m Tc-DMSA renograms showed a strong positive correlation. Moreover, estimation of the time to the peak height from 99mTc-DTPA and 99m Tc-DMSA renograms for right and left kidneys showed non-significant changes and strong positive correlation. ***Conclusion:*** In the light of the results obtained from the present study, it could be suggested that 99m Tc-DMSA could be successfully replaced 99mTc- DTPA in dynamic renogram. This will be money and time consuming, and will lower the radiation dose. In addition, the same qualities of results are obtained with both radiopharmaceuticals.

Testicular Scintigraphy as a Post-Surgical Evaluation Exam

A. S. Pinto, V. Alves, T. Vieira, A. R. Fernandes, T. Faria, A. Oliveira, M. Pérez, J. Pereira; Centro Hospitalar de São João, Porto, PORTUGAL.

Introduction: Testicular Scintigraphy (TestSci) is a Nuclear Medicine (NM) exam with proved utility in the setting of acute scrotal pain. It is used to distinguish between a variety of entities, namely testicular torsion, orchitis and epididymitis. In our NM Department, it is also requested as a follow-up exam after testicular surgical intervention, in order to evaluate testicular viability and atrophy. Aim: To evaluate the utility of TestSci as a post-surgical exam in our NM Department. **Materials and Methods**: We reviewed data from all patients who underwent TestSci at our Department from 2005 to 2015 (n=44) and selected the patients whose exam was requested for post-surgical evaluation. A total of 22 patients were included. TestSci Protocol: in adults, a dose of 185 MBq of ^{99m}Tc-pertechnetate is administered by intravenous injection; in children, there is an adjustment of the dose according to the "Administration of Radioactive Substances Advisory Committe" standards. Image acquisition begins immediately, with 1 minute dynamic phase followed by planar static images (anterior projection) of the pelvis and inferior abdomen during 15 minutes. When necessary, SPECT/CT is performed. **Results:** Our patients had a mean age of 7.7±5.41 years old. Testicular torsion (n=9) and cryptorchidism (n=9) were the most frequent pre-surgical diagnosis, leading to orchiopexy as the most frequent surgery (n=18), followed by herniorraphy to repair strangulated hernia (n=3) and a varicocele repair (n=1). TestSci was required to evaluate testicular viability in 5 patients, atrophy in 12 and both of these characteristics in 17 patients. In the majority of patients (n=16), the exam was requested 6 months after the surgical procedure. TestSci was considered "normal" in 9 cases, positive for atrophy in 9 cases and positive for non-viable testicle in 4 cases. In 15 patients it was also requested a Testicular Doppler Ultrasound, whose results matched with those of TestSci in 14 cases. There was a discordant result between TestSci and Doppler Ultrasound. Based on the results of both exams, 7 patients were submitted to a new surgery, which was an orchiectomy in all cases. **Conclusion**: TestSci allows the evaluation of blood perfusion and location of the testicles, which makes it useful in the post-surgical context at the evaluation of testicular atrophy and ischemia as possible sequelae, being a good option as a routine post-surgical exam.

Using ^{99m}Tc-HMPAO SPECT as tool to compare two Transcranial Magnetic Stimulation protocols and their long-term effects in dogs

R. Dockx[1], C. Baeken[1], L. Vlerick[2], R. Duprat[1], F. De Vos[3], B. De Spiegeleer[3], A. Dobbeleir[2], J. H. Saunders[2], I. Polis[2], E. Achten[4], K. Audenaert[1], K. Peremans[2]; [1]University of Ghent, Faculty of Medicine, Ghent, BELGIUM, [2]University of Ghent, Faculty of Veterinary Medicine, Ghent, BELGIUM, [3]University of Ghent, Faculty of Pharmaceutical Sciences, Ghent, BELGIUM, [4]University of Ghent, Department of Radiology, Ghent University Hospital, Ghent, BELGIUM.

A single day protocol of repetitive Transcranial Magnetic Stimulation (rTMS) elevates the regional cerebral perfusion in dogs. Optimalization of this rTMS protocol is necessary to use this technique as a treatment for anxiety in dogs. We hypothesize that a 4 day stimulation protocol will elicit a higher and longer response compared to a single day protocol. **Aim**: To assess the effects and their duration on the regional cerebral bloodflow between two High Frequency Accelerated Repetitive Transcranial Magnetic Stimulation (HF-rTMS) protocols on the normal canine left frontal cortex. **Material and Methods**: Eight dogs were included in a crossover study. They underwent a 3 Tesla MRI scan at the Ghent University Hospital. This scan was the basis for pointer-based neuronavigation (Brainsight 2, Rogue Resolutions, LTD) a technique used to externally locate the stimulation site. Each dog was subjected to two protocols. Protocol 1: a single stimulation day applying 5 consecutive aHF-rTMS (20 Hz) sessions and Protocol 2: the same stimulation protocol for 4 consecutive days. Stimulation was applied with a figure - of - eight coil (Magstim Company Limited, Wales, UK) over the left frontal cortex. The stimulation intensity was set at 110% of the motor threshold. One day prior to, one day after and 12 weeks after the last stimulation day, a 99mTc-HMPAO SPECT scan was acquired under general anesthesia. SPECT data were acquired with a triple head gamma camera (Trionix, Triad) 30 minutes after tracer injection (step and shoot, 120 steps of 3°, 10" per step). The data were reconstructed with OSEM reconstruction (Hermes, NUD, Sweden). A BW filter was applied (cut-off 1.6 cycles/cm, order 5). The perfusion indices (PI) in the frontal, parietal, temporal as well as subcortical regions (thalamus, striatum) were obtained by semi quantification (normalization to total brain counts). **Results**: Both protocols elicited a significant difference in perfusion at the stimulation site 24h post stimulation. The stimulation responses between both protocols did not differ in intensity. After stimulation the regional perfusion returned to baseline within three months. **Conclusions**: The performed aHF-rTMS protocols of the frontal cortex in dogs provoke an increase in rCBF at the stimulation site. Shorter 99m-Tc-SPECT scans acquisitions intervals could reveal differences in response duration. Determining the response duration may help refine an aHF-rTMS protocol to treat anxious dogs.

PET for Neurology: Short Acquisition Neuro-PET Enabled by Digital Photon Counting

K. Binzel, R. Revan, J. Zhang, D. Scharre, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

Aim: Positron emission tomography (PET) is increasingly being used as an imaging biomarker for neurologic applications, such as traumatic brain injury, dementia, and Alzheimer's disease. Standard acquisition times for PET neuro imaging can be quite long, typically greater than 10 minutes. For these specialized patient populations, motion during imaging can become a significant problem for such long imaging over a single anatomic area. We explored the feasibility of shortening neuro PET acquisitions, as enabled by the improved sensitivity of next-generation digital PET. **Materials and Methods**: 10 patients recruited for various neuro related trials with acquisition times ranging from 10-20 min over the brain, following injection of 185-555 MBq ^{18}F-imaging agents. Images were acquired on a pre-commercial release next-generation digital photon counting system (Vereos Philips). Listmode data from the full acquisition were clipped into increments from 15 s to 5 min for re-reconstruction using the standard definition 4 mm voxel length methodology with point spread function correction. Images were then quantitatively evaluated using an atlas based z-score and SUV measurement. Visual quality was reviewed by 2 blinded reviewers, and the patient motion over the entire acquisition duration was tracked. **Results**: We found that excellent visual quality is maintained for time clipped reconstructions up to a[MVK1] 50% reduction in reconstructed acquisition time. Quantitative accuracy was robust as well, there were no significant differences in either z-score or SUV measures for 50% time clipped images as compared to full duration images ($p>0.5$). Motion tracking revealed that patients exhibited most motion beyond the 10 minute point of the acquisition despite using a firm head positioning device. Image sets of shorter than10 minute duration markedly reduced the amount of motion within the images. After optimization of reconstruction that used a combined PSF, Gaussian filtering approach with a reduced number of subsets in the iterative recon, full visually and quantitatively equivalent brain images were obtained with even improved delineation of cortical area observed, likely due to less motion. **Conclusion**: PET for neurologic applications uses traditionally longer acquisition times. We are able to demonstrate, that using a next generation digital PET/CT system enables a substantial reduction of acquisition times with preserved visual quality and quantitative accuracy. Overall reduction by 50% can be readily achieved. Shorter acquisition enables noticeable reduction in patient motion. [MVK1]There could be more data here

P226

Changes of Some Resting State Networks in Patients with Dysexecutive Syndrome

D. Susin, G. Kataeva, Y. Khomenko, I. Zavolokov, Y. Irishina; Institute of Human Brain of the Russian Academy of Sciences, Saint-Petersburg, RUSSIAN FEDERATION.

Introduction. The executive function (EF) is a set of abilities that allows us to control voluntary behavior responses. The dysexecutive syndrome (DES) is a disability of EF. One of the possible reason of DES is difficulties for some reason to switch attention between dorsal attention network (DAN) and ventral attention network (VAN), the first of these networks is responsible for voluntary (top-down) attention, the second responds to relevant external environmental stimuli. The goal of the study is to estimate the changes in attention networks in patients with DES and their interconnection with the default mode network (DMN) working. Methods: 31 patients (age 53-77) with DES (14 person with Parkinson's disease (PD) and 17 with chronic cerebral ischemia), 26 patients (age 41-77) without DES (17 person with PD and 9 with chronic cerebral ischemia) and 19 healthy controls with normal EF (age 20-29) were investigated with PET-FDG, performed on PC2048-15D Scanditronix scanner and standard protocol. Relative estimation of regional glucose cerebral metabolic rate (rCMRglu) in regions of interest (ROI), corresponding to Brodmann's areas (BA), were calculated by WFU PickAtlas after spatial normalization by SPM8. Psychological examination of EF was performed with frontal assessment battery (FAB). The functional connectivity of brain structures, resting state networks (RSN) were revealed by factor analysis of PET data. Results. In our research of RSN, we focus on four groups of ROIs, which belong to four networks, namely DMN, DAN, VAN and visual network. Healthy controls and patients without DES show similar structures of RSNs, consisting of the same four typical groups of ROIs. The patients with DES show the structural changes of the dorsal and ventral attention systems: the combination of the part of dorsal attention system and visual cortex with posterior cingulate cortex (PCC) (main element of DMN). We have also registered disintegration of ventral attention system. Our study gives the reason for the assumption that DES is based not only on the frontal cortex dysfunction, but also on some complicated reorganization of the attention networks.

P227

Astrocyte Involvement in TSPO Signal After Microglia Depletion in mice

M. Tóth, L. Harald, J. Häggkvist, A. Forsberg, A. Varrone, C. Halldin, R. Harris, L. Farde; Karolinska Institutet, Stockholm, SWEDEN.

Aim In the newly developed CX_3CR_1Cre-ERxRosa26-DTA mice, we aimed to study the changes of [^{11}C]PBR28 signal after specific depletion of CX3CR1-expressing microglia. With the longitudinal follow up we have focused on the TSPO signal changes shortly after microglia depletion (7 days) and after re-population (30 days) in the brain. As TSPO signal might not only originate from microglia, but also from binding to other cell types such as astrocytes and from non-displaceable binding, we have investigated the astrocyte involvement in vitro as well as conducted pretreatment experiments with PK11195 in different cohorts of animals. **Matherials and Methods** Seven CX3CR1-CreER(+/-) x Rosa26-DTA (+/-) and four control mice [CX3CR1-CreER(+/-) x Rosa26-DTA (-/-)] were imaged at baseline condition and 7 and 30 days after tamoxifen treatment. Additionally, we also performed pre-treatment experiments with PK11195 after baseline in three mice. All PET measurements were done using the NanoScan PET/MRI and PET/CT systems (Mediso Ltd, Budapest Hungary) after a tail vein bolus injection of [^{11}C]PBR28. PET scans were co-registered to an inbuilt MRI brain atlas in PMOD 3.7 (Zurich, Switzerland) and the corresponding template VOI set was used for time activity curve generation. As a primary outcome value the area under the curve (AUC) was used. **Results** In contrast to the expected outcome based on immunohistochemistry results, injection of tamoxifen did not result in the reduction of [^{11}C]PBR28 uptake at day 7, but resulted in a non-significant increase. At day 30 the striatum, thalamus, hippocampus, CAG and superior colliculi have shown a significant uptake increase of 32-37% compared to the baseline AUC in microglia depleted mice. Pretreatment with PK11195 resulted in a significant decrease of AUC values ranging from 27% in the striatum to 45% in the cerebellum compared to baseline. Preliminary immunohistochemistry results indicate an upregulation of astrocytes after microglia brakedown at day 7, but not at day 30. **Conclusion** The involvement of astrocytes in the general TSPO signal is often neglected or regarded as non-significant. The results presented here, show the possibility of a large enough increase in astrocyte related TSPO signal after total microglia depletion, that hides the depletion of brain microglia. Therefore care should be taken when interpreting the results of TSPO in vivo imaging in mice, regarding the contribution of microglia and astrocyte related signal changes.

P228

Quantification of Brain Glucose Metabolism by ^{18}F-FDG PET in Diabetic Mice

P. Branger[1], M. Joubert[1], D. Bellevre[2], **A. Manrique**[1]; [1]University Hospital of Caen, Caen, FRANCE, [2]University Hospital of Lille, Lille, FRANCE.

Introduction. Brain glucose exposure has been implicated in cerebral dysfunction and cognitive impairment. We assessed brain glucose metabolism with dynamic and static ^{18}F-FDG-PET in type 1, type 2 diabetic mice model and control. **Materials and Methods**. Nine male Swiss mice with streptozotocin induced diabetes (type 1 diabetes model) (D1), 5 control Swiss mice (C1), 6 male C57BL/6 seipin KO mice (type 2 diabetes model) (D2) and 6 control C57BL/6 mice (C2) were studied. A 60-min dynamic PET (Inveon micro-PET/CT scanner) was performed on isoflurane anesthetized mice after intravenous injection of ^{18}F-FDG (15-20 MBq in 50-100μL). Quantitative analysis was assessed by ^{18}F-FDG uptake constant (K_i) using a vena cava image-derived input function and time-activity data from the 15- to 60-min. Cerebral metabolic rate of glucose (CMR_{Glu}) was then calculated using Ki and the lumped constant. Static analysis was performed estimating mean and maximum standardized uptake values (SUV) from the 45- to 60-min frame. **Results**. K_i and CMR_{Glu} were significantly lower in D1 (0.004 and 9.560 respectively) than in C1 (0.012 and 25.646, $P<0.05$) and higher in D2 (0.010 and 19.018) than in C2 (0.006 and 9.372, $P<0.05$). There was no difference on SUV_{mean} or SUV_{max} between D1 (1.078 and 2.171 respectively) and C1 (1.218 and 2.427), and between D2 (1.424 and 2.318) and C2 (1.406 and 2.087). K_i were negatively correlated to glucose level ($R=-0.73$, $P<0.05$) in D1 but not in D2. Animal weight, which is an indirect marker of insulin secretion (the more insulinopenic animals displaying the lower body weight), was positively correlated to K_i in D1 ($R=0.74$, $P<0.05$) but not in D2. **Conclusion**. Brain glucose metabolism differ between diabetic and non-diabetic mice, and between type 1 and type 2 diabetes. Our results suggest that insulin level might be a key determinant of brain glucose metabolism with a decreased CMR_{Glu} in insulinopenic type 1 animals whereas this parameter was increased in hyperinsulinemic insulin resistant type 2 animals. These different behaviour of brain glucose metabolism in response to blood glucose and insulin levels may lead to a potential neurotoxicity and cognitive impairment.

P229

Effects of Random, Scatter, Attenuation, and Partial Volume Corrections on the Quantification of Dopaminergic PET imaging

K. H. Lue[1], H. H. Lin[1,2], C. S. Lin[1], C. C. Chiang[1], K. S. Chuang[1]; [1]Department of Biomedical Engineering and Environmental Sciences, National Tsing Hua University, Hsinchu, TAIWAN, [2]Medical Physics Research Center, Institute for Radiological Research, Chang Gung University/Chang Gung Memorial Hospital, Taoyuan, TAIWAN.

Aim Quantitative analysis of nigrostriatal dopamine function is important for the differential diagnosis of parkinsonian disorders in dopaminergic PET imaging. However, the accuracy of quantitative measurements is limited by a number of image degrading factors. This study investigated the effects of random events, scatter events, attenuation, and partial volume effect (PVE) on the quantification of striatal subregional uptake in dopaminergic PET images. **Materials and methods** Monte Carlo simulations were performed using an in-house integrated GATE and SimSET software. The Siemens Biograph^{TM} 6 PET scanner was built. A modified Zubal MRI head phantom was used to model realistic healthy and neurodegenerative radioactivity distributions. The simulated sinograms were sorted to mimic ideal random correction (RC) or scatter correction (SC). Attenuation correction (AC) was executed on the basis of the non-uniform attenuation maps. The random-, scatter-, and attenuation-corrected sinograms were reconstructed using an OSEM algorithm. The reconstructed images considered the PVE based on the recovery coefficients, which were derived from a combination of conventional image analysis and the technique of large regions of interest. The binding potential (BP) values for the entire striatum and its subdivisions were calculated for different correction schemes. **Results** Without any correction, the BPs were underestimated by 45.5% and 44.7% on average for healthy and neurodegenerative conditions, respectively. Given the low counting rates, the accuracy of BP estimates did not improve after only RC was carried out. The BPs remained the same as those observed without any correction. Adding SC to RC decreased the average bias in BP estimates. The bias values were 42.5% and 42.6% on average for healthy and neurodegeneration, respectively. The association of AC, RC, and SC was not adequate for the accurate quantification of BPs, which remained underestimated by more than 27.2% for each simulated conditions. The key correction for obtaining accurate BP estimates was partial volume correction (PVC). When PVC was combined with AC, RC, and SC, the

average bias values of BPs were 0.1% and 2.2% for healthy and neurodegeneration, respectively. **Conclusion** Our results indicate that the highest error in BP estimates was induced by PVE, the second largest source of error was attenuation, followed by scatter, and random coincidences. The correction of these image degradations can improve quantitative accuracy. PVC plays a major role in the quantification of dopaminergic PET imaging.

P230

There is more to "Lassen" plots than Lassen's plot

M. S. Vafaee[1], J. Araj Khodaei[2], M. Araj Khodaei[3], **A. Gjedde**[4]; [1]University of Southern Denmark, Odense, DENMARK, [2]Amirkabir University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Shahed University,, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]University of Copenhagen, Copenhagen N, DENMARK.

Introduction: Neuroreceptor studies by PET often compare radioligand binding potentials in baseline and inhibition states in cases where an apparent reference region of no binding is unknown. The purpose is to obtain separate estimates of receptor saturation and non-displaceable radioligand volume of distribution, according to an equation linearized by Turton et al (1995), Gjedde & Wong 2000, and Cunningham et al (2010), as the Saturation, Inhibition, and Occupancy plots. The Saturation plot uses ΔVT as the X component, and VT(b) as the Y component, while the Occupancy plot uses ΔVT as the Y component, and VT(b) as the X component, yielding similar trend and regression accuracy parameter values. We determined the linearization with the best convergence to measured data of the fraction of receptors occupied (s) and the volume of distribution of non-displaceable radioligand (VND). Methods: We subjected 24 published reports of 98 sets of data to reanalysis. In six cases, the authors submitted data, and for the remaining 18 reports, we extracted the data from published graphs. We used two linear regressions, the Least Squares (LSM) and Deming methods to obtain parameter estimates by calculating s (fraction of receptors occupied) and VND. In LSM, the R2 value is the linearization accuracy. When the R2 value is closer to unity, the results are more accurate. In the Deming II method, Sigma X2 is the standard error. When the Sigma X2 value is closer to zero, the results are considered more accurate. As example, values of VT(b) and ΔVT were extracted from the report of Kågedal et al. 2013, and VT(i) values were calculated from the digitization. We obtained the parameter values from the Inhibition, Saturation, and Occupancy plot linearizations and the LSM and Deming method regressions. Results: The comparisons revealed that the mean value of R2 (for 86 samples) was closest to unity for the Inhibition plot, and the mean value of Sigma X2 in the Deming Method was closest to zero also for the Inhibition plot, as the most accurate of the three plots. Conclusions: Linearizations were derived from the equation of receptor availability. In comparison of 98 cases from the literature, the accuracy for each of the linear regressions was evaluated by Least Squares and Deming methods of regression. Due to the absent commingling of dependent and independent variable, the Inhibition plot emerged as the most accurate of the regressions.

P231

Delayed damage of cerebral tissue after hypoxic-ischemic encephalopathy in immature rats as observed in longitudinal hybrid MR/PET scanning with spontaneous ^{15}O-oxygen inhalation

M. Oshima, M. Tsuji, J. Enmi, M. Yamazaki, **H. Iida**; National Cerebral & Cardioascular Ctre - Res Inst, Suita City, Osaka, JAPAN.

Backgrounds: Hypoxic ischemic encephalopathy (HIE) is a common type of brain damage in infant, causing severe developmental and cognitive delays, or motor impairments. The primary causes of HIE are hypoxemia and/or reduced oxygen supply, to which hypothermia is the only evidence-supported therapy for neonatals earlier than 6 hours of the birth. Other treatment techniques are currently under investigation, but variation of disease progression even in animal models makes systematic investigation difficult. This study was aimed at assessing sequential changes of disease status in an immature rat model of acute HIE. Particularly intention was to detect the longitudinal alterations using hybrid MR/PET system with spontaneous $^{15}O_2$/C$^{15}O_2$/C^{15}O inhalation procedures. **Methods:** Scans were carried out on 9 immature rats using PET (MicroPET Fucus120, Siemens) and MRI (Biospec 70/30, Bruker) at 0, 1, 2, 7 and 42 days after the ischemic hypoxic stress as presented previously (Oshima et al, Exp Neurol 2012). Series of PET scans were carried out during spontaneous inhalation of ^{15}O-labeled gases, then followed by MRI scan for T2WI, FA, DTI images. Functional images of CBF, $CMRO_2$, OEF and CBV were calculated by the 3-step autoradigraphy using the left-ventricular input function. **Results:** At day 0 immediately after onset of HIE, CBF in the left hemisphere was reduced to 38.8 ± 22.2 % compared with the contralateral hemispheres, but $CMRO_2$ was normal, suggesting preserved cerebral tissue. CBF was restored on day 1. $CMRO_2$ became reduced to 29.9 ± 27.4 % at day 7, and the reduced area was further expanded after 2days. T2WI indicated high intensity at day 1 and turned to low density after day 2. FA showed no changes at the beginning, and then turned to low intensity after day 2. Defect volume in CBF, $CMRMO_2$, T2WI and FA at day 42 agreed with the infarct volume estimated from histochemical analysis. **Conclusion:** Despite large variation of brain damage among animals, the present study demonstrated that the delayed damage of the cerebral tissue was present after acute HIE. Repeat MR/PET imaging for quantitatively assessing CBF, $CMRO_2$, OEF, and CBV, together with series of MR parametric images may be useful in evaluating/optimizing various new therapeutic approaches for HIE in immature rats.

P232

Transferring a brain imaging protocol from PET-only to PET/MR imaging: Implications for kinetic modeling

M. L. Lassen[1], J. Cal-Gonzalez[1], O. Langer[1], I. Rausch[1], O. Muzik[2], T. Beyer[1], M. Bauer[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]Wayne State University, Michigan, MI, UNITED STATES.

Objectives. In this study we investigate the feasibility of transferring a validated neuropharmacological imaging protocol from a PET-only to a fully-integrated PET/MR system. **Methods** Five subjects underwent dynamic PET-acquisitions using (*R*)-[^{11}C]verapamil to study P-glycoprotein transport activity at the blood-brain barrier. All subjects underwent a single-day, dual-injection dynamic imaging protocol in a (a) PET system (GE-Advance) and (b) a PET/MR system (Siemens Biograph mMR). All subjects had arterial blood-sampling for kinetic modelling in both imaging sequences. An additional low-dose CT was acquired on a PET/CT (Siemens Biograph TPTV) for all subjects for attenuation correction purposes. The PET-data was reconstructed in a dynamic set-up (1x15, 3x5,3x10,3x30,2x150,2x300 and 2x600 s) using the Transmission-based attenuation correction in (a) (aTX), and DIXON (bDi) and CT (bCT) in (b). All data were reconstructed using 2i28s followed by a subsequent post-filtering (6mm FWHM Gaussian). We report %-wise differences ((b-aTX)/aTX*100) for rate constants describing transport of (*R*)-[^{11}C]verapamil across the blood-brain barrier (K_1 and k_2) estimated with a 1-tissue-2-rate constant compartment model using PMOD for three regions of interest (whole-brain gray-matter (WBGM), insula and cerebellum). Average soft-tissue attenuation correction values were calculated for all attenuation correction maps in a 5cm^3 VOI. **Results**. In WBGM, relative cross-subject differences in K_1 values were +15.0% (bDi:aTX) and +42.6% (bCT:aTX) and differences in k_2 values were +12.5% (bDi:aTX) and +19.1% (bCT:aTX). Relative differences for K_1 values

were +16.8% (bDi:aTX) and +42.3% (bCT:aTX) for cerebellum and +13.8% (bDi:aTX) and +34.9% (bCT:aTX) for the insula. Differences in k_2 values were -1.6%(bDi:aTX) and +9.5% (bCT:aTX) for cerebellum and -10.7% (bDi:aTX) and -3.3% (bCT:aTX) for insula. Average attenuation correction values were measured to be 0.087cm^{-1}(TX), 0.1cm^{-1} (DIXON) and 0.0983cm^{-1} (CT) **Conclusion**. Significant differences were observed between kinetic modelling outcome parameters obtained in a stand-alone PET and a PET/MRI system when using CT-based attenuation correction in the PET/MR. However, differences in outcome parameters between DIXON and transmission based reconstructions were acceptably small, thus, suggesting the possibility to transfer the scan-protocols.

P233

Individual Patient Contribution to Group-based Cerebral Blood Flow and Gray matter volume Co-variance Networks in Mild Cognitive Impairment

C. A. Sánchez-Catasús[1,2], A. Willemsen[1,3], R. Boellaard[1,3], L. Melie-Garcia[4], J. Samper-Noa[5], A. Aguila-Ruiz[6], P. De Deyn[1,3], R. Dierckx[1,3]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]University of Groningen, University of Groningen, NETHERLANDS, [3]University of Groningen, Groningen, NETHERLANDS, [4]Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, SWITZERLAND, [5]Cuban Neuroscience Center, Havana, CUBA, [6]Center for Neurological Restoration (CIREN), Havana, CUBA.

Graph theoretical analysis of co-variance networks derived from neuroimaging data provides measurements of brain connectivity. However, due to the group-based nature of this methodology, it is not possible to assess the relationship between brain connectivity and patient characteristics and/or underlying pathophysiological conditions at the individual level. Although methods for extracting individual patient contribution have been recently reported, these have not yet been widely applied. **Aim:** We aimed to explore whether the individual contributions to cerebral blood flow (CBF) and gray matter volume (GMV) co-variance networks of patients with amnestic mild cognitive impairment (MCI) correlate to global cognitive function. **Materials and Method**: CBF SPECT, corrected for partial volume effect, and volumetric MRI (for GMV estimation) were obtained from 26 amnestic MCI patients (14 females; 64.7 ± 6.9 years; MMSE: 26.9 ± 1.24). Two group-based co-variance networks were constructed based on the AAL atlas (90 ROIs): one using CBF data and another one using GMV data. The individual contribution of each patient to each group-based network was operationalized as the change in the global correlation strength (CS) when the patient was excluded from the dataset (the "leave-one-out" approach). The global CS is the average of the regional CS (mean of Pearson's correlation coefficients between a particular ROI and each ROI in the network). Global cognitive function was evaluated through to the Mini-Mental State Examination (MMSE) and the association between estimated individual contributions to each network and the MMSE score was calculated. The same analysis was performed for a subset of ROIs that correspond to the two subsystems (dorsal medial and medial temporal) of the default mode network (DMN) due to their relevance in MCI. **Results**: Individual contributions to the CBF co-variance network were the only ones that showed a significant and positive correlation with the MMSE score (R=0.45, p=0.02 for global CS; and R=0.40, p=0.04, for CS of the dorsal medial subsystem). The medial temporal subsystem showed no significant correlation in both co-variance networks. **Conclusions**: Our results suggest that MCI patients who have better cognitive performance contribute more to the global CS of the CBF co-variance network (i.e. more "connectivity" of the whole network). We have also documented this phenomenon for the dorsal medial subsystem of the DMN. Our results warrant further research into the potential utility of the individual patient contribution as a "network connectivity"-based biomarker in patients with MCI.

P234

Assessment of Training Efficacy in Scoring and Reporting 18F-Fluorbetaben PET Imaging

M. Scarlattei[1], G. Baldari[1], C. Cidda[1], S. Migliari[1], A. Sammartano[1], G. Serreli[2], O. Ortenzia[2], C. Ghetti[2], **L. Ruffini**[1]; [1]Nuclear Medicine Dept, University Hospital of Parma, Parma, ITALY, [2]Medical Physics, University Hospital of Parma, Parma, ITALY.

Amyloid imaging by PET (Amy-PET) can assist in the early and accurate diagnosis of Alzheimer disease and other dementias. Training for accurate image interpretation is essential for clinical use. Current clinical method for interpretation of 18F-florbetaben (18F-FBB) beta-amyloid PET is visual assessment. Reader training is performed before starting clinical activity and required by Italian Medicines Agency (AIFA). Aim of this work was to test training efficacy, intra- and inter-readers' agreement and compliance in assessing 18F-fluorbetaben PET.**METHODS** In-person reader training (n=2) and electronic training (n=1) were administered to the medical staff. Training modules were identical in approach and content focused on brain anatomy to identify normal white matter using MRI and coregistered PET images to detect white-gray matter boundaries. Positive scan demonstrates tracer uptake beyond cortical white matter to adjacent gray matter in reference regions. 18F-FBB PET scans were assessed visually by all readers, blinded each other, using a three-grade scoring system comparing regional cortical tracer uptake (RCTU) in gray matter (frontal, parietal and temporal cortex, posterior cingulate cortex/precuneus) with adjacent white matter. RCTU scores (1 no binding, 2 minor, 3 pronounced) are condensed into a single three-grade scoring system, BAPL score (1 no beta-amyloid load, 2 minor, 3 significant) and BAPLs condensed into a binary interpretation (score 1 negative; 2 or 3 positive). Intra- and inter-reader agreement were assessed by a re-evaluation session (30 random selected images) and Cohens' kappa, compliance by a questionnaire. **RESULTS** 18F-FBB PET was performed in 83 patients, 82 classified equally by in-person trained readers: 47 B.P. 3, 9 B.P. 2 and 26 B.P. 1. The e-trained reader results were different: 44 B.P. 3, 11 B.P. 2, 28 B.P. 1. RCTUs were classified equally in frontal and parietal regions, different in the precuneus (8 pts) and in the temporal lobe (11 pts) in pts with severe atrophy. Different RCTUs did not change global assessment of amyloid plaque burden (BAPL). Reader's compliance and confidence were evaluated optimal independently from training method. Inter- and intra-reader agreement were excellent (k=0.98) for in-person training group. **CONCLUSIONS** Results demonstrate good efficacy of the reader training; a supervision seems to be necessary for-e-trained staff at starting. Inter- and intra-readers agreement was excellent for global scoring (BAPL) in the in-person trained group. More complex appears regional assessment suggesting the need of a quantitative method particularly necessary when it's critical to establish relationship between anatomy, memory and extra-amnesic disorders and amyloid deposition.

P235

Computation strategy for CBV estimation from a single PET scan with sequential administration of $^{15}O2$ and $C^{15}O2$

N. Kudomi[1], Y. Maeda[2], H. Yamamoto[1], Y. Yamamoto[1], T. Hatakeyama[1], Y. Nishiyama[1]; [1]Faclty Of Medicine, Kagawa University, KAGAWA, JAPAN, [2]Clinical Radiology, Kagawa University Hospital, KAGAWA, JAPAN.

Objectives: PET with ^{15}O-labeled tracers is capable of providing unique and essential information in patients with cerebro-vascular disorders, and has been promoted as a clinical diagnostic tool. A novel DBFM method, allowing an extremely shortened examination period of <10 min, has been developed to assess parametric images of cerebral blood flow (CBF), oxygen extraction fraction (OEF) and metabolic rate of oxygen ($CMRO_2$), from a dynamic single PET scan in conjunction with

sequential administration of $^{15}O_2$ and $H_2{}^{15}O$ [1]. The DBFM, however, misses information of cerebral blood volume (CBV) because of elimination of $C^{15}O$ scan. This study was intended to develop a further improved computation strategy for estimating CBV image, from the single PET scan data. **Methods**: The computation formula applied involves differential term which allows for improving sensitivity to CBV estimation. The CBV image was computed with the developed formula after correction for blood appearance time [2]. Validity was tested on subjects with (n=12) and without (n=12) cerebro-vascular disorders. Regions of interest (ROIs) were placed on frontal, temporal, occipital cortical regions, white matter regions and sinus regions. Also, ROIs were placed on ischemic region for subjects with disorder. The CBV values were extracted from CBV image by the present method ($V_{B,Dual}$) and CO scan method ($V_{B,CO}$), and were compared between the methods. **Results**: The mean of CBV values in cortical region for subjects without disorder were 0.042 ±0.030 and 0.039±0.011 ml/g, for $V_{B,Dual}$ and $V_{B,CO}$, respectively. Those with disorder were 0.043±0.027 and 0.039±0.015 ml/g, respectively. Those for ischemic region were 0.035±0.010 and 0.040±0.025 ml/g, respectively. Differences between $V_{B,Dual}$ and $V_{B,CO}$ were not significant for all regions. Regression analysis showed tight correlations between $V_{B,Dual}$ and $V_{B,CO}$, namely, r=0.92 and r=0.89, for subjects with and without disorders, respectively. The obtained V_B images seemed to be similar between $V_{B,Dual}$ and $V_{B,CO}$, particularly CBV elevated regions due to ischemia were identical between the methods. **Conclusion**: The present method is of use for assessing CBV as well CBF, OEF and $CMRO_2$ rapidly in clinical settings. P236

Comparison of delay of appearance time of blood in brain region with elevation of oxygen extraction fraction

N. Kudomi[1], Y. Maeda[2], H. Yamamoto[1], Y. Yamamoto[1], T. Hatakeyama[1], Y. Nishiyama[1]; [1]Faclty Of Medicine, Kagawa University, KAGAWA, JAPAN, [2]Clinical Radiology, Kagawa University Hospital, KAGAWA, JAPAN.

Objectives: PET with ^{15}O-labeled tracers is capable of providing unique and essential information in patients with cerebro-vascular disorders, and quantitative images of cerebral blood flow (CBF), oxygen extraction fraction (OEF), and metabolic rate of oxygen ($CMRO_2$) have been promoted as a clinical diagnostic tool. We have recently developed a novel DBFM method, allowing extremely short examination period <10 min for CBF and OEF [1], and also a computation method for appearance time of blood in arterial territories (ATB) [2]. SPECT, so far, can only provide CBF, but not OEF. This study was intended to compare elevation of OEF with delay of ATB from PET data and also that from SPECT CBF examination data. **Methods:** PET measurement was performed for patient subjects with suspected disorders, and the subjects were separated to two groups with OEF elevated (G1, n=71) and without that (G0, n=221). Two of subjects received SPECT ^{99m}Tc-ECD examination for each group. From the PET data, OEF and ATB images were obtained, and from the SPECT data, ATB images were obtained. Regions of interest (ROI) were placed on both hemispheres in temporal region in G0, and in G1, ROI was placed on OEF elevated region and its contralateral region. OEF values and ATBs were extracted from the placed ROIs. Differences of OEF (ΔOEF) and ATB (ΔATB) between hemispheres were calculated, and differences between ΔOEF and ΔATB were compared. **Results**: The obtained OEF values were 0.42±0.04 and 0.42±0.04, and ATBs were 0.0 ±1.9 s and 0.0±2.0 s, for left and right hemispheres in G0, respectively. Differences were not significant between hemispheres. In G1, apparent delayed regions were seen in the ATB images similar to the OEF elevated regions, the OEF values were 0.43±0.06 and 0.53±0.08, and ATBs were 0.1±2.1 s and 2.2±2.3s, for contra- and ipsi-laterals, respectively. Differences were significant between hemispheres. Regression analysis showed weak correlation: r=0.16, in G0 and moderate correlation: r=0.39, in G1 between ΔOEF and ΔATB. In ATB image from SPECT data, apparent delay was seen in the similar region of PET ATB image, and ATB was around 3 s in disease region. **Conclusion**: The present results suggest that ATB could provide similar information as OEF, and that the ATB can be also estimated from SPECT scan data. Semi-quantitative CBF parameters derived from [^{15}O]H_2O studies

T. Koopman[1], D. F. R. Heijtel[2], M. Yaqub[1], E. Bakker[1], A. J. Nederveen[3], B. N. M. van Berckel[1], A. A. Lammertsma[1], R. Boellaard[1]; [1]VU University Medical Center, Amsterdam, NETHERLANDS, [2]Philips Healthcare, Best, NETHERLANDS, [3]Academic Medical Center, Amsterdam, NETHERLANDS.

Aim: Quantification of cerebral blood flow (CBF) using [^{15}O]H_2O positron emission tomography (PET) requires the use of an arterial input function. Invasive arterial sampling, however, is not always possible, for example in ill-conditioned or paediatric patients. Therefore, it is of interest to explore the use of non-invasive (simplified) methods for the quantification of CBF. The purpose of this study was to investigate and compare the performance of several simplified quantification methods. *Methods:* Data from 16 healthy volunteers were included in this study. For each subject five dynamic [^{15}O]H_2O brain PET studies of 10 min duration and including arterial sampling were acquired. At baseline a test-retest study was performed followed by a study at hypercapnia (increased perfusion). After three to four weeks the same subject underwent two further studies, one at baseline and the other at hypercapnia. Hypercapnia was achieved by switching air delivery from normal medical air to a pre-mixed gas mixture of 5% CO_2 and 95% air. For each study absolute CBF within 67 cerebral volumes of interest were calculated using full kinetic analysis. In addition, various simplified methods, such as area under the curve (AUC) integrated over several time intervals, time-to-peak, peak height, wash-in and wash-out slopes, were used. Performance of these simplified methods was assessed using correlation and Bland-Altman analysis of simplified CBF parameters with fully quantitative CBF values. These analyses were repeated with normalization to cerebellar CBF, providing relative regional CBF (rCBF). *Results:* For relative rCBF, best overall (pooled over all scans and subjects) correlation between simplified and full quantitative CBF data was obtained for the 0-60 s AUC method (R^2=0.89 ± 0.01). Corresponding correlations of time-to-peak, peak height, whole AUC, wash-in and wash-out slopes were R^2=0.09 ± 0.02, R^2=0.78 ± 0.01, R^2=0.46 ± 0.02, R^2=0.55 ± 0.02 and R^2=0.09 ± 0.02, respectively. For absolute rCBF, the 0-60 s AUC method also showed good correlation per individual scan (R^2=0.86 ± 0.09), but with variable regression slopes, i.e. with low reproducibility between scans and patients. *Conclusion:* Simplified quantification of relative rCBF is reasonable using the 0-60 s AUC method. Reliable absolute rCBF values could not be obtained with any of the simplified methods, due to the uncertainty and variability in the input functions. This variability was probably magnified by variance in the amount of injected activity.

In vivo PET imaging of the cerebellar cholinergic innervation using ^{18}F-FEOBV: preliminary quantitative evaluation

J. Mazère[1,2,3], J. Debatisse[2,3], F. Lamare[1,2,3], D. Vimont[2,3], P. Fernandez[1,2,3], P. Burbaud[4,5], W. Mayo[2,3]; [1]Service de médecine nucléaire, CHU de Bordeaux, F-33000, Bordeaux, FRANCE, [2]Univ. Bordeaux, INCIA, UMR 5287, F-33000, Bordeaux, FRANCE, [3]CNRS, INCIA, UMR 5287, F-33000, Bordeaux, FRANCE, [4]Univ. Bordeaux,

Institute of Neurodegenerative Disorders, UMR 5293, F-33000, Bordeaux, FRANCE, [5]CNRS, Institute of Neurodegenerative Disorders, UMR 5293, F-33000, Bordeaux, FRANCE.

INTRODUCTION The cerebellum plays a role in regulating the cognitive and emotional processes (1,2) and post-mortem, the cholinergic innervation of the human cerebellum was evidenced (3), highlighting the interest to explore *in vivo* cerebellar cholinergic innervation in various neurological disorders. ^{18}F-fluoroethoxybenzovesamicol (^{18}F-FEOBV) is a highly selective PET radioligand for a pre-synaptic cholinergic marker, the Vesicular Acetylcholine Transporter (VAChT). However, quantification of ^{18}F-FEOBV requires the use of the cerebellar hemispheres as a reference region (4), thus preventing any possible VAChT quantification in this part of the cerebellum. We propose to validate a reference region based method allowing the quantification of ^{18}F-FEOBV in the whole brain including several cerebellum sub-regions, by testing two reference regions: the visual cortex and the white matter of the posterior cingulate cortex (PCC-WM). **MATERIALS AND METHODS** Three healthy human volunteers underwent a dynamic brain PET imaging 0-80 and 130-150 min after injection of ^{18}F-FEOBV and a magnetic resonance imaging (MRI) scan. Segmentation of MR images using Freesurfer® and SPM® softwares provided several extra-cerebellar and cerebellar regions of interest (ROI). PET data were partial-volume effect corrected and for each ROI, a complete pharmacokinetic analysis based on both Multilinear (MRTM2) and Simplified (SRTM2) Reference Tissue Models allowed to calculate the ^{18}F-FEOBV nondisplaceable binding potential (BP_{ND}). **RESULTS** In the cerebellum sub-regions, only the PCC-WM provided standard error values of BP_{ND} (BP_{ND} % COV) lower than 10%, the highest BP_{ND} values being found in vermis and lobule X and the lowest in crus I-II. Goodness-of-fit R2 values greater than 0.90 were found in any sub-regions except the lobule X. In the rest of the brain, only the PCC-WM provided BP_{ND} % COV lower than 10 % in all ROIs and R2 values were greater than 0.90 in any ROIs except the amygdala for MRTM2. BP_{ND} values strongly correlated with those calculated using the cerebellar hemispheres as reference region. **DISCUSSION-CONCLUSION** The use of PCC-WM allows a reliable ^{18}F-FEOBV quantification in the whole brain. The cerebellar distribution of ^{18}F-FEOBV we find is consistent with previous histochemical results indicating the greatest cholinergic innervation in the vermis, lobule X, IX and VIII and the lowest in the remaining lobules (3). This ongoing study demonstrates that ^{18}F-FEOBV is relevant for evaluating *in vivo* the involvement of cerebellar cholinergic deficit in cognition and emotion. **BIBLIOGRAPHY** 1. P239

Can Spatially Inaccurate CT Based Attenuation Correction of EEG Electrodes Create Artificial Foci in Subtraction SPECT Images of Epilepsy Patients?

O. Sipilä, M. Pitkonen, A. Loimaala; HUS Medical Imaging Center, Clinical Physiology and Nuclear Medicine, University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND.

Aim: Epilepsy patients may have EEG electrodes on the scalp during ictal and/or interictal SPECT/CT imaging. Impact of spatially mismatched attenuation correction (AC) CT data, with our currently used electrodes and their typical distribution, on the reconstructed SPECT image and thus on the subtraction analysis of the ictal and interictal images was studied. Materials and Methods: A Siemens Symbia T SPECT/CT-camera was utilized with the following parameters: LEHR collimators, imaging matrix 128x128, pixel size 3.3 mm, 60 frames over 180^{O}, frame time 20 s, AC-CT with 35 mAs and 110 kV. In ictal imaging of three patients, 40-50 Ambu Neuroline 720 Ag/AgCl electrodes were present. Before interictal imaging, the electrodes were removed. In addition to the properly reconstructed ictal and interictal SPECT images, the following test images were reconstructed with Flash 3D, scatter correction, CT-AC, 4 iterations, 6 subsets, Gaussian filter 8.4 mm: 1) Interictal SPECT image, attenuation corrected with the coregistered ictal CT, simulating effects of adding attenuation correction in areas were no attenuation caused by the electrodes exists. 2) Ictal SPECT, attenuation corrected with the coregistered interictal CT, simulating the effects of missing attenuation correction in areas where the electrodes cause attenuation. 3) For one patient, the interictal SPECT was reconstructed with both the interictal and coregistered ictal AC-CT transferred 10 mm in x, y, or z direction or rotated 10 degrees to check the relative effects of wrong placement of the electrodes and head tissues. The SPECT images from these reconstructions were subtracted from the corresponding proper reconstructions for A) statistical analysis using the BioImage Suite Differential SPECT Tool (bioimagesuite.yale.edu) and B) detecting foci with SD of 1.0, 1.5 and 2.0 in the brain (in-house-developed module for Siemens SyngoMI). Results: Image reconstruction errors due to 1) falsely added electrode information in CT-AC and 2) to missing electrode attenuation information did not produce significant foci ($p<0.05$) in statistical analysis (A). Significant foci were detected in the brain with all SDs (B), but they usually had peculiar shapes and extended outside the brain, evident when reviewed with different SDs and slice directions. However, wrongly placed head tissues (3) caused significant foci (both A and B) totally inside the brain. Conclusion: Electrodes in spatially mismatched AC-CT data did not cause significant foci totally inside the brain in SPECT subtraction images. To recognize artificial foci, subtraction images should be carefully reviewed with different SDs and slice directions.

Repeat assessment of total hemispheric glycolysis by FDG-PET/CT: Variability with reuse of baseline masks defined by dedicated software

E. A. Segtnan[1,2], S. B. Christlieb[1], P. Grupe[1], O. Gerke[1,3], P. F. Høilund-Carlsen[1,4]; [1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]University of Southern Denmark, Odense, DENMARK, [3]Centre of Health Economics Research, University of Southern Denmark, Odense, DENMARK, [4]Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, DENMARK.

Aim: The dedicated PET processing software tool ROVER (ABX, Radeberg, Germany) targets problem of quantitative 3D ROI evaluation of PET scans including repeat studies. We wanted to investigate if automated reuse of baseline masks for processing of follow-up PET scans caused serious deviations in measured variables. **Material and methods:** Prospectively, cerebral FDG-PET/CT was performed in seven patients with glioblastoma, each of whom underwent two to five examinations during their treatment course resulting in a total of 21 FDG-PET/CT scans obtained before and after tumour resection, radio-chemotherapy, and chemotherapy alone. 3D-masks needed for measuring cerebral total hemispheric glycolysis (THG) and to circumscribe the entire cerebellum were defined at baseline, i.e., at the preoperative scan, and stored. These masks were automatically reused at all ensuing scans in the same patient to yield SUVmax, SUVmean, metabolic volume (ccm), THG, partial volume corrected SUVmean and THG, i.e., cSUVmean and cTHG, respectively. For validation of this automated procedure (A), each of the 21 PET studies was also segmented independently (I), meaning that the operator manually aligned the baseline mask to the follow-up PET scan, when this was processed. Mixed effects regression test was used to compare the two methods. Visual analysis was also performed for validation of the location of the interpolated masks. **Results:** The mean differences calculated from

all time points (with 95% CI) in absolute quantitative measures obtained by methods A and I were 0.01 (-0.10 to 0.13), 0.012 (-0.06 to 0.08), 0.03 (-0.12 to 0.2), 5.77 (-24.7 to 36.3), -0.19 (-4.2 to 3.8), and 12.25 (-30.2 to 54.7) for SUVmax, SUVmean, metabolic volume, THG, cSUVmean, and cTHG, respectively. No statistically significant differences between methods was observed (p>0.05). We also compared reuse of baseline masks stratified to any specific treatment intervention, i.e., post-operation or post chemotherapy; no statistical significant difference was found either (p-value range 0.055-0.96). According to visual assessment, the automatically reused cerebral hemispheric and cerebellar 3D-masks delineated the respective target structures excellently on follow-up PET scans. **Conclusion**: The ROVER software furnishes reliable automated reuse of cerebral hemispheric and cerebellar baseline mask for processing of follow-up FDG-PET scans. The large size of the masks and the anatomically relatively fixed shape of the target structures could be an explanation of these good results, which indicate that the automated reuse of cerebral hemispheric and cerebellar masks provided the ROVER software is applicable for routine clinical use.

P241

Errors in data recording in cerebral FDG-PET/CT scans: Consequences for quantitative outcome when measuring whole brain glycolysis

E. A. Segtnan[1,2], S. B. Christlieb[1], O. Gerke[1,3], P. F. Høilund-Carlsen[1,4]; [1]Odense University Hospital, Odense, DENMARK, [2]University of Southern Denmark, Odense, DENMARK, [3]Centre of Health Economics Research, University of Southern Denmark, Odense, DENMARK, [4]Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, AUSTRIA.

Aim: We analysed data recordings used in PET/CT research protocols to examine consequences of errors for calculatation of whole brain glycolysis (WBG) derived from FDG-PET/CT scans in glioma patients. **Material and methods:** Prospectively, 14 glioma patients, aged 35-77 years, were enrolled in a research protocol with FDG-PET/CT performed before any treatment intervention. Dedicated software (ROVER, ABX, Radeberg, Germany) was used for delineation of the whole brain, excluding the cerebellum. WBG was calculated as the product of the segmented volume (cm^3) of cerebral FDG uptake and the partial volume corrected SUVmean (cSUVmean). Firstly, segmentation was applied on PET scans in the DICOM format. Secondly, information stored in the DICOM format, i.e. tracer dose, injection time and time of scan, was compared with the hand written reports for each scan. If information deviated between the hand written report and the DICOM file, the hand written report was used as reference, and thus, information was corrected in the DICOM file. Values of quantitated WBG obtained before and after correction were compared. **Results**: Overall, the mean WBG was 5942 and 6208 before and after correction. By comparing each patient´s values head to head, the two largest deviations were 2379 (30%) and 3604 (41%) in WBG due to injection time being typed 60 and 45 minutes incorrectly in the DICOM file, respectively. Two other patients had large deviations in WBG, i.e., -771 (-17%) and -667 (-18%), respectively, due to incorrectly typed injection dose, -19 and -6 Mbq, respectively. The other 1O patients, after correction of information from the handwritten reports, had deviations in WBG below 10% (- 8% to - 2%). This was either because the injection time had been incorrectly (maximum 11minutes) entered, and/or because the injection dose had been incorrectly (-18 to -5 MBq) entered. **Conclusion:** This example, in a small sample, elucidates how typing errors may result in huge and minor deviations in calculated quantitative outcome, in this case WBG. Thus, the challenge of transferring information correctly from paper to digital format should not be neglected and should be taken into account for single and repeat studies and comparison of data obtained at different institutions.

P242

Impact of reconstruction algorithms and CT-based attenuation correction in I-123-Ioflupane SPECT

E. Richetta[1], M. Balma[2], A. Guida[1], A. Codegone[1], M. Manfredi[2], C. Cutaia[1], S. Valzano[1], L. Radici[1], R. Pellerito[1], M. Stasi[1]; [1]AO Ordine Mauriziano, Turin, ITALY, [2]Città della Salute e della Scienza, Turin, ITALY.

AIM Dopamine transporter scintigraphy with ^{123}I FP-CIT is an established part in the diagnosis of parkinsonism. The consistency between qualitative and semi-quantitative analysis are still under debate. In this study SPECT images were analyzed in order to evaluate the variability among different attenuation correction techniques and reconstruction algorithms, as well as intra-operator dependence. **MATERIALS AND METHODS** Integrated SPECT-TC acquisitions (Siemens SymbiaIntevo, 128x128, 120 views, 40s/view; 130 kV,3mm) were performed on 16 patients (8M,8F) with suspected Parkinson's disease after the administration of ^{123}I-ioflupane. Images were reconstructed both with FBP algorithm without any attenuation correction (FBP_NOAC) and Iterative algorithm (Flash3D, #8iterations, #8subset) with CT low-dose attenuation correction map (IT_AC) or with uniform Chang's matrix (IT_Chang). Two experienced physicians, unaware of the reconstruction-attenuation correction methods, inspected qualitatively the images and assigned a negative, positive or doubtful score. Percentage differences between physicians as well as among methods were calculated. To investigate the possibility to distinguish positive to negative patients in a semi-quantitative way, specific-to-background ratios in caudate and putamen were calculated by drawing volume of interest in these areas. The diagnostic power was tested using ROC analysis. AUC results were compared (Hanley and McNeil z-values) in order to find statistical significant discrepancies and to individuate the best images processing method. **RESULTS** In the qualitative analysis the first physician gave an assessment other than the second one in 3/16 (19 %) images reconstructed with FBP_Chang ; these value increased to 4/ 16 (25%) for FBP_NOAC method and up to 6/16 (38%) for IT_AC method. Also comparing images within the same observer differences were found. For the first physician FBP_Chang and FBP_NOAC showed discrepancies in 1/16 (6,3%) patient and 3/16 (19%) for IT_AC; for the second assessor IT_Chang variability was the same (1/16) and becomes greater in patients comparisons with FBP_NOAC 3/16 (19%) and IT_AC 4/16 (25%) methods. Similar AUC values were found among the tree methods both for caudate and putamen with a slightly higher value for IT_Chang method (caudate right 0.714 and left 0.746, putamen right 0.937 and left 0.999). When AUCs were compared z-values always lower than 1.96 confirmed that low-dose CT attenuation correction method hasn't significantly improved the diagnostic power. **CONCLUSION** The impact of CT-based attenuation correction compared to other methods (Chang or FBP_NOAC) on the interpretation of^{123}I-ioflupane SPECTimages is negligible. Therefore CT-based AC cannot be recommended for routine use in clinical patient care, not least because of the additional radiation exposure.

P243

Unsupervised quantitative assessment of Beta amyloid images using Florbetaben(18F)

E. Giovannini[1], M. Riondato[1], R. Leoncini[1], C. Passera[2], E. Carabelli[1], O. Ferrando[1], A. Tartaglione[2], A. Mannironi[1], A. Ciarmiello[1]; [1]S. Andrea Hospital, La Spezia, ITALY, [2]Memory Laboratory CNS-ONLUS, La Spezia, ITALY.

Background Amyloid PET imaging is used to detect brain amyloid accumulation which is considered a key event in the onset of Alzheimer's disease. There are no standard methods for unsupervised assessment of tracer binding. Brain segmentation procedures are limited by poor signal differences between gray (GM) and white matter (WM). This work is

aimed to propose an automated method for brain tissues segmentation and unsupervised quantification of brain amyloid binding. Methods Subjects were recruited within a prospective study (EudraCT number: 2015-001184-39) at Neurology Unit of S.Andrea Hospital and Memory Laboratory CNS-ONLUS of La Spezia. Subjects underwent a neuropsychological battery for assessing different cognitive domains, executive functions and attentional systems. So far a population of 11 patients was enrolled in the study (Age 74±10; MMSE, 25±6) . PET images were acquired in 3D mode 90 to 110 minutes after intravenous injection of 300 MBq of Florbetaben(^{18}F) (Neuraceq^{TM}) on a DISCOVERY TM 710 PET/CT scanner (GE Medical Systems,Milwaukee,WI). PET scans were converted to standardized uptake values (SUV) and normalized into MNI space using SPM8 T1 template (http://www.fil.ion.ucl.ac.uk/spm/software/SPM8). Image analysis procedure was implemented under Matlab 7.14 (MathWorks Inc.,Sherborn,MA).PET images were evaluated by two trained independent readers who were blinded to the clinical results. Whole brain analysis resulted in a scores condensed into a binary interpretation of 0,1 for negative and positive scan respectively.Amyloid PET images were segmented by using hybrid segmentation technique incorporating apriori brain tissues probability distribution and gradient-based approach. GM and WM segmented tissues were used for extracting regional mean SUV values. Data extracted from each patient were grouped according to visual rating results. One-Way analysis was used to test group differences. The linear dependence of SUVs values on MMSE and age was determined by a simple regression. A significance level of p<0.05 was chosen.Results Visual rating of PET images led to the diagnosis of 6 positive and 5 negative subjects. WM-to-GM ratio was 1.1±0.09 and 1.3±0.03 in positive and negative patients respectively (Anova, F=7.1, P=0.025). We found a significant correlation between GM-SUVs and MMSE (R=0.52; P=0.01) in contrast WM-SUVs did not show significant correlation on MMSE. We found positive correlation between WM-to-GM SUVs ratio with MMSE (R=0.73, P=0.0008), whereas no correlation of GM and WM-SUVs on age was found.Conclusion Our findings suggest that unsupervised quantitative assessment of PET amyloid binding may be useful to improve diagnosis and predict disease progression in Alzheimer's disease.

P244

Biodistribution Analysis of a Labeled Exogenous Protein Following Intranasal Delivery in Cynomolgus Macaques Using PET/CT Imaging and Autoradiography

C. M. Finucane[1], D. Kentala[2], A. W. Novicki[1], M. Qutaish[1], H. Dobson[1], H. Huttunen[3]; [1]inviCRO, Boston, MA, UNITED STATES, [2]MPI Research, Mattawan, MI, UNITED STATES, [3]Herantis Pharma PLC, Helsinki, FINLAND.

The aim of this study was to assess the kinetics and biodistribution of a ^{124}I-labeled exogenous protein in the brain of Cynomolgus monkeys after intranasal administration using a commercial nasal administration device. The success of intranasal administration into the brain is important due to the potential neuroprotective and neuroregenerative effects of this compound for use as a potential therapy administration procedure. Following radiochemistry development to radiolabel the protein at the required specific activity and mass dose, four female Cynomolgus monkeys received an intranasal administration of 0.5 mCi ^{124}I-protein (400 µg) in 2 actuations per nostril (200 µl total volume). Immediately after administration a focused brain scan was acquired for 3.75 hours, followed by a whole body PET scan and a whole body CT for anatomical registration. The focused PET scan was binned into 45 x 5 minute frames. Focused and whole body scans were also acquired at 24 hours post-administration. The administration technique was improved on advice from the commercial device manufacturer to improve the delivery of the dose to the upper nasal epithelium upon review of the initial results. Changes were made to the time between administration, the angle of administration and the position of the device in the nostril. In addition, autoradiography was performed on the brain of one monkey following the 4 hour time point. A Cynomolgus brain atlas was registered to the data to quantify uptake brain regions and regions of interest (ROIs) were drawn in the upper nasal cavity, throat and thyroid. Quantitative ^{124}I autoradiography was performed on sagittal sections of the brain encompassing the area between both eyes. The qualitative analysis of the PET images revealed that any visible brain uptake was below the detectable range of the PET/CT system. A quantitative comparison showed signal in the brain (approximately 4% injected dose) of which over 90% was cleared by 24 hours. It is possible that high signal in the nasal cavity may also have affected the accuracy of PET quantitation. Autoradiography was performed to confirm the uptake in the brain and clearly showed signal in the lateral ventricles, indicating transport of the ^{124}I-protein across the cribriform plate into the CSF. *In vivo* imaging is a useful technique to evaluate the success of an intranasal administration and provides important information on tracer kinetics and biodistribution. Autoradiography is a valuable complementary assay to confirm that the brain signal detected by quantitative analysis is real.

18F-Florbetaben SUVR cutoff quantification across reference regions and standards of truth and comparison to visual assessment

S. Bullich[1], A. M. Catafau[1], J. Seibyl[2], H. Barthel[3], O. Sabri[3], S. De Santi[4]; [1]Piramal Imaging GmbH, Berlin, GERMANY, [2]Molecular Neuroimaging, New Haven, CT, UNITED STATES, [3]Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [4]Piramal Pharma Inc, Boston, MA, UNITED STATES.

Background: Thresholds of 18F-florbetaben (FBB) standardized uptake value ratios (SUVRs) to categorize scans as positive or negative between 1.39 (Barthel et al., Lancet Neurol 2011;10:424-35) and 1.48 (Sabri et al., Alzheimers Dement. 2015;11(8):964-74) have been reported using cerebellar grey matter (GCER) as the reference region (RR). The aims of this study were 1) to generate 18F-Florbetaben (FBB) SUVR cutoff values for different reference regions (RRs) using blinded visual assessment (VA) as standard of truth (SoT); 2) to validate them in a different clinical population and SoTs and 3) to compare VA and SUVR cutoffs. **Methods**: For aim 1, SUVR cutoff was generated using FBB scans from 143 subjects (69.5±7.5 yrs; n=75 Alzheimer's disease (AD), n=68 healthy volunteers (HVs)) who were visually assessed by 3 readers. SUVR was calculated using cerebellar gray matter (GCER), whole cerebellum (WCER), pons (PONS), and subcortical white matter (SWM) as RRs. A SUVR cutoff value for each RR was generated using Receiver Operating Characteristic analysis, VA as the SoT, and highest Youden's index as the selection criteria. For aim 2, SUVR cutoffs were validated in 78 end-of life subjects (80.1±10.4 yrs) using VA from 8 readers and histopathological confirmation of the presence of neuritic beta-amyloid plaques as SoT. For aim 3, FBB scans from 78 subjects were visually assessed by 8 readers. The number of correctly or incorrectly classified scans according to pathology results using VA and SUVR cutoffs for each RR was compared. **Results**: Aim 1: Composite SUVR cutoffs were 1.43 (GCER); 0.96 (WCER); 0.78 (PONS); 0.71 (SWM). Aim2: Accuracy values were high and consistent across SUVR cutoffs and VA methods and SoTs (range 83-94% for histopathology, and 86-94% for VA). Aim 3: A range of 63-71 cases were correctly classified by both SUVR cutoff (across RRs) and VA, while 1-3 cases (across RRs) were incorrectly classified by both SUVR cutoff and VA. SUVR cutoff method misclassified more cases (range: 3-10 cases) than VA (range: 1-3 cases) for any RR. **Conclusion:** VA and SUVR cutoff quantification perform similarly in classifying FBB scans. These results indicate that VA is a robust method for the correct classification of FBB scans. However, the

use of SUVR cutoff did not improve VA classification of FBB scans independently of the RR used in this end-of-life population.

P246

Initial feedback on hybrid brain PET-FDG/MR imaging in the clinical evaluation of cognitive disorders

M. O. Habert[1], A. Bertrand[2], G. Bera[1], B. Law-Ye[2], N. Yeni[1], P. David[1], D. Dormont[2], A. De Villanueva[2], A. Kas[1]; [1]Hopital Pitié Salpetriere, Nuclear Medicine, PARIS, FRANCE, [2]Hopital Pitié Salpetriere, Neuroradiology, PARIS, FRANCE.

Introduction - Hybrid PET/MRI allows for accurately combining PET molecular information with a large variety of MRI sequences. The acquisition of both modalities in a single session minimizes the disagreements for the patient while maximizing collected information thanks to the spatial and temporal fusion of both modalities. Our objective was to evaluate the feasibility and, through pictorial examples, the potential interest of PET/MRI in the routine evaluation of patients with cognitive disorders. Patients and methods: - 274 patients underwent a PET-FDG/MRI for the evaluation of a cognitive impairment from October 2015 to March 2016. Patients were referred for suspicion of Alzheimer's disease (AD, n=107), fronto-temporal degeneration (FTD, n=38), primary progressive aphasia (n=34), Lewy body disease (n=27), mild cognitive impairment (n=48), posterior cortical atrophy (PCA, n=6), vascular dementia (n=4), or other rare diagnoses (n=10).Images were performed with the PET/MR SIGNA 3T (GE Healthcare). A dose of 2 MBq/kg was administered 30 minutes before the acquisition. The protocol included simultaneous PET list-mode acquisition and MRI sequences (3DFLAIR, 3DSWAN, 3DT1 and axial diffusion) for a 25 minutes duration. PET images were reconstructed with the Vue Point FX algorithm (8 iterations, 28 subsets) including spatial resolution and time of flight corrections. Attenuation correction was based on a MR Dixon-based sequence and a pseudo CT atlas-based method. Both a nuclear medicine physician and a neuroradiologist were present for interpretation, with a joint conclusion. Results: - PET and MR images were of good quality. Although not entirely accurate, attenuation correction did not yield artefacts hindering visual assessment. In early onset AD and its clinical variants such as logopenic aphasia or posterior cortical atrophy, PET usually showed a marked hypometabolism while MRI was normal or showed a moderate non specific atrophy. In more focal pathologies, such as FTD or semantic dementia, MRI and PET abnormalities were usually associated. Vascular lesions (leucopathy, microbleeds, ischemic lesions) were easily detected on 3D FLAIR and magnetic susceptibility sequences. In such cases, PET images often showed evidence of an associated neurodegenerative component, or even the remote impact of a subcortical lesion (deafferentation). Conclusion: - Our results highlight the clinical feasibility and the performance of hybrid PET/MRI in the clinical evaluation of dementia. The fusion of high-resolution PET images with morphological images improved the confidence in PET assessment. The simultaneous interpretation by two specialists provided to the clinicians an optimized diagnosis, particularly in complex cases.

Dementia with Lewy body and Alzheimer's disease: a continuum? First results of a striatal [18F]Fluorodopa Positron Emission Tomography pilot study

A. Pallardy[1], P. Olivieri[1], T. Carlier[1], T. Lebouvier[2], S. Le Dily[1], H. Courtemanche[1], F. Kraeber-Bodéré[1], C. Boutoleau-Bretonnière[1]; [1]Nantes University Hospital, Nantes, FRANCE, [2]Lille University Hospital, Lille, FRANCE.

Aim : Dementia with Lewy bodies (DLB) is the second neurodegenerative dementia in autopsy series. Concomitance of Lewy pathology with AD pathology is the main cause of the poor sensitivity of DLB diagnosis. Current diagnostic criteria for MCL do not reflect the clinical and pathological overlap between MCL and Alzheimer disease (AD). DLB syndrome is indeed at the end of a pathological spectrum spanning from AD with occasional Lewy pathology to 'pure' DLB. The improvement of diagnostic tools is a challenge. We presented the initial results of a clinical study ongoing at Nantes (France), assessing the correlation between the amount and intensity of DLB features evaluated by a clinical score in validation in Nantes, and dopaminergic nigrostriatal function. Materials and methods : A clinical score (LEwy pathology Screening in COgnitive Disorders LESCOD) was constructed from a selection of 36 putative clinical features of Lewy pathology divided into 9 categories (genitourinary dysfunction, orthostatic hypotension, olfactory dysfunction, REM sleep behavior disorder, Parkinsonism, fluctuations, visiospatial/attention deficits and illusions/hallucinations). Patients with possible or probable AD, possible or probable DLB or considered as coexisting mixed AD - DLB pathology were included in the study and underwent (1) a LESCOD score assessment and (2) a [18F]fluorodopa Positron Emission Tomography (PET). Cerebral [18F]fluorodopa PET consisted of one single 'static' 20-min PET acquisition starting 70 to 90 min after injection. Patients received 2 MBg/Kg of body weight [18F]fluorodopa. Antiparkinsonian medication, haloperidol and reserpine were discontinued. PET data were assessed by volume-of-interest (VOI) analysis using the software PMOD - Dopasoft (*IBA*®). Caudate and putamen striatal to occipital ratio of [18F]fluorodopa were measured. Results : Of the first 10 patients included, one presented with probable AD, 5 with possible or probable DLB, and 4 were considered as mixed AD-DLB. There was a correlation between the number of pathological categories (LESCOD dissemination score) and [18F]fluorodopa uptake values in the putamen ($r=-0.88$, $p < 0.01$) and in the caudate ($r=-0.81$, $p < 0.05$). There was a correlation too between the sum of pathologic clinical features (LESCOD severity score) and [18F]fluorodopa uptake values in the putamen ($r=-0.83$, $p<0.01$) and in caudate ($r=-0.81$, $p<0.01$). No significant correlation was observed between MMSE and dopaminergic binding. Conclusion : These initial results pave the way to new perspectives on the assessment of Lewy pathology burden in the AD - DLB spectrum through [18F]fluorodopa PET quantification of nigrostriatal dysfunction.

P248

Differentiation of dementia with Lewy bodies and Alzheimer disease using standardized I-123 metaiodobenzylguanidine heart-to-mediastinum ratio based on Japanese multicenter study

K. Nakajima[1], J. Komatsu[1], M. Yoshita[2], M. Samuraki[3], K. Okuda[4], S. Kinuya[1], M. Yamada[1]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]National Hospital Organization Hokuriku National Hospital, Nanto, JAPAN, [3]Hirata Chuo Hospital, Hirata, JAPAN, [4]Kanazawa Medical University, Uchinada, JAPAN.

Purpose: I-123 metaiodobenzylguanidine (MIBG) has been used for differentiating dementia with Lewy bodies (DLB). While heart-to-mediastinum ratio (HMR) has been used for quantification of myocardial MIBG uptake, camera-collimator difference has hampered creating common databases in multicenter study. The aim of this study was to investigate diagnostic ability of MIBG for differentiating DLB from Alzheimer disease (AD) using standardized HMRs. Methods: A total of 133 patients (male/female = 59/74, age 76 ± 6 years) were registered in Japanese multicenter study involving ten hospitals. The definitive diagnosis was made as probable DLB (n = 61), possible DLB (n = 26) and probable AD (n = 46) at the end of 1-year follow-up, and reevaluated in a subset of patients with complete 3-year follow-up (n = 65). After administration of I-123 MIBG (111 MBq), myocardial MIBG uptake was quantified using HMR in the core center. Four types of collimators were used in this study including low-energy (LE) high-resolution, LE general-purpose, extended-LE general purpose and low-medium-energy collimators. All

HMRs were calibrated using phantom experiments and converted to medium-energy (ME) collimator-comparable values (stdHMR) (conversion coefficient of 0.88). Probable DLB and probable AD patients were compared excluding patients with possible DLB. Results: Using the 3-year data, late HMRs for LE and ME collimator groups were 2.2 ± 0.2 and 3.1 ± 0.6, respectively (p < 0.0001) in AD patients. However, late stdHMR became 3.0 ± 0.4 and 3.2 ± 0.6 for LE and ME groups, respectively (p = ns), and the collimator difference disappeared. In DLB patients, no significant difference was observed before and after standardization (stdHMR =1.8 ± 0.7 and 1.7 ± 0.7 for LE and ME groups). When stdHMR was compared in the 1-year data, late HMR was 2.9 ± 0.7 and 1.9 ± 0.8 (p < 0.0001, F ratio = 46) for AD and DLB patients, whereas it was 3.1 ± 0.6 and 1.7 ± 0.7 (p < 0.0001, F ratio = 75), respectively for the 3-year data. Diagnostic accuracy of late stdHMR using the 3-year data, demonstrated receiver operating characteristic curve-area under the curve of 0.92: sensitivity 77% and specificity 97% using a threshold of stdHMR = 2.2. Conclusion: DLB could be differentiated from AD using I-123 MIBG HMR. Standardization of HMR eliminates differences in camera-collimator systems and might be used effectively in multicenter comparison.

P249

Higher metabolism in the mesial temporal lobe is associated with poorer performance in verbal semantic fluency in patients with cognitive impairment

I. Apostolova[1], C. Lange[2], A. Mäurer[3], P. Suppa[4], L. Spies[4], E. Steinhagen-Thiessen[2], R. Buchert[2]; [1]University Hospital Magdeburg, Magdeburg, GERMANY, [2]Charité - Universitätsmedizin Berlin, Berlin, GERMANY, [3]Evangelisches Geriatriezentrum Berlin, Berlin, GERMANY, [4]jung diagnostics GmbH, Hamburg, Hamburg, GERMANY.

Background: Alzheimer's disease (AD) is associated with disruption of functional connectivity between the mesial temporal lobe (MTL) and cortical brain regions which results in increased intra-MTL connectivity and increased MTL metabolism. The present study tested MTL metabolism as measured by FDG PET for correlation with neuropsychological performance scores in cognitively impaired geriatric inpatients and in ADNI MCI subjects. Methods: The sample of geriatric inpatients included 80 subjects (82.0 ± 5.4 y, 54 females) with mild cognitive impairment or mild dementia hospitalized in a geriatrics unit for an acute indication. FDG PET and MRI of the brain as well as detailed neuropsychological testing had been performed as part of a prospective study. The etiological diagnoses included non-neurodegenerative etiology (n = 15), AD (n = 17), cerebrovascular disease (CVD, n = 23) and mixed disease (MD, defined as concurrence of AD and CVD, n = 25). Unilateral FDG uptake ratios (SUVR) in the MTL were derived by region of interest (ROI) analysis using predefined standard ROIs for left and right MTL and with the pons as reference. Atrophy and partial volume effects were taken into account by correcting for hippocampus volume estimated from the individual MRI. The maximum of the corrected MTL-SUVR over both hemispheres was tested for associations with subscores of the CERADplus battery (z-scores corrected for age, gender and education). The Spearman test and multivariate linear regression were used for this purpose. The same analyses were performed in a sample of 634 ADNI MCI subjects. Results: There was a significant negative correlation between MTL-SUVR and several CERADplus subtests, most pronounced for the animals subtest (rho=-0.389, p<0.0005 uncorrected for multiple comparisons). Pons-scaled FDG uptake in an AD-signature meta-ROI (comprising posterior cingulate / precuneus and parietotemporal cortex; AD-SUVR) showed a positive correlation with the CERADplus animals z-score (rho=0.341, p=0.001). Stepwise linear regression of the CERADplus animals score with MMSE z-score, AD-SUVR and MTL-SUVR included all 3 parameters in the final model (beta = 0.346, 0.254, -0.336; p=0.001, 0.013, 0.001). This was confirmed in the ADNI cohort (beta = 0.181, 0.146, -0.135; p = 0.000, 0.001, 0.002). Conclusion: In cognitively impaired patients, higher mesial temporal glucose metabolism is associated with poorer verbal semantic fluency performance, independent of overall cognitive performance and glucose metabolism in AD-characteristic brain regions.

P250

Automated FDG-PET data analysis for AD diagnosis in the prodromal phase: a comparison between statistical mapping software tools

S. TROMBELLA[1], L. ANTELMI[2], H. LIM[1], P. BOSCO[3], A. REDOLFI[4], C. TABOURET-VIAUD[5], O. RAGER[6], G. GOLD[7], P. GIANNAKOPOULOS[7], EADC-PET Consortium, O. RATIB[7], G. B. FRISONI[7], V. GARIBOTTO[7]; [1]University of Geneva, Geneva, SWITZERLAND, [2]IRCCS Istituto Neurologico C.Besta, Milano, ITALY, [3]IRCCS Fatebenefratelli, BRESCIA, ITALY, [4]IRCCS Fatebenefratelli, Brescia, ITALY, [5]University Hospitals of Geneva, Geneva, SWITZERLAND, [6]Institut IMGE (Imagerie Moléculaire de Genève), Geneva, SWITZERLAND, [7]University and University Hospitals of Geneva, Geneva, SWITZERLAND.

Aim: Aims of this study are to evaluate: 1) Extent and severity of the regional hypometabolism detected in single subjects by two software tools used in their standard settings: GridSPM and Hermes BRASS; 2) The diagnostic properties of metabolic deficit detection when software-assisted by the two programs. **Methods:** We included in the study 41 healthy controls and 101 MCI patients (followed-up until conversion to dementia or for at least 36 months) from the EADC PET Dataset. We investigated the accuracy of software-assisted diagnosis (by three independent expert readers) versus the clinical diagnosis at follow-up. 1) SPMgrid is the implementation of SPM8 into neuGRID. With SPMgrid, the FDG-PET scans are voxel-wise analyzed for hypometabolism, by testing the single scan versus a control group of 106 healthy subjects from the EADC PET Dataset (only subjects not belonging to the software control group were included). Results are provided by means of as an unthresholded statistical 3D Students' T-map of the brain in the ICBM152 atlas space. 2) With BRASS, abnormalities are quantified voxel-wise against a database of 30 normal subjects on a voxel-by-voxel basis. Results are provided by means of an unthresholded statistical 3D Gaussian Z-map of the brain. 3) Mean z-values and t-values were computed for every anatomical VOI defined in the AAL Atlas. Each VOI mean value from BRASS was plotted against the corresponding value from SPMgrid, and a Pearson's R correlation coefficient computed as a measure of agreement. A histogram of frequencies for all R coefficients was produced. 4) Inter-reader agreement among readers was evaluated when supported by each of the two software tools using Fleiss' kappa test; 5) Statistical values of the two software tools were evaluated for the majority rating obtained across the three readers. **Results:** An excellent regional correlation between the two software tools was found when studying mean statistical map values over defined VOIs (R=0.73 ± 0.16). Higher inter-rater agreement was observed for GridSPM (k=0.48) than for BRASS (k=0.36). The two tools showed nearly equivalent AUC (GridSPM: 0.72, BRASS 0.67), however, BRASS revealed higher sensitivity (0.82 vs 0.58) and SPMGrid higher specificity (0.87 vs 0.52). **Conclusions:** The results of this study: (i) Confirm the validity of automated-assisted metabolic deficit detection in MCI, (ii) Show similar accuracy but differences in inter-rater agreement and diagnostic performance between tools, (iii) Represent the basis to develop guidelines on the use of these tools in the diagnostic workup of MCI patients.

P251

First Experience of 100 Clinical F-18 Florbetapir (Amyvid) PET/CT Scans in the Investigation of Cognitive Impairment:Imaging Characteristics, Inter-observer Agreement, Confidence of Read and Clinical Outcomes

S. R. Khan, N. H. Patel, K. L. Wallitt, N. D. Soneji, D. Fakhry-Darian, C. J. Carswell, P. A. Malhotra, R. Perry, K. S. Nijran, S. Khan, W. Svensson, T. D. Barwick, Z. Win; Imperial College NHS Healthcare Trust, London, UNITED KINGDOM.

Aim: Amyvid brain PET/CT is a powerful new tool in the investigation of suspected Alzheimer's disease in vivo. As one of the 1st global institutions to perform in excess of 100 clinical Amyvid PET/CT examinations, we aim to assess the imaging characteristics of positive or negative scans, inter-observer agreement, reader confidence and clinical outcomes. **Materials and Methods**: 70 (100 examinations to be reviewed prior to presentation) F-18 florbetapir PET/CT examinations were subtyped into positive or negative type A (typical features) or non-type A (atypical features) scans. The examinations were anonymised, randomised and independently reviewed by 3 experienced PET radiologists, blinded to the subtype of scan. The radiologists were asked to perform a binary read, stating a confidence level of 1-5 (1- not confident, 3- moderate confidence, 5- very confident) and the results compared to the final report. Clinical follow-up at the Imperial Cognitive Clinic and subsequent management was documented. **Results:** 46% of scans were reported positive and 54% negative in the final consensus clinical report. Overall, there was good/excellent inter-reader concordance between the 3 readers [k = 0.84 (reader 1 & 2), k = 0.77 (reader 1 & 3), k = 0.74 (reader 2 & 3)], and to the final report [k = 0.80 (reader 1), k = 0.71 (reader 2), k = 0.97 (reader 3)]. Inter-observer agreement improved when analysing type A scans alone [k = 0.91 (reader 1 & 2), k = 0.94 (reader 1 & 3), k = 0.92 (reader 2 & 3)]. Overall, 87% of cases were interpreted with high confidence (4-5), of which 70% were type A and 17% non-type A scans. The percentage of cases interpreted with high confidence increased when reading type A scans (90%) compared to non-type A scans (75%). 25% non-type A scans were interpreted with low confidence (1-3), compared to 9% of type A scans. F-18 florbetapir PET/CT confirmed clinical suspicion in 68% of patients, caused a change in diagnosis in 32% and induced a change in management in 47%. **Conclusion:** The vast majority of type-A/typical scans can be read with excellent inter-observer concordance and with high confidence. Atypical/non-type A scans can be more difficult to interpret, with lower inter-observer agreement and confidence highlighting the importance of optimising image acquisition and having at least one 2nd reader. Amyvid imaging commonly confirms diagnostic suspicion when investigating dementia, and leads to change in diagnosis in 32% and management in 47%.

P252

Amyloid load and cognitive performances in non-demented elderly population: preliminary results of a ^{18}F-Flutemetamol PET study

M. MEYER[1], P. ZANOTTI-FREGONARA[1], F. LAMARE[2], G. CATHELINE[2], C. HELMER[3], K. PERES[3], M. ALLARD[2], J. DARTIGUES[3], P. FERNADEZ[1]; [1]Nuclear MedicIne department CHU of Bordeaux, BORDEAUX, FRANCE, [2]INCIA, University of Bordeaux, BORDEAUX, FRANCE, [3]ISPED, University of Bordeaux, BORDEAUX, FRANCE.

Background: In the early stages of Alzheimer's disease, the impact of amyloid load on cognitive performance is variable, in particular in subject with high level of education due to the cognitive reserve. Previous studies have shown that between 20 and 50% of asymptomatic elderly subjects had high amyloid load. Purpose: To explore the relationship between amyloid load and cognitive performances, and its modulation by educational level in a non-demented elderly population. Methods: This is the preliminary results of the EDUMA study, including 89 subjects. The amyloid load was assessed by 18F-flutemetamol PET-CT. We also collected for each subject: age, sex, ApoE status, educational level, the scores of MMSE test, Grober and Buschke test (episodic memory) and Isaacs set-test (semantic memory). We also performed a subgroup analysis on 36 subjects, for which we have evaluated the cognitive decline during the 10 years before the passage of PET examination. Results: 24% of the subjects had a positive 18F-Flutemetamol PET-CT. These were significantly older (p=0.003), had a mutation of the ApoE (p=0.035), and alterations of episodic and semantic memories (p=0.028 and p=0.013, respectively). Subjects with higher level of education had better cognitive performance, even though they were older (p=0.003) and they had a comparable amyloid load (p=0.272). Finally, in the subgroup analysis, high amyloid load is associated with cognitive decline (p=0.018). Conclusion: In non-demented elderly subjects, the impact of the amyloid load on cognitive performance is modulated by the level of education. These results confirm the interest of amyloid PET imaging in the early diagnosis of Alzheimer's disease.

P253

Metabolic differences in posterior cortical atrophy with and without amyloid pathology

G. Marotta[1], A. Arighi[2], P. Basilico[2], M. Longo[1], G. Fumagalli[2], D. Galimberti[2], E. Scarpini[2], R. Benti[1]; [1]Department of Nuclear Medicine, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY, [2]Department of Neurology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY.

Introduction. Posterior cortical atrophy (PCA) is a rare variant of Alzheimer's disease characterized by predominant complex visuo-spatial deficits and parieto-occipital or temporo-occipital cortical atrophy. As in typical Alzheimer's disease, amyloid cascade with deposition of plaques and tangles seems to play a key role in pathogenesis of PCA. However, a minority of cases without evidence of amyloid deposition may present with similar clinical manifestation. Materials and methods. We studied 16 patients with a clinical diagnosis of PCA, according to 2012 UCL criteria. All the patients underwent a neurological examination, neuropsychological evaluation, brain imaging with brain MRI or CT, lumbar puncture and brain FDG-PET. FDG-PET images were analyzed using statistical parametric mapping (SPM8, Wellcome Department of Imaging Neuroscience, London). Results. All patients had predominant visuo-spatial deficits on neuropsychological evaluation and posterior (parieto-occipital or temporo-occipital) atrophy on brain imaging (MRI or CT) or hypometabolism on FDG-PET in posterior cortical areas. CSF analysis showed a pattern of amyloid pathology in 10 cases, while 6 patients had normal Aβ42 levels. The two groups were not significantly different from a clinical point of view. Using SPM8, the two groups showed a different pattern on FDG-PET ($p<0.001$): patients with normal Aβ42 levels had a higher temporal and insular hypometabolism bilaterally, while patients with low Aβ42 had a higher right posterior parietal and left mesial parietal hypometabolism. Moreover, considering all the patients together, occipito-parietal hypometabolism on FDG-PET correlates significantly ($p<0.001$) with low Aβ42 CSF levels. Conclusion. There are cases of PCA without evidence of amyloid pathology and they have a different hypometabolism pattern on brain FDG-PET, involving insular and temporal region. Patients with amyloid pathology have a higher hypometabolism in parietal areas respect patients without amyloid pathology. The occipito-parietal hypometabolism is correlated with low Aβ42 in CSF in all PCA.

P254

Brain perfusion pattern in semantic variant of primary progressive aphasia with Alzheimer's disease CSF profile

G. Bera, R. Migliaccio, T. Michelin, F. Lamari, M. Teichmann, A. Kas; Groupe Hospitalier Pitié-Salpêtrière, PARIS, FRANCE.

Background and Objective Semantic variant of primary progressive aphasia (SvPPA) is nearly always associated with underlying non-Alzheimer pathology, such as TDP-43 (TAR DNA-binding protein 43) pathological aggregates (75%-100% in clinicopathological series). Very few anatomopathological studies have found the presence of other underlying pathologies, such as Alzheimer's disease (AD) in a very low percentage. Here, we aim at investigating *in vivo* cerebrospinal fluid (CSF) biomarkers profiles (AD *vs*. non-AD) and corresponding brain hypoperfusion patterns in SvPPA patients. **Methods** We included 21 SvPPA patients (mean age 64 ± 7.9 years, symptom duration 3.4 ± 2.5 years) who underwent lumbar puncture and brain perfusion SPECT (ECD-Tc99m). The PPA patients were classified into two subgroups according to the profile of CSF biomarkers, suggestive of AD (SvPPA-AD, n=3, age 79/63/60 years, symptom duration 3/7/2 years) or not (SvPPA-nonAD, n=18, mean age 63.5 ± 7.7 years, symptom duration 3.6 ± 2.5 years). We compared the brain perfusion profiles of the SvPPA subgroups with that of twenty-four healthy subjects (mean age 69 ± 7 years), and 24 amnesic, typical AD patients (mean age 65.1 ± 11 years, symptom duration 3.8 ± 2.1 years), on the voxel-basis using the Statistical Parametric Mapping software. **Results** All SvPPA patients had a severe left-side temporopolar hypoperfusion. In the SvPPA-AD, the hypoperfusion also extended to the left parietal associative cortex including the posterior cingulate ($p < 0.001$ uncorrected) while the SvPPA-nonAD patients had additional hypoperfusion in the anterior cingulate and orbitofrontal cortices ($p < 0.001$ uncorrected). **Conclusion** We observed a specific hypoperfusion pattern in SvPPA with AD pathology involving not only the temporal pole but also the left associative parietal lobe and the posterior cingulate cortices. These results highlight the critical role of the parietal cortex in the AD pathology irrespectively of the clinical presentation.

P255

Probability of conversion to Alzheimer's dementia (AD) in long-term non converters mild cognitive impairment (NC-MCI) patients: a volume of interest-based multivariate approach to 18F-FDG PET

M. Bauckneht[1], M. Pagani[2,3], A. Giuliani[4], J. berg[5], A. Chincarini[6], D. Arnaldi[7], A. Picco[7], F. Bongioanni[1], A. Nieri[1], E. Pomposelli[1], S. Maggio[1], F. Peschiera[1], G. Sambuceti[1], F. Nobili[7], S. Morbelli[1]; [1]Nuclear Medicine Unit, IRCCS AUO San Martino IST, Genova, ITALY, [2]Institute of Cognitive Sciences and Technologies, CNR, Roma, ITALY, [3]Department of Nuclear Medicine, Karolinska Hospital, Stockholm, SWEDEN, [4]Environment and Health Department. Istituto Superiore di Sanità, Roma, ITALY, [5]Department of Hospital Physics, Karolinska Hospital, Stockholm, SWEDEN, [6]Istituto Nazionale di Fisica Nucleare, Sezione di Genova, Genova, ITALY, [7]Clinical Neurology, Department of Neuroscience (DINOGMI), University of Genoa and IRCCS AOU San Martino-IST, Genova, ITALY.

AIMS: to identify those baseline variables influencing the probability of having an 18F-FDG-PET pattern classified as MCI due to AD, by means of a volume of interest-based multivariate approach, in a group of MCI patients still non-converted to AD after a minimum follow-up (FU) of 4 years. METHODS: 121 subjects were included: 44 normal aged subjects (CTR; mean age 69±10), 28 NC-MCI at 4 years follow up after PET scan (mean age 72±6), 36 MCI-AD converters more than 2 years later (earlyMCI, eMCI; mean age 75±7), 58 MCI-AD converted within 2 years since PET scan (lateMCI, lMCI; mean age 76±7) and 54 patients with mild-AD dementia (AD; mean age 73±7). Mean 18F-FDG-PET uptake was computed on normalized images in 45 anatomical volumes of interest (VOIs) bilaterally as defined by the AAL Atlas. An in-house Matlab-based script automatically processed mean 18F-FDG uptake from each of the 90 VOIs normalizing them on cerebellar metabolism. Regions with similar anatomo-functional characteristics were merged into meta-VOIs and Area Under the Curve (AUC) differentiating NC-MCI from the other groups was computed through ROC analysis. Analysis of variance was used to compute the influence of age, gender, years of formal education and baseline MMSE on the probability of each of the 121 subjects to be classified as normal aging (p(CTR)). Pearson Correlation Coefficients was used to assess the correlation between the tested variables and p(CTR). RESULTS: AUC differentiating NC-MCI from the other groups was 84% for eMCI, 98% for lMCI and 100% for AD. None among the tested variables demonstrated significant influence on p(CTR) in CTR, lMCI, eMCI as well as in mild-AD. By contrast, years of education, age and gender but not baseline MMSE significantly affected p(CTR) in NC-MCI (p=0.006, p=0.02 and p=0.02, respectively). In particular, education (the higher the educational level, the lower p(CTR)) showed the most significant effect and was able to influence p(CTR) even when included alone in the model (p=0.0013). Conclusion: this approach to 18F-FDG-PET was able to tell apart long-term NC-MCI from mild-AD patients and both eMCI and lMCI, all undergoing 18F-FDG-PET at first visit. In this framework only in NC-MCI, even after a long-term FU, higher education (reflecting higher cognitive reserve) may affect the residual risk of conversion to AD-dementia. Older age and female gender have a milder effect. There results reflect the role of cognitive reserve as one of the main determinants of long-term clinical stability in NC-MCI.

P256

Aging effect on F-18 florbetaben uptake in cognitive normal and visually PET negative older adults

K. Shin, J. Oh, M. Oh, H. Moon, J. Hwang, J. Roh, J. Lee, J. Kim; Asan Medical Center, Seoul, KOREA, REPUBLIC OF.

Objectives : Amyloid positive rate in cognitively normal adults is known to be depending on the age of the cohort and the threshold for defining positivity on amyloid PET. But, it is unknown there is an aging effect on tracer uptake in amyloid PET negative normal adults. We investigated the aging effect on F-18 florbetaben (FBB) uptake of cerebral cortex and deep white matter in cognitive normal and visually PET negative older adults. ***Methods and materials:*** F-18 FBB PET of 33 healthy subjects (54-79 yrs old, median 67, M:F = 6:27) with normal cognitive function, were analyzed visually by using the Brain Amyloid Plaque Load (BAPL) score and quantitatively using FreeSurfer software. We assessed the association of age and standardized uptake value ratios (SUVRs, reference: cerebellar cortex) of cerebral cortex and deep white matter. ***Results:*** Among 33 healthy subjects, 29 (88%) showed negative (BAPL score 1) and four (12%) showed positive (BAPL score 3) amyloid PET finding. In total 33 cases regardless of BAPL score, composite cortical SUVRs showed increasing tendency with age but not statistically significant (r=0.239, p=0.09). In 29 cases with visually negative PET finding, age were positively correlated with composite cortical SUVR (r=0.559, p=0.001) as an incline of 0.5% per yr. Regional cortical SUVRs (e.g. cingulate) also showed significant age-related increase (p<0.05). But, there was no correlation between age and deep white matter SUVRs (r=-0.015, p=0.469). ***Conclusion:*** FBB uptake of cerebral cortex increased with age in cognitively normal older adults with visually negative PET finding. This result may reflect preclinical amyloid deposition rather than hemodynamic effect.

P257

What ^{99m}Tc-HMPAO SPECT adds to memory function assessment in predicting conversion from amnesic Mild Cognitive Impairment (MCI) to Alzheimer's disease (AD)

D. Di Giuda[1], F. Cocciolillo[1], D. Quaranta[2], D. Maccora[1], V. Rizzo[1], D. Fortini[1], C. Marra[2], G. Gainotti[2], A. Giordano[1]; [1]Università Cattolica del Sacro Cuore - Nuclear Medicine Institute, Rome, ITALY, [2]Università Cattolica del Sacro Cuore - Research Center for Neuropsychology – Neurology Institute, Rome, ITALY.

Aim: Identifying pre-clinical AD in MCI subjects is a major issue in clinical diagnosis. In this follow-up study we assessed if the ability to predict conversion from amnesic MCI (aMCI) to AD is improved by considering, at baseline, SPECT abnormalities in addition to delayed recall defects. **Materials and methods**: Forty-two aMCI patients (22 females, mean age: 69.6±7.2 years) underwent neuropsychological assessment. The Episodic Memory Score, EMS (Marra et al., J Alzheimers Dis. 2015), was obtained by integrating results from immediate and delayed recall as well as delayed recognition of the Rey Verbal Learning Test and delayed recall of the Rey-Osterrieth Complex Figure Test. ^{99m}Tc-HMPAO SPECT was performed within two weeks from the baseline evaluation. Every six months patients underwent neuropsychological assessment for a two-year follow-up. Baseline SPECT scans in patients converted to AD (aMCI-conv) and patients with stable aMCI (aMCI-stable) were compared using SPM8 and two-sample *t*-test. Region masks were extracted from significant clusters through the MarsBaR toolbox. Receiver Operating Characteristic (ROC) curves and areas under ROC curves (AROCs) were obtained for ROI and EMS results. Reliability indices of single and combined investigations were calculated. Analyses were performed using three EMS cut-off points (e.g.,7,8,9), whereas SPECT cut-off was set at ROI activity value displaying the highest sum of sensitivity and specificity. **Results**: During the two-year follow-up, 15 patients (36%) progressed to AD. SPM8 analysis showed hypoperfusion in the left posterior cingulate cortex (PCC) of aMCI-conv group, compared to aMCI-stable subjects (height threshold of $p<0.005$). The mean activity extracted from the left PCC ROI differed between the two groups ($p=0.002$). The AROC was 0.79 (95%CI=0.65-0.93); the best cut-off point corresponded to 91.5, showing the highest sum of sensitivity (0.87) and specificity (0.63). The EMS AROCs were: 0.77 (95%CI=0.64-0.91) for EMS<7 (sensitivity=0.73; specificity=0.81); 0.80 (95%CI=0.55-0.78) for EMS<8 (sensitivity=0.93; specificity=0.67); 0.67 (95%CI=0.68-0.91) for EMS<9 (sensitivity=0.93; specificity=0.41). The combination of EMS cut-off (<7, <8, <9, respectively) with SPECT data (left PCC perfusion<91.5) yielded fair results in sensitivity (range: 0.60-0.80) and good results in specificity (range: 0.74-1.00), with a high percentage of subjects properly classified (range: 76% to 90%). **Conclusion:** We showed that the combination of results from available and low-cost investigations, such as memory function assessment (EMS) and perfusion SPECT, allows to predict aMCI conversion with a high percentage of patients properly classified. If our results are replicated with different neuropsychological tests, significant advances could be achieved in this important area of public health.

P258

Influence of Education on Cognitive Performance and Dopamine Transporter Binding in Dementia with Lewy Bodies

G. Lamotte, C. Nganoa, P. Branger, R. Morello, G. Bouvard, V. De La Sayette, G. Defer, D. **Agostini;** CHU Caen, Caen, FRANCE.

Objectives. Dementia with Lewy bodies (DLB) and Alzheimer's disease (AD) are the two most common forms of dementia. These two diseases share some clinical and pathological similarities, yet the loss of dopaminergic neurons confirmed by 123-I-Ioflupane Single Photon Emission Computed Tomography (SPECT) is a suggestive feature of DLB. Current evidence suggests that higher education has a protective effect on the risk of developing clinical AD. However, how education influences cognitive performance and the presynaptic dopamine transporter marker in DLB is unknown. **Materials and Methods**. We reviewed 56 consecutive patients with DLB who underwent a 123-I-Ioflupane SPECT from January 2009 to August 2013 at the University Hospital of Caen. We collected clinical and neuropsychological data from medical files and 123-I-Ioflupane SPECT data for all patients. **Results**.There was no correlation between education and global cognitive performance in patients with DLB. However, there was a positive correlation between education and tests exploring visuoconstructive functions (Rey complex figure copy and recall) and verbal retrieval strategies (Grober and Buschke free recall test). There was also a positive correlation between education and dopamine transporter binding. Higher educated patients had higher binding in the striatum, putamen and caudate nucleus ($p=0.001$ for each regions of interest). Dopamine transporter binding in the striatum, putamen and caudate nucleus was lower in the subgroup of patients with REM sleep behavior disorder, but was not associated with other DLB symptoms. **Conclusion**. Higher education may have a protective effect on visuoconstructive performance and verbal retrieval strategies and may influence dopaminergic nigrostriatal neurodegeneration in patients with DLB.

P259

Florbetapir PET/CT in the evaluation of patients with Parkinson dementia: a preliminary study

D. Volterrani, G. Puccini, G. Tognoni, S. Mazzarri, F. Guidoccio, M. Gennaro, G. Manca, R. Ceravolo; University of Pisa, Pisa, ITALY.

Cognitive impairment is a common non motor complication of Parkinson's disease (PD) which increases in severity and frequency over time leading most patients with PD to an overt clinical picture of dementia (PDD). Over the past 10 years, there was a growing evidence of a possible synergistic role of Alzheimer- type brain lesions containing ß-amyloid (Aß) and tau proteins in determining a PDD. Moreover, several clinical and pathological studies have stressed the co-existence of Lewy- and Alzheimer-type pathologies in PDD suggesting the correlation between greater cortical Aß plaques and cortical alfa-syn load. Aim of this study was to find correlates between the pattern of deposition of Aß and the variable expression of cognitive impairment in patients with PDD. of the cognitive deficits in PD. Ten patients (age 62.4±6.6) was enrolled at the Neurology Unit of the University of Pisa. The diagnosis of PD will be made according to UK Brain Bank criteria and PDD according to the Movement Disorder Society criteria. All patients performed neuropsychological tests exploring memory, executive, visuospatial, language and praxis and underwent a [^{18}F]Florbetapir PET/CT. All PET/CT scans of (20 min acquisition) were acquired starting 40±5 min after intravenous injection of [^{18}F]Florbetapir using a scanner GE Discovery 710. [^{18}F]Florbetapir PET/CT images were visually and semiquantitatively analized. After spatially transformation of each scan into Montreal Neurological Institute (MNI) space, cortical-to-cerebellum mean standard uptake values (SUVr) were calculated for each subjects. Results: 3/10 patients resulted clearly positive on the visual analysis of [^{18}F]Florbetapir PET/CT for the presence of cortical Aß deposition. An inverse statistically significant correlation was found between global SUVr and the MMSE score, assessed at the time of PET/CT scan. A positive correlation was found between left and right putamen SUVr and the age of onset of PDD. Conclusions: few studies are available on the use of PET imaging in assessing cognitive deficits in PD. Although our data should be considered preliminary because of the limited number of studied patients in our series, the uptake of [^{18}F]Florbetapir PET/CT seems to be related to the severity of cognitive impairment. More data are needed to understand the aetiology of cognitive deficits in PDD and the differing patterns and degrees of amyloid deposition.

Brain SPECT with ^{99m}Tc-HMPAO in assessing the effectiveness of surgical treatment of patients with occlusion of the carotid arteries

N. E. Kudryashova, V. A. Lukyanchikov, I. M. Godkov, O. G. Sinyakova, O. S. Kozmina; Sklifosovsky Inst.for Emerg. Medicine, Moscow, RUSSIAN FEDERATION.

AIM: Assessment of cerebral perfusion changes in the zone of occlusion of the carotid artery after surgery using brain SPECT with 99mTc-HMPAO.MATERIAL AND METHOD. The object of studing - 61 patients with occlusion of the internal carotid artery (ICA), preferably with one side (78.7%). 50 patients before surgery suffered stroke of various prescription and 11 had repeated transient ischemic attack (TIA).13 patients (21.3%) had bilateral carotid atherosclerotic lesions. All patients before surgery performed SPECT with 99mTc-HMPAO (740 MBq) and vasodilatory breakdown (acetazolamide), based on the indications for surgical treatment: carotid endarterectomy (CEA) or extra-intracranial mikroanastamosis (EICMA) ih terms of three days to one and a half years (from 45.9% - up to 1 month) after stroke or TIA. Again through 6-14 days after surgery of brain perfusion as assessed by SPECT. The regional CBF was determined by the formula N. Lassen, where the reference area was cerebellum (CBF 55 ml/100g/min).RESULTS. Before the surgical intervention was found the place of hypo/aperfution in the zone of occluded carotid artery with an average CBF=27,54±6,75 ml/100g/min. Test with acetazolamide was positive (increased perfusion to 12-33%) in 13 patients with critical stenosis of ICA - were performed CEA (group 1). The last 48 patients with negative vasodilatory breakdown ("steal syndrome" or increase less than 10%) imposed EICMA between the branches of the superficial temporal artery and a cortical branch of the middle cerebral artery (group 2). After surgical treatment the most of perfusion (from 20 to 90%) in the ischemic area was found in 68.8% of patients whom made EICMA (group 2, 33 of the 48 people.), and 15.4% after CEA (group 1, 2 of 13 people.). No effect or a slight increase perfusion (0 to 17%) was observed in 26 patients with bilateral carotid atherosclerosis, and prolonged ischemia: 84.6% in group 1 (11 of 13 patients) and 31.3% in group 2 (15 of 48 patients).Increase in perfusion after surgery in group 1 (CEA) on average amounted to 15,5% (Med = 11,0%; 95% CI, 8.1%, 22.9%) in group 2 (EICMA) - 31.4% (Med = 27,0%; 95% CI, 24.8%, 38.0%). Obtained a significant difference in the increase of perfusion as a result of two kinds of surgery ($p < 0,05$).CONCLUSION. The results of brain SPECT with 99mTc-HMPAO showed high efficiency EICMA with a significant strengthening of perfusion in the ischemic area in 68.8% of patients with occlusion of the ICA.

P261

Audit of DaTSCAN™ Referrals at East Kent University Hospitals, UK, According to the Current Guidelines and Financial Impact on Health System

R. Vickers, G. Shabo; East Kent University Hospitals Foundation Trust, Canterbury, UNITED KINGDOM.

To assess the appropriateness of DaTscan™ (^{123}I-Ioflupane) requests to our department in line with the current British NICE and the European Association of Nuclear Medicine (EANM) guidelines and the sufficiency of provided clinical information for accurate reporting. DaTscans come at significant financial cost, around £1000 per scan, and as such must be used appropriately, particularly in the current difficult economic climate. **METHODS** Retrospective review was carried out of 64 referrals between 1/10/14-31/12/14 and 85 referrals between 1/10/15-31/12/15, to look at any change in trend. They were assessed as regards the appropriateness of referrals and the content of clinical information using a combination of the electronic records and ordering system as well as electronic radiology and imaging systems (CRIS and PACS). The referrals were divided into three groups: 'Good' meeting guidelines with sufficient clinical information, 'Poor' lacking clinical details or 'Inappropriate' *i.e.* not in line with the guidelines. **RESULTS** 44/64 scans (68.75%) in the 2014 study group were deemed 'good' whereas 20/64 scans (31.25%) were 'poor' or 'inappropriate'. 11/20 scans (55%) were subsequently negative for evidence of Parkinson's disease or dementia. In the 2015 study group, there were 85 scans, an increase of 32.8% on the same period of the previous year. 54/85 scans (63.53%) were deemed 'good' whereas 31/85 scans (36.47%) were deemed 'poor' or inappropriate. 21/31 (67%) scans were subsequently negative for evidence of Parkinson's disease or dementia. **CONCLUSION** There are a large number of inappropriate referrals resulting in negative scans. In these two small study groups; 32 scans were performed over a total of 6 month period that were poor/inappropriate referrals with negative results, at a cost of more than £30,000. At an approximate cost of £5000 per month, this equates to more than £60,000 per year to the Trust. It also appears that the number of inappropriate referrals is increasing, however this is a trend seen only in two sets of year on year results and therefore may be an anomaly. This does however present an opportunity for expansion of this audit to other years. In recommendation, it would be prudent to design a specific referral pro-forma that has mandatory clinical information section, requiring the referring clinician's signature before considering the request. This would provide an opportunity to cut down on unnecessary and expensive scans that are not clinically indicated.

P262

Role of 99mTc-HMPAO brain perfusion SPECT in the clinical management of autoimmune brain vasculitis (ABV)

V. Frantellizzi, M. Pontico, A. Farcomeni, A. Francia, M. Morreale, F. Monteleone, G. De Vincentis, M. Liberatore; Sapienza University of Rome, Rome, ITALY.

Vasculitis of the central nervous system (CNS) is a rare event and generally occurs as a manifestation of a systemic disease or as primary form of the CNS. Brain SPECT seems to be useful in the diagnosis and monitoring of the disease. The purpose of our study was to evaluate, with this investigation, the trend of brain perfusion in relation to the treatment duration. Fifty consecutive patients with ABV were enrolled in this study. 18 were affected by Systemic Lupus Erythematosus (LES), 22 by Undifferentiated Vasculitis (UV), 5 by Behcet's disease (BD) and 5 by Sjogren's syndrome (SS). All patients underwent a full neuropsychiatric investigation, objective examination and various serological tests. A brain SPECT was carried-out before the onset of appropriate treatment and was repeated during the follow-up at different time interval (12, 24 and 36 months). Brain SPECT with 99mTc-HMPAO, was performed by a dual-head gamma camera equipped with high-resolution low-energy collimators. Image analysis was performed using a specific software capable of providing for each cerebral area the mean and the SD of the counts recorded expressed as a percentage of the maximum count registered on the encephalon. Ten regions of interest were selected for each patient (entire right and left emicortex, parietal, temporal, frontal and occipital regions). Basal SPECT results were compared with those obtained during the treatment. In BD and SS results demonstrate an increase of the cerebral perfusion after treatment in agreement with clinical evaluation, even if no statistical analysis was performed due to the limited number of patients studied. The differences between the overall means and SDs calculated on the areas of interest before and after the treatment gave the following results. No significant differences resulted at 12, 24 and 36 months in the LES group. In the UV group no significant differences were found at 12 months, while such differences became significant at 24 ($p = 0.027$) and 36 months ($p = 0.001$). Similar results were obtained taking into account LES and UV together (p values: 12 months = 0.128, 24 months = 0.009, 36 months < 0.001). Even these results are consistent with the clinical course observed in patients. The results obtained with brain SPECT in this study suggest that a global improvement of brain perfusion can be achieved in UV only after a prolonged period of treatment.

P263

Brain FDG-PET quantification after chronic administration of benzodiazepines . An animal study

J. Silva-Rodríguez[1], L. García-Varela[1], E. López-Arias[2], I. Domínguez-Prado[3], J. Cortés[3], J. Pardo-Montero[2], A. Fernández-Ferreiro[1], A.

Ruibal[3], T. Sobrino[2], P. Aguiar[2]; [1]Fundación Ramón Domínguez, Santiago de Compostela, SPAIN, [2]Health Research Institute (IDIS), Santiago de Compostela, SPAIN, [3]Nuclear Medicine Department, University Hospital, Santiago de Compostela, SPAIN.

Introduction: In order to minimize unspecific radiotracer uptake, patients undergoing brain FDG-PET are usually told to rest, lying down and with their eyes closed, for about 45 minutes before the examination. On this context, benzodiazepines might be useful when dealing with non-collaborative patients, which may be the case on several applications of brain PET such as dementia. Different authors have studied the effect of the acute administration of benzodiazepines on brain glucose uptake, reporting a decrease on global uptake around 20%. Due to this, current guidelines for brain PET imaging recommend to avoid the injection of diazepam prior to brain FDG-PET examination. Nevertheless, many patients undergoing PET studies are likely to be under chronic treatment with benzodiazepines due to the use of different medications such as sleeping pills. This chronic consumption of benzodiazepines has been related to cognition impairment even after stopping the treatment, and its impact on brain PET imaging remains to be studied. Animal studies may provide an extensive and accurate estimation in a well-defined and controlled framework. **Aim**: We are aimed at evaluating the impact of the chronic administration of benzodiazepines on brain FDG uptake and its evolution after the discontinuation of the treatment. **Methods**: Twelve healthy rats were randomly divided into two groups, one treated with diazepam and the other one used as control group. All the subjects underwent PET/CT examinations on basal state, after single-dose administration and chronic administration (during twenty-eight days) of diazepam (treated) or saline (controls), and one week after stopping the treatment. Different quantification methods were applied to evaluate the differences on total brain FDG uptake and uptake patterns of FDG between both groups. **Results**: Our analysis revealed a significant reduction of global FDG uptake after acute (-16.2%, $p<0.02$) and chronic (-23.2%, $p<0.03$) administration of diazepam. Moreover, a strong trend pointing to differences between acute and chronic administrations ($p<0.08$) was also observed. Uptake levels returned to normal after interrupting the administration of diazepam. On the other hand, patterns of FDG uptake were not affected by the administration of diazepam. **Conclusions**: The administration of diazepam causes a progressive decrease of the FDG global uptake in the rat brain, but it does not change regional patterns within the brain.

Is cerebral glucose metabolism related to blood brain barrier dysfunction and intrathecal IgG synthesis in Alzheimer Disease?

A. Chiaravalloti[1,2], A. Fiorentini[1], F. Ursini[3], A. Martorana[4], P. Sannino[5], G. Koch[4], M. Bozzali[6], B. Di Pietro[1], E. Di Giorgio[2], O. Schillaci[1,5]; [1]Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY, [2]IRCCS Neuromed, Rome, ITALY, [3]Rheumatology Research Unit, University Magna Graecia, Rome, ITALY, [4]Department of Neurosciences, University Tor Vergata, Rome, ITALY, [5]IRCCS Neuromed, Pozzilli, ITALY, [6]IRCCS Santa Lucia, Rome, ITALY.

Aim: To investigate the relationships between blood brain barrier (BBB) dysfunction, intrathecal IgG synthesis and brain glucose consumption as detectable by means of Serum/Cerebrospinal fluid (CSF) albumin index (Q_{alb}) and IgG index [(CSF IgG/serum IgG) x Serum albumin/CSF albumin)] and 2-deoxy-2-(^{18}F) fluoro-D-glucose (^{18}F-FDG) Positron Emission Tomography/Computed Tomography (PET/CT) in a selected population affected by Alzheimer's Disease (AD). **Material and methods**: The study included 134 newly diagnosed AD patients according to the NINCDS-ADRDA criteria. The mean (±SD) age of the patients was 70 (±6) years; 60 were male and 64 were female. Mini mental State Examination was equal to *18.9* (±7.2). All patients underwent serum and CSF assay for IgG index and $Q_{alb.}$ Contextually we measured amyloid ($A\beta_{1-42}$) and tau [phosphorylated-tau (p-tau) and total-tau (t-tau)]. A Magnetic Resonance before ^{18}F-FDG PET scanning was performed as well. The relationships were evaluated by means of statistical parametric mapping (SPM8) using sex, age, MMSE, scholarity and CSF amyloid and tau values as covariates. **Results:** We found a significant negative correlation between the increase of Q_{alb} and ^{18}F FDG uptake in the Brodmann Area 42 and 22 that correspond to the left superior temporal gyrus, with higher Q_{alb} values being related to a reduced glucose consumption in these areas (p FEW-corr=0.001; p FDR corr=0.000). Cerebellum-normalized ^{18}F FDG PET values for BA 42 and 22 resulted equal to 1.05±0.12 (mean±standard deviation) and were not normally distributed (K^2=32.2 and $P<0.001$). Spearman correlation analysis showed a good correlation between albumin ratio levels and normalized ^{18}F FDG uptake further showing that low levels of albumin ratio were related to lower levels of ^{18}F FDG uptake (r=-0.22 and P=0.009). No significant relationships were found between brain glucose consumption and IgG index.**Conclusions**: The results of our study suggest that BBB dysfunction is related to reduction of cortical activity in the left temporal cortex in AD subjects.

P265

Does F-18-choline PET/CT Have a Role in Primary Brain Tumor Characterization?

M. Nicod Lalonde, V. Dunet, G. Allenbach, P. Mitsakis, A. Van-der-Gucht, N. Schaefer, B. Lhermitte, P. Maeder, A. Hottinger, J. Bloch, J. O. Prior; Lausanne University Hospital, Lausanne, SWITZERLAND.

Study Aim: To determine whether F-18-choline (FCH) PET/CT can contribute to lesion characterization in patients with suspected primary brain tumors on MRI. Materials and Methods: We enrolled 42 consecutive patients from July 2009 to March 2016 presenting with a suspicion of primary brain lesion on MRI and with an intention to biopsy this lesion. FCH PET/CT was performed on all patients and lesion SUVmax were measured. The tumor-to-background ratio (TBR) was calculated by dividing lesion SUVmax by contralateral normal brain tissue SUVmean. The patients then underwent a biopsy or a resection of the tumor. Association between SUVmax (respectively TBR) and gadolinium (Gd) enhancement on MRI was examined by student t-test. One-way ANOVA was used to determine the relationship between MRI enhancement, SUVmax (respectively TBR) and tumor grade. Results: In total, 42 patients (30M, 12W) with a mean age of 47 y (range: 24-76) were enrolled. Histological findings showed WHO grade II brain tumor in 18 patients, grade III tumor in 16 patients and grade IV tumor in 8 patients. In 21 lesions, there was no Gd enhancement. SUVmax was significantly lower in patients with no Gd enhancement compared to patients with Gd enhancement on MRI: SUVmax 0.55±0.44 g/ml versus 1.47± 1.11g/ml (p=0.001). Likewise TBR was significantly lower in patients with no Gd enhancement (3.29±2.17 vs. 7.59±5.74); p=0.003). SUVmax significantly increased with tumor grade (grade II: 0.72 ±0.52, grade III: 0.94±0.79, and grade IV: 1.8±1.55; p=0.02). The same was true for TBR (grade II: 4.18 ±2.53, grade III: 4.67±3.26, and grade IV: 9.81±8.34; p=0.01). When taking into account Gd enhancement on MRI, FCH uptake was also useful in characterizing brain lesions. In patients with Gd enhancement, TBR helped to predict brain tumor grade, as TBR increased with tumor grade (grade II: 6.46 ±1.93, grade III: 5.09±3.82, and grade IV: 12.25±8.3; p=0.05). Patients with no Gd enhancement had a similar TBR for all tumor grades (grade II: 2.73±1.66, grade III: 4.25±2.78, and grade IV: 2.5±0.71; p=0.29). Conclusion: As predicted, when using FCH PET/CT for characterization of primary brain tumors, our study shows a significant increase in SUVmax and TBR with tumor grade. Interestingly, when used in combination with MRI, FCH PET/CT helps in determining tumor grade only in patients with Gd enhanced lesions.

P267

Is cerebral glucose metabolism related to TSH, fT3 and fT4 in Alzheimer disease? A 18F FDG PET/CT study with cerebrospinal fluid amyloid and tau correlates

A. Chiaravalloti[1,2], A. Fiorentini[1], F. Ursini[3], A. Martorana[4], P. Sannino[2], C. Di Russo[1], E. Palombo[1], O. Schillaci[1,2]; [1]Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY, [2]IRCCS Neuromed, Pozzilli, ITALY, [3]Rheumatology Research Unit, University Magna Graecia, Catanzaro, ITALY, [4]Department of Neurosciences, University Tor Vergata, Rome, ITALY.

Aim: To investigate the relationships between thyroid stimulating hormone (TSH), freeT3(fT3) and freeT4 (fT4) and brain glucose consumption as detectable by means of 2-deoxy-2-(^{18}F) fluoro-D-glucose (^{18}F FDG) Positron Emission Tomography/Computed Tomography (PET/CT) in a selected population with Alzheimer disease (AD). **Materials and methods**: 87 subjects (47 males and 50 females, mean age 70 (±6) years old) with AD according to the NINCDS-ADRDA criteria were enrolled in this study. Mini mental state examination (MMSE) was *18.9* (±7.2). All of them were subjected to TSH, fT3 and fT4 assay and to cerebrospinal fluid amyloid ($A\beta_{1\text{-}42}$) and tau [phosphorylated-tau (p-tau) and total-tau (t-tau)] assay prior PET/CT examination. Mean values for TSH, fT3 and fT4 were *1.38 (*±0.84), 3.34 (±0.33) and1.16 (±0.17). Mean values for $A\beta_{1\text{-}42,}$ p-tau and t-tau were 344.28 (± 134.31), 96.7 (± 76.9) and 679.15 (± 330.5). The relationships were evaluated by means of statistical parametric mapping (SPM8) using age, sex, MMSE, scholarship and CSF values of amyloid and tau as covariates. **Results**: We found a significant positive correlation between TSH values and cortical glucose consumption in a wide portion of the anterior cingulate cortex bilaterally (BA 32) and left frontal lobe (BA25) (p FEW-corr=0.001; p FDRcorr=0.000; cluster extent 66950). No significant relationships were found between cortical ^{18}F FDG uptake and T3 and T4 serum levels. A significant relationship was found between t-tau levels and cortical glucose consumption in right BA32 (r=-0.25, P=0.019) and left BA32 (r^2=0.054 and P=0.033) while no significant relationship was found in BA25 (r=-0.11;P=0.29). No significant relationships were found between cortical ^{18}F FDG uptake and p-tau and $A\beta_{1\text{-}42}$ in these sites. **Conclusions**: the results of our study suggest that a cortical dysfunction in anterior cingulate and frontal lobes affects serum values of TSH in AD patients. Pathological accumulation of tau protein could play a role in this phenomenon.

P268

Value of cerebral perfusion SPECT in HaNDL Syndrome

L. Reguera Berenguer, J. Orcajo Rincón, A. Rotger Regí, C. Durán Barquero, R. Pascual Pérez, M. L. Lozano Murgas, J. Ardila Manjarrez, J. C. Alonso Farto; HGU Gregorio Marañón, Madrid, SPAIN.

HaNDL syndrome or pseudomigraine with pleocytosis is a bening and autolimited disease characterized by severe headache with at least one transient neurologic deficit and spontaneous resolution in less than 4 months. In addition, it is accompanied by cerebro spinal fluid (CSF) pleocytosis with lymphocytic predominance and negative etiological studies. In neuroimaging, cerebral perfusion SPECT with ^{99}mTc-HMPAO has shown local blood flow alterations consistent with focal neurological deficits that tend to normalize in the period of clinical remission, although there is currently insufficient bibliographic support. Aim: To describe the perfusional pattern of this disease in the acute phase, assessing possible patterns relating symptomatology with perfusion SPECT findings and their normalization in the resolution phase. Materials and methods: Descriptive analysis of a series of 4 patients treated at HGU Gregorio Maranon from December 2009 to April 2016, in which HaNDL syndrome was suspected. All patients underwent EEG, CSF puncture and conventional imaging tests (CT and MRI), in addition to brain perfusion SPECT with ^{99}mTc-HMPAO in the symptomatic phase and at clinical remission. Results: All patients (2 males and 2 females) had lymphocytosis with protein concentration in CSF with no pathologic results in conventional imaging, whereas cerebral SPECT showed perfusional abnormalities consistent with the clinical manifestations, consisting of marked hemispheric hypoperfusion, contralateral to the neurological symptoms, showing reversibility in the control study. Conclusions: Cerebral perfusion SPECT appears to be an effective tool, not only in the early confirmation of the diagnosis of HaNDL syndrome, but also in monitoring its resolution.

Assessment of collateral circulation in chronic cranial arterial occlusive disease using 123I-IMP CBF SPECT: delayed accumulation through collateral formation in dynamic phase

K. Sohara[1], S. Mizumura[2], T. Kuwako[1], T. Kiriyama[1], Y. Fukushima[1], N. Sugo[3], S. Kumita[1]; [1]Nippon Medical School, Tokyo, JAPAN, [2]Dept of radiology, Omori Medical Center, Toho University, Tokyo, JAPAN, [3]Dept of neurosurgery, Omori Medical Center, Toho University, Tokyo, JAPAN.

<The aim> The collateral circulation plays a pivotal role in the hemodynamics of cerebral ischemia in chronic cranial arterial occlusion disease. This study investigated the effects of collateral circulation using 123I-Iodoamphetamine (IMP) CBF SPECT. <Materials and methods> Twenty five patients with chronic cranial arterial obstruction, diagnosed by angiography, were performed with dynamic (0-8min) and static (15-40min) SPECT after the injection of 123I-IMP. Sixteen patients of them showed three types of the collateral circulation (positive case): the pathways of 1) arterial segments of the circle of Willis, 2) extracranial sources, 3) leptomeningeal anastomosis. The other 9 had no collateral circulation (negative cases). Stereotactic voxel-based VOIs were drawn on 7 vascular territories in a hemisphere: anterior cerebral artery (ACA), middle cerebral artery (MCA), internal carotid artery (ICA), and the central and peripheral zones of these vascular territories. To evaluate the VOI accumulation difference between affected and unaffected hemispheres in dynamic phase, "dynamic uptake ratio" was defined as the ratio of VOI values (count-standardized by VOI values on static image) in affected hemisphere to in unaffected hemisphere. We compared the dynamic uptake ratios of 7 sets of vascular territories in the positive and negative cases, and employed the receiver operating characteristic (ROC) curves when discriminating collateral formation positive and negative cases. <Results> The dynamic uptake ratios in all vascular territories of the positive cases tended to be lower than of the negative cases, but in all vascular territories, except for the central zone of MCA, there was no significant difference. The dynamic uptake ratios of the central zone of MCA in the positive cases were significantly lower than in the negative cases ($p<0.05$), while those of the peripheral zone of in the positive cases was not in the negative cases. In ROC curves, the dynamic uptake ratio in the central zone of MCA is exhibited the highest areas under the curves of 0.718, accuracies of 79%, sensitivity of 69% and specificity of 100% with cut off values of 0.99. <Conclusion>The patients with collateral formation would have a retrograde filling of patent but proximally obstructed branches. The delayed uptake in the central zone of MCA territory would reflect the existence of collateral circulation.

P271

Brain perfusion SPECT in Myalgic Encephalomyelitis: Normal database comparison for improved interpretation

S. Neubauer[1], B. M. HYDE[2]; [1]Clinica Las Condes, Santiago, CHILE, [2]Nightingale Research Foundation, Ottawa, ON, CANADA.

Myalgic encephalomyelitis (ME) and Chronic Fatigue Syndrome (CFS) are acquired complex syndromes including a variety of symptoms and physical findings affecting multiple systems of the body like severe, debilitating, unexplained fatigue for many months often a lifetime, frequent cognitive dysfunction and symptom flare-up in relation to physical or cognitive effort. ME may occur as an epidemic outbreak (e.g.1905 Sweden, 1934 California) or may only affect individuals. Most investigators agree that the disorder can be related to an abnormal immune system and brain function in response to an infection or virus. There are no universally accepted diagnostic tests. Regional cerebral blood flow has consistently been abnormal on brain perfusion SPECT and different from depression. **Aim**: Based on previous experience of perfusion brain SPECT in ME/CFS patients with conventional 2D transaxial, coronal and sagital projections, we evaluate the added value of a normal database comparison for analysis. **Material and Method**: We report on brain perfusion SPECT rCBF findings in 11 ME/CFS patients diagnosed according to the Canadian Consensus Criteria by one of the investigators (BH).They all were injected with Tc99m-HMPAO in resting condition, five of them also during exercise (Treadmill stress), one additionally during symptom triggering stimulus (inhaling certain perfume) and 4/5 also at 24 hours post-stress (recovery). All studies were compared against a normal age matched data base in Chile. Results are expressed in standard deviations of the normal mean in each of 14.000 voxels and are visually analyzed. **Results:** At rest all patients showed hypoperfusion in the lateral temporal lobes and multifocal hypoperfusion in the parietal lobes. There was also hypoperfusion in the posterior cingulate gyrii in 9/11 patients, in the anterior cingulate gyrii in 8/11 and in the occipital lobes in 8/11. During stress 5/5 patients had significant worsening of perfusion in the same areas and 3/5 had additionally hypoperfusion in the anterior frontal lobes. **Conclusions**: Brain perfusion SPECT comparison to a normal data base showed abnormal temporo-parietal perfusion in all ME/CFS patients by simple visual analysis of the images. Exercise caused worsening of brain perfusion abnormalities as expected from clinical data. Normal data base comparison is useful for intrasubject comparison of rest versus stimulated brain perfusion.

P272

Role of Ictal SPECT in medically refractory epilepsy: Post-surgical correlation

A. S. Manglunia[1], S. Pawar[2], S. Ravat[2], D. Mazumdar[2]; [1]Bombay Hospital & Medical Research Centre, Mumbai, INDIA, [2]KEM hospital & Seth G. S. Medical College, Mumbai, INDIA.

Introduction: An epileptic seizure is a manifestation of abnormal and excessive paroxysms of involuntary activity of neurons in the brain. Seizures are controllable with medication in about 70% of cases. For the others, surgery remains an appealing treatment option. The common methods of seizure focus localization include electroencephalography (EEG), neuropsychological testing, and magnetic resonance imaging (MRI). As far as brain perfusion SPECT is concerned, there is large variation in the stated sensitivity of this technique. Also, the relationship between SPECT and surgical outcome has not been established. The purpose of this study was to evaluate the role of ictal brain SPECT in localization of the epileptogenic focus in patients with epilepsy. Materials & Methods: The study included patients referred to our department for ictal SPECT. The patients were subjected to a Brain MRI, inter-ictal EEG and video-EEG monitoring. Ictal and inter-ictal Brain Perfusion SPECTs were acquired. The patients then underwent surgery and were followed-up for 1 year, when their post-surgical outcome was classified according to Engel's system. Results: 30 patients, comprising of equal number of males and females were included. Mean age of the patients was 24.4 years (SD 9.8 years). MRI could localise the seizure focus in 15 patients, inter-ictal EEG in 12 patients, whereas ictal-EEG was localizing in 21 patients. SPECT could localize the seizure focus in 24 patients out of 30. Pre-operative comparison of SPECT results with that of MRI, inter-EEG and ictal EEG showed concordance of 33.33%, 30.00% & 50.00% respectively. However, the differences were statistically insignificant. When using Engel's system as the standard of reference for post-operative state, SPECT showed maximum concordance rate of 80% (24/30). The difference in the concordance rate of SPECT when compared to both MRI and Inter-ictal EEG was statistically significant ($P < 0.01$). Of the patients with normal MRI (2/30), ictal EEG showed concordance with the resected site in 2/2 cases. MRI showed bilateral abnormal findings in 13 patients. SPECT in these patients correctly localized the lesion in 92.3% (12/13). Conclusions: In epilepsy cases with bilaterally abnormal MRI findings, brain SPECT is a useful modality for pre-surgical evaluation. Also, in cases with discordant results, SPECT can be employed as a supplementary tool for confirmation. SPECT also has a role in localizing the epileptogenic focus in patients with normal MRI finding.

Comparison of the diagnostic performance of two methods of semi-quantitative analysis of ^{123}I-FP-CIT brain SPECT images in mild Parkinson's disease

B. Palumbo[1], S. Nuvoli[2], S. Cascianelli[3], A. Santonicola[1], M. L. Fravolini[3], N. Tambasco[4], M. Scialpi[5], A. Spanu[2], G. Madeddu[2]; [1]Section of Nuclear Medicine and Health Physics, Dept of Surgical and Biomedical Sciences, University of Perugia, PERUGIA, ITALY, [2]Unit of Nuclear Medicine, University of Sassari, SASSARI, ITALY, [3]Dept of Engineering, University of Perugia, PERUGIA, ITALY, [4]Unit of Neurology, Perugia University Hospital, PERUGIA, ITALY, [5]Section of Diagnostic Imaging, Dept of Surgical and Biomedical Sciences, University of Perugia, PERUGIA, ITALY.

Aim: To investigate the differential diagnosis between Parkinson's disease (PD) and healthy subjects the diagnostic performance of two methods of semiquantitative analysis of ^{123}I-FP-CIT brain SPECT data, Basal Ganglia V2 software (BasGan) and Neurotrans3D (Segami Corp.), was compared by using a Support Vector Machine classifier (SVM), a powerful supervised classification algorithm based on ground-truth training data. **Materials and Methods**: ^{123}I-FP-CIT brain SPECT with semiquantitative analysis (according to EANM guidelines) with the two semiquantitative methods was performed in 91 patients with mild symptoms (bradykinesia-rigidity) to confirm or exclude PD, resulted 49 PD and 42 normal subjects. A clinical follow up of at least six months confirmed final diagnosis. Each patient was described by 4 descriptors (caudate-nucleus left/right - CL, CR- putamen left/right - PL, PR -) and a class label: 'PD' for PD and 'N' for normal subjects. For each semiquantitative method a nonlinear SVM with Radial Basis Function kernel was trained to predict the diagnostic categories. A 10-fold cross-validation was performed on the training set for SVM parameters tuning. The same protocol was used in further subsequent classification experiments, either on the entire feature set and on specific subsets of the initial features to assess their prediction capabilities: the first one using only caudate-nucleus left/right, the second one using only putamen left/right. **Results**: Both methods were able to correctly classify labels in the experiment using all the 4 descriptors; BasGan and Neurotrans3D showed respectively specificity of 96.16±7.98% and sensitivity of 86.43±13.38% and specificity of 98.49±5.26% and sensitivity of 87.79±12.43%. When using only putamen left/right as descriptors, both methods disclosed higher performances values, namely specificity of 96.37±7.63% and sensitivity of 90.48±11.96% for BasGan and specificity of 99.01±1.09% and sensitivity of 88.27±12.55% for Neurotrans3D. Conversely, using only caudate-

nucleus left/right as descriptors, performances decreased for both methods: BasGan achieves specificity of 80.79±14.62% and sensitivity of 77.17±18.80%, while Neurotrans3D obtains specificity of 82.76 ±15.35% and sensitivity of 74.98±18.01%. Therefore, putamen descriptors alone were able to correctly discriminate patients and controls. **Conclusion:** Both BasGan and Neurotrans3D were accurate in identifying PD in early phase, presenting a similar diagnostic performance. Furthermore, in our group of patients, among the different features used to classify subjects, putamen (either left or right) resulted as the most discriminative descriptor for mild disease using both semiquantitative methods.

P274

[^{18}F]-FDG PET-CT identifies extraorbital muscle impairment in progressive supranuclear palsy

G. Petyt[1], A. Jaillard[1], G. Collet[2], D. Bellevre[1], H. Lahousse[1], F. Semah[1]; [1]CHU Lille, Lille, FRANCE, [2]CH Valenciennes, Valenciennes, FRANCE.

Vertical supranuclear gaze palsy is a key symptom for the diagnosis of progressive supranuclear palsy (PSP, Steele-Richardson-Olszewski syndrome). PSP neurofibrillary tangles affects the mesencephalic motor nucleus of the oculomotor nerves (N.III). N.III controls superior rectus muscle (>RM), inferior rectus muscle (<RM), medial rectus muscle (MRM) and inferior oblique muscle. Superior oblique muscle (>OM) and lateral rectus muscle (LRM) are respectively under control of trochlear nerve (N.IV) and Abducens nerve (N.VI), not involved in PSP. Ocular symptoms earlier affects down glaze by <RM involvement. AIM: Our work evaluate the ability of high definition FDG PET-CT to identify the ocular muscle hypometabolism in patient with possible or probable PSP on brain FDG scans. Patients,Materials and Methods: Five patients with PSP diagnosis were enrolled and compared to 33 successive FDG brain scans (10 epilepsy, 19 other neurodegenerative disorders (ND), 4 patients without evidence of ND). Images were acquired for 10 min, 30 min after injection of 185 MBq of [^{18}F]-FDG, on mCT flow 20 (Siemens). UHD iterative algorithm (gaussian 2mm FWHM post filter) was applied. SUVbw max of extraoccular muscles were measured (>RM,>OM,MRM,<RM,LRM). Relative uptake of each muscle were computed after normalization to the mean SUVmax for both eyes. Ratios between <RM uptake (earlier involved muscle) and LRM uptake (not involved in PSP) were computed for each eye. For each patient, lowest <RM/LRM ratio was recorded (Rmin) . Relative uptake for each muscle, <RM/LRM ratio for each eye and Rmin for each patient were compared by unpaired t test with Welch's correction. Results: On patient based analysis, minimal ratio between <RM and LRM was lower in PSP patients than non PSP controls (p=0.026, respective mean 1.07 and 1.29) . On eyes based analysis, <RM uptake was lower in PSP group (mean = 1.14 vs 1.42 in controls; p=0.0001). <RM/LRM ratio was lower in PSP patients (1.13 vs 1.39 in controls ; p=0.02). Mean relative uptake of >RM, >OM,MRM and LRM were respectively 0.95 (p=0.10), 0.77 (p=0.61), 1.02 (p=0,9) and 1.05 (p=0.19) in PSP versus 0.82, 0.79, 1.01, 1.38 and 0,99 in controls. Conclusion: FDG scan identifies specific involvement of inferior rectus orbital muscle in PSP patients.

P275

^{123}I-FP-CIT brain SPECT: tracer uptake values of right putamen are the most discriminant to diagnose Parkinson's disease

B. Palumbo[1], S. Cascianelli[2], A. Santonicola[1], M. Minestrini[1], T. Buresta[1], M. L. Fravolini[2], N. Tambasco[3], M. Scialpi[4], S. Nuvoli[5], A. Spanu[5], G. Madeddu[5]; [1]Section of Nuclear Medicine and Health Physics, Dept of Surgical and Biomedical Sciences, University of Perugia, PERUGIA, ITALY, [2]Dept of Engineering, University of Perugia, PERUGIA, ITALY, [3]Unit of Neurology, Perugia University Hospital, PERUGIA, ITALY, [4]Section of Diagnostic Imaging, Dept of Surgical and Biomedical Sciences, University of Perugia, PERUGIA, ITALY, [5]Unit of Nuclear Medicine, University of Sassari, SASSARI, ITALY.

Aim: Classification Tree algorithm (ClT) is an automatic classifier composed of a set of logical rules, organized as a decision tree to produce an optimised threshold based classification of data, thus providing discriminative cut-off values. We applied a ClT to 123I-FP-CIT brain SPECT semiquantitave data, to obtain cut-off values of radiopharmaceutical uptake ratios in basal ganglia able to identify PD and other conditions. Materials and Methods: 123I-FP-CIT brain SPECT (Millenium VG, G.E.M.S.) was performed using semiquantitative analysis with Basal Ganglia (BasGan) V2 software according to EANM guidelines in 141 patients with mild movement disorders. Amng them 99 resulted as PD [51M and 48 F; range of age: 60-81 yrs, Hoehn and Yahr score (HY): 0.5-1.5; Unified Parkinson Disease Rating Scale (UPDRS) score: 6-38] and 42 resulted as non-PD (Essential Tremor and drug-induced PD, 20 M and 22 F; range of age 60-80 yrs). The final diagnosis was confirmed by a clinical follow-up of at least 6 months. A 10-fold cross validation was applied by repeating 1000 random experiments. This allowed the statistical evaluation the "average performance" of ClT. Results: According to ClT, the probability of correct classification in patients with PD was 85.38 ±13.17% % (mean±SD) and in non-PD patients 93.96±8.57%. For ClT, the first decision rule gave a value for the right putamen (RP) of 2.23 ±0.14, thus meaning that if RP values were lower patients were classified as PD, while if RP values were higher patients were classified as non-PD. More complex ClT structures, including caudate nuclei and left putamen values, were tested to refine the classification performance, but in our data these additional features appeared to be less significant. Conclusion: ClT accurately classified PD and non-PD patients by means of 123I-FP-CIT brain SPECT data, allowing to obtain cut-off values able to differentiate these groups of subjects. Furthermore RP uptake values in our patients resulted as the most discriminant to provide the diagnosis, probably due to a certain number of patients with initial prevalence of left clinical symptoms.:

P276

The utility of the combination of a SPECT study with I-123-ioflupane (DaTSCAN) and I-123 MIBG myocardial scintigraphy in differentiating Parkinson disease from other degenerative parkinsonian syndromes

N. Uyama[1], H. Otsuka[2], T. Shinya[1], Y. Otomi[1], M. Harada[1]; [1]Tokushima University Hospital, Tokushima, JAPAN, [2]Department of Medical Imaging/Nuclear Medicine, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, JAPAN.

Objectives: The molecular imaging of presynaptic nigrostriatal neuronal degeneration and sympathetic cardiac innervation with SPECT (DaTSCAN and MIBG scintigraphy) are useful tools for differentiating idiopathic Parkinson disease (PD) from other degenerative parkinsonian syndromes (non-PD) in the clinical setting. Nevertheless, these imaging modalities are often not sufficient to diagnose PD. The aims of this study were to semi-quantitatively evaluate the diagnostic capacities of DaTSCAN and MIBG scintigraphy and to explore the diagnostic accuracy of the combination of these modalities in degenerative parkinsonian syndromes. Materials and Methods: The SPECT radiotracers 123I-2β-carbomethoxy-3β-(4-iodophenyl)-N-(3-fluoropropyl) nortropane (FP-CIT) and meta-123I-iodobenzylguanidine (MIBG) were used to research presynaptic membranes of the terminals of dopaminergic projections (DaTSCAN) and myocardial adrenergic innervation (MIBG scintigraphy), respectively. Patients with PD (n=16; male 5, female 11; age 59.8 ± 13.1 years) and patients with non-PD (n=20; male 12, female 8; age 62.1 ± 14.8 years) who underwent both DaTSCAN and MIBG

scintigraphy were enrolled in this retrospective study. We used the ROC analyses in setting the cut-off values of specific binding ratio (SBR) in DaTSCAN and the heart to mediastinum ratio in delayed scan (delayed H/M ratio) in MIBG scintigraphy for differentiating PD from non-PD. The sensitivity, specificity, and test accuracy for the individual imaging methods were calculated. In addition, we compared these diagnostic accuracies with that of the combination of two modalities. Results: The sensitivity and specificity of SBR were 81.5% and 45.0%, respectively, with the cut-off value of 3.245. The sensitivity and specificity of delayed H/M ratio were 68.8% and 65.0%, respectively, with the cut-off value of 2.23 on MIBG scintigraphy. The analyses showed low accuracies for differentiation of PD and non-PD using each molecular approach, respectively (DaTSCAN, 61.1%; MIBG, 66.6%). In contrast, the accuracy was increased by the combined use of the two semi-quantitative analyses using a cut-off value of SBR of <3.245 and a cut-off value of delayed H/M ratio of <2.23. These indices distinguished PD from non-PD with a sensitivity of 68.7%, specificity of 85%, accuracy of 77.8%, predictive positive value of 77%, and predictive negative value of 78.5%. Conclusion: These results suggested that the combination of DaTSCAN and MIBG scintigraphy may improve the diagnostic accuracy in differentiating PD from non-PD.

P277

The Loss of Extrastriatal As Well As Striatal [^{123}I]FP-CIT Binding Is More Pronounced in MSA-P and PSP Than in Parkinson's Disease

M. Joling[1], C. Vriend[1], O. A. Van den Heuvel[1], P. G. H. M. Raijmakers[1], H. W. Berendse[1], J. Booij[2]; [1]VU University Medical Center, Amsterdam, NETHERLANDS, [2]Academic Medical Center, Amsterdam, NETHERLANDS.

Purpose: [^{123}I]FP-CIT SPECT is a well-validated technique to assess dopamine transporter (DAT) binding in vivo, and it can be used to detect dopamine cell loss in parkinsonian syndromes like Parkinson's disease (PD), progressive supranuclear palsy (PSP) and multiple system atrophy (MSA). In addition to its affinity for DAT, [^{123}I]FP-CIT has modest affinity for the serotonin transporter (SERT). Extrastriatal [^{123}I]FP-CIT binding, for example in the diencephalon and the midbrain/pons, predominantly represents SERT binding. A growing body of evidence suggests that DAT and SERT binding in the midbrain of PSP and the parkinsonian variant of MSA (MSA-P) patients is lower than in patients with PD, indicating a possible use to improve differential diagnostics. In this light, we hypothesised that in addition to striatal DAT binding, extrastriatal [^{123}I]FP-CIT binding in SPECT scans may contribute to the differentiation between PSP, MSA-P and PD in clinical practice. **Methods**: We included 9 MSA-P, 7 cerebellar variant of MSA (MSA-C), 13 PSP and 30 PD age- and gender matched consecutive cases from the outpatient clinic for movement disorders at the VU University Medical Center in Amsterdam, The Netherlands. The [^{123}I]FP-CIT SPECT images were acquired 3 hours after bolus injection on a dual-headed system using a fanbeam collimator. [^{123}I]FP-CIT binding was analysed with region of interest (ROI) and voxel-based methods in the DAT-rich caudate nucleus and posterior putamen (striatum) and SERT-rich hypothalamus, thalamus and pons (extrastriatal). Non-specific binding was determined by assessing cerebellar binding. The specific to non-specific binding ratio was used as the outcome measure. **Results**: In ROI- or voxel-based analyses we observed lower striatal [^{123}I]FP-CIT binding in the caudate nucleus in PSP (P=0.001 left; P=0.010 right) than in PD patients, and a trend in MSA-P (P=0.078 left, P=0.081 right). PSP patients showed lower caudate binding than MSA-C patients (P=0.004 left; P=0.005 right). In the posterior putamen we observed lower binding in PSP (P=0.001 left; P=0.003 right), MSA-P (P=0.001 left; P=0.002 right) and PD (left: P=0.020) than in MSA-C. Furthermore, voxel based analysis of extrastriatal [^{123}I]FP-CIT binding showed lower binding in the hypothalamus of MSA-P and PSP patients than PD patients (P=0.003, P<0.001 respectively). **Conclusion**: In addition to striatal DAT, hypothalamic SERT binding in MSA-P and PSP patients was significantly lower than in PD and MSA-C patients. Consequently, combining information on striatal and extrastriatal [^{123}I]FP-CIT binding to DAT and SERT, respectively, may increase the role of SPECT imaging in the differential diagnosis of parkinsonian syndromes.

P278

Combined 123I Ioflupane SPECT and 123I MIBG cardiac scintigraphy use in Parkinson Disease (PD) and Vascular Parkinsonism (VP) differential diagnosis

S. Nuvoli[1], M. Piras[2], A. Mulas[1], S. Contu[1], B. L. J. Pung[1], B. Piras[1], B. Palumbo[3], A. Spanu[1], G. Madeddu[1]; [1]Unit of Nuclear Medicine, Clin. and Experimental Medicine DPT, University of Sassari, Sassari, ITALY, [2]Unit of Neurology; Clin. and Experimental Medicine DPT, University of Sassari, Sassari, ITALY, [3]Section of Nuclear Medicine, Surg. and Biomed. Sciences DPT, University of Perugia, Perugia, ITALY.

AIM: Despite 123I Ioflupane SPECT clinical relevance in PD and VP differential diagnosis, vascular damage (Vd) in basal ganglia or correlated cortical areas could reduce its specificity. In this study we evaluated 123I Ioflupane SPECT and 123I MIBG cardiac scintigraphy clinical usefulness in differentiating PD from VP, occurring Vd. METHODS: We studied 38 patients with Vd at MRI who underwent brain SPECT, 3-4 hrs after 148 MBq 123I Ioflupane i.v. injection, using dual head gammacamera. SPECT images were evaluated by qualitative and quantitative analyses, the latter by dedicated software which quantifies specific dopaminergic activity as Binding Potentials (BP) with cut-off value of 3.3. After 15-21 days, cardiac planar scintigraphy in anterior and left anterior oblique views in both early (15 min.) and delayed (240 min.) phases, was performed after 111 MBq 123I-MIBG i.v. injection. Qualitative and semi-quantitative analyses were evaluated, the latter calculating heart/mediastinum (H/M) ratio by mean count density measurement in manually drawn ROIs in anterior view (cut-off value: 1.56). RESULTS: 123I Ioflupane SPECT showed reduced tracer uptake in 33/38 patiens (86.9%; Group A) and normal in 5/38 cases (13.1%; Group B). In Group A, 123I MIBG cardiac uptake, in early and delayed phases, was homogeneous in 18/33 cases (54.5%; Group A1) and reduced in 15/33 (45.5%; Group A2). H/M values were>1.56 in Group A1 and <1.56 in Group A2 cases, in both early and delayed phases. Group A1 early and delayed H/M mean values (1.71±0.10 and 1.74±0.08, respectively) were significantly ($p<0.001$) higher than Group A2 values (1.31±0.0.21 and 1.34±0.16, respectively). No statistical difference was found between early and delayed H/M mean values in the two groups. In Group B, 123I MIBG cardiac uptake was homogenous in 5/5 cases, in both early and delayed phases, and H/M was >1.56 in all cases. No statistical difference was found when early (1.70±0.04) and delayed (1.82±0.09) H/M mean values were compared. Groups A1 and B cases (23/38; 60.5%) were clinically considered as VP, while Group A2 (15/38; 39.5%) as PD. CONCLUSION: 123I MIBG cardiac scintigraphy with H/M ratio calculation proved a useful tool in PD and VP differential diagnosis in our cases occurring basal ganglia Vd, while 123I Ioflupane SPECT alone showed lower performance. Cardiac scintigraphy with H/M ratio, also in early phase alone, combined with 123I Ioflupane SPECT can be considered a valid support to achieve correct diagnosis, to better define disease progression and prognosis and to perform appropriate treatments.

P279

Dopamine transporter imaging using ^{99m}Tc-TRODAT-1 SPECT in Parkinson's disease with and without levodopa-induced dyskinesias

F. A. Pitella, L. A. Santos, A. Trevisan, E. Itikawa, M. Kato, L. Wichert-Ana; HC-FMRP-USP, Ribeirão Preto, BRAZIL.

Levodopa is the most effective and commom drug for treating Parkinson's Disease (PD). However, long-term use of levodopa is often complicated by significantly disabling fluctuations and dyskinesias. Younger age of Parkinson's disease onset, disease severity, and high levodopa dose increase the risk of development of levodopa-induced dyskinesias (LID). The underlying mechanisms for LID are unclear. Some authors have shown evidence that presynaptic dopaminergic denervation in PD plays a role in the development of LID. Objective: To evaluate the dopamine transporter (DAT) density in Parkinson's disease patients with ^{99m}Tc-TRODAT-1 and compare with other clinical data. Methods: This study included 60 volunteer patients, 20 healthy and 40 patients of the Clinical Hospital of Ribeirão Preto Medical School, University of São Paulo (HC-FMRP-USP), with confirmed PD by UK Parkinson's Disease Society Brain Bank Clinical Diagnoistic Criteria. All patients were evaluated by an expert neurologist in extrapyramidal disease and underwent SPECT with ^{99m}Tc-TRODAT-1. The images analysis and DAT quantification were performed blindly and separately by two experienced nuclear physicians (examiner 1 and 2). RESULTS: The preliminary results shows: 34,4 % of patients with PD developed LID. LID group (group 1): mean age = 61,2 years (SD = 9,3), mean duration of the PD = 8,9 years (SD = 7,2), mean L-dopa dose = 1060 mg (SD = 340), mean number of daily doses of levodopa = 3,6 (SD = 1,6), UPDRS-3 = 20,75 (SD = 12,8), mean binding potential (BPI) of ipsilateral striatum: 0,41 (SD = 0,28), mean binding potential (BPI) of contralateral striatum: 0,42 (SD = 0,16). DP without dyskinesias (group 2): mean age = 56,9 years (SD = 8,4), mean duration of the PD = 8,3 years (SD = 5,9), mean L-dopa dose = 498 mg (SD = 340), mean number of daily doses of levodopa = 6,3 (SD = 1,8), mean UPDRS-3 = 23,9 (SD = 17), mean binding potential (BPI) of ipsilateral striatum: 0,56 (SD = 0,28), mean binding potential (BPI) of contralateral striatum: 0,52 (SD = 0,31). Healthy patients: mean binding potential (BPI) of ipsilateral striatum: 1,17 (SD = 0,22), mean binding potential (BPI) of contralateral striatum: 1,20 (SD = 0,23). Conclusion: Decrease of dopamine transporter density in Parkinson's disease patients seems to correlate with LID.

P280

Use of 123I-MIBG SPECT in association with 123I-FP-CIT in patients with Early Parkinson's Disease: a new point of view

V. Frantellizzi, M. Ullo, G. A. Follacchio, M. Pontico, M. Ricci, S. Sollaku, B. Berloco, M. Filauri, M. Liberatore, F. Monteleone, G. De Vincentis; Sapienza University of Rome, Rome, ITALY.

Early diagnosis of Parkinson's disease (PD) is often difficult. In the differential diagnosis of PD from parkinsonisms, Single Photon Emission Computed Tomography (SPECT) using 123I-FP-CIT (Ioflupane,DaTSCAN) is recommended. Myocardial innervation imaging using 123I-MIBG (Iobenguane,Adreview) has emerged as a useful method to support the clinical diagnosis of PD. However, recent studies have shown that Heart to Mediastinum (H/M) ratio, derived from 123I-MIBG scan, is not always helpful to identify Early PD while the role of Late Summed Scores (LSS) has never been assessed. Purpose of our study was to evaluate the role of LSS derived from123I-MIBG SPECT, combined with 123I-FP-CIT in these patients. 15 consecutive patients affected by suspected PD were staged by using the Hoehn-Yahr classification. No patient had evidence of cardiac disease, diabetes mellitus, cerebrovascular diseases or other Central Nervous System disorders. Patients were given an intravenous injection of 185 MBq of 123I-FP-CIT and brain SPECT images were obtained 3 hours after injection. Semiquantitative analysis was performed by selecting three consecutive slices with the highest striatal uptake. Regions of interest of a fixed size were bilaterally drawn over the striatum (caudate nucleus and putamen); the occipital cortex was used as the reference region and Striatum/occipital lobe ratio (R/L) was calculated. Within 2 months from the previous study, patients underwent 123I-MIBG study. 20 and 240 minutes after i.v. administration of 123I-MIBG (185 MBq), planar and SPECT cardiac images were obtained. On planar images, Late H/M ratio was calculated. SPECT studies were processed with Myovation software (GE Healthcare) and row data for each one of the 17 segments of a standard polar map were obtained. Using a 5-point visual scoring model, data were semi-quantified and LSS was obtained. All patients presented a H-Y stage 1. 123I-FP-CIT images were normal in 3 out of 15 cases (R/L>3.5). Of them, 2 patients showed normal MIBG scan (H/M>1.43; LSS<26), whereas the last patient showed normal late H/M ratio, but pathological LSS value. Among the 12 patients with pathological 123I-FP-CIT, LSS resulted >26 in all cases, while only 8 patients showed a late H/M ratio<1.43. Early differentiation of PD and other neuro-degenerative parkinsonism is crucial, so there is an important need to improve the diagnostic accuracy.Our data shows how the extent of cardiac MIBG distribution, expressed in terms of LSS, appears as a sensitive marker for early detection of PD. Those preliminary data should be validated in a larger cohort of patients.

P281

Computed tomography guided anatomic standardization for quantitative assessment of dopamine transporter SPECT

K. Yokoyama[1], E. Imabayashi[2], T. Sako[1], D. Sone[1], Y. Kimura[1], N. Sato[1], H. Matsuda[2]; [1]National Center of Neurology and Psychiatry, Kodaira, JAPAN, [2]Integrative Brain Imaging Center, National Center of Neurology and Psychiatry, Kodaira, JAPAN.

PURPOSE: For quantitative assessment of dopamine transporter (DAT) using 123I-FP-CIT SPECT (DaTscan), anatomic standardization is preferable for achievements of objective and user-independent quantification of striatal binding using a volume-of-interest (VOI) template. However, low accumulation of DAT prominently in posterior striatum in Parkinson`s disease (PD) would lead to deformation error stretching anterior striatum posteriorly when using DaTscan-specific template without any structural information for anatomic standardization. To avoid this deformation error, we applied computed tomography (CT) data obtained from SPECT/CT equipment to anatomic standardization of DaTscan. METHODS: We retrospectively analyzed DaTscan images of 130 patients (67 women and 63 men, 66.5 ±11.9 y.o.) with parkinsonian syndromes (PS): 80 PD (36 women and 44 men, 67.5 ± 10.4 y.o.) and 50 non-PD patients (31 female and 19 male, 64.9 ± 13.8 y.o.). First we segmented grey matter (GM) from CT images using statistical parametric mapping (SPM) 12. Then these GM images were anatomically standardized using the diffeomorphic anatomical registration using exponentiated Lie algebra (DARTEL) algorism. Next, DaTscan images were warped with the same parameter as used in the CT anatomic standardization. The target striatal VOIs for decreased DAT in PD were generated from the SPM12 group comparison of 20 DaTscan images from each group. We applied these VOIs to DaTscan images of remaining patients of both groups and calculated the specific binding ratios (SBR) using nonspecific counts in a reference area. In terms of differential diagnosis of PD and non-PD groups using SBR, we compared the present method with other two methods, which have been already released as software programs for quantitative assessments of DaTscan images, DaTQUANT and Tossici-Bolt`s methods. RESULT: SPM12 group comparison showed significant DAT decrease in PD patients at bilateral whole striatum. Of all three methods the present CT-guided method showed the greatest power for discriminating PD and non-PD groups, completely separating the two groups. CONCLUSION: CT-guided anatomic standardization using DARTEL algorism was promising for quantitative assessment of DaTscan images.

P282

Different roles of dopamine transporter SPECT and I-123 MIBG myocardial scintigraphy to assess clinical severity in patients with Parkinson's disease

N. Okano[1], T. Sasaki[2], K. Takahashi[2], N. Araki[2], T. Yamamoto[2], m. Niitsu[1], S. Nishimura[3], I. Matsunari[4]; [1]Department of Radiology,

Saitama Medical University Hospital, Saitama, JAPAN, [2]Department of Neurology, Saitama Medical University Hospital, Saitama, JAPAN, [3]Department of Cardiology, International Medical Center, Saitama Medical University, Saitama, JAPAN, [4]Division of Nuclear Medicine, Saitama Medical University Hospital, Saitama, JAPAN.

Purpose: The aim of our study was to comparatively investigate the roles of dopamine transporter (DAT) single photon emission computed tomography (SPECT) and I-123 metaiodobenzylguanidine (MIBG) myocardial scintigraphy in the clinical severity of the Parkinson's disease (PD), especially focusing on impaired motor function affecting the activity of daily living (ADL). **Materials and Methods**: Data for 65 consecutive PD patients who underwent both DAT and MIBG SPECT imaging were reviewed. Associations between the imaging variables, and the Hoehn and Yahr (H&Y) and the self-supportive care (SSC) scale were investigated. Univariate and multivariate regression analyses were performed to determine the factors associated with dependent ADL. **Results**: After applying the exclusion criteria, 45 patients were analyzed (age, 73.1 ± 9.3 years; 23 male; H&Y stage 1: n = 12, stage 2: n = 14, stage 3: n = 10, stage 4: n = 5 and stage 5: n = 4; SSC scale dependent ADL: n = 29). DAT SPECT variables were significantly associated with the clinical severity of PD as assessed by H&Y staging, while MIBG variables were not. After dividing the H&Y stages into 2 groups, both DAT and MIBG uptakes in the severe stage group were lower than in the mild-to-moderate stage group; because DAT variables gradually changed throughout progressive stages, while the MIBG variables only changed in the advanced stage. In multivariate analysis that included clinical and imaging variables, a lower average specific binding ratio for DAT SPECT and early heart-to-mediastinum ratio for MIBG myocardial scintigraphy were significantly associated with dependent ADL. **Conclusions**: Both DAT and MIBG findings are associated with the clinical severity and dependent ADL. In the early and middle stages of PD, DAT SPECT is a stronger indicator of the severity than MIBG myocardial scintigraphy.

P283

Quantitative Structure-Activity Relationship Study to Elucidate the Structural Requirements for Positron Emission Tomography Tracers in Neuroimaging of Parkinson's Disease

M. salahinejad[1], Z. Tamiji[2], A. Niazi[2], M. Aboudzadeh[1]; [1]Nuclear Science and Technology Research School, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Chemistry, Arak Branch, Islamic Azad University, Arak, IRAN, ISLAMIC REPUBLIC OF.

Parkinson's disease (PD) as a serious neurological disorder has attracted great interest due to fail current manner of treatment to achieve long-term control. Since adenosine receptors antagonists have been shown to restore the deficits arise from decline of the striatonigral dopamine system, which is compromised by the loss of striatal neurons in this disease, A_{2A} antagonism provides a possible treatment for PD. Positron emission tomography (PET) is non-invasive medical imaging modality for in vivo imaging and eventual diagnostic central nervous system. Quantitative structure activity relationship (QSAR) technique is one of the significant research fields in drug design and medicinal chemistry. The QSAR approach assumes that differences in the structural or physical properties measured experimentally account for differences in the observed biological or chemical properties. In the present investigation, we perform quantitative structure activity relationships (QSAR) analysis for a series of 35 Xanthine ligands as PET tracers for mapping adenosine receptors as probes for diagnosis PD's disease. Several hundred numbers of molecular descriptors was used as independent variables and binding affinity of ligands to $A_{2A}R$ receptors was considered as dependent variable. Several variable-selection techniques were applied to choose the best subset of molecular descriptors that would lead to good regression equations. Multi linear regression (MLR) was applied to model construction. Among several models developed, the best model was a five-variable MLR model with a leave one out cross-validated correlation coefficient (Q^2) of 0.84±0.02 and a correlation coefficient (R^2) of 0.90 ±0.01 for prediction power of $A_{2A}R$ binding. The QSAR model identified the molecular properties such as van der Waals surface area combination with the electrostatic property, the number of double bonds and rotatable bonds, partial charge, hydrophilic properties and molecular potential energy played important roles in the prediction models of $A_{2A}R$ antagonist PET tracers. We expect the provided model to be a helpful tool in the prediction of the $A_{2A}R$ Binding affinity and $A_{2A}R$-selectivity, in a fast and costless manner, for any future studies that may require an estimation of these important characteristics of $A_{2A}R$ antagonist PET tracers.

P284

18F-DOPA for Multipurpose PET Imaging to Detect Amino Acid Metabolism and to Assess Brain Dopamine Function

M. Scarlattei[1], G. Baldari[1], C. Carla[1], S. Migliari[1], A. Sammartano[1], R. Dalla Valle[2], S. Calzetti[3], **L. Ruffini**[1]; [1]Nuclear Medicine Dept, University Hospital of Parma, Parma, ITALY, [2]Surgery and Transplant Unit, University Hospital of Parma, Parma, ITALY, [3]Neurology Unit, University Hospital of Parma, Parma, ITALY.

Functional PET imaging has been growing rapidly developing different radiopharmaceuticals (with different uptake mechanisms) to provide accurate staging of catecholamine-secreting tumours. In particular, 18F-DOPA has been proposed as a useful PET imaging tool to detect neuroendocrine cells able to take up, decarboxylate and store amino acids and their amines. Moreover, 18F-DOPA is a viable radiotracer for glioma imaging and treatment planning and to investigate presynaptic dopaminergic function. This study aimed to assess clinical settings for 18F-DOPA PET/CT utilization as highly sensitive non-invasive diagnostic tool for early detection of mass lesions in patients with catecholamine-secreting tumours and brain tumor. Moreover, we evaluate DOPA-PET imaging as simple method of image analysis in routine clinical studies, associated with more complex approaches revealing hidden aspects of brain dopamine in the pathophysiology of Parkinson's disease. METHODS We prospectively enrolled all the PET studies performed with 18F-DOPA since Dec 2014. The intravenously injected dose of 18F-DOPA (IasoDOPA®, Iason GmbH, Austria) was 260 MBq. The radiochemical purity exceeded 95% in every case. Whole body PET studies were acquired using an integrated system (GE Discovery ST and GE IQ) 60 min after i.v. tracer injection, from the skull basis to the middle thigh. A dynamic 90-min brain PET study was performed, in a 3D mode, for pts with Parkinson's disease. RESULTS PET imaging with 18F-DOPA was performed in 38 patients: 9 pts with brain tumor, 15 pts with suspicion of catecholamine-secreting tumours (pheocromocytoma, paraganglioma, insulinoma, medullary thyroid carcinoma) and 11 pts with rest-less leg syndrome and Parkinson disease to characterize dopaminergic transmission. PET showed residual neoplastic tissue in 4/9 brain tumors with doubtful MR. Pheocromocytoma and paraganglioma were confirmed by imaging and surgery in 8 cases. Insulinoma was detected in 3 cases. In Parkinson's disease DOPA-PET allowed characterizationd of basal ganglia function and subregional activity assessment (i.e. hypothalamus). PET informations have driven patient management in all pts with neoplastic lesions, and changed treatment options or sequence in 5 pts with brain tumor and 9/15 pts with catecholamine-secreting tumors. CONCLUSIONS Results demonstrate that 18F-DOPA is a flexible multipurpose tracer for clinical routine and pathophysiology investigation. In the oncologic setting DOPA-PET allows appropriate use of resources in patient management, changing or well driving treatment option in most of them. In the motor syndrome PET with 18F-DOPA PET is a particularly useful tool for the *in vivo* assessment of dopamine terminal density and dopamine neurotransmission.

Quantification of time-related decline of dopamine transporter from consecutive DaTSCAN images

H. Fayolle[1], P. Gantet[2], A. Salabert[3], J. Delrieu[1], C. Brefel-Courbon[1], T. Voisin[1], P. Payoux[3]; [1]CHU Toulouse, Toulouse, FRANCE, [2]University Paul Sabatier, Toulouse, FRANCE, [3]Toulouse neuro-imaging center ToNIC, Toulouse, FRANCE.

BACKGROUND: Dopamine neurodegeneration has been widely studied in population as for example in the international multicentric database of PPMI (*Parkinson's Progression Markers Initiative)*. However, such studies has been realised on population mainly as transversal analysis. The aim of this longitudinal study is firstly to compare by innovative quantification tool the evolution of dopaminergic neurodegeneration between a normal (NG) and a pathological groups (PG), and secondly to test the impact of the antiparkinsonian treatment. METHODS : 60 patients who underwent two consecutive DaTSCAN were enrolled in this retrospective study in the Nuclear Medecine Department of Toulouse from 2002 to 2016. We have analysed the evolution of the striatum binding ratios (SBR: mean counts of Striatal ROI −mean counts of Background ROI)/ (mean counts of Background ROI)) with DaTsoft3D®, a software using an innovative self-calibrated based correction of partial volume effect. SBR were compared to PPMI database to be classify as NG or PG (SBR <1.7). We found 25 patients in NG, (age :63 ± 10.4 yo, sex ratio 11F/14M, delay between the 2 scans : mean 2,4 years, SD 2,2 years), and 35 patients in PG (age :68 ± 10.6 yo, sex ratio 11F/35M, delay : mean 3,3years, SD 2,6 years). In PG, we analyzed patients receiving treatment (PG1 group, 18 patients, treatment duration : 4 ± 3 yo) or not (PG0 group, 17 patients). RESULTS : The variation of SBR in NG did not significantly differ from 0 (1% per year, p=0.54), while it declined significantly in PG (-11% per year, p=0,0003). DaTsoft3D has shown significantly differences (-12%, p=0.0007 for Welch-test assuming unequal variances) between NG and PG, while PG0 (mean -11%) and PG1 (-9%) did not differ significantly (2,2%, p=0.74). CONCLUSION : DATSoft3D software was effective for the monitoring of dopaminergic presynaptic loss. The decrease of the SBR value observed in NG is closer that one observed in the literature (6.8% by decade p=0.34, Nicastro et al. 2016) and PG differs from physiological value (p=0.0007). Unexpectedly in our study the dopamine loss rate was more important in the pathological group compared to the PPMI database which have not consider the loss for single patients (-11% vs -0,006% per year). Probably due to the low number of patients, we could not demonstrate a benefit from the antiparkinsonian treatment on the presynaptic neurodegeneration. DATSoft3D may be helpful for prospective studies comparing the impact of various treatments on dopamine loss slowdown.

P286

Evaluation of a novel extracellular matrix radiotracer: expression of proteases uPA and KLK8 is correlated with seizure outcome in an animal model of acquired epilepsy

S. Missault, H. Amhaoul, D. Thomae, A. Van Eetveldt, P. Van Der Veken, J. Joossens, S. Staelens, S. Dedeurwaerdere; University of Antwerp, Wilrijk, BELGIUM.

Aim: Serine proteases urokinase-type plasminogen activator (uPA) and kallikrein-8 (KLK8) are modulators of the extracellular matrix. They may play an important role in plasticity following an insult and hence the development of epilepsy. In order to assess uPA/KLK8 following brain insult, a new SPECT probe, [^{111}In]MICA-401 with high affinity for both proteases was recently developed. This study evaluated the radiotracer *post-mortem* and *ex vivo* in animal models of acquired epilepsy. **Methods**: a) The tracer was implemented in an *in vitro* autoradiography (ARG) study in two rat models, the kainic acid-induced *status epilepticus* (KASE) and controlled cortical impact (CCI) models. KASE and control rats were sacrificed at 7d (n=11, n=6 respectively) and 12w post-SE (n=9, n=6 respectively); CCI and sham rats at 4d post-injury (n=5/group). Brain sections were incubated with 50nM [^{111}In]MICA-401 to assess total binding. 1mM of UAMC-01162, from which the cold standard is derived, was added to assess non-specific binding. b) Three CCI and sham rats were injected with radiotracer at 3d post-injury (39.1±2.2MBq). 7d post-injury, brains were resected for *ex vivo* ARG. **Results**: a) In the KASE model a significant decrease of [^{111}In]MICA-401 binding was observed in the latent phase of epileptogenesis in CA3 subregion of the hippocampus ($p \leq 0.05$) and extrahippocampal temporal lobe ($p \leq 0.01$) vs controls. Decrease in [^{111}In]MICA-401 binding further progressed in the chronic phase when spontaneous seizures were present in CA1/CA2, dentate gyrus, parietal cortex ($p \leq 0.05$), and temporal lobe ($p \leq 0.001$) vs controls. A correlation was observed between specific binding of [^{111}In]MICA-401 in hippocampus and i) the number of seizures and ii) the seizure severity in KASE rats at 12w post-SE ($p \leq 0.05$). In the CCI model a significant signal decrease was found in perilesional cortex and ipsilateral dentate gyrus ($p \leq 0.01$) vs shams. b) On the contrary, an increased tracer uptake was observed in the perilesional cortex and ipsilateral hippocampal formation of CCI rats vs shams at 4d post-injection ($p \leq 0.1$), confirmed by *ex vivo* ARG. This is due to an increase in blood-brain barrier (BBB) penetrability. **Conclusion**: KASE rats with a high number of seizures or proportion of generalised convulsive seizures showed a more pronounced decrease in uPA/KLK8 expression compared to rats with low number of seizures or less severe seizures. This decrease in uPA/KLK8 may be due to interictal hypometabolism, which has to be further investigated. While [^{111}In]MICA-401 is an interesting tracer for *post-mortem* assessment of uPA/KLK8, its *in vivo* implication is hindered by limited BBB penetrability.

P287

Changes in Cerebral Metabolism in Parkinson's Disease: Combined PET and MRS Study

I. G. Khomenko[1], G. V. Kataeva[1], E. A. Gromova[1], D. S. Susin[1], A. A. Bogdan[1], I. V. Milukhina[2], M. N. Karpenko[2]; [1]N.P.Bechtereva Institute of the Human Brain, RAS, St.Peterburg, RUSSIAN FEDERATION, [2]Institute of Experimental Medicine, RAMS, St.Peterburg, RUSSIAN FEDERATION.

Introduction. Novel neuroimaging techniques allow getting valuable information about brain metabolism in vivo. A large amount of studies dedicated to the evaluation of the diagnostic role of proton magnetic resonance spectroscopy (H-MRS) and positron emission tomography (PET) data in neurodegenerative diseases, but there are only few studies matching these findings. We consider that such combined studies could contribute to the understanding of neurodegeneration pathogenesis. The aim of the current research was to investigate regional cerebral metabolism according to the FDG PET and H-MRS data in patients with Parkinson's disease (PD). Methods. 26 patients suffered from PD (age 62,8±9,6; 14 males; 1,0-3,0 stages by Hoehn and Yahr scale) were examined. Multivoxel H-MRS was performed on Achieva 3T scanner, Philips (2D PRESS, TE/TR=53/1500 ms) and included supraventricular white matter (WM) and medial cortex. Anatomical localization: the area of MRS study (8*9 voxels (10*10*15 mm), whole volume 80*90*15 mm) was divided into 9 ROIs: 6 in WM (3 ROIs: anterior, medium and posterior for each hemisphere) and 3 ROIs in medial cortex. NAA/Cr, NAA/Cho, Cho/Cr. Glx/Cr ratios (NAA - N-acethylaspartate, Cr -

creatine, Cho - choline, Glx - glutamin + glutamate) were analyzed. FDG PET study was performed with GE Discovery-710. PET images were normalized with SPM8, cerebral glucose metabolism rate (CMRglu) in Brodmann areas (BA) were calculated using WFU Pickatlas. Results. Correlations of H-MRS data and CMRglu in frontal and parietal cortex bilaterally were revealed: CMRglu in BA 8,9,10,47 and 39 correlated negatively with Cho/Cr in WM of semioval centers of the ipsilateral hemisphere ($r = -0.6$ -0.8; $p<0.01$). CMRglu in left and right cingulate cortex correlated positively with NAA/Cho ratio ($r=0.6$-0.7; $p<0.01$) in ipsilateral WM. Conclusions. NAA is commonly considered to be the neuronal integrity marker, so the obtained correlations of its concentration with glucose metabolism can be easily explained. However, the clinical significance of Cho/Cr ratio obtained in spectroscopy of visually intact neural tissue is not so clear: different studies found both its elevation and decrease in neurodegenerative diseases. Increase of Cho/Cr ratio coupled with the decreased CMRglu revealed in the present study can be related to the neurodegeneration process (neuron membranes degradation causes elevation of Cho in WM and decrease of cortex glucose metabolism). Further research should be performed to clarify the diagnostic role of the revealed metabolites interrelations.

P288

Effect of noradrenergic denervation on alpha2-adrenoceptor binding in rat brain in vivo

J. Phan[1], S. Jacobsen[1], **A. Gjedde**[2]; [1]Aarhus University, Aarhus, DENMARK, [2]University of Copenhagen, Copenhagen N, DENMARK.

Introduction: Disrupted noradrenergic neurotransmission is implicated in Parkinson's and Alzheimer's diseases. However, the relative effects on noradrenaline levels and receptor density in vivo are uncertain. Tracer [11C]yohimbine is a radioligand of alpha2 adrenoceptors with sensitivity to noradrenaline release in pigs and rats. Here, we use measures of [11C]yohimbine binding to alpha2 adrenoceptor sites and noradrenaline release in rat brain in vivo to test the hypothesis that noradrenaline levels decline more than the available receptors in selected brain regions after noradrenergic denervation. Methods: Noradrenergic denervation was induced by IP treatment (50 mg/kg) of the selective neurotoxin (N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine (DSP-4)) 7 days prior to positron emission tomography (PET). We determined [11C]yohimbine binding potentials at two levels of receptor occupancy, at baseline followed by amphetamine challenge (2 mg/kg) in DSP-4 pretreated and naïve animals. We calculated [11C]yohimbine binding potentials as bound vs. free ratios, using the yohimbine partition coefficient (VND), obtained from the Inhibition plot, a linearization of the Michaelis Menten equations applied to baseline and inhibition. Results: The binding potentials in naïve animals were greatest in striatum, followed in descending order by thalamus, frontal cortex, pons and cerebellum. Amphetamine challenge significantly reduced the binding potentials with a uniform magnitude of 38% in all regions of interest, indicating uniform noradrenaline increase. DSP-4 denervation exhibited significantly lower binding potentials than naïve animals, suggesting acute decline of alpha2 adrenoceptor density. The effect of amphetamine challenge after DSP-4 treatment was greater than in naïve animals but with regional heterogeneity. With amphetamine, the binding potentials declined 51-67%, indicating variable and regionally differential release from surviving projections. Conclusion: The greater decline of receptors than of noradrenaline levels is at variance with the original hypothesis stated above.

P289

FDG-PET pattern of C9orf72 positive and Amyotrophic Lateral Sclerosis

P. **SOPENA-NOVALES**; HOSPITAL UNIVERSITARIO Y POLITECNICO La FE, valencia, SPAIN.

Aim: Under the hypothesis that C9orf72 positive and amyotrophic lateral sclerosis (C9ORF72-ALS) patients could have a distinctive FDG-PET findings, the aim was to evaluate FDG-PET pattern of ALS-C9orf72 positive patients. **Materials and Methods:** ALS patients were screened for the C9ORF72 mutation in the ALS Unit of Hospital La Fe between January 2014 and June 2015. In those who tested positive for this mutation and accepted to participate, clinical data were collected, a brain MRI and a FDG-PET were performed. Healthy relatives of C9ORF72 mutation patients, carrying the same mutation were also offered to participate. The genetic analysis done by repeat primer PCR and confirmed by Southern blot. Neuroimaging FDG-PET acquisitions was made according the EANM procedure guidelines on PET-CT Philips Gemini TF. The data were processed using 3.5 software version of NeuroQ^{TM} which through the quantification of the average values of pixel of regions of interest identifies those with a standardized uptake below or upper 1.65 standard deviations of the mean regard to database normal subjects with pons as reference region. Also we used the OASIS^{TM} software for the 3D representation of the brain. **Results**: A total of eighty-one patients accepted to be subjected to screening the hexanucleotide repeat expansion in the C9orf72 gene, only 5 were carriers including one healthy carrier. Patients were two men and two women with a mean age at onset of symptoms 63 years old. Symptoms onset was bulbar in one patient and spinal in three (two in lower limbs and one in upper limbs). Two patients associated mild cognitive impairment. The asymptomatic case was a female 48 years old and had been previously diagnosed of schizophrenia and mild mental retardation. The analysis shows hypometabolism in bilateral inferior frontal cortex, left Brocca´s area and left posterior cingulate cortex in all patients. Instead of patients, the healthy carrier not had alteration uptake in right inferior frontal cortex and left posterior cingulate cortex. The two patients with mild cognitive impairment were more deeply affected in bilateral frontal (inferior, medial y middle) cortex, right lateral temporal cortex, right parietal cortex and right anterior cingulate gyrus. The patient with bulbar onset was the only with hypometabolism in right superior frontal cortex, right parietotemporal cortex, left lentiform and left thalamic nucleus. Not hypermetabolism areas were found. **Conclusion:** The C9ORF72-ALS gene mutation carriers show a marked hypometabolism in bilateral inferior frontal cortex, left Brocca´s area and left posterior cingulate cortex.

P290

Different pattern of brain glucose consumption in Alzheimer disease. Is cerebral glucose metabolism related to epsilon phenotype?

A. Chiaravalloti[1,2], A. Fiorentini[1], A. Martorana[3], A. Cimini[1], R. Giancipoli[1], P. Sannino[2], M. Zinzi[2], E. Di Giorgio[2], R. Danieli[1], O. Schillaci[1,2]; [1]Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY, [2]IRCCS Neuromed, Pozzilli, ITALY, [3]Department of Neurosciences, University Tor Vergata, Rome, ITALY.

Aim: The aim of our study was to investigate the impact of epsilon phenotype in brain glucose consumption in a population with Alzheimer disease. **Materials and methods**: Statistical Parametric Mapping (SPM8) was used in order to investigate differences in brain glucose consumption (as detectable by means of 18F FDG PET/CT) in the population examined. A total of 140 patients (77 females and 63 males) with a diagnosis of probable AD according to the NINCDS-ADRDA criteria underwent the PET/CT examination. The mean (SD) age of the patients was 70 (± 7) years; mean mini mental state examination was 19(±5.6). 59 expressed epsilon 4 phenotype (E4), 70 the epsilon 3 phenotype (E3) and 12 the epsilon 2 phenotype. Cerebro spinal fluid

amyloid, tau and t-tau have been measured resulting equal to *367.4* (±149.1), *584.7* (±312.1) and *79.2*(±45.9) pg/ml respectively. Age, sex, MMSE, scholarship and CSF parameters were used as covariate in the SPM analyses. **Results**: We did not find significant differences in age, gender, MMSE and CSF values among groups. As compared to E3, E4 subjects show a significant reduction of brain glucose consumption in frontal lobe bilaterally and in the right insula (BA 47, 11, 13). As compared to E2, E4 showed a reduction of brain glucose consumption in the left frontal lobe (BA6). As compared to E4, E3 subjects showed a significant reduction of brain glucose consumption in right parietal lobe (BA7, 40). We did not find significant differences in brain glucose consumption when comparing E3 vs. E2 and when subtracting E2 to E4. **Conclusion:** epsilon phenotype is related to different metabolic patterns in Alzheimer Disease. In particular, E4 is related to a major involvement of frontal cortex while E3 is related to a major involvement of parietal cortex.

P291

Glucose metabolism in subcortical cerebral structures and its interrelation with cognitive state in patients with Parkinson's disease

E. Gromova, G. Kataeva, J. Khomenko, D. Susin, J. Irishina, I. Zavolokov; Institute of Human Brain RAS, Saint-Petersburg, RUSSIAN FEDERATION.

Introduction. Cognitive impairment is a frequent symptoms of Parkinson's disease (PD). Better understanding of brain mechanisms underlying cognitive impairment in PD is of greate importance because of their negatively influence on the patients' life quality and social adaptation. The aim of this research was to investigate interrelations of cerebral glucose metabolism in subcortical structures and cognitive state and disability degree in PD. Methods. 27 patients with PD (11 male, 16 female, age 41-77) were examined. Positron emission tomography (PET) with 18F-fluorodesoxyglucose (FDG) was performed in Scanditronix 2048 tomograph and standard protocol. All patients underwent clinical and neuropsychogical examination including Unified Parkinson's Disease Rating Scale (UPDRS), Mini Mental State Examination (MMSE), clock drawing test and Frontal Asessment Battery (FAB). All patients recieved the antiparkinsonic medications. PET images were normalized with SPM8. Regional cerebral glucose metabolism rate (rCMRglu) were calculated using WFU Pickatlas. Results. UPDRSoff scores («off» - measured in the period of cessation of antiparkinsonic medication) correlated negatively with rCMRglu in dorsal nuclei (r=-0.5; p=0.01) and globus pallidus (r=-0.5; p<0.01) bilaterally; nucleus lenticularis (r=-0.6; p<0.001) and putamen (r=-0.5; p<0.01) in right hemisphere. Positive correlation of FAB scores and rCMRglu in nucleus caudatus were revealed in right hemisphere (r=0.7; p<0.001). No significant correlations were revealed with clock drawing test and MMSE scores. Also we found that rCMRglu in nucleus caudatus correlated positively with rCMRglu in a number of ipsilateral cortical areas: Brodmann areas (BA) 9,10, 23,24,31,32, 39, 45,46,47 (r=0.6-0.7; p<0.001) and BA 8,11,40,44 (r=0.5; p<0.01). In the previous study (Khomenko et al., 2015) correlations of the similar cortical areas and FAB scores in PD patients were revealed. Conclusions. Obtained correlations of UPDRSoff scores with rCMRglu in a number of subcortical structures could be easily explained because of wellknown role of subcortical nuclei in PD pathogenesis. However, the fact that only UPDRS «off» scores (measured during the antiparkinsonic medications cancellation) correlated with rCMRglu could indicate that antiparkinsonic medications did not influence on the glucose metabolism of subcortical structures, but to confirm this assumption futher study is required. Significant positive correlation of FAB scores and rCMRglu in nucleus caudatus could indicate that the pathogenesis of cognitive disfunction was related with the degradation of the frontostriatal network. Revealed correlations between rCMRglu in nucleus caudatus and a number of cortical areas known to be associated with the cognitive functions in PD confirm this conclusion.

2-^{18}F-fluoroacetate as an imaging biomarker cerebral ischemia

H. Onoe[1], H. Mizuma[1], S. Kagawa[2], M. Ohno[1], K. Kakumoto[1,3], Y. Matsumoto[1], H. Yamauchi[2], T. Higashi[2], R. Nishii[4]; [1]RIKEN Center for Life Science Technologies, Kobe, JAPAN, [2]Shiga Medical Center Research Institute, Moriyama, JAPAN, [3]Foundation for Biomedical Research and Innovation, Kobe, JAPAN, [4]Molecular Imaging Center, National Institute of Radiological Science, Chiba, JAPAN.

Aim: Fluoroacetate (FACE), a metabolic toxin that acts by blocking the tricarboxylic acid (TCA) cycle, is known to be preferentially incorporated into astrocytes mediated by monocarboxylic transporter (MCT). FACE was known to be accumulated in astrocyte by PET with ^{18}F-FACE using rat models of stroke and glioma (Marik et al., 2009). Recently, astrocyte has been reported to play an important role in neuronal cell death after ischemic injury in response to intracellular acidosis driven by its emergent lactate production (Beppu et al., 2014). To investigate changes in glial metabolism during ischemia, we performed PET imaging with ^{18}F-FACE in rat model of ischemic/reperfusion injury. Materials and Methods: ^{18}F-FACE-PET scan was conducted in the rats after ischemic /reperfusion injury by occluding in the right middle cerebral artery under isoflurane anesthesia. In comparison with ^{18}F-FACE, we measured ^{11}C-acetate uptake in the ischemic rats by PET. We also assessed neuronal cell death and astrocytic activation by immunohistochemical analysis. Results: ^{18}F-FACE was highly accumulated in the ischemic region during MCA occlusion with low cerebral flow, whereas ^{11}C-acetate was decreased as compared with that in the contralateral region. Immunohistological analyses revealed that ^{18}F-FACE accumulation was not associated with appearance of reactive astrocyte. Conclusion: These finding indicate that ischemia causes ^{18}F-FACE accumulation by changing in astrocyte energy metabolism and transportation, in other words ^{18}F-FACE can be a promising PET probe for the early detection of cerebral ischemia.

Evaluation of Lewy bodies disease for the differential diagnosis of patients with parkinsonism using DAT SPECT, MIBG cardiac scintigraphy, and cerebral perfusion SPECT

T. Yoneyama, K. Yokoyama, S. Tuji, T. Michigishi; Department of Radiology, Public Central Hospital of Matto Ishikawa, Ishikawa, JAPAN.

Aim: We investigated the usefulness of dopamine transporter (DAT) SPECT and the relationship between DAT SPECT, ^{123}I-MIBG cardiac scintigraphy, and cerebral perfusion SPECT for the diagnosis of Lewy bodies disease (LBD). Methods: Of 112 cases who had undergone DAT SPECT, 79 cases who could be confirmed diagnosis were subjected. The diagnostic values (sensitivity, specificity, positive predictive value, negative predictive value, and accuracy) of DAT SPECT and ^{123}I-MIBG scintigraphy were calculated. Patients evaluated by DAT SPECT and ^{123}I-MIBG scintigraphy were divided into 4 groups based on the result of both studies for the diagnosis of LBD. A correlation between Specific Binding Ratio (SBR) calculated in DAT SPECT images and Heart/Mediastinum (H/M) ratio on early and delayed

^{123}I-MIBG planar images were determined in Parkinson's disease (PD) patients and PD patients considered as Yahr's stage 3 and above. Patients diagnosed as LBD were evaluated by DAT SPECT, ^{123}I-MIBG scintigraphy, and cerebral perfusion SPECT. Results: The diagnostic values of DAT SPECT in 79 cases were 98.3%, 72.7%, 91.9%, 94.1%, and 92.4%, respectively. In 39 out of 79 cases evaluated by both DAT SPECT and ^{123}I-MIBG scintigraphy, those of DAT SPECT were 96.8%, 87.5%, 96.8%, 87.5%, and 97.4%, and those of ^{123}I-MIBG scintigraphy were 80.6%, 87.5%, 96.2%, 53.8%, and 82.1%, respectively. In 39 cases divided into 4 groups, 7 cases were in a group of DAT normal/MIBG normal (Normal Pressure Hydrocephalus (NPH) 1, Amyotrophic lateral sclerosis 1, Alzheimer's disease 1, Mild Cognitive Impairment 1, psychiatric disorder 3), 1 in DAT normal/MIBG decrease (dementia with Lewy bodies (DLB) 1), 6 in DAT decrease/MIBG normal (PD 6), 25 in DAT decrease/MIBG decrease (PD 22, DLB 2, NPH 1). There was no significant correlation between SBR and H/M ratio in this study, however a moderate correlation was found between SBR and delayed H/M ratio in PD patients considered as Yahr's stage 3 and above. In 21 cases diagnosed as LBD (PD 18, DLB 3), hypoperfusion of occipital cortex on cerebral perfusion SPECT image was detected in 17 cases (PD 15, DLB 2: DAT decrease/MIBG decrease 14, DAT decrease/MIBG normal 2, DAT normal/MIBG decrease 1), and 4 cases with DAT decrease/MIBG decrease (PD 3, DLB 1) had no hypoperfusion of occipital cortex. Conclusions: DAT SPECT was superior to ^{123}I-MIBG cardiac scintigraphy for the diagnosis of LBD. Hypoperfusion of occipital cortex in cerebral perfusion SPECT was highly detected in patients with LBD who had decrease of DAT and/or MIBG uptake.

Dopamine transporter levels in mice with over expression of GDNF in striatum and midbrain studied using dynamic SPECT-imaging of ^{123}I-β-CIT

M. Pitkonen[1,2], E. Hippeläinen[1,2], J. Andressoo[3], J. García-Horsman[4], K. Bergström[1,4]; [1]HUS Medical Imaging Center, Helsinki University Central Hospital, Helsinki, FINLAND, [2]Department of Physics, University of Helsinki, Helsinki, FINLAND, [3]Program of Molecular Neurobiology, Institute of Biotechnology, University of Helsinki, Helsinki, FINLAND, [4]Real Time Imaging Unit, Faculty of Pharmacy, University of Helsinki, Helsinki, FINLAND.

Aim Glial cell line-derived neurotrophic factor (GDNF) promotes survival of dopamine neurons *in vitro* and *in vivo*. In previous studies using voltammetry measurements in acute striatal slices of GDNF hypermorphic mice it was found that enhanced GDNF levels up-regulated striatal dopamine transporter (DAT) activity. The aim of the current work is to compare DAT levels in striatum and midbrain, measured with ^{123}I-β-CIT SPECT between mice with over-expression of GDNF (hypermorphs) and littermate controls. The kinetics and binding of ^{123}I-β-CIT into striatum and midbrain regions was analyzed using Logan graphical analysis method. **Materials and methods** Five healthy wild type and five GDNF mice were scanned dynamically after intravenous tracer injection (39.7 ± 7.3 MBq, mean ± SD) of ^{123}I-β-CIT (MAP Medical Technologies Oy, Finland). Dynamic SPECT acquisitions were performed with NanoSPECT/CT system (Mediso, Hungary). Dynamic imaging begins within 15 minutes post tracer injection. Scanning time varied between 7.5 to 25 minute per scan, depending on the time point and protocol used. Latest imaging point was between 4-7.4 hours post tracer injection. Data was reconstructed, masked, and co-registered with the mice SPECT-brain atlas. Atlas defined four volumes of interest: both striata, cerebellum and midbrain regions. In those regions, time-activity curves were calculated and further analyzed using Logan Plot method, giving estimates of the distribution volume ratio (DVR). Cerebellum time activity curve was used to represent tracer in the non-specifically bound brain area. **Results and Conclusion** In the striatal areas, hypermorphs DVR values (10.0 ± 0.7) compared to controls (13.2 ± 2.7) was statistically different ($p = 0.032$, t-test). Also, in the midbrain, DVR values were significantly different between the groups (DVR = 3.3 ± 0.3 and = 3.8 ± 0.5 for hypermorphs and controls respectively; $p = 0.044$). Significantly different DVR value refers that there is less DAT binding in the striatum and midbrain of hypermorph mice. In conclusion, by using SPECT and ^{123}I-β-CIT, we are able to study central DAT density in genetically modified GDNF mice.

P295

Visual Cortex Reactions to Light in Humans: Functional Activity in Visual Cortex Stimulated at Different Light Complexities

A. Gjedde[1], S. Marrett[2]; [1]University of Copenhagen, Copenhagen N, DENMARK, [2]McGill University, Montreal, QC, CANADA.

Objectives. Functional imaging of the visual cortex is based on the premise that changes of flow and energy metabolism are linked to the same incremental excitation of neurons. The baseline conjecture holds that a default mode of brain function is the baseline for added and coupled changes of blood flow and oxidative metabolism, both when activity falls and when activity rises. To locate the hypothetical baseline in visual cortex in relation to functional demands, we compared increments of (rCBF) and oxidative metabolism (rCMRO2) during visual stimulation of humans with light at three different levels of complexity.Methods. Healthy volunteers underwent positron emission tomography (PET) with [15O] water and [15O]oxygen while they viewed three stimuli in random order; a cross-hair fixation stimulus without color or spatial frequency (FX), an achromatic white disc stimulus with an 8 Hz on-off rate (WD), and a circular yellow-blue chromatic checkerboard with an 8 Hz color-reversing frequency (YB). For the baseline conjecture to hold, the sum of any pair of contrasts must equal the third at any site of significant change, such that the sum of the contrasts [YB-WD] and [WD-FX] must equal the contrast [YB-FX].Results. The rCMRO2 and rCBF changes averaged 21% and 52% of the whole-brain average, implying excitation by increasing stimulus complexity. The color reversal contrast ([YB-WD]) revealed bilateral sites of significant change of rCMRO2 and a single left hemisphere site of significant rCBF change in the general region of Brodmann's areas (BA) 17 and 18 of the lingual gyrus. The spatial frequency contrasts ([YB-FX] and [WD-FX]) revealed single sites of significant change of rCMRO2 and rCBF also in the lingual gyrus but close to the midline. For the midline sites, the [YB-FX] and [WD-FX] contrasts were identical and revealed a baseline between the FX and WD/YB stimulus conditions. For the lateral sites, the [YB-WD] stimulus contrast revealed a baseline between the YB and WD stimulus conditions.Conclusions. The intermediate positions of the baselines indicated the existence in BA 17/18 of at least two populations of cells, a lateral group responding to the absence or presence of color reversal in the presence of a spatial frequency, and a midline group responding only to the absence or presence of spatial frequency.

P296

Hypoglycemia Reduces Cognitive Performance with Changes of Cerebral Blood Flow in Subjects with Type 1 Diabetes.

A. Gjedde[1], M. Gejl[2], B. Brock[2], A. Møller[2], E. Van Duinkerken[3], H. Haahr[4], C. Hansen[5], P. Chu[6], K. Stender-Petersen[4], J. Rungby[1]; [1]University of Copenhagen, Copenhagen N, DENMARK, [2]Aarhus University, Aarhus, DENMARK, [3]VU University Medical Center,, Amsterdam, NETHERLANDS, [4]Novo Nordisk A/S, Søborg, DENMARK, [5]Novo-Nordisk A/S, Søborg, DENMARK, [6]Novo Nordisk, Inc, Princeton, NJ, UNITED STATES.

This randomized single-blinded, two-period cross-over trial investigated cognitive performance and associated regional cerebral blood flow (rCBF) during hypoglycemia. Subjects (n=26) with type 1 diabetes (T1D) underwent hypoglycemic and euglycemic clamps with target plasma glucose concentrations of 2.8±0.2 mM and 5.5±0.55 mM, respectively. Working memory was scored with a modified digit symbol substitution test (DSST), adjusted for sight and finger movements (control DSST [cDSST]) at both visits. During DSST and cDSST, rCBF was measured in 19 prespecified brain regions with positron emission tomography of tracer water uptake. DSST scores and response times were analyzed using a linear mixed-effect model with glycemic condition and period as fixed factors and subject as random factor. All rCBF values were normalized to cerebral cortex and we compared these values by ANOVA with glycemic condition, period, and subject as fixed factors. DSST scores were significantly lower (estimated treatment difference [ETD]: –0.63, P=0.014) and the response times significantly longer (ETD: 2.86 s, P=0.0126) in hypoglycemia vs euglycemia. During DSST, rCBF was significantly lower (P<0.05) in medial temporal lobe and hippocampus, and significantly higher (P<0.05) in dorsolateral prefrontal cortex, middle and inferior frontal gyrus, superior parietal lobe and thalamus during hypoglycemia vs euglycemia. During cDSST, rCBF measures were significantly lower (P<0.05) in hippocampus, medial temporal lobe, parahippocampal gyrus and striatum, and significantly higher (P<0.05) in the regions of the frontal lobe, orbitofrontal cortex, superior frontal gyrus, ventromedial prefrontal cortex, superior parietal lobe and thalamus during hypoglycemia vs euglycemia. When the DSST was adjusted for control movement (DSST-cDSST), rCBF was elevated only in the striatum during hypoglycemia vs euglycemia. We conclude that even hypoglycemia at plasma glucose levels just below 3.1 mM reduced cognitive performance, accompanied by significant changes of rCBF, indicating raised activity in the attention network, at the expense of activity in the default mode network.

Evaluating neuroprotective effects of Radix Scutellaria in depression-like rat model using 4-[^{18}F]-ADAM/animal PET

C. Cheng[1], K. Ma[2], S. Lu[1,3], C. Shiue[1]; [1]Department of Nuclear Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, TAIWAN, [2]Department of Biology and Anatomy, National Defense Medical Center, Taipei, TAIWAN, [3]Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, TAIWAN.

Aims: Depression may lead to an enormous loss to society and economy. Previous studies have reported that depression may cause a decrease in brain serotonin transporter (SERT) density. Further understanding of the pathogenesis and finding of the treatment are imperatively needed. The aim of this study was to evaluate neuroprotective effects of *Radix Scutellaria* (a Chinese herbal medicine) in chronic mild stress (CMS)-induced depression-like rat model using the animal positron emission tomography (animal-PET) coupled with 4-[^{18}F]-ADAM. **Materials and methods:** Eighteen male Sprague-Dawley rats (weighted in 350±10 g) were divided into the control, CMS, and CMS+RS (CMS with *Radix Scutellaria* treatment) groups. A thirty-five-day protocol of unpredictable CMS was applied to CMS and CMS+RS groups, respectively. The body weight measurement and force swimming test (FST) were carried out to evaluate the depression-like symptoms in groups of CMS and CMS+RS rats. The 4-[^{18}F]-ADAM (a selective radioligand for SERT) coupled with animal positron emission topography (animal-PET) was used to examine the status of SERT in depression-like rat model and the images were calculated and expressed as specific uptake ratios (SURs). **Results**: Five weeks after the operation of CMS protocol, CMS+RS rats showed less body weight loss than that in CMS rat. The data of FST showed that CMS+RS rats had less depression-like behavior compared to that of CMS rats. We also found that the SURs of 4-[^{18}F]-ADAM in various brain regions of CMS+RS rats were obviously higher than those of CMS rats. **Conclusion**: These results suggest that *Radix Scutellaria* may have neuroprotective effects against SERT loss in CMS rat brain. In addition, the CMS-induced depression-like rat model coupled with 4-[^{18}F]-ADAM/animal-PET may be a feasible platform to evaluate the new neuroprotective drugs.

P298

Brain metabolic changes after psychodynamic psychotherapy

G. Allenbach[1], N. Sierro[1], G. Ambresin[2], Y. de Roten[2], P. Marquet[3], J. Prior[1], J. Despland[2]; [1]Nuclear medicine and molecular imaging department, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]University Institute of Psychotherapy, Lausanne University Hospital, Prilly, SWITZERLAND, [3]Center for psychiatric neurosciences, Lausanne University Hospital, Prilly, SWITZERLAND.

Objective: To determine the effects of an intensive psychodynamic psychotherapy on brain metabolism in moderately to severely depressed patients.Methods: Patients belong to randomized controlled trial examining the efficacy of an intensive and brief psychodynamic psychotherapy (IBPP) in hospitalized depressed patients in adjunction to treatment as usual (TAU). Patients admitted to the psychiatric hospital for a moderate to severe episode were included and randomized in two groups (TAU and IBPP). Montgomery-Asberg Depression Rating Scale (MADRS) rating was obtained before inclusion. After informed consent, participants to this neuroimaging substudy underwent 3 F-18-FDG PET scans before treatment (t=0), at the end of the treatment (t=1 month) and at distance to the treatment (t=3month). We presently analyzed the two first PET scans. Images were matched to a standardized atlas, normalized and a voxel analysis using SPM12 and regional uptake analysis using PMOD were performed. Changes between 1st and 2nd scans were computed for each patient separately and then analyzed as a group. Responders were defined as a decrease of ≥50% in MADRS.Results: Out of 42 patients included in the neuroimaging study, 40 completed the first two PET scans and MADRS assessments. At the baseline scan, a correlation between depression severity and metabolism was measured in the left parahippocampal gyrus (R=0.39, p=0.021), the left putamen (R=0.36, p=0.035) and pallidum on both sides (Left: R=0.47, p=0.005; Right: R=0.42, p=0.012). The comparison

between IBPP and TAU groups after treatment, (significance level p<0.001, 10 voxels) showed significantly higher metabolism in the TAU group in the left frontal medial cortex (z=4.26) and higher metabolism in the IBPP group in the left temporal anterior (z=3.77) as well as in the posterior parietal area (z=3.50). Responders were 5/21 (24%) in the TAU group and 6/19 (32%) in the IBPP group (p=0.6). Comparisons of responders in both groups found significant differences in the precentral right area (p=0.024) and in the left superior motor area (p=0.048). Conclusions: In a group of moderately to severely depressed inpatients, depression severity at baseline was associated with an increased metabolism in different cortical and subcortical areas. Metabolic changes after adjunctive IBPP differed from those after TAU alone, suggesting different mechanisms of response.

P299

Regional cerebral blood flow, prolactin and cortisol levels changes in acute and transient psychotic disorders

R. Petrovic[1], A. Golubic[1], M. Rojnic[2], T. Samardzic[1]; [1]Clinical Department of Nuclear Medicine and Radiation Protection, University Hospital Zagreb, ZAGREB, CROATIA, [2]Psychiatry Clinic, University Hospital Zagreb, ZAGREB, CROATIA.

Aim: To assess and evaluate brain perfusion single-photon computerized tomography (SPECT), together with stress-related biomarkers prolactin and cortisol, as part of a continuing effort to understand the pathophysiology of the brain in acute and transient psychotic disorders (ATPD) and to correlate any found abnormalities with psychopathology of these disorders. They present as an acute psychosis associated with acute stress, with sudden onset and polymorphous symptomatology, including psychotic symptoms such as hallucinations and delusions. Method: 45 newly referred patients with an ATPD diagnosis underwent regional cerebral blood flow (rCBF) examination brain SPECT (25 female, mean age 30,8, range 18-63). Brain rCBF SPECT data from age- and sex-matched healthy volunteers were used as controls. Patients were diagnosed following ICD-10 criteria and were off psychoactive medication. SPECT scans were started 30 minutes after administration of 740 MBq of 99mTc-HMPAO in resting state, eyes closed and with low ambient noise. Tomograms were normalized to the mean brain activity and analyzed visually by two independent observers, unaware of clinical diagnosis. Results: Majority of scanned patients - 39 pt - 86,7% had brain perfusion changes, from small regions of decreased perfusion to widespread global cortical hypoperfusion and disseminated cerebral blood flow defects. Almost half (48,8%) had right/left asymmetries, and most (88.8%) had more than one region affected, predominantly prefrontal cortex and the temporal lobes. Half had frontal lobe hypoperfusion (53,3%). We had prolactin and cortisol measurments for 38 patients - 33 patients (86.84%) had elevated levels of prolactine, mean 64,5 ug/l, 12 patients (32.43%) had elevated cortisol levels, and 12 patients had both, cortisol and prolactin levels elevated. All 12 patients with elevated prolactin and cortisol levels had pathological rCBF. All but one patients with elevated prolactine levels had pathological rCBF. Additionally, detailed neurologic and laboratory examinations were within normal limits in all patients. Conclusions: Compared with the normals, majority of patients with ATPD were characterized by abnormal rCBF, predominantly affecting prefrontal cortex and the temporal lobes, and, in some cases, whole cerebral cortex. Different factors might explain pathological brain rCBF, partially as the consequence of neurophysiological changes which reflects dysfunction in neuronal activity responsible for psychotic symptoms - hallucinations and delusions, and/or the result of some associated symptoms such as acute stress. Our study also underscores the role of stress-related biomarkers in the pathogenesis of psychosis and their correlation with changes in rCBF.

Upgrading Siemens software from Caredose mAs to both Caredose mAs and kV: Impact on patient radiation doses

B. Dall, C. Schulze, C. S. Knudsen, A. E. Ljunggren; Rigshospitalet, Copenhagen, DENMARK.

Background and Aim: Dose modulation based on the overview (Topogram) with respect to mAs and standard kV (120 kV) has been used in CT scans for many years by different companies. In Siemens terminology this function is called Caredose. In 2013 the software on Siemens Biograph mCT was upgraded, which made it possible also to adjust kV based on the Topogram. The standard 120 kV was adjusted to either 100 kV or 140 kV. We wanted to examine the impact from Care kV on radiation doses based on the calculated doses in Siemens software.**Materials and methods:** 102 consecutive patients were included in the study. The patients' height and weight were recorded in order to calculate Body Mass Index (BMI). The Topogram was conducted, and the desired scan area was adjusted. Dose in mGrey (mGy) with Care mAs and standard 120 kV was recorded. The Care kV function was then turned on, and the kV that the scan would be performed with, was recorded. The estimated dose in mGy was recorded as well. **Results:** For 67 patients the Voltage was downgraded from 120 kV to 100 kV, which led to a dose reduction (mGy) of 17 percent for this group. 19 patients were scanned with 120 kV, which was unchanged compared to the previous software, resulting in an unchanged dose (mGy). The Voltage was upgraded for 16 patients from 120 kV to 140 kV, resulting in an increased dose (mGy) of 17 percent for this group. The Voltage was correlated with BMI. The dose (mGy) for the total group was reduced by 5 percent. **Conclusion:** Upgrading Siemens software from Caredose mAs to both Caredose mAs and kV resulted in a dose reduction (mGy) of 5 percent for the total group. For patients with low or normal BMI, there was an average dose reduction of 17 percent. However, patients with high BMI had an average increase in dose of 17 percent.

TP002

Calculating the Effective Dose from the CT Component of a SPECT/CT Study

A. M. Cheetham, G. Havariyoun, E. Kalogianni, D. Ruiz, L. Devlin, N. Gulliver, A. Eccles, N. Mulholland, G. Vivian; King's College Hospital NHS Foundation Trust, London, UNITED KINGDOM.

Introduction SPECT/CT is part of routine practice. The CT may be a low-dose localisation study or a relatively higher dose diagnostic acquisition. The effective dose (ED) from the radionuclide is well described, based on MIRD methodology. However, a CT will increase the total radiation dose. **Aim** To calculate the effective dose from the CT component of the SPECT/CT study, for a range of nuclear medicine procedures. **Method** 428 SPECT/CT studies from Dec-2014 to Dec-2015 were analysed. The patient's weight and Dose-Length Product (DLP) were recorded and studies categorised by examination procedure and CT scan anatomical location. Median DLP was calculated for patients weighing 50-90kg, and the ED calculated using conversion factors from Huda (2011). **Results** Parathyroid: Median DLP=196mGycm, ED=2.4mSv. Hepatobiliary: Median DLP=74mGycm, ED=1.2mSv.^{131}I Post-Therapy scans: Median DLP=95mGycm, ED=1.2mSv. Neuro-Endocrine Tumour imaging: DLP and ED is dependent upon the scan volume: Abdo Pelvis, median DLP=77mGycm, ED=1.3mSv. Chest Abdo Pelvis, median DLP=171mGycm, ED=3.2mSv. Head to Pelvis, median DLP=269mGycm, ED=4.1mSv. Bone scans: DLP and ED is dependent upon the volume scanned and choice of CT (localisation versus diagnostic): Torso localisation CT, median DLP=84mGycm, ED=1.6mSv. Feet diagnostic CT, median DLP=462mGycm, ED=0.4mSv. Knees diagnostic CT, median DLP=395mGycm, ED=0.3mSv. Hips diagnostic CT, median DLP=388mGycm, ED=2.9mSv. Pelvis diagnostic CT, median DLP=276mGycm. ED=3.9mSv. Lumbar spine diagnostic CT, median DLP=446mGycm, ED=7.6mSv.Thorax diagnostic CT, median DLP=352mGycm, ED=7.2mSv. **Discussion** For comparison the ED due to the radionuclide (administered activities taken from UK guidelines): 8.1mSv from 900MBq ^{99m}Tc-MIBI. 2.4mSv from 150MBq ^{99m}Tc-T-BIDA. 11.9mSv from 220MBq ^{111}In-Octreotide. 2.6mSv from 200MBq ^{123}I-MIBG. 3.9mSv from 800MBq ^{99m}Tc-HDP. The percentage increase in ED due to the CT is: Parathyroid scans=30%. Hepatobiliary scans=50%. NET studies with ^{111}In-Octreotide=11-34%. NET studies with ^{123}I-MIBG=50-158%. Bone scans=8-195%. **Conclusion** The effective dose is dependent upon the choice of CT (localisation or diagnostic) and the anatomical volume scanned. The CT contributes a significant percentage to the total effective dose of SPECT/CT studies. **Reference** Huda W., Magill D., He W. (2011) CT effective dose per dose length product using ICRP 103 weighting factor Med. Phys. 38, 1261-1265

TP003

Dosimetry of absorbed doses of Radioiodine-131 in Therapy for Hyperthyroidism

Y. Koshiba[1], S. Abe[2], N. Fujita[2], T. Nishimoto[2], Y. Sakuragi[2], K. Kunimoto[1], M. Honda[1], T. Odagawa[1], K. Kato[1]; [1]Nagoya University Graduate School of Medicine, Nagoya-shi, JAPAN, [2]Nagoya University Hospital, Nagoya-shi, JAPAN.

Purpose: It is important to evaluate accurately absorbed doses of ^{131}I in therapy for patients with Graves' disease. The purpose of this study was to evaluate the absorbed dose of ^{131}I in therapy for patients with Graves' disease using the SPECT/CT images acquired after the therapy. *Patients and Methods*: 13 patients (11 females, 2 males; age range, 27 - 79 years; mean age ± SD, 48.9 ± 15.7 years) with hyperthyroidism who received ^{131}I therapy between December 2014 and September 2015, were enrolled. SPECT/CT scans were taken 1 day after the therapy. The count density map from the SPECT/CT image was converted into an activity concentration map with a calibration phantom approach. Using this map and the effective half life, an accumulated activity map was obtained. This map was then convolved with ^{131}I voxel S values which were given in MIRD pamphlet to yield three-dimensional distribution of absorbed dose. We compared the virtual absorbed dose obtained with the SPECT/CT images and the expected absorbed dose calculated according to the Quimby formula, and evaluated the effect of ^{131}I therapy for the patients with hyperthyroidism. *Results*: The virtual absorbed dose was 55.4±4.4 Gy, and the expected absorbed dose was 194.4±47.7 Gy. The ratio of the volume which was irradiated over 50 % of the expected absorbed doses to the total volume of the thyroid grand was 21.7±8.7%. The therapeutic effect of ^{131}I therapy was found in all the study patients. In 12 (92%) of the total 13 study patients, the thyroid function became euthyroid and the ^{131}I therapy was finished. *Conclusion*: Although the virtual absorbed dose was lower than the expected absorbed dose, high therapeutic effect was observed. We will examine the absorbed dose of ^{131}I obtained with SPECT/CT images by using more clinical data.

TP004

Radiation exposure of patients with primary hyperparathyroidism with SPECT/CT and subtraction scintigraphy

S. Rep[1], S. Sustar[1], B. Simonic[1], M. Hocevar[2], L. Lezaic[1]; [1]Department for Nuclear Medicine, Ljubljana, SLOVENIA, [2]Department for oncological surgery, Ljubljana, SLOVENIA.

Introduction: Parathyroid scintigraphy is based on the accumulation and distribution of radiopharmaceutical 99mTc-MIBI. Subtraction scintigraphy is performed using the combination of tracers 99mTc-MIBI and 99mTc-pertechnetate; SPECT/CT is performed using a single tracer, 99mTc-MIBI in combination with low-dose computerized tomography (SPECT/CT) for precise anatomical localization of parathyroid adenomas. Objective: The aim of the study was 1) to evaluate the performance of early and delayed (5 and 60 min after administration) SPECT/CT scintigraphy for localization of parathyroid adenomas in comparison to subtraction scintigraphy using histology as the gold standard; 2) to compare the radiation exposure to patients after administration 600MBq of 99mTc-MIBI, 150 MBq of 99mTcO4 and after low-dose CT acquisition (25mAs and 130keV). Materials and methods: The study included 41 patients in whom we performed early and delayed SPECT/CT imaging and subtraction scintigraphy. Radiation exposure after administration of radiopharmaceuticals was calculated on the basis of dose coefficients obtained from the ICRP (International Commission on Radiological Protection) and the ImPACT CT dosimetry calculator. Results: The sensitivity and specificity of early SPECT/CT, delayed SPECT/CT and subtraction scintigraphy was 65.1% and 97.5%, 67.4% and 95.5% and 51.1% and 98.3%, respectively. Combined early and delayed SPECT/CT had sensitivity and specificity of 74.4% and 95.1%. The radiation exposure was significantly higher after subtraction scintigraphy (mean 7.37±0.40 mSv) in comparison to early SPECT/CT (mean 6.13±0.38 mSv), delayed SPECT/CT (mean 6.11 ±0.36 mSv) and combined early and delayed SPECT/CT (mean 6.81±0.44 mSv) (p 0.05). Conclusion: The most sensitive method of preoperative localization of parathyroid adenomas is combined early and delayed SPECT/CT. The highest radiation exposure occurs with subtraction scintigraphy.

TP005

Radiation dose of nurses during the care of thyroid cancer patients treated with I-131 in isolation room

T. Lin, P. Lee, Y. Huang; Department of Nuclear Medicine, Koo Foundation Sun-Yat Sen Cancer Center, Taipei, TAIWAN.

Background: I-131 is widely used to treat patients with differentiated thyroid cancer. However, nurses may be subjected to radiation exposure during inpatient care of these patients due to emission of gamma ray by I-131. The objective of this study was to evaluate the radiation dose of nurses during the care of patients treated with I-131 in isolation room. *Materials and Methods:* A prospective study was conducted at our hospital from January 2014 to June 2015. Thermoluminescent detectors (TLD) were used to measure radiation-related whole body doses of nurses. One TLD was provided to all nurses every month. The nurses were required to wear the TLD upon entering isolation room, and placed the TLD in the background area after leaving the room. In addition, lead apron was worn by nurses on the first day of treatment upon entering the isolation room. Purpose of entering the room, duration of stay in the room and distance from patient were recorded. The TLD was sent to the Institute of Nuclear Energy Research every month for radiation dose measurement, and a new TLD was given to the nurses each month. *Results*: A total of 192 patients were admitted for I-131 treatment during this period. Seventy-four of 192 patients were treated with 100mCi, 113 patients with150mCi, and 5 patients with 200mCi. The hospital stay ranged from 2-3 days. One-hundred and five patients (54.6%) were released on the second day after treatment, and 87 patients (45.4%) were released on the third day after treatment. During this period, 21 nurses were involved in the care of these patients. The purposes of entering the room were as follow: delivering discharge instruction (96%), administration of medication (1%), unknown (3%). The average frequency of entering isolation room was 7.3 times/month. The average duration of stay was less than 5 minutes in 1.0 times/month, between 5-10 minutes in 6.1 times/month and more than 10 minutes in 0.2 times/month. The average distance from the patient was approximately 30cm in 7.2 times/month and approximately 100cm in 0.1 times/month. A total of 18 TLDs were measured in our study. The radiation dose of nurses measured by all 18 TLDs were within background level. *Conclusion*: Based on our study, radiation dose of nurses during the care of thyroid patients treated with I-131 in the isolation room is within background level, which is much lower than the annual dose limit for general public (<1mSv).

TP006

A comparison of the left- and right hand skin dose in nuclear medicine

R. Kraack; Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, DENMARK.

Aim: There is an increasing focus on monitoring finger dose on staff who works in radiopharmacy. Radiation exposure of the hands of personnel in nuclear medicine is a real concern, and therefore it is important that the staff use ring dosimeters to monitor the radiation dose to fingers. The aim of this study is to demonstrate why ring dosimeters on both the dominant and the non-dominant hand seem to be preferable. **Materials and methods:** We have collected data using finger ring dosimeters from 2013 to 2016. At Aarhus University Hospital we use finger rings one month at a time. We use the rings on the palmar base of the left- and right forefinger under a pair of gloves. Each technologist use the same finger rings when working with radioactivity for diagnostics or radionuclide therapy. I have used my own fingerdosimeter data to the results, but I will also use my 2 colleagues' results to substantiate my results. **Results**: I have compared my own and my 2 pharmacy colleagues finger doses and found, that we all acquire more dose on our non-dominant hand, than on our dominant hand. In a period of 23 months with preparing and administering both ^{99m}Tc and ^{90}Y, I have received radioactivity on my non-dominant hand: 5,0 mSv/month and on my dominant hand: 2,3 mSv/month. In a period of 12 months without handling ^{90}Y, I received on my non-dominant hand: 4,5 mSv/month and on my dominant hand: 2,1 mSv/month. It is particularly important to use finger rings on the non-dominant hand when preparing and administering ^{90}Y, since we are receiving a higher dose per GBq activity handled, compared working with ^{99m}Tc. **Conclusion:** All of our data show, that we receive a higher dose on our non-dominant hand compared to the dominant hand. Therefore it seems important to use rings on both hands when handling radioactivity. While Laffonti *et al.* [1] suggests using only a dosimeter on the forefinger of the dominant hand, this study indicates the relevance of using a finger ring dosimeter on both hands. Failing that, the forefinger of the non-dominant hand, rather than on the dominant hand is preferred. **References:** [1] Sophie Laffont *et al.* Eur J Nucl Med Mol Imaging (2016) 43:824-831

TP007

Worker dose evaluation result from cardiac scan

H. M. Yassin, I. Kamal, R. M. Abdel-Halim; Cairo Univeristy, cairo, EGYPT.

Introduction Reducing radiation exposure has become an important aim for nuclear cardiology in nuclear medicine departments the purpose of this study was to Measurement of effective dose to cardiology staffs who operate near the patient and are exposed to non-uniform radiation field due to patient scattered radiation. **Materials and Methods**: This study was performed in nuclear medicine department of Kasr EL- Eini Hospital for 6 months and 455 cardiac scan procedures studied. Doses were recorded with thermoluminescence dosimeter (TLD) for 5 cardiologists, 12 nurses and 4 physicists and the effective dose were estimated using the Niklason algorithm. **Results**: Mean annual effective dose (μSv) to cardiologist and nurses and physicists from scans procedures were 475.5 (53.9 - 1711.7) μSv and 138.1 (48.4 - 235.9) μSv respectively. Mean effective dose (μSv) per cardiology procedure for cardiologist and nurses and physicists were 1.98 and 0.299 μSv respectively. **Conclusion**: The results indicate large variation in radiation exposure between staffs. No correlation was found between the number of procedures and effective dose. None of the annual effective dose appear to exceed the annual effective dose limit of 20 mSv. **Keywords:** TLD, worker dose, Nuclear Medicine.

TP008

Radiation Exposure Analysis of Female Nuclear Medicine Radiation Workers

J. Lee[1], H. Park[2]; [1]Chungbuk National University, Chungbuk, KOREA, REPUBLIC OF, [2]Shingu College, Seongnam, KOREA, REPUBLIC OF.

In this study, radiation workers who work in nuclear medicine department were analyzed to find the cause of differences of radiation exposure from General Characteristic, Knowledge, Recognition and Conduct, especially females working on nuclear medicine radiation, in order to pave the way for positive defense against radiation exposure. The subjects were 106 radiation workers who were divided into two groups of sixty-four males and forty-two females answered questions about their General Characteristic, Knowledge, Recognition, Conduct, and radiation exposure dose which was measured by TLD (Thermo Luminescence Dosimeter). The results of the analysis revealed that as the higher score of knowledge and conduct was shown, the radiation exposure decreased in female groups, and as the higher score of conduct was shown, the radiation exposure decreased in male groups. In the correlation analysis of female groups, the non-experienced in pregnancy showed decreasing amount of radiation exposure as the score of knowledge and conduct was higher and the experienced in pregnancy showed decreasing amount of radiation exposure as the score of recognition and conduct was higher. In the regression analysis on related factors of radiation exposure dose of nuclear medicine radiation workers, the gender caused the meaningful result and the amount of radiation exposure of female groups compared to male groups. In the regression analysis on related factors of radiation exposure dose of female groups, the factor of conduct showed a meaningful result and the amount of radiation exposure of the experienced in pregnancy was lower compared to the non-experienced. The conclusion of this study revealed that radiation exposure of female groups was lower than that of male groups. Therefore, male groups need to more actively defend themselves against radiation exposure. Among the female groups, the experienced in pregnancy who have an active defense tendency showed a lower radiation exposure. Thus, those who have never been pregnant need to have a more active defensive conduct for the future possibility of pregnancy.

TP009

The impact of scatter subtraction coefficient on the image quality

S. Rep, S. Sustar, B. Simonic, L. Lezaic; Department for Nuclear Medicine, Ljubljana, SLOVENIA.

Introduction: Detection of scattered radiation degrades image contrast of single-photon emission computed tomography (SPECT) imaging. Traditionally scatter correction methods were limited in accuracy, noise properties and were not very widely applied. This contrasts with phantom or patient imaging where better accuracy can lead to significant improvement of image quality. In concert with the increasing number of energy windows on modern SPECT systems and excellent attenuation maps provided in SPECT/CT, some of these methods give new opportunities to remove degrading effects of scatter with improved noise properties. Aim: The aim of our presentation is determine the impact of scatter subtraction coefficient on image quality Method: The phantom which was used for the determination the impact of scatter subtraction coefficient on image quality were filled with technetium. After acquisition, the reconstruction were performed with the different scattered subtraction coefficient (between 10% and 100%). We compared the average number of counts in the region of interest for the hot sphere and the background. OASIS SEGAMI® processing software was used for reconstruction and measurements analysis. Results: Our results showed that the average value of counts decries when the scatter subtraction coefficient increase. When the scattered subtraction coefficient increase more than 20% the results were statistically significant ($p<0.05$). The scattered subtraction coefficient improve image contrast and were statistically significant ($p<0.05$) when we use all coefficient. Conclusion: We concluded that the image quality is improved by using scattered subtraction.

TP010

Studies on the Effect of Scattered Radiation Out of Field of View on Tau Imaging

M. Honda[1], H. Yamaguchi[2], Y. Sakuragi[3], S. Abe[3], N. Fujita[3], Y. Koshiba[1], K. Kato[1]; [1]Department of Radiological and Medical Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, JAPAN, [2]Brain and Mind Research Center, Nagoya University, Nagoya, JAPAN, [3]Department of Radiological Technology, Nagoya University Hospital, Nagoya, JAPAN.

Background and Purpose: Tau imaging is an important imaging method for accurate diagnosis and clinical evaluation of Alzheimer's disease. A degree of ^{18}F-THK-5351 uptake into brain tau varies due to progress of the disease, and it is hardly accumulated in healthy brain. Thus, there is a possibility that scattered radiation out of field of view (FOV) affects the images and makes accurate detection of tau difficult. In this study, we determined the content of scattered radiation out of FOV at the detector which was located at various distances from the cylindrical phantom which mimiced the trunk (liver) by using PET system with 3D acquisition modes. In addition, we determined the influence of scattered radiation out of FOV when the radioactivity of the cylindrical phantom was increased and also examined whether the effect of scattered radiation from out of FOV was reduced by using a lead-made neck shield. Materials and Methods: A solution of ^{18}F was enclosed into the brain phantom and the cylindrical phantom which mimiced the trunk (liver). The brain phantom was placed on the headrest, and the cylindrical phantom was placed on the bed. Distances between the brain phantom and the cylindrical phantom examined were 0, 10, 20, and 30 cm with or without a neck shield. PET data were acquired with 3D modes, and reconstructed under the same conditions as used in a clinical setting. Circular ROIs were drawn on the axial images and the total counts were measured. The content of scattered radiation out of FOV was estimated. Results: The maximum content of scattered radiation in the images obtained was 7.84%. As the distance between the cylindrical phantom and the detector increased, the content of scattered radiation in the images decreased. When the distance was longer than 25cm, the content of scattered radiation was close to about 1.0%. Scattered radiation from out of FOV was not reduced by using a lead-made neck shield in the images. Conclusion: When the distance between the cylindrical phantom and the detector was longer than 25 cm, there was no influence of scattered radiation out of FOV in 3D acquisition mode. The same results were obtained when the radioactivity of the cylindrical phantom was increased. Even when a lead-made neck shield was used, scattered radiation from out of FOV was not reduced.

TP011

A simulation study for estimating scatter fraction of human body in FDG-PET/CT

S. Hosokawa; National Cancer Center East, Chiba, JAPAN.

In the FDG-PET/CT examination, the quality of an image depends on body size of the subject. Although It has been reported that constant image quality without depending on body type is obtained by adjusting the imaging time with Noise Equivalent Count density ($NEC_{density}$,) Noise Equivalent Count Rate (NECR) divided by the imaging volume, to be constant, decrease of visual score is observed at a higher BMI subject. It is assumed that calculating the NECR using device-specific fixed Scatter Fraction(SF) is the cause. The purpose of this study is to clarify the difference between the estimated SF of various phantoms using Monte Carlo simulation and device-specific fixed SF. To simulate the 3D-PET device, code (*Geant4*) was used. A sinogram was drawn by identifying Line of Response (LOR) with coincidence counting. Scattered radiation was defined as those scattered within the subject and a source more than 20 mm in distance from LOR. Cylindrical phantoms (length:70 cm, a diameter: 10-50 cm), NEMA/IEC Body Phantom (Scatter phantom nonuse and use) and the human body phantom in which radiation sources were uniformly placed were used as scatterer. The imaging range of

the human body simulation phantom has a length for 5 beds and estimated each bed and average SF. The estimated SF of the cylindrical phantom (10-50 cm) which line source was inserted in was 32.1-74.1% of device-specific fixed SF. In accordance with the diameter increases, the rate of increase in SF became smaller. This is considered to be because the effect of absorption was increased. In the case of use of scatter phantom and nonuse, the SF of the body model was 34.3 % and 39.5 %, respectively. The average SF of each bed of the human body simulation phantom was 38.7 %. There was a difference between the maximum 13.3% in each bed. It can be said that device-specific fixed SF is assuming standard body types. The value of SF varies greatly depending on the size and shape of the scatterer, and impact on the visual score by SF was suggested

TP012

Evaluation of Quantitative Accuracy of Trans-PET® BioCaliburn® System for in Vitro Study

J. Li, L. Wan, X. Liang, S. Han, Q. Xie; Huazhong University of Science and Technology, Wuhan, CHINA.

Aims: Recently, the small animal positron emission tomography (PET) has been employed for *in vitro* cell uptake studies. In cell uptake studies, the radioactivity of the tracers is usually below 1 μCi, which is two orders of magnitude lower than *in vivo* studies (50~200 μCi in mice, 500~2000 μCi in rats). Therefore, for *in vitro* experiments using small animal PET, the activity of the source which is enough for achieving data statistic and accurate quantitative results need to be measured. Hence, we aim to assess the measuring range of the activity when using the Trans-PET® BioCaliburn® system for *in vitro* studies. **Materials and Methods:** The 96-well plate experiments and the Monte Carlo (MC) simulation studies were performed respectively to evaluate the quantitative accuracy of the Trans-PET. Eight wells of a 96-well plate was filled with ^{18}F-FDG(12.5 kBq, 5.43 kBq, 2.85 kBq, 1.47 kBq, 685 Bq, 361 Bq, 196 Bq, 102 Bq for 96-well plate tests and 2560, 1280, 640, 320, 160, 80, 40, 20 Bq for MC tests). The data acquisition time of MC simulations and 96-well plate experiments were both 20 min. And the ROI value of PET images were calculated for quantification. The results generated from 96-well plate experiment were compared with gamma counter. While the MC simulation results were compared with the known true values. **Results**: High degree of correlation was observed between the real activities and the ROI value of the PET image (r^2 = 0.9998 for the 96-well plate tests and r^2 = 0.9998 for the MC tests). Meanwhile, the Trans-PET system also demonstrated a wide available measuring range, from 12.5 KBq to 685 Bq (the fractional errors of these 5 wells are under 3%, while the fractional errors of the 3 wells under 314 Bq are over 10%) for the acquisition of 96-well plate test and from 2.56 Kq to 320 Bq (the fractional errors of these 4 wells are under 6%, while the fractional errors of the 4 wells under 160 Bq are over 10%) for the MC test. **Conclusions**: The available measuring range can reach ~700 Bq for the Trans-PET® BioCaliburn® system detected in the *in vitro* experiment with data acquisition time of 20 min.

TP013

Simulation and theoretical calculation for production of ^{63}Zn by neutron induced reaction

M. Rostampour[1], S. Hamidi[1], **M. Aboudzadeh Rovais**[2], M. Sadeghi[2]; [1]Arak University, Arak, IRAN, ISLAMIC REPUBLIC OF, [2]Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction The ^{63}Zn is a short lived beta emitter, which is very suitable for using in PET. It is proposed to produce ^{63}Zn via neutron induced reaction. The primary purpose of this investigation is to quantify the production yield of ^{63}Zn nuclei via ^{64}Zn(n,2n)^{63}Zn reaction by utilizing the Monte Carlo codes and theoretical method. **Method** In the present study, a cylindrical target having a diameter of 1 cm has been implemented into the simulation code. The thickness of cylindrical ^{64}Zn target was calculated using SRIM-2013 code. The beam was designed to reach the target at 90° angle and impinge on the target in the z-direction. The residual nuclei were estimated using model option in "FT8 RES" card in MCNPX and G4HadronPhysics INC LXX, G4NeutronHP and G4 Photo Nuclear Process have been used as physics list in the Geant4 code. Subsequently, estimated residual nuclei were used to calculate the simulated excitation function. Based on the available neutron induced reactions experimental data, a set of optical potential parameters and the level densities parameters has been obtained for evaluating reaction cross section for this reaction. Based on the available neutron induced reactions experimental data of ^{64}Zn, a set of neutron optical potential parameters at En=12.5→14.5 MeV has been obtained. With adjusting the level densities parameters, the reaction cross sections of ^{64}Zn(n,2n)^{63}Zn is calculated. The yields of ^{64}Zn(n,2n)^{63}Zn reaction were estimated by using the simulated and calculated excitation functions and stopping power calculations. **Results and discussion**: The theoretical method and the Monte Carlo codes, MCNPX and Geant4, reproduced experimental data and theoretical values from the TENDL-2015 library for the incident energies from 12.5 MeV to 14.5 MeV. The average of the production yields of ^{63}Zn via ^{64}Zn(n,2n)^{63}Zn reaction over the energy range En=12.5→14.5 MeV are 0.1675, 0.1665, 0.167, 0.167 MBq/μAh for experimental, MCNPX, Geant4, theoretical based cross sections. **Conclusion** The theoretical method could be applied to provide a useful tool for calculating the ^{64}Zn(n,2n)^{63}Zn reaction cross section for the incident energies from En=12.5→14.5 with good accuracy. Also, MCNPX and Geant4 codes can be used for estimating the production yield of beta emitter nuclides. **Keywords**: ^{63}Zn, Cross-section, GEANT4, MCNPX, Optical potential, Level density

TP014

Characterisation & implementation of pinhole collimator for thyroid scintigraphy

N. Nielsen, K. Lajgaard, A. Arveshoug, P. Staanum; Dept. Nuclear Medicine & PET-Centre, Aarhus University Hospital, Aarhus C, DENMARK.

Aim The clinical value of thyroid and parathyroid scintigraphy can be improved by using a pinhole collimator rather than a high-resolution parallel hole collimator. The purpose of this study was, firstly, to characterise a newly installed gamma camera (Mediso Nucline TH45) equipped with pinhole collimator. Secondly, to implement a procedure for thyroid scintigraphy based on this characterisation. **Materials and Methods** Magnification and spatial resolution were determined by imaging of ^{99m}Tc in two parallel capillary tubes 3 cm apart and subsequent determination of their imaged distance and full-width-at-half-maximum (FWHM). Sensitivity was measured for ^{99m}Tc as a point-source and in a Petri dish. Pinhole-aperture diameters of 3, 4 and 6 mm and object-aperture distances between 5 and 13 cm were applied. All measured parameters were compared to theoretical models. For estimation of the most suitable object-aperture distance in thyroid scintigraphy, images of a thyroid phantom were recorded at various distances. For a direct comparison of pinhole collimator and parallel hole collimator, comparative images of a thyroid phantom and selected patients were recorded. **Results** For the employed range of distances the magnification was 1-3 and inversely proportional to object-aperture distance. For large magnifications, images of 3-dimensional objects like the thyroid phantom were heavily distorted due to the distance-dependent magnification. FWHM was reduced with about 1/3 from the largest to the smallest applied distance. FWHM was approximately proportional to the pinhole aperture diameter. The sensitivity was higher for the point source than the distributed source due to the reduced sensitivity for activity located off-centre. The point-source sensitivity dropped by a factor of about 8, when the distance increased from 5 cm to 13 cm, while the drop was less for the distributed source. A pinhole-aperture diameter of 4 mm yields a good compromise between spatial resolution and sensitivity, while an imaging distance of 7-10 cm is most appropriate with respect to magnification and spatial resolution. For the chosen

parameters the magnification was 1.4-1.9, the spatial resolution 5.3-4.6 mm and the point-source sensitivity 185-87 cps/MBq. **Conclusion** The gamma camera with pinhole collimator was characterized, and a suitable pinhole size and imaging distance was determined for thyroid scintigraphy. Judged from the determined parameters and visual evaluation of comparative images, the pinhole images represent an improvement compared to parallel hole collimator images in particular with respect to spatial resolution.

TP015

When is less more. Small but dedicated

B. Hoyer Mathiasen, D. L. Nielsen; Vejle Hospital, Vejle, DENMARK.

Aim: To explore the possibility of reducing costs, but increasing output, by (re)introducing simple planar imaging. **Background**: The European field of Nuclear Medicine has had a significant increase in the number of procedures performed over the last decade. This has resulted in an increase in the number of multi-purpose cameras. [1] These multi-purpose cameras, have special demands regarding shielding, cooling and ambient consistency. They have large footprint, and require a large amount of space. Space and money are two sparse resources in the current public healthcare service. This leads departments of Nuclear Medicine to seek new ways to meet the growing demand for nuclear imaging. In the Department of Nuclear Medicine, Vejle Hospital, Hospital Lillebaelt, this growing demand of imaging, and the fact that money within healthcare is sparse, has led to an increase the number of dedicated and more simple gamma cameras for renal, heart and thyroid imaging. The current dedicated modalities include: NephroCam & SoloMobile (booth DDD-Diagnostic A/S) and CardioMD III (Philips Denmark A/S, Healthcare), primary used for renal, thyroid and heart imaging respectively. **Results**: The price of the simple dedicated modalities, varies from 75.000€ to 130.000€ witch is often up to 1/10 the price of a SPECT/CT. The price for a full service agreement, range from 1/10 to 1/20 of the price of a SPECT/CT. The more simple cameras reduce or eliminate the need for motions of the camera prior to the acquisition, and therefore give a better patient flow, with less idle time at the modality. A price comparison shows that if a single detector study (>41 minutes a day), is moved from a moved from a multipurpose camera. The purchase and service of a simple and dedicated camera is feasible. With the Danish reimbursement rates only 1 kidney scan a day can make the simple camera purchase feasible. Where a multimodality SPECT/CT needs to conduct >7 kidney scan a day to be economical feasible. **Conclusion**: The simple and less expensive gamma cameras, does have the ability to increase production at a lower cost, if production is moved from a multi-purpose camera. The less often demand for periodic maintenance gives more available camera time, also helping to boost production. Therefore the small simple gamma camera is, and should continue to be, the production workhorse for supplementing the more and more frequent multi-purpose gamma cameras.[1] http://www.fsnm.org/home/wp-content/uploads/2011/12/Results_EANM_Survey_20101.pdf (31.03.2015)

TP016

Comparison of calculated attenuation corrected FDG brain scans with CT

J. Wiegers, A. Willemsen, D. Vállez Garcia, R. Dierckx; UMCG, Groningen, NETHERLANDS.

Without attenuation correction (AC) PET images exhibit strong artifacts and do not allow quantitative imaging. Therefore, current PET-CT systems perform a low-dose CT-AC scan. Although of low dose, this still increases the total radiation dose to the patient which is a special concern when scanning children. In addition, patient motion between or during the CT-AC scan and the PET scan can introduce motion AC artifacts. For brain scans a calculated AC is possible which alleviates both problems. **Aim**: To compare the calculated AC corrected brain scans, using the Siemens Neuro-AC tool, with the gold-standard i.e. CT-AC. **Methods**: For Alzheimer suspected patients, 10 FDG brain scans were included. (Age: 55-77, M: 6, F: 4) Subjects where positioned using a CT scout scan after which a CT-AC was performed (80 kV, 40 mAs). Scans of 5 min duration where made, 30 min after the injection of 200 MBq FDG. During the uptake period, patients remained in a darkened and quiet room. The scans were reconstructed using the CT-AC scan and the Neuro-AC tool. The reconstructions resulted in different dimensions of the data. Therefore, the scans where first co-registered and then both absolute and relative error images where calculated (Vinci). To prevent extra-cranial voxels to influence the analysis, the differend images where masked using the CT-AC corrected FDG scan. The current analysis is based on a visual interpretation of the data, displayed in transaxial, coronal and sagittal sections. **Results:** Relative errors were largest in areas with low uptake which is a direct result of the division by low values. This is particularly evident for the skull. The smallest relative errors were observed for the cortical regions particularly the more cranial slices. More caudal structures, particularly at the level of the nasal cavities were more susceptible for errors. **Conclusion:** Calculated AC using the Neuro-AC tool may give large relative errors, although these are usually in low uptake areas. For a visual interpretation of FDG brain scans, particularly of cortical areas, its use seems appropriate. The same holds for the quantitative assessment (i.e. using SUV) of follow-up scans of patients. Generally, the use of SUV ratios is advised since this will reduce potential systematic errors. However, more research is required if this approach is to be used in a research setting.

TP017

Datscan® (123I-FP-CIT) brain SPECT: comparative analysis of differ-ent quantification methods

R. Correia[1], L. Roldão Pereira[1], D. Faria[2,3], L. Vieira[4,5], J. Vale[2,3], A. Martins[2], J. Patrina[2], J. Fernandes[2], J. Teixeira[2], D. Sousa[2], J. Oliveira[2]; [1]Licenciatura em Medicina Nuclear - Escola Superior de Tecnologia da Saúde de Lisboa, Lisbon, PORTUGAL, [2]HPP-Medicina Molecular, SA; Lenitudes SGPS, SA, Lisbon, PORTUGAL, [3]ESSUA - Escola Superior de Saúde de Aveiro, Lisbon, PORTUGAL, [4]Área Científica de Medicina Nuclear, Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisbon, PORTUGAL, [5]Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisbon, PORTUGAL.

INTRODUCTION DaTSCAN® (^{123}I-FP-CIT) brain SPECT studies are of extreme importance on differential diagnosis of movement disorders in the assessment of dopaminergic degeneration in the nigrostriatal pathway. Quantitative algorithms have great impact on obtaining more objective data and to enable higher confidence in the diagnosis, inter-group analysis and longitudinal evaluation of patients. PURPOSE To investigate the impact of different types of quantitative algorithms in the quantification of specific uptake binding (SUB). **MATERIALS AND METHODS** Retrospective quantification of 37 DaTSCAN® (^{123}I-FP-CIT) brain SPECT individual studies (22 female, 15 male, mean age 61 years) was performed using the commercial software Quantispect®, a computational solution for automated quantification (CSAQ) and a manual method (Costa's Method - CM). **RESULTS** Our results show a positively strong Pearson correlation between all three methods, better for CM and CSAQ (0.90, P<0.0001) than for automatic method (0.80-0.88, P<0,0001). Friedman test showed statistically significant differences between all the methods (P<0,05). ROC curve with Younden maximization pointed out high sensitivity for all (mean of 88,4%, STD of 0,02%), with Quantispect® presenting the lowest specificity (83,33% vs 91.67% demonstrated by the others). **CONCLUSION** Preliminary results indicate that automatic quantification of the SUB in DaTSCAN® SPECT is more consistent and that quantification method choice is clinically relevant in the delivery of reliable patient care. The study is still ongoing and we hope to include more commercially available programs and a larger validated database of normal and abnormal individuals.

TP018

Discovery IQ - Acquisition and reconstruction optimization of ^{18}F-FDG PET-CT Brain studies

S. Ferreira[1], D. Faria[2], J. Fernandes[3], A. Martins[3], J. Teixeira[3], D. Sousa[3], J. Patrina[3], J. Vale[3], L. Vieira[4], F. Silva[3], J. Oliveira[3]; [1]ESTSL-IPL - Lisbon School of Health Technology, Lisbon, PORTUGAL, [2]HPP-Medicina Molecular, SA; Lenitudes SGPS, SA; ESSUA- Aveiro University's Health School, Porto, PORTUGAL, [3]HPP-Medicina Molecular, SA; Lenitudes SGPS, SA, Porto, PORTUGAL, [4]Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisboa, Portugal, Lisbon, PORTUGAL.

Introduction PET-CT scanner Discovery IQ (GE D-IQ) represents the latest advance of GE in Molecular Imaging with 6.3mm x 6.3mm x 30mm BGO crystals and a dual energy acquisition channel that is able to reduce dead time and pileup at high-count rates providing the highest sensitivity among commercial scanners. Along with the improvement in hardware, GE introduced Q.Clear, a Bayesian penalized-likelihood reconstruction algorithm for PET, providing more accuracy in PET quantitation. **Aim** Acquisition and reconstruction optimization of ^{18}F-FDG PET-CT brain studies in order to determine the optimum penalization factor β (beta) of Q.Clear, according to image acquisition parameters. **Methods** Images were obtained of a 3D-Hoffman phantom, filled with 35-90 MBq of F18, varying from 5 seconds to 30 minutes of duration, with a total number of 60 images reconstructed with Q.Clear algorithm with β values of 100-600. Maximum and mean SUV values were accessed for the left, right, anterior and posterior cortex, striatum and white matter. The right to left cortex (RL), anterior to posterior cortex (LP), caudate to white matter (CW), putamen to white matter (PW), putamen to caudate (PC) and grey to white matter (GW) ratios were obtained. Final images were visually evaluated by 2 scorers for overall image quality, contrast and noise level. **Results** Preliminary results showed a loss in contrast and overall image quality as β value is increased. β values above 400 have a significant impact in CW, PW and GW ratios affecting the overall image quality. Results also showed an inverse linear relation between image duration (number of prompts obtained) and β value used in the reconstruction algorithm, with higher β values for studies with poor statistics. **Conclusion** Study is still ongoing and preliminary results show a significant impact of β value on the in overall image quality. Optimum penalization factor β of Q.Clear needs to be adjusted according to image statistic obtained.

TP019

A comparison study on acquisition counting with SPECT tomography

Y. Wang; Huashan Hospital, Fudan University, Shanghai, CHINA.

Objective: To compare "Both, Either" different acquisition method parameter count in nuclear medicine SPECT tomography scan in clinic. Methods: 100ml water and 2ml radioactive nuclide $^{99}Tc^{m}$ (2mCi) liquid were poured into three cylindrical sealed container respectively. The container was placed on headrest of Siemens Symbia T16 SPECT examination bed, bed height was adjusted and fixed, a circular and step-fault method was used to collect. Tomographic imaging were divided into A, B, C groups, the collection counts were "Both 50kcts", "Either 50kcts", "Either 52kcts" counts per frame respectively, and 64 frames were collected totally. Radionuclide was added before each imaging and ensure that the error between the three containers of less than 1%. Repeat and each sealed container was measured after adjusting the dose and repeated five times. Results: The acquisition time of three different modes was spent 2896.3 ± 3.4 seconds, and 2648 ± 2.3 seconds, and 2784.5 ± 2.8 seconds. Total acquisition counts of dual probe were 64075 ± 23counts, 62971 ± 43counts, 65796 ± 53counts. A pairwise comparison was carried on all these data. Acquisition duration was groups A> C> B, t = 59.497, P <0.001, t = 46.694, P <0.001, t = 62.071, P <0.001. Acquisition count was groups B> A > C, t = 36.523, P <0.001, t = 57.234, P <0.001, t = 53.827, P <0.001. The counts of group C previous ten frames was low and count exceeds 50Kcts. Conclusion: If select "Both" to collect in the actual collection process, the probe A reaches the specified count and B has not reached the probe, the probe A will stop counting until the probe B reaches the count. When you select "either" acquisition, any probe reaches the specified count, the two probes will stop counting. Although there was "Both, Either" acquisition mode, the second half of the radioactive probe and can not reach the set count in 30 minutes collecting process, the acquisition program have logic design and assign acquisition time rules after acquisition starts, and the collecting results met the objectives not because of set "Both, Either". From the statistical results, Group C results were the highest efficiency and it can be recommended. In clinical practice, we can set the acquisition "Either" parameter, the count is slightly higher than the objectives and requirements, the amount of information will be enough reasonable acquisition time data.

TP020

Influence of CT attenuation correction on image quality of reconstructed SPECT image on stress Thallium-201 SPECT-MPI using CZT detector SPECT device

K. Shogo[1], S. Tomiguchi[2], R. Matsuda[1], N. Katsuta[3], S. Shiraishi[4], Y. Yamashita[4]; [1]Graduate School of Health Sciences, Kumamoto University, Kumamoto-shi, JAPAN, [2]Faculty of Life Sciences, Kumamoto University, Kumamoto-shi, JAPAN, [3]Division of Medical Technology, Kumamoto University Hospital, Kumamoto-shi, JAPAN, [4]Department of Diagnostic Imaging, Faculty of Life Sciences, Kumamoto University, Kumamoto-shi, JAPAN.

Object: In a single-photon emission-computed tomography myocardial perfusion imaging (SPECT-MPI) using CZT detector SPECT device (CZT camera), a decrease in radiation exposure to patient or shortening of data acquisition time is obtained by its high count sensitivity. However, attenuation is considered to be one of the factors deteriorating the image quality of reconstructed Thallium-201 SPECT-MPI image (SPECT image) obtained by CZT camera. The aim of this study was to evaluate the influence of CT attenuation correction (AC) on image quality of SPECT image in patients with visually normal myocardial perfusion. Optimal data acquisition time for SPECT-MPI was also assessed. **Methods**: Twenty-six consecutive patients without perfusion abnormality on visual assessment were enrolled in this study. They were 14 males and 12 females with their mean age of 73.1 years. Stress Thallium-201 SPECT-MPI and CT were performed in all patients. SPECT data were acquired for 7 minutes with list mode on CZT camera (NM530c: GE) and CT data on SPECT/CT device (NM/CT670: GE). Three SPECT images were reconstructed by iterative reconstruction algorithm. They were SPECT image without attenuation and scatter correction (NC), that with attenuation correction (AC) and that with attenuation and scatter correction (ACSC), respectively. Image quality of uniformity was evaluated by using a coefficient of variance (CV) of count distribution on polar map of each SPECT image. In addition, SPECT data acquired for 7 minutes were reconstructed every one minute to calculate normalized mean square errors (NMSE). Optimal data acquisition time was determined by NMSE of each acquisition time from 1 to 6 minutes SPECT image showing under 0.05 as compared with reference value (NMSE of 7 minutes SPECT image). **Results**: CV of SPECT images were 0.178±0.024 on NC, 0.135±0.022 on AC and 0.130±0.020 on ACSC, respectively. Significant statistical difference was observed between NC and AC image ($p<0.01$), but was not between AC and ACSC image. Artificial decrease in count of inferior wall was found on NC image. However, this was not observed on both AC and ACSC image. NMSE under 0.05 was obtained by 5 and 6 minutes data acquisition in three images. **Conclusion**: Uniformity of SPECT image on CZT camera is significantly increased by AC and ACSC. AC is necessary for improving a specificity of diagnostic performance in case of using CZT camera. In addition, optimal data acquisition time is considered to be 5 minutes.

TP021

Comparison of the dual-energy window method and the triple-energy window method for quantitative single photon emission computed tomography

Y. ITO, M. KUNIYOSHI, M. SUETAKE, K. MOCHIZUKI, **K. MATSUMOTO**, K. ENDO; Kyoto College Of Medical Science, KYOTO, JAPAN.

Aim: Several factors adversely affect quantitative analysis in the single photon emission computed tomography (SPECT). Among these, the most significant are Compton-scattered photons mixing into the preset energy window. However, the energy resolution of the sodium iodide used gamma camera-based SPECT is relatively poor. Therefore, several techniques have been proposed for Compton scatter compensation. The dual-energy window (DEW) method is easy to implement in the clinical studies and has been shown to produce an improvement in image quality. On the other hand, the triple-energy window (TEW) method obtained the counts from three windows and estimates the amount of scatted photons mixing into the main window and this method is widely used in the cerebral blood flow SPECT. The purpose of this study was to compare the DEW method and the TEW method in the brain SPECT image. Methods: A gamma camera, GE Healthcare Millennium MG with a low-energy high resolution collimator, was used to scan images of a Hoffman 3-D brain phantom filled with Tc-99m. The main window of the DEW method was set at 130-151 keV (nominally 15%) and the scatter window was set at the same width (100-116 keV). The main window of the TEW method was 24% (set at 123-157 keV), the lower and upper scatter rejection window were 4% (set at 118-122 keV and 158-164 keV, respectively). A total of 128 projections were acquired at 40 sec per view, resulting in a total scan time of 45 min. The DEW method was changing the weight coefficient ("k"). Image reconstruction was done using filtered back projection and attenuation correction was not performed. Quality of the reconstructed images was evaluated in terms of a contrast and a two dimensional power spectrum analysis. The program was implemented using C (Cygwin: version 2.4.1) and a personal computer (Core i5 4300U, 1.9 GHz, 8 GB memory). Results: As for the DEW method, the contrast became high-valued in a bigger "k" setting, and the pixel counts decreased with increasing "k". In the TEW-corrected images, the contrast was approximately 16% higher than that the without correction images. The contrast of TEW method was comparable with the DEW method at k=0.8.Conclusions: The TEW method allows easily reliable scatter correction for SPECT system. Further work is necessary to validate the method for different phantom imaging and different radionuclide tracer.

TP022

Intrapatient Variability in Blood-Pool and Liver SUV for 18F-FDG PET/CT

Y. Parlak, D. Goksoy, G. Gumuser, E. Sayit; Celal Bayar University, Manisa, TURKEY.

The purpose of the study was to show variations in blood-pool and liver SUVmax between two 18F-FDG PET/CT scan of an individual patient to make true evalution of therapy response. Two hundred fift yoncology patients had PET/CT scans using a Philips True Flight Select 16 PET/CT scanner. Patient preparation, acquisition parameters and reconstruction protocols for all patients were standardized. All patients were divided into ten cancer groups, including 25 patients (esophagus, stomach, colon, rectum, larynx, lung, breast, endometrial, ovarian and lymphoma cancer) in each group. SUVs were obtained from 2-dimensional regions of interest in the aortic arch blood pool and in the right lobe of the liver. The group's mean serum glucose level for first and second scan was 5.5, 5.7mmol/L, respectively. The group's mean blood-pool and liver SUVmax for firsts can were 2.55±0.2; 1.79±0.2, respectively. The group's mean blood-pool and liver SUVmax for second scan were 3.13±0.2; 2.03±0.2, respectively. The reference range, in all patient groups, for intrapatient variation was 0 to 1.5 for blood pool SUV max and 0 to 1.8 for liver SUVmax. These ranges are applicable in clinical practice as they indicate practical limitation on qualitative tumor response assessment or tumor to background ratios in comparision of 18F-FDG PET/CT images.

TP023

Correlating Time per Frame and Injected Activity in bone SPECT/CT scanning: the case for consistent practice

A. C. A. Gomes Moura, D. G. Sharp, A. Nunes, F. Ul-Hassan, V. Lewington; Guy's and St Thomas NHS Foundation Trust, London, UNITED KINGDOM.

Aim: The recommended activities for ^{99m}Tc MDP bone scintigraphy in the UK are 600MBq (+/-10%) for planar and wholebody imaging and 750MBq(+/-10%) for SPECT/CT. Bone SPECT/CT scanning is a common procedure in our department accounting for 10% of all scans performed during 2015 but, as the decision to proceed with tomographic imaging is often taken following review of planar images, not all patients having SPECT/CT scans are injected with 750MBq. This study's objective is to establish whether SPECT/CT operators take the injected activity into consideration when choosing the time per frame used for scanning. **Method**: Injected activities and SPECT/CT acquisition parameters were retrieved from electronic records for all patients who underwent SPECT/CT scanning in 2015 and data analysis was done on Microsoft Excel. **Results:** Data from 532 consecutive patients was analysed of whom 162 (Group 1) were injected with 600 MBq (range : 546-659 MBq) and 370 patients (Group 2) were injected with 750MBq (range: 690-824 MBq). For group 1, the average time per frame was 12.61 sec/frame and the mode was 10 sec/frame. For group 2, the average time per frame was 12.95 seconds/frame with a mode of 15 seconds/frame. **Conclusion**: Although it was expected that operators would select longer acquisition times for patients undergoing ^{99m}Tc MDP SPECT CT following injected activities of 600 MBq (+/-10%) compared with those receiving 750 MBq (+/-10%), our study shows that this was not always the case. On the basis of this data, we have changed our bone scan acquisition protocols to improve consistency and ensure that injected activity is always considered when selecting the time per frame used for bone SPECT/CT scanning. Adherence to this protocol and impact upon workflow will be assessed prospectively.

TP024

Halo artefacts around kidneys and bladder in [^{68}Ga]PSMA PET/MRT scans: Influence of different scatter correction settings

A. Kanzog, S. Milachowski, F. Büther, T. Krähling, L. Stegger; University Hospital Münster, Münster, GERMANY.

Introduction: [^{68}Ga]PSMA PET is becoming an established imaging technology to assess prostate cancer. However, scanning with this tracer on current PET/MRT systems often leads to apparent extinction zones ("halos") around highly-active structures, especially kidneys and bladder. This can be attributed to imperfections in the current scatter correction algorithm. To analyse these artefacts, we reconstructed affected datasets with different scatter correction algorithms. *Methods*: Data for this study was acquired on an mMR scanner (Siemens, Erlangen, Germany). 30 Patients were scanned one hour after injection of 2 MBq/kg [^{68}Ga]PSMA tracer. The PET scan comprised 5 - 7 bed positions that were scanned for 3 minutes each. Standard DIXON MR sequences with MLAA-based extension of the field-of-view were performed to calculate PET attenuation maps for air, lung, fat, and soft tissue attenuation. As a standard, scatter correction was performed using a relative scaling of the simulated scatter estimate to the scatter tails outside the patient. Additionally, both an absolute scaling of the scatter based solely on the scatter estimate and a non-scatter-corrected reconstruction were performed. Reconstruction was done using OSEM with 3 iterations and 21 subsets. The whole-body images were afterwards analysed for visual halo artefacts around kidneys and bladder. *Results*: Distinct halo artefacts were present in the relatively-scaled images in

13 out of 30 studies. Of these, 9 were around the kidneys and 10 around the bladder. Absolute scaling of the scatter estimate did not improve image quality; instead, the artefacts were often just relocated to slightly different positions. Images without scatter correction did not show halo artefacts, although the scatter background in the images makes quantitative PET values difficult to obtain. *Conclusion*: Halo artefacts around hot structures are a prominent problem in current state-of-the-art PET/MRT. This seems to be caused by imperfect scatter estimates, probably based in part on limited attenuation map quality and ^{68}Ga-specific prompt gamma emission that is not accounted for in the current software. Absolute scaling of the scatter estimate - although implemented by the vendor as a remedy for this kind of artefacts - does not lead to a substantial improvements. In cases where quantification is not important, images reconstructed without scatter correction might help to get image information from halo areas.

TP025

Sparkling water for better visualisation of the myocardium and reduction of extra cardiac activity in patients for PET-CT with rubidium-82

H. Slootweg, V. J. W. Slender, P. C. M. Pasker-de Jong, J. J. Boer, J. P. Esser; Meander Medical Centre, Amersfoort, NETHERLANDS.

Introduction During myocardial perfusion imaging with rubidium-82 (PET) extra cardiac activity often occurs in stomach, intestines and liver. This may lead to difficulties in visualization and interpretation of the inferior myocardium. The aim of this study is to assess whether ingestion of sparkling water prior to imaging would improve the image quality by reducing activity in the stomach. **Methods** The study group consists of 77 patients: 44 males (age range 50-83 mean 65) and 33 females (age range 32-89 mean 70) who were referred for myocardial perfusion imaging by PET. Caffeine (including derivates) and dipyridamol is discontinued 12 hours and theophylline is discontinued 48 hours before acquisition. 27 patients had nothing to drink prior to the scan, 26 had sparkling water, and 24 had tap water. The examination protocol begins with a topogram and low dose CT. Then two acquisitions follow during rest and stress (the latter after intravenous administration of regadenoson 400 mcg) both after injection of 1110 MBq rubidium-82 followed by 7 minutes of acquisition in list mode. There is a break of several minutes between rest and stress acquisition to allow recovery of the strontium-82 generator. For both rest and stress images, physicians scored for stomach activity, scoring 'yes' when having trouble interpreting the image because of interfering stomach activity. **Results** During the rest phase interfering stomach activity was found in 28% of the cases after sparkling water, 38.1% after tap water and 46.2% after drinking nothing. During the stress phase interfering stomach activity was found in 20% of the cases after sparkling water, 18.2% after tap water and 23.1% after drinking nothing. There was a higher occurrence of stomach activity compared to females OR=3.5 [1,1 - 11,4] The size of the study group will be expanded to increase the statistical significance and power. **Conclusion** During rest phase image quality is improved by prior administration of sparkling water resulting in better interpretation when compared to drinking nothing. Prior administration of tap water yields worse results compared to sparkling water. Statistical significant differences could not be found for the stress phase. During stress there is more myocardial activity as compared to rest, while stomach activity remains the same in both situations, thus increasing discrimination during stress. Male patients had higher occurrences of extra cardiac activity than female patients.

TP026

Experience from the first two years of Radium-223 treatment in Denmark

M. M. Joergensen, S. Holm, J. Mortensen; Rigshospitalet, Copenhagen, DENMARK.

Ra-223 is an alfa-emitting radionuclide approved for treatment of patients with castration-resistant prostate cancer and symptomatic bone metastases based upon a phase 3 study showing prolonged survival, time to bone-related complications, and improved quality-of-life (QoL). As calcium mimic Ra-223 binds into newly formed bone tissue, and accumulates in bone metastases. 95% of the emitted Ra-223 energy is alpha-radiation with a high linear energy transfer, while 1.1% of the radiation energy is X-ray and gamma radiation that can be detected with gamma monitors, gamma cameras and whole body counters (WBC). Method: Since the dose coefficient for intake is high (1.0 x 10^{-7} Sv/Bq) it is essential during handling the Ra-223 to avoid internal contamination either from inhalation, ingestion or adsorption. Therefore, the staff needs to apply special safety precautions. If an accumulated activity of > 300 MBq is handled over a year by a staff member in Denmark, a potential exposure of 0.5 mSv or more on a monthly basis must be detectable. This can be achieved by measurement in our WBC immediately after handling the Ra-223 to the patients. Also to avoid internal contamination a protective dress is used and control measurement of gloves/hands are performed after each handling, both dispensing and injection, of the dose. Results: As yet, Rigshospitalet is the only centre in Denmark providing Ra-223 treatment. Through the first two years we have administered 430 Ra-223 doses to 120 patients on 48 treatment days (1-16 patients each day). At each treatment day two of the three Ra-223 dedicated technicians and one of the three physicists handle between 36 to 96 MBq Ra-223. The accumulated Ra-223 activity handled by each staff member was 300-1400 MBq over the last year. The level of handling 300 MBq is reached by handling 10-14 patients (~ max. 50 vials of 6 MBq each) per staff member yearly. Alternatively, our patient through-put could be served by at least 5 pairs of two technicians plus one physicist dedicated to Ra-223 treatment. At each treatment day minor spillage of Ra-223 (Bq-amounts) is usually detected and gloves need to be changed regularly (1-6 times per treatments day). However, the WBC measurements have demonstrated no internal contamination to any staff member. Conclusion: When special radiation safety precautions are used Ra-223 is a safe treatment for the dedicated staff and no internal contamination occurs.

TP027

Comparisons of quantitative data between anterior and posterior views in sialoscintigraphy

C. LIN; Taipei Veterans General Hospital, TAIPEI, TAIWAN.

Introduction: Sialoscintigraphy is an invasive and useful examination for evaluation of salivary gland function. Either anterior or posterior view is applied in clinical procedure. The purpose of the study was to compare the quantitative data of sialoscintigraphy acquired in anterior and posterior views. Materials and methods: Thirty-three patients (5 males, age 61±14 y/o) underwent sialoscintigraphy. After 5mCi ^{99m}Tc pertechnetate intravenous injection, both anterior and posterior views of dynamic images (10 seconds/frame) were simultaneously acquired by Siemens E.Cam Gamma Camera for 30 minutes. At the 20th min, 10ml lemon juice was given as an oral salivary stimulant. Patients were instructed to keep it in mouth for 2 minutes before swallowing. Data were analyzed by Siemens E-soft software. Bilateral parotids, oral cavity and partial cerebrum were measured as the regions of interest (ROIs). Time-activity curves were then derived from these ROIs. During the time period from 18 to 24 min, the following functional parameters of bilateral parotids were calculated: Excretion fraction (EF), Tmax (time of maximum count), Tmin (time of minimum count), Cmax (the maximum count rate), Cmin (the minimum count rate). In ROI of oral cavity, Tmax and Cmax were recorded. Comparisons of those quantitative sialoscintigraphy data between anterior and posterior views were evaluated. Results: Of the right parotid, there were no differences between anterior and posterior views in Tmax (19.03 ±0.67 vs. 19.12±0.54 min, p=ns) and Tmin (22.19±0.98 vs. 22.09±0.99 min, p=ns), respectively. Of the left parotid, there were no differences between anterior and posterior views in Tmax (19.36±0.85 vs. 19.23±0.53 min, p=ns) and Tmin (22.17±0.95 vs. 22.37±0.94 min, p=ns), respectively. The calculated EF of anterior view was higher than that of posterior view in right (68.04

±14.69 vs. 64.11± 14.89%, p=0.005) and left (70.44± 13.93 vs. 65.45 ±12.41%, p=0.004) parotids, respectively. Cmax and Cmin of bilateral parotids were significantly higher in posterior than in anterior views (p<0.05). In oral cavity, there was a difference between anterior and posterior views in Tmax (21.22±1.23 vs. 21.56±1.23 min, p=0.033). The Cmax of anterior view was significantly higher than that of posterior view (178.45±87.58 vs. 73.82±23.68 counts/sec, p<0.001) Conclusion: The detector orientation does not affect the Tmax and Tmin in time-activity curve of bilateral parotids in sialoscintigraphy. Using anterior view leads to a higher excretion fraction of bilateral parotids and oral activity, whereas the posterior view causes a higher count rate of bilateral parotids.

DOPA PET-CT In Medullary Thyroid Cancer: Early Vs Late Acquisition

F. Sciume, L. Pavanello, D. Grigolato, M. Zuffante, M. Cucca, M. Ferdeghini; AOUI VERONA, Verona, ITALY.

AIM: This study wants to show the importance of the early acquisition at 20 minutes in the restaging of patients with medullary thyroid cancer (MTC). **MATERIALS AND METHODS**: We have studied 51 patients with MTC from 2013 to 2016. PET-CT Philips Gemini TF Big Bore has been used for the acquisition scans with [18F]fluorodopa (^{18}FDOPA). The protocol foresaw: an early acquisition of the neck and mediastinum (3-4 beds) and the standard total body acquisition at 60 minutes after administration of 2.5 MBq/kg of ^{18}FDOPA. The CT parameters used for the acquisition of the neck and mediastinum/total body were: 120 KV, 60-80 mAs pitch 0.813, 16x1.5 mm collimation, thickness 1,5, FOV 600. PET parameters: 2 min bed position, FOV 576 mm. We had to arrange our scheduled resources in MBq (range 590-740) towards three patients for each daily section, it inserted between them without delayed the each acquisition. While early scanning of a particular anatomical region (neck-mediastinum) lasts about 6-10 minutes and the 20 to 30 minutes for the total body scan, the better strategy in the overall timing organization was the following: Patient one was injected at time zero and acquired 20 min later; patient two injected immediately after 10 min and acquired at 30° min; the third patient was injected 30 min later and acquired at 50° min. Immediately after the completion of all the early scans we started the total body PET-CT acquisition at 1 hour. **RESULTS**: It was evident that images at 20 minutes showed better visual definition and higher SUVmax values compared to the ones obtained in the whole body at one hour. In fact, the uptake of 18F-FDOPA decreased by 40% between the two acquisitions in all the regions of interest (ROIs). **CONCLUSION**: In all the patients with MTC, the early acquisition with 18FDOPA PET-CT (20 minutes) seemed to be more appropriate in the detection of lesions with respect to the late scan, because these tumors usually show a rapid wash-out, so we suggest to usually perform an early study.

TP029

Sequential dual time point PET-CT scan in the evaluation of physiologic, benign and malignant 18F-FDG uptake in head and neck region

A. Pietrzak, M. Smolen, P. Cegla, W. Cholewinski; Greater Poland Cancer Centre, Poznań, POLAND.

INTRODUCTION: 18F- FDG has been widely used for cancer diagnosis, however 18F-FDG is not a tumor specific agent. It can accumulate in benign lesions as well as in various organs not affected by any disease, making a proper diagnosis more complicated and demanding. Several approaches were made for increase the specificity of FDG-PET scan, including a variety of dual time point scanning. The aim of this study was to assess whether sequential dual-time-point (18)F-fluoro-2-deoxyglucose-PET/CT imaging may be helpful in differentiation of physiologic, benign and malignant structures. **METHODS**: Eighty nine patients with suspected malignancy were investigated by performing two sequential PET/CT static acquisitions started at 60min and 90min after intravenous injection of 18F-FDG (370MBq). In each patient nine normal structures were evaluated (cerebellum, parotid, neck muscle, tongue, thyroid, tonsils, larynx, vertebra and carotid arteries) as well as any benign and malignant foci of abnormal 18F-FDG uptake, visualized during scan evaluation. All lesions were verified by histology or 2 years of follow-up. Visual and semiquantitative analysis was performed on both sets of images based on VOI technique with metabolic activity of chosen structure/lesion assessed by SUVmax value. **RESULTS**: Normal structures of head and neck showed in majority similar 18F-FDG uptake at 60min and 90min post injection. There was marked but not significant decrease in SUV value at 90min in vessels and larynx (-4.5% and -4.5%, respectively) and pronounced increase in cerebellum and thyroid (+2.8% and +4.7%, respectively). Benign lesions showed at 60min significantly lower average SUVmax value than malignant (3.09±2.29 vs 5.88±3.80, 7.08±3.00 p<0.01). Analysis of SUV change between 60min and 90min post injection showed decrease of average SUV value in benign foci (3.09 ±2.29 vs 2.88±1.78, ns) while malignant lesions showed significant increase in SUV value (5.88±3.80 vs 6.77±4.04, p<0.05). In benign lesions average relative change in SUV values ranged from -55.5% to +30.0% (1.6±0.3%) but in malignant ranged from -5.0% to +132.0% (17.0±0.2%), and the difference was statistically significant (p<0.05). **CONCLUSIONS**: Sequential, dual time point PET/CT scan may increase the specificity of 18F-FDG in management of benign and malignant lesions in head and neck cancer. Additionally, the sequential scanning allows to avoid time delays and repositioning of the patients for acquiring delayed set of images.

TP030

[^{18}F]Fluoride for clinical use

P. Saipa, N. Savisto, A. K. Kirjavainen, S. Forsback, O. Solin, R. Purtanen, E. Kokkomäki, T. Saarinen, S. Vauhkala; Turku PET Centre, Turku, FINLAND.

Aim: [^{18}F]Fluoride ([^{18}F]NaF) is a highly sensitive bone imaging PET tracer used for detection of skeletal abnormalities. The aim was to automate the production of [^{18}F]NaF for clinical use in Turku PET Centre (TPC). The new production method required a new synthesis device and analysis method for quality control. In a GMP environment all production processes and quality control procedures have to be validated. **Materials & Methods**: An automated synthesis device, enabling a synthesis in a closed system, was designed and built at TPC. The synthesis device was placed in a qualified hot cell located in cleanroom class C. An existing automated sterile filtration unit was connected to the device. The synthesis device was qualified according to the quality system at TPC. A new HPLC analysis method for [^{18}F]NaF was developed to ensure the quality of the end product. The method described in the European Pharmacopoeia was not applicable. Chemical and radiochemical purity of the end product were determined using a radioHPLC method. The same method was used to detect impurities as a limit test. The validation parameters for the method were specificity and detection limit with UV and radioactivity detectors. The manufacturing process was validated in compliance with our quality system. Three consecutive batches of [^{18}F]NaF were produced and all quality control tests were performed on the final product according to the method description. In addition to the parameters determined using the HPLC method, pH, shelf-life for six hours, residual solvents, sterility and bacterial endotoxins were analysed. One bioburden batch was produced to determine if the end product has a microbiological effect on sterilization. **Results**: All process validation batches complied with the product specifications and the process was confirmed to be appropriate for the production of [^{18}F]NaF. **Conclusion**: The new automated production method was taken into clinical use. The new production method is user-friendly, quick and safe from the viewpoint of radiation protection and sterility of the end product.

TP031

Could the image quality for 18F-Choline PET in obese patients be improved by prolonged acquisition time?

B. Olsson[1], J. Hagerman[1], A. Stenvall[2], F. Hedeer[1], H. Almquist[1], C. Hindorf[2], J. Oddstig[2]; [1]Clinical Physiology and Nuclear Medicine, LUND, SWEDEN, [2]Radiation Physics, LUND, SWEDEN.

Aim Patients with prostate cancer are in clinical routine examined with ^{18}F-Choline PET. The administered activity is 4 MBq/kg body weight, maximum 400 MBq, and images are acquired for 2 min/bed position. For patients with a body mass index (BMI) >30 a decreased image quality can be expected. The aim of this study was to investigate if the image quality could be improved with increased acquisition time for patients with BMI>30. **Material and Methods** 21 patients (11patients with BMI>30) were included in the study. The patients received 4MBq/kg (maximum 400 MBq) of ^{18}F-Choline and were imaged on a GE Discovery PET/CT690 60 minutes after administration. The acquisition time for patients <105kg was 2.0min/bed. For patients with a weight over 105kg the acquisition time per bed was prolonged: 105-125kg, 2.5min/bed; 126-150kg, 3.0min/bed. Acquisition in listmode allowed studies for patients with BMI>30 to be truncated to correspond to a study of 2.0min/bed. Three regions of interest were drawn in consecutive sections in the liver. The mean value of kBq/ml and the standard deviation of the kBq/ml were used as input to obtain the SNR (signal-to-noise ratio), calculated as the mean kBq/ml divided by the standard deviation of the kBq/ml. One expert reader scored the image quality. Scores were given by a five grade image quality scale (1=unacceptable image quality and 5=very high image quality). **Results** After increasing the acquisition time per bed for patients with BMI>30 the SNR increased from 11.1 to 12.0 ($p<0.05$) and the score of the image quality increased from 2.7 to 2.9 ($p<0.05$). For patients with BMI<30 the SNR was 14.0 and the score of the image quality was 3.5. **Conclusions** Increasing the acquisition time per bed for patients with BMI>30 will significantly increase the SNR and the scored image quality. However, both the SNR and the scored image quality will still be significantly lower than for a population with a BMI<30.

TP032

Comparison of metabolic activity of metastatic bone lesions assessed in vivo by 18F-FDG-PET/CT and 99mTc-phosphonates bone scan

A. Pietrzak[1], M. Smoleń[1], E. Wierzchoslawska[1], R. Czepczynski[2], W. Cholewinski[1]; [1]Greater Poland Cancer Centre, Poznań, POLAND, [2]Poznan University of Medical Sciences, Poznań, POLAND.

Background: The presence of bone metastases characterizes the advanced stage of cancer disease in over 70% of patients. There is a noticeable conviction that molecular imaging of metastases with 18F- FDG - PET/CT is an important tool in diagnosis and monitoring treatment response as more sensitive, accurate and specific than bone scintigraphy. However, 99mTc-phosphonates bone scintigraphy is still performed as a method of choice in detecting bone metastases . The aim of this study was assess the difference between these two methods in detecting bone metastases with special focus on the comparative analysis of skeletal activity and glucose utilization in metastatic focus. **Material and methods**: 54 patients (26 male and 28 female), mean age of 62±12 (between 34-84 years) with confirmed neoplastic disease of prostate and breast and suspected bone metastases were included in this study. All patients underwent two studies on separate days - bone scan with 99mTc-phosphonates (activity of 740 MBq, WB scan 150 minutes post injection) and 18F-FDG-PET/CT (activity of 370MBq, WB scan 60 minutes post injection) within 4 weeks time. Number of metastatic foci was evaluated and the semiquantitative analysis based of the assessment on tracer uptake within abnormal foci was performed. Analysis was based on comparison of count rate in metastasic and physiologic area (R factor) on bone scan images. The metastatic glucose metabolism was evaluated based on SUVmax value on the corresponding 18F-FDG-PET scans. **Results:** The mean R value within bone metastatic foci was 2.11±0.84 and it was higher but not significant in patients with prostate cancer than in breast cancer patients (3.37±3,66 vs 1.87±0.60; ns). The SUVmax average in whole group was 2.11±0.84 and it was significantly higher in breast patients than in prostate cancer patients (5.61±3.52 vs 4.74±1,76; $p<0.05$) Analysis of correlation showed no significant correlation between R and SUVmax values (correlation coefficient in whole group, prostatic and breast patients was 0.004, 0.11 and 0.16, respectively). 18F-FDG-PET/CT detected more bone lesions in 27 patients than scinitigraphy, however the difference was statistically insignificant. **Conclusion**: No significant correlation was observed between osteoblastic activity and glucose utilization in metastatic foci and this observation validate the independent value of analyzed diagnostic methods and suggests negligible influence of glucose utilization in bone modeling cells.

TP033

The added value of ^{99m}Tc-Nanocolloid SPECT to ^{68}Ga-DOTApeptide PET/CT in pancreatic neuroendocrine tumors (NETs)

L. Pavanello, F. Sciume', M. Zuffante, D. Grigolato, M. Cucca, M. Ferdeghini; AOUI, Verona, ITALY.

AIM: to clarify with ^{99m}Tc-nanocolloid SPECT doubtful lesions at ^{68}Ga-DOTApeptide imaging located in pancreatic tail or perisplenic. Pancreatic NETs, both primary or secondary lesions have usually high uptake of ^{68}Ga-DOTApeptide. There are some areas with elevated uptake of the somoatostatin analog, perisplenic with or without splenectomy, or in the pancreatic tale, which are not NETs but only accessory or atypical spleens. In these cases it could be useful to demonstrate the presence of reticuloendothelial splenic tissue before surgery to exclude NET and to avoid massive surgery. **MATERIALS AND METHODS**: ^{68}Ga-DOTApeptidi PET/CT Philips Gemini TF Big Bore has been used for acquisition scans. We analized 11 patients that presenting suspicious lesions with elevate ^{68}Ga-DOTApeptidi in the pancreatic tail or in the splenic area (generally after splenectomy). All patients underwent PET/CT at one hour post injection in supine. The CT parameters used for the acquisition: 120 KV, 60-80 mAs pitch 0.813, 16x1.5mm collimation, FOV 600. The PET parameters were: 2 min bed position, FOV 576 mm, 1.5/2.5 MBq/kg of 68Ga-DOTApeptidi. In another day we performed a ^{99m}Tc-Nanocolloid SPECT, dispensed activity of 740 MBq, patientin supine position, acquisition started 15min after injection, we acquired planar static images of the abdomen, followed by SPECT. We used a Gamma-camera Marconi Irix 3 heads with parallel holes LEHR collimator and a computer Odyssey Fx. The SPET parameters: orbit circular type, motion step and shoot, matrix 128 x 128 with zoom 1, angular step 3° at 25 secs/step, FOV includes the upper abdomen. In the image reconstruction we applied iterative algorithms (OSEM), in the image reading we gave importance to sagittal, coronal and axial sections, looking for sites of accumulation of the radiopharmaceutical. In addition we performed image fusion between PET/CT and SPET to reach the best clarifying results. **RESULTS**: In 3 of 11 patients studied with these methods we obtained important results which helped the surgeons to decide a personalized approach, sometimes avoiding unnecessary splenectomy because the areas in pancreatic tales or closed to the spleen with elevated ^{68}Ga-DOTApeptidi had also high ^{99m}Tc-Nanocolloid concentration, demonstrating atypical endothelial pattern, which stayed for accessory spleen. **CONCLUSION**: ^{99m}Tc-Nanocolloid SPECT correctly identifies the doubtful lesions located in pancreatic tale or perisplenic, positive with ^{68}Ga-DOTApeptide, which could be accessory spleen.

TP034

Quantification of myocardial glucose uptake for viability assessment in routine clinical setting

M. Mortensen, N. L. Christensen, H. J. Harms, K. Bouchelouche, L. C. Gormsen, L. P. Tolbod; Dept. of Nuclear Medicine and PET-Centre, Aarhus University Hospital, Aarhus N, DENMARK.

Purpose: 18F-fluorodeoxyglucose (18F-FDG) PET has been used for decades to characterize the myocardial metabolism non-invasively. The identification of viable myocardium is important for the patients' further qualification for medical or surgical treatment. So far only static imaging has been used for this purpose clinically, thus only providing relative values for the myocardial glucose uptake (MGU). Our purpose was to implement a protocol to perform dynamic imaging clinically. This way, instead of measuring the relative myocardial glucose uptake, we are able to measure the absolute myocardial glucose uptake. **Method and results**: We have had 31 patients undergo a 60 minute 18F-FDG dynamic viability PET scan. One hour prior to the injection of 18F-FDG, a hyperinsulinemic-euglycemic clamp was performed. A low-dose CT scan was performed prior to the 18F-FDG injection for attenuation correction and anatomical localization. The total duration of the exam was two hours, during which blood glucose (BG) was measured every 10 minutes. Analysis of the scans was done using a Patlak-Gjedde model and an image derived input function in the Cardiac VUer software. MGU was determined as BG x lc x Ki, where a value of 1 was used for the lumped constant (lc) and Ki was the Patlak influx rate. Global MGU ranged from 0,09 umol/g/min to 0,41umol/g/min with a mean of 0,24umol/g/min. **Conclusion**: We were able to perform dynamic viability exams with hyperinsulinemic-euglycemic clamp without prolonging the total examination time; actually the examination time was shortened by 15 min, compared to standard static viability exams. However, on-scanner time was increased from 15 min to 60 min. We did not experience any issues with patient compliance. This tool will be used to assess the added value of the hyperinsulinemic-euglycemic clamp over simple glucose loading.

TP035

The Comparison of the F18 FDG SUV Value of Lesion Depending on the Depth, Size and Time Using Pet Phantom

T. ERTAY[1], I. EVREN[1], M. ALSALEM[2], H. DURAK[1]; [1]DOKUZ EYLUL UNIVERSITY, DEPARTMENT OF NUCLEAR MEDICINE, izmir, TURKEY, [2]DOKUZ EYLUL UNIVERSITY, INSTITUE OF HEALT SCIENCES,DEPARTMENT OF MEDICAL PHYSICS, izmir, TURKEY.

PET imaging is unique technique that describes chemical and metbolic changes in the body. SUV(standart uptake value) is important for differenciating malign and benign lesion. In this study PET/CT imaging studies were performed (Philips Medical Systems GEMINI TF 16) using PET fantom. Fantom as soft tissue, different size spheres (9.5, 12.7, 15.9, 19.1, 25.4, 31.8 mm) as lesion models were used. Imaging was performed at1., 2. and 3. hours. Imaging times were durıng 30 s, 60 s, 120s. F-18 FDG activity concentration was adjusted as 30.4 MBq/mL in the spheres and of 3.8 kBq/ml in the fantom. Fantom was imaged by the same protocol with the patients. The rate of the total radioactivity of the fantom to total weight of fantom was calculated as SUV for each lesion at 1., 2. and 3. hours. Repeated Measure Anova (RMA) and Friedman Pearson Corelation analysis as statistical methods were applied to the data of the experimental study results. The values of the lesion location, size and concentrations were obtained. Display time did not create difference in assessments, lesion size and depth have created significant differences in SUV. In evaluation benign and malign differantiation the size and depth of lesion localization should be considered.

TP036

The utility of PET-CT "breath-hold" protocol in the study of solitary pulmonary nodules. Preliminary results of a small case-series

J. Molina, J. Chinchilla, M. Oporto, S. Rubí, C. Peña, E. Perez, M. Gimenez; Hospital Universitario Son Espases. Departamento de Medicina Nuclear, Palma de Mallorca, SPAIN.

Aim: To evaluate the utility of a short PET acquisition "breath hold" protocol in a better definition of the pathologic FDG uptake in solitary pulmonary nodules (SPN) suspicious of malignancy.Methods: 6 patients with a SPN detected on lung CT were studied: 1 suggestive of primary lung tumor, 1 indeterminate and 4 suspicious of lung metastasis (3 from rectal and thyroid malignancies and 1 from an osteosarcoma). After the standard whole-body (WB) PET-CT acquisition (GE Discovery PET-CT 600) at 50-80 min post-injection, a delayed (77-150 min) lung image centered on the PN was obtained with the "breath-hold" technique: the patients held their breath (apnea) at a medium expiration during the acquisition of a low-dose CT (10 sec) followed by a PET image of 1 bed of 20-30 sec of duration. In three out of 6 patients, an additional PET-CT lung image was acquired immediately after the "breath-hold protocol" with a conventional free respiration protocol (3min/bed). Then, PET images were evaluated on a visual and semiquantitative basis (SULmax). Result: Based on standard WB PET-CT images, 3 SPN in 3/6 patients were reported as visually positive (SULmax between 3-4.7), and all of them showed a marked increase of uptake in the "breath-hold protocol" images (SULmax between 7.9-8.3). In 2 out of these 3 SPN, a delayed respiration-free lung image also showed an increase FDG uptake, though it was less marked than in the "breath-hold protocol" (SULmax between 2.8-5.6). In 2/6 patients neither the standard WB PET-CT images nor the late "breath-hold protocol" images showed any significant uptake in the SPN. In 1 of these 2 patients a very mild positivity was reported on an additional respiration-free delayed PET image (SULmax=1.2). The remaining patient had a SPN suspicious of a thyroid cancer metastasis, and it showed no noticeable changes between the initial WB standard (SULmax=2) and the delayed "breath-hold" image (SULmax=2.2). Conclusion: A short PET-CT "breath-hold protocol" seems useful in the better evaluation of SPN, as significant increase in the uptake value was observed in some patients, without elevating the timing of imagen acquisition. Nevertheless, its clinical role compared to a delayed conventional respiration-free images remains uncertain so far in our small case-series, for which further research are needed.

TP037

Hanging Breast technique scan

D. M. J. Luikel-Hooghof; Spaarne Gasthuis, Hoofddorp, NETHERLANDS.

Introduction: In the comparison of prone MR images with supine PET images the loss of normal landmarks is a limitation. It has been proved that a Hanging Breast technique scan (HB scan) followed by the routine (supine) 18F-FDG PET acquisition, can achieve a better visualization and localization of lesions for patients who have been diagnosed with breast cancer. These results supports the inclusion of Hanging Breast scans in the acquisition guidelines of PET/CT imaging in breast cancer patients. Aim: This poster describes a simple method to make the PET Hanging Breast technique scan, in order to obtain better visualization and localization of the breast tissue for a side-by-side comparison with MRI. Material&Methods: Patients diagnosed with breast cancer, who have small or multiple lesions, are selected to make HB scans. A *Mamma Matrass* is used to position the patient for prone studies and can be placed on the scanner couch. The arms of the patient should be in a upward position, besides the patient head, resting on pillows. The HB study (surview(40 cm.)- lowdose CT- PET(1 bed position)), starts approximately 45 min. after FDG injection, so the FDG is distributed in the patients body. Followed by a routine PET whole body scan and if necessary a diagnostic CT with contrast agent. In this way, the patient is not repositioned between the WB PET and diagnostic CT. Side-by-side comparison with MR images are performed by a nuclear medicine physician. Results: Photos of few case examples that visualize the difference between a prone scan and supine in comparison to MRI. Evaluation: Using the HB method adds 5 minutes to the acquisition protocol, however it proofs useful in lesion visualization and localization due to the corresponding position of the patient. Footnotes: Added value of prone position technique for PET-TAC in breast cancer patients. Esp Med Nucl 2010, 29(5):230-235. Improved breast cancer detection of prone breast FDG-PET in 118 patients. TP038

The Importance on Lesion Detection of Arm Position for PET/CT Imaging

Y. parlak, D. Goksoy, G. Mutevelizde, G. Gumuser, E. Sayit; Celal Bayar University, Manisa, TURKEY.

In many clinical PET/CT studies, PET/CT acquisition is commonly performed with the patient's arms raised above the head. For patients who can not raise arms, PET/CT scan is usually performed arms by the patient's side. For CT, this positioning increases the incidence of beam hardening artifacts and can give rise to striking artifacts on PET images. A 53-year-old male patient with lung cancer underwent PET/CT imaging for restaging in December 2014.The lumbar and thoracic spine metastasis were observed. Therefore, the patient received chemotherapy and PET / CT imaging as response to treatment was taken in December 2015. The PET/CT imaging was performed with the arms positioned patient's side because of his widespread body pain. Approximately 60 min later, a PET/CT examination was obtained from mid thigh to skull base with a Truflight Select PET/CT system (16 slices, 120 kV, 50mAs, Philips Medical Systems, USA). Striking artifacts, evident at the abdomen level, were detected on PET/CT images the arms down. A second image obtained as arms positioned above a rolled blanket. The second scan revealed increased F-18 FDG uptake at T12 (first scan SUV max; 3.7, second scan SUV max; 7.1) and L2 (first scan SUV max; 3.4, second scan SUV max; 4.9) regions. In the first scan, due to the artifact, SUV max were underestimated. When we compare the both PET/CT scan images, new multiple costal metastasis observed and metabolic progression of spine metastasis were detected. Arms down introduce CT artifacts depending on arm position. It is advisable to take notice of the positioning if there is a special region of interest. We suggest that the arm positioning above a rolled blanket is essential especially in the assesment of columna vertebralis, in patients who can not raise arms.

TP039

Impact of Harderian Gland Uptake in the Quantification of ^{18}F-FDG PET Studies in Rat Brain

X. Liang, S. Han, J. Li, L. Wan, Q. Xie; Huazhong University of Science and Technology, Wuhan, CHINA.

Aims: The aim of the study was to evaluate the effect of the high accumulation of radioactivity in the Harderian glands on ^{18}F-FDG-PET quantification of rat brain images. The evaluation was based on Monte Carlo simulation. **Materials and Methods**: Small animal PET was performed with the scanner Trans-PET BioCaliburn LH(Raycan Technology Co., Ltd.). An adult male Sprague Dawley rat weighing 340 g was injected with ^{18}F-FDG(14.8MBq), and taken a 10 min static scan centered over the brain 70 min after ^{18}F-FDG injection. After scanning, the PET image was reconstructed by using 3D ordered subsets expectation maximization (OSEM) method. Images were analyzed using AMIDE to quantify the tissue activity concentration (Bq/ml) and standardized uptake values (SUVs) over the following regions of interest (ROIs): olfactory bulb, cortex motor, cortex somatosensory, cortex visual, caudate putamen, thalamus, midbrain and Harderian glands. In the Monte Carlo simulation study, we used several phantoms modeling according to the rat imaging data to represent the ROIs calculated above. The data were acquired with and without the Harderian glands phantom using the same scanner and acquisition protocols as the animal imaging. The methods of reconstruction and quantitation were also the same as the animal study. We compared the ratio of the same ROI in two kinds of background to evaluate the effect. **Result**: The animal study showed that Harderian glands had high accumulation of ^{18}F-FDG(ratio of ROI-gland/ ROI-other was 1.64- 2.12). The simulation study revealed that ROIs in brain had different values with and without Harderian glands phantom and the ratio of each other also had changed. Among them, both the ratio of cortex somatosensory and caudate putamen to the whole brain are of significant difference(p<0.05). **Conclusions:** The high accumulation of radioactivity in the Harderian glands has an effect on the ^{18}F-FDG-PET quantification of rat brain images. It should be considered in the quantification of brian, especially in the quantification of cortex somatosensory and caudate putamen.

TP040

Positron-Emission Tomography In The Diagnosis Of Solitary Pulmonary Nodules: Relation Of The SUV Measurement With The Histopathologic Types Of Lung Cancer And Clinical Outcome

M. Pombo Pasín, Ms., M. Garrido Pumar, V. Pubul Núñez, A. Bejarano García, J. Cortés Hernández, I. Domínguez Prado, A. Golpe Gómez, Á. Ruibal Morell; Clinic Universitary Hospital of Santiago de Compostela, Santiago de Compostela, SPAIN.

OBJECTIVE: The Positron Emission Tomography (PET) is a useful tool for the diagnosis of the nature of pulmonary nodules. The aim of this study is to stablish the possible influence of the semiquantitative valoration in the PET of solitary pulmonary nodules (SPN) by measuring the Standard Uptake Value (SUV) with the different histopatological types of lung cancer, and with the posterior outcome of the patiens. METHODS: From 334 patiens that permormed a PET for the characterization of a SPN, we selected 213 that had positive visual uptake in PET. We used the higher value of SUV in the nodule (SUVmax). The final diagnosis of the nodule came from histopathological analisis or radiological follow-up in cases with low risk of malignancy. The histopathological classification of the pulmonary nodules included benign nodules, squamous-cell carcinoma, adenocarcinoma, neuroendocrine carcinoma, small-cell carcinoma, methastasis from extra-pulmonary cancer, and other types/unclassified lung cancer. Patiens were followed after the PET and clinical otcome data included cancer recurrence, methastatic disease and exitus. Statistical analyses included ANOVA and t-student tests. RESULTS: Median SUV was significantly higher in squamous cell carcinoma (Median SUV 13.6 [10-19]), followed by small cell cancer (Median SUV 12.8 [9.2-16.4]), the other type/unclassified lung cancer (Median SUV 10.2 [7.5-15.7]), neuroendocrine cancer (9.5 [6.7-13.4]), methastasis (8.3 [4,3-10.9] and adenocarcinomas (7,4 [3.9-11.35]). Benign nodules had the lower SUV values (Median SUV 3.2 [2.2-4.6]) ANOVA/Kruskal-Wallis p <0,001. In the posterior outcome, higher SUV values showed relation with recurrence (11.3 ±5.8 vs 7.2 ±6.4; p 0.003), methastasis (10.5±7.1 vs 7.2±5.7; p 0.001) and exitus (10.4±6.5 vs 6.6±5.3; p <0.001). CONCLUSION: SUV values had significant relation with histopatological types, specially stablishing differences between bening and malignant lesions. From malignant nodules, squamous-cell carcionas showed the highest SUV values, and adenocarcinomas were the lesions with lower SUV values.

TP041

^{18}F-Choline PET/CT *vs* Bone Scintigraphy for bone metastasis detection in patients underwent radical prostatectomy and radiotherapy.

I. Baeta[1], H. Delgado[1], R. Oliveira[1], L. Vieira[1], E. Carolino[1], M. Vazquez[2], J. Alonso[2]; [1]Escola Superior de Tecnologias da Saúde de Lisboa, Lisboa, PORTUGAL, [2]Departamento de Medicina Nuclear MD Anderson Cancer Center, Madrid, SPAIN.

AIM: Prostate Carcinoma (PC) is one of the most common malignancies pathologies in male, with high recurrence rates even after radical prostatectomy or radiotherapy. Positron Emission Tomography/Computed Tomography (PET/CT) with ^{18}F-Choline and Bone Scintigraphy (BS) are currently used to detect PC recurrence in addition to the information provide by biochemical analysis, biopsy and other image modalities. The aim of the present study is to evaluate and compare both imaging technics, PET/CT and BS, for the detection of bone metastasis. **MATERIAL AND METHODS**: It was performed a

retrospective analysis of 42 ^{18}F-CholinePET/CT studies and BS studies in 42 patients underwent radical prostatectomy and/or radiotherapy with evidence of biochemical recurrence. The conclusions of imaging and pathologic studies results were obtained through the patient history and medical reports of PET/CT and BS. A database was formulated with the collected data in SPSS (Statistical Package for the Social Sciences), version 22.0. Spearman statistical test was applied, as also many other correlations related with the number of lesions detected and PSA values. **RESULTS**: In 35.7% of the population bone metastatic lesions were detected by BS. Otherwise, only 30.9% of the population presents evidence of bone metastasis in PET/CT scan. After being applied Spearman statistical test, a percentage of 64.2% were obtained in terms of an equal number of detected lesions in both image techniques. Concordant findings between PET/CT and BS occurred in 64.2% of the population. In addition, a low-intensity positive correlation was found between the number of lesions detected by BS and PET/CT (r_s=0.448, p=0.003). In this study, BS detected more lesions than PET/TC in 19.04% of cases. **CONCLUSIONS**: Both image techniques are useful for the detection of bone metastasis caused by PC. In the present study, BS revealed more efficiency in the detection of bone metastasis than PET/CT. **Keywords**: Radical Prostatectomy, PSA, Biochemical recurrence, ^{18}F-Choline PET/CT, Bone Scintigraphy.

TP042

Salivary glands uptake from FDG PET/CT in the patients with IgG4-related disease

Y. Chen, Y. Wu, H. Wang, R. Yen, C. Ko, M. Cheng; National Taiwan University Hospital, Taipei City, TAIWAN.

Aim: The immunoglobulin G4-related disease (IgG4-RD) is associated with elevated serum IgG4 concentration and commonly involves the salivary glands. However, FDG activity from salivary glands in healthy subjects and patients diagnosed with IgG4-RD have not been compared. This study aims to establish clinical useful PET indices in identifying patients diagnosed with IgG4-RD affecting the salivary glands. Materials and Methods: From August 2008 to August 2014, 47 patients with IgG4-RD prior to steroid therapy and 134 health volunteers were enrolled. Images of the parotid and submandibular glands obtained using FDG PET/CT were analyzed. Parotid and submandibular glands were measured for standardized uptake values by placing volumes of interest (VOI) in the salivary glands seen in the coregistered CT images. All placed VOIs were corrected for blood pool activity. The results were also correlated with serum IgG4 level. Results: IgG4-RD group showed higher SUVmax in salivary glands compared with healthy group (parotid: 2.44 ±1.12vs 2.01±0.43; submandibular: 3.19±1.78 vs. 2.63±0.49 , both P<0.05), regardless whether symptoms of sialadenitis were present. The serum IgG4 level showed better correlation with SUVmax of submandibular glands than with parotid glands (r=0.52 and 0.32, respectively; P<0.05) while there was no significant correlation with serum IgG. IgG4-RD group with submandibular SUVmax≧ 2.63 (mean value from the healthy group) had higher serum IgG4 level than SUVmax < 2.63 (1590.72 mg/Dl vs. 592.43 mg/Dl, P<0.05). Conclusion: Salivary glands uptake, especially submandibular glands, were significantly higher in patients with IgG4-RD than in healthy subjects, regardless whether symptoms or signs of IgG4-RD sialadenitis was present.

TP043

Influence of smoking on ^{18}F-Choline uptake in normal lungs

A. L. L. Canudo, B. Freitas, D. Dantas, V. Santos, S. Chaves, C. Oliveira, J. Castanheira, D. Costa; Champalimaud Foundation, Lisboa, PORTUGAL.

Introduction Choline is a phosphatidylcholine precursor, necessary for the cell membrane synthesis. Malignant tumors show increased synthesis of cell membranes, reflecting cellular proliferation. Malignant tissues show high uptake of ^{18}F-Choline compared to normal tissues. This enables the identification and localization of malignant lesions. Unfortunately ^{18}F-Choline uptake is not specific to cancer cells and can occur in granulomatous tissue. It is possible that reduced ^{18}F-Choline uptake may be observed in other diseases with reduced viability and/or function of the phospholipid cell membranes **Objective** To investigate the relationship between tabacco smoking and ^{18}F-Choline lung uptake in individuals with no known lung disease Material and methods Retrospective analysis of 25 consecutive patients referred for staging and restaging of prostate cancer without known lung disease. According to the clinical history, patients were divided into 3 groups: smokers (S=8), never-smokers (nS=8) and former, but no more, smokers (fS=9). VOIs (28mm diameter) were drawn in the left (upper and lower lobes) and right lungs (upper, middle and lower lobes) in 3 consecutive axial, sagittal and coronal slices of the whole body images acquired 15minutes after injection. Measured maximum and average SUVs were compared between the three groups. **Results** There were no differences in the measured SUVs for the different lobes within each study group. However, it was interesting to note that SUVs in the lower lobes showed the highest uptake of ^{18}F-Choline in all 3 groups. Despite no statistically significant differences, we found the lowest SUVmax (1.36) in the group S (smokers). The fS group revealed SUVmax of 1.92 and the SUVmax (2.11) was recorded in the nS (never-smokers) group. **Discussion/ Conclusion** This quantitative mapping of pulmonary ^{18}F-Choline lung uptake in patients without a known pulmonary disease demonstrates greater uptake of ^{18}F-Choline in the lower lobes, most probably due to physiological pattern. The lower ^{18}F-Choline uptake in the lungs of smokers may be due to reduction of metabolic viability and/or function (phospholipid) of the alveolar-capillary membranes. Ongoing work is underway to better understand the relationship between tabacco smoking and lower ^{18}F-Choline lung uptake.

TP044

PET/MRI in clinical routine: initial experience in Brazil

S. A. Nogueira, T. Vitor, K. M. Martins, M. F. Barboza, A. F. Thom, J. Wagner; Hospital Israelita Albert Einstein, São Paulo, BRAZIL.

PET/CT is already an established imaging technique in various areas of oncology, as well as in neuroimaging. Recently, the integration of positron emission tomography (PET) and magnetic resonance imaging (MRI) has been ongoing research. Due to their ability to obtaining anatomical, functional and metabolic information in a single examination, this combination provides significant advantages over PET/CT such as less ionizing radiation and better soft-tissue contrast that facilitate the differentiation between normal tissue and disease. In September 2015 we received the first full integrated PET/MRI scanner in Brazil. The aim of this study is describe the first clinical PET/MRI cases and discuss some of the areas of PET/ MRI imaging application and its relevance in the Albert Einstein Hospital clinical routine. The scans were performed in a Biograph mMR PET/MRI scanner (Siemens Medical Solutions, Erlangen, Germany). Cases described herewith include whole body, abdomen, pelvis, hip, prostate, chest, breast, brain and head and neck examination performed with ^{18}F-FDG, ^{18}F-FNa, ^{68}Ga-DOTATATE or ^{68}Ga-PSMA-11. In this study the protocols used the main MRI sequences for association with PET acquisition, looking for the shortest time and better resolution in both methods. The majority of our studies were indicated as a complement to PET/CT imaging. The scan time varied 30 - 90 minutes, resulting in high anatomical resolution and excellent soft tissue contrast. Despite the complexity of its operation, PET/MRI is proving to be a valuable tool in clinical practice.

TP045

Variations in the Indications of Myocardial Perfusion Gated-SPECT After the Inclusion of a Coronary-CT In Clinical Practice

B. PEREZ LOPEZ, R. RUANO PEREZ, M. DIEGO DOMINGUEZ, A. DIEGO NIETO, L. G. DIAZ GONZALEZ, F. GOMEZ-CAMINERO LOPEZ, P. L. SANCHEZ FERNANDEZ, M. P. TAMAYO ALONSO;

HOSPITAL UNIVERSITARIO CLINICO DE SALAMANCA, SALAMANCA, SPAIN.

Objetive: To evaluate changes in number and indications of myocardial perfusion gated-SPECT after the inclusion of coronary CT in diary clinical practice in our hospital in April 2015. **Methods:** Patients from July-2014 to December-2015 were classified in two groups: A-group : pre CT-CR and B-group: post CT-CR. We considered as variables: amount of patients, gender, age, hospitalized status, indication (diagnosis, ischemia severity, ischemia follow-up, postinfarction, post- unstable angina pectoris, viability, incomplete PTCA) and gMPS result. Statistical analysis was made with SPSS, signification level considered was p<0.05. **Results:** A-group: 572 patients (401 males, 171 females), average age 69.4 years old, 15.6% hospitalized. B-group: 581 patients (392 males, 189 females), average age 69.1 years old, 15.1% hospitalized. There were not statistically significant differences (p>0.05) between amount of patients, propotion of patients hospitalized, age or gender. Regarding indication for gMPS in males, there was a reduction in ischemia follow-up studies (from 20.2% to 12.8%), viability studies (5.2% vs 2.6%) and postinfarction (4.4% vs 1.8%), differences statistically significant (p=0.000). On the other hand, there was an increase in post-PTCA incomplete (1.2% vs 7.3%), diagnostics and evaluating ischemia severity (67.8% vs 75.2%). Furthermore, there were not statistically significant differences between the other indications. When evaluating gMPS result there was a significant rise in normal studies, in males from 36.1% to 50.1% (p=0.000); and a non-significant rise in females: 47.3% vs 54.2% (p=0.192). However when ischemia was detected the proportion of moderate to severe ischemia was similar (p=0.294). **Conclusion**: Inclusion of coronary CT in clinical practice has not changed the amount of g-MPS studies,however there has been an increase in the number of normal gMPS. There were variation in indications of gMPS in males, mainly in myocardial viability studies and in those patients with recent heart attack.

TP046

The added value of SPECT/CT at Whole body bone scintigraphy performed for staging in detecting skeletal metastasis from prostate cancer

K. Schouten-Stadnik, A. van Dongen, M. Lakeman; Department of Nuclear Medicine, Westfriesgasthuis, Hoorn, NETHERLANDS.

Introduction: Prostate cancer is the most common cancer among men in The Netherlands. Prostate cancer often metastasizes to bone. The malignant cells from the prostate spread mainly to bones in the hips, pelvis and spine. Bone metastases lead frequently to bone pain and pathological fractures. Early detection of metastatic bone disease is critical for accurate staging and can help determine the most effective treatment strategy. Whole body bone scintigraphy is a standard technique used in many hospitals to detect bone metastases. Aim: The aim of this study was to investigate the additional value of Single Photon Emission Computed Tomography with CT (SPECT/CT) at each first Whole bone scintigraphy performed for staging, in detecting skeletal metastasis from prostate cancer. **Materials en methods**: This study is based on data from 40 patients with prostate cancer (mean age 74 years) who underwent ^{99m}Tc-hydroxymethane diphosphonate (HDP) Whole body bone scintigraphy and SPECT/CT of the lumbar spine and pelvis between march 2015 and march 2016. The images were evaluated by nuclear medicine physician. The reviewer used 4 - points diagnostic scale (1, malignant; 2, probably malignant; 3, benign; 4, probably benign) to score each lesion with abnormal tracer uptake. All lesions were double analyzed and scored. The first time using only the planar bone images and the second time the SPECT/CT images. **Results**: The analysis of the planar images showed that reviewer rated 10 % of lesions as malignant, 18% as probably malignant, 31% as benign and 41% as probably benign. The analysis of the SPECT/CT images showed that reviewer rated 18 % of lesions as malignant, 5% as probably malignant, 70% as benign and 7% as probably benign. **Conclusion**: The addition of SPECT/CT at first staging Whole bone scintigraphy improved higher accuracy in detecting skeletal metastasis from prostate cancer. Furthermore, using of SPECT/CT resulted in a substantial reduction of equivocal bone lesions.

TP047

Characteristics of single- and dual-energy images with thallium-201 myocardial IQ-SPECT-CT system

T. Shibutani[1], M. Onoguchi[1], H. Yoneyama[2], T. Konishi[2], S. Matsuo[3], K. Nakajima[4], S. Kinuya[4]; [1]Department of Quantum Medical Technology, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, JAPAN, [2]Department of Radiological Technology, Kanazawa University Hospital, Kanazawa, JAPAN, [3]Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, JAPAN, [4]Department of Biotracer Medicine, Graduate School of Medical Science, Kanazawa University, Kanazawa, JAPAN.

Objectives: Although dual-energy (DE) acquisition with conventional thallium (Tl)-201 myocardial perfusion SPECT has several advantages such as improved attenuation of the inferior wall and increased acquisition counts, characteristics of IQ-SPECT have not been fully evaluated. The aim of this study was to evaluate the difference of characteristics between single-energy (SE) and DE imaging using Tl-201 myocardial IQ-SPECT.Methods: Myocardial phantoms created in this study were normal and abnormal patterns simulating infraction of the inferior wall. SPECT scans were acquired with a Siemens dual-head SymbiaT6 SPECT-CT scanner equipped with multifocal SMARTZOOM collimators. Energy windows were set on 70 keV ±10% for SE, and additional 167 keV±15% for DE. SPECT images were reconstructed using ordered subset conjugate gradient minimization method using order 3 and iteration 13, and a Gaussian filter (FWHM 9.6 mm) was used as a post filter. Three kinds of myocardial images were created; namely (1) without scatter and attenuation correction (NC), (2) with attenuation correction (AC), and (3) with both attenuation and scatter corrections (ACSC), while DE image with ACSC could not be created due to system limitation. The SE and DE images were assessed visually using a five-point (1 worst to 5 best) scale and quantitatively assessed with a 17-segment polar map. Results: The average scores of the SE and DE images for the normal myocardium were 3.9 and 4.4 for NC, and 4.5 and 4.7 for AC, respectively, and that of the SE image of ACSC was 3.4. Although the defect score was more than 4 for both of the SE and DE images with NC and the SE images with ACSC, the DE image with AC showed a significantly lower score than the SE image. Furthermore, the percentage uptake values of the SE and DE image in the inferior wall (segments 4 and 10) were 50% and 55% with NC, 69% and 77% with AC, respectively, and 65% for the SE image with ACSC. The SE image with ACSC showed high defect detectability; however, the visual score of normal myocardium was the lowest. Conclusion: The DE image with NC can improve attenuation of the inferior wall. DE image with AC, however, showed low defect detectability. Thus, myocardial image with AC should be SE rather than DE. Furthermore, while SE image with ACSC can detect the defect, it needs to be carefully interpreted, including the possibility of artificial inhomogeneity even in the normal myocardium.

TP048

Inter-Operator Variability in Assessing and Planning Bone SPECT/CT

A. C. A. Gomes Moura, D. G. Sharp, A. Nunes, F. Ul-Hassan, V. Lewington; Guy's and St Thomas NHS Foundation Trust, London, UNITED KINGDOM.

Background Published guidelines for ^{99m} Tc MDP bone SPECT/CT scanning lack specific information regarding the optimal length of time per frame, mainly due the variety of acquisition systems and reconstruction software available. Although our local protocol stipulates acquisition parameters according to the body area under investigation, there is scope for individual operators to tailor procedures to suit individual patients' circumstances. We studied

differences in inter-operator SPECT CT practice by asking 5 experienced operators to define the acquisition parameters they would use when provided with detailed information regarding patients referred for SPECT/CT scan. **Method** 10 Whole body bone scans and accompanying static images were shown to 5 experienced SPECT/CT operators. Each data set included relevant clinical information such as patients' age, comorbidities, mobility, body mass index, analgesic requirements, urinary continence, and mental state. Operators were asked to state the time per frame that they would use for each SPECT/CT scan and how this varied from the department protocol. The scans chosen represented the 5 most commonly scanned anatomical areas. **Results** For head and neck scans, there were some inconsistencies between operators' responses with respect to patient specific factors such as claustrophobia. Lower variability was observed in adapting protocols for limb extremity and pelvic scans but higher inter-operator variability was recorded for spine SPECT/CT. Factors contributing to these decisions were analysed. **Conclusion** Inter-operator variability in acquiring bone SPECT/CT images reflects operator experience, interpretation of clinical information provided, and adaptation to patient's condition. While our study confirms the value of specific protocols to support decision making, it also demonstrates the importance of clinical judgement in optimising bone SPECT/CT scan acquisition.

TP049

The importance of SPECT/CT for abdominal blood pool scintigraphy: a case study

M. Koehner, C. Rischpler; Rechts der Isar, Munich, GERMANY.

Aim: The abdominal blood pool scintigraphy is a well-established method for localizing the source of blood loss in a patient. Although other methods like CT and Ultrasound have proved themselves as good and fast methods for finding severe bleedings the abdominal blood pool scintigraphy is the most sensitive method of finding small bleedings. The newer technology of SPECT/CT imaging has been able to further increase the sensitivity of the method as well as to provide better localization. Method: With a case study of a patient who was suffering of chronic blood loss, the importance of the abdominal blood pool scintigraphy for the clinic routine could be demonstrated. The patient had been undergoing several colonoscopies, angiograms as well as a camera colonoscopy with the aim of finding the source of his blood loss. All of those methods did not show the actual source of the bleeding. The patient underwent an abdominal blood pool scintigraphy in order to find the source of the bleeding problem. Dynamic images and planar images were acquired as well as SPECT/CT's. Findings: The planar images as well as the dynamic images themselves proved inefficient in finding the source of bleeding. SPECT images alone were able to show a bleeding in the upper intestines but only the utilization of SPECT/CT allowed the exact localization.

TP050

Multimodal Neurophysiology in presurgical evaluation of Epilepsy at the University Hospital in Lund, Sweden

A. Melin, **I. L. Erlandsson**; Neurofysiologiska kliniken, Lund, SWEDEN.

Purpose: Presenting neurophysiological tests used for epilepsy surgery evaluations preformed at the Department of Neurophysiology at the University Hospital in Lund, Sweden. Metods: • Electroencephalography (EEG) • Extra cranial video-EEG (EvEEG) • Single-photon emission computed tomography (SPECT) • Subtraction ictal SPECT co- registered to MRI (SISCOM) • Invasive intracranial video-EEG (IvEEG) • Co-registration: localization of intracranial electrodes using CT, co-registered to MRI • Electrical Brain Stimulation (EBS) Results: To illustrate the methods, we are using a case of a 16 year old female who has had seizures with feelings of discomfort and fear since age 12. For identifying the epileptogenic focus we preformed EEG, EvEEG, SPECT, SISCOM, IvEEG and EBS. Routine-EEG was normal, EvEEG showed in 50 % of the seizures low voltage rhythmic theta activity over the right hemisphere, otherwise no typical epileptic activity. At SPECT examination Tc^{99m}-HMPAO was injected, 7 sec after clinical seizure onset. SISCOM showed a hotspot located in the right Cingulate gyrus. MRI was initially interpreted normal, after SISCOM, MRI was re-examinated and a cortical lesion was found close to the SISCOM hotspot. Invasive electrodes where placed. Co-registration with MRI showed strip-electrodes over medial interhemispheric fissure and depth electrode in the right medial frontal hotspot. IvEEG revealed epileptic seizure activity in depth electrode 5 sec before clinical seizure onset, spreading after 10 sec to one of the strips. Interictal activity and high frequency discharges were seen in the depth electrode. EBS, stimulating depth electrodes induce the same aura as the patient experience at spontaneous seizures. Surgery was performed and a volume including the hotspot was removed. PAD showed focal cortical dysplasia type. The girl has been seizure free since 3 months. Conclusion: SISCOM and intracranial electrodes co- registered to MRI is an important tool in presurgical epilepsy evaluation.

TP051

Preoperative localisation of hyperfunctioning parathyroid glands; A preliminary comparison between ^{99m}Tc-sestaMIBI / ^{123}I scintigraphy and ^{18}F-fluorocholine PET/CT

E. Jansen, M. Wondergem, F. M. Van der Zant, R. J. J. Knol; Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS.

Introduction/Aim Preoperative localisation of hyperfunctioning parathyroid glands is essential before minimally invasive surgical extirpation. Recent literature suggests improved sensitivity of ^{18}F-fluorocholine PET/CT over the conventional combined ^{99m}Tc-sestaMIBI / ^{123}I parathyroid scintigraphy. Other important advantages of ^{18}F-fluorocholine PET/CT include that it does not require withdrawal of certain medications, sometimes needed for up to 2 months prior to conventional scintigraphy, while the whole procedure can be completed in merely 2 hours instead of 2 days, which is typical for conventional parathyroid scintigraphy protocols. **Patients and Methods** Two cohorts were compared. Cohort A included 56 patients who underwent ^{99m}Tc-sestaMIBI / ^{123}I scintigraphy and cohort B included 50 patients who underwent ^{18}F-fluorocholine PET/CT for detection of hyperfunctioning parathyroid glands. Both cohorts were compared regarding to sensitivity of the scan procedure, number of patients that went for surgical intervention, pathological findings after surgery and effects of surgery on PTH and serum calcium levels. **Results** In cohort A and B respectively, 44.6% and 66.0% of the scans showed a parathyroid adenoma, 0.0% and 2.0% showed hyperplasia, 26.8% and 14.0% were negative and 28.6% and 18.0% were equivocal. For cohort A 15/56 patients underwent surgery, while preliminary analysis of cohort B revealed that 20/40 patients were found suitable for surgery. For 10/50 patients decisions on further treatment were not made at time of evaluation. In cohort A pathological findings showed a parathyroid adenoma in 10/15 (66.7%), in 3/15 (20.0%) hyperplasia and in 2/15 (13.3%) no parathyroid tissue was found. In cohort B 12 patients had been operated at the time of the preliminary evaluation. In 9/12 (75.0%) patients a parathyroid adenoma was found while in 3/12 (25.0%) patients a normal parathyroid was detected. In cohort A normalisation of serum PTH and calcium was found in 12/15 (80.0%) of the patients operated, in cohort B normalisation was found in 12/12 (100%) of the patients. **Conclusion** In the present data, ^{18}F-fluorocholine PET/CT localises more hyperfunctioning parathyroid glands than ^{99m}Tc-sestaMIBI / ^{123}I scintigraphy. The preliminary analysis of cohort B indicates that already more patients went for surgery after ^{18}F-fluorocholine PET/CT in whom normalisation of serum PTH and serum calcium was detected more frequently. These data will be updated upon completion of all surgical procedures.

Clinical Application Specialist

W. Lin[1], **C. Lee**[2], Y. Liang[3], Y. Hsu[1]; [1]Nuclear Medicine department of Jan-Ai Hospital DaLi Branch, Taichung, TAIWAN, [2]Philips Health

Systems, Taipei, TAIWAN, [3]PET Center of Jan-Ai Hospital DaLi Branch, Taichung, TAIWAN.

1.Introduction A pheochromocytoma is a rare, catecholamine-secreting tumor and paragangliomas arising from neural crest tissue is meant extra-adrenal tumor. Because of excessive catecholamine secretion, pheochromocytomas may precipitate life-threatening hypertension or cardiac arrhythmias. If the diagnosis of a pheochromocytoma is overlooked, the consequences can be disastrous, even fatal however, if a pheochromocytoma is found, it is potentially curable. Approximately 10% of pheochromocytomas and 35% of extra-adrenal paragangliomas are malignant. Only the presence of metastases defines malignancy. The clinical manifestations of a pheochromocytoma result from excessive catecholamine secretion by the tumor. Tumors in patients with germline mutations of succinate dehydrogenase subunit genes (SDHB and SDHD), which cause familial paraganglioma, principally produce dopamine ***2. Case Report*** A 39-year-old man without hypertension or heart disease complained with left flank pain for several months. He visited to ER and CT showed left huge tumor and several bony metastasis was noted, bone scan also showed radioactivity increased of upper and lower T-spine and left shoulder area. With surgery recession, radiotherapy and chemotherapy, the tumor was confirmed paraganglioma which invades to renal parachyma. Before surgery dissection, the imaging study was performed as description, CT study showed visualized 15x12x12cm hypodense mass in left upper kidney with central necrosis and multiple bony metastases at T-spine Bone scan showed high radioactivity in left humeral head, T4-T5, T10-T11, and right femoral neck. (In OP finding: Multiple, diffuse metastatic tumor almost over both the thoracic and lumbar spine and pathologic fracture and severe spinal cord compression at T4-5 and T9-11) In 2016 Feb, CT and Bone Scintigraphy were highly suggested a new bony metastasis in left femoral neck, the patient was arranged the F-18 FDG PET scan for further evaluation. The FDG PET showed multiple FDG-avid bony foci were noted, at right C2, right 10th rib, the coccyx and left proximal femur and an extra-ordinary brain focus at right hemisphere. ***3. Discussion*** I-131 MIBG is frequently used in cases of familial pheochromocytoma syndromes, recurrent pheochromocytoma, or malignant paragangliomas. But with shortage of I131-MIBG in Taiwan, the diagnosis of pheochromocytomas and paraganglioma is still depended on CT and scintigraphy for evaluation. FDG PET wholebody scan with higher specificity and sensitivity will be the most valuable tool for diagnosis pheochromocytomas and paraganglioma with metastasis. With genetic study development in pathology, PET/CT will become approaching 100% sensitivity in SDHB-related metastatic paraganglioma and excellent in detecting primary, recurrent and metastases pheochromocytomas and paraganglioma.

Establishment of a simple simultaneous production of two different ^{11}C radiopharmaceuticals using two precursors in one reactor and HPLC

J. Lee, Y. Cho, Y. Lee, H. Park, C. Yoon, Y. Lee, H. Lee, J. Kim, K. Kang, J. Jeong; Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.

Aim: We have reported a method for producing two ^{11}C radiopharmaceuticals simultaneously using two HPLC loops and HPLC systems in 2012. In order to simplify this method further, we tried to label two different precursors by reacting with $[^{11}C]CH_3I$ in a single HPLC loop and purify the resulting products using one HPLC system in the present study. Materials and Methods: $[^{11}C]CO_2$ was produced by a PETtrace cyclotron, converted to $[^{11}C]CH_4$ and $[^{11}C]CH_3I$ in a TRACERlab FXC Pro successively. Precursors of flumazenil (0.3 mg) and PBR28 (1 mg) were dissolved in N,N-dimethylformamide (30 μL) and dimethyl sulfoxide (150 μL), respectively. And then 1 M potassium hydroxide solution (1.5 μL) and sodium hydride (7 mg) were added as bases. The mixture was vortexed and loaded into a HPLC loop (2 mL). Prepared $[^{11}C]CH_3I$ as described above was delivered to the HPLC loop for 5 min and then the reaction mixtures was purified using one semi-preparative HPLC column (Waters, XTerra Prep RP18, 10 μm, 10 × 250 mm). Each $[^{11}C]$flumazenil and $[^{11}C]$PBR28 peak was collected into a glass vial. Results: The syntheses were performed 5 times. The retention times of $[^{11}C]$flumazenil and $[^{11}C]$PBR28 were 11.1 ± 0.75 and 22.8 ± 0.78 min, respectively (Figure 1). The non-decay corrected yields of $[^{11}C]$flumazenil and $[^{11}C]$PBR28 were 25.2 ± 4.3% and 16.3 ± 3.3%, respectively. Radiochemical purities of both of the compounds were higher than 95%, and no cross-contamination by each compound was observed. The specific activities of $[^{11}C]$flumazenil and $[^{11}C]$PBR28 were 221 ± 102 and 509 ± 346 GBq/μmol, respectively. Conclusion: We established a straightforward preparation system of $[^{11}C]$flumazenil and $[^{11}C]$PBR28 simultaneously using one synthesis module and one HPLC system.

Preliminary evaluation of ^{89}Zr-Labeled Affibody for PET imaging of Tumors Expressing HER2

Y. Xu[1], Z. Bai[2], D. Pan[1], L. Wang[1], J. Yan[1], R. Yang[1], M. Yang[1]; [1]Jiangsu Institute of Nuclear medicine, Wuxi, CHINA, [2]Nanjing Medical University, Nanjing, CHINA.

Aims: Human epidermal growth factor receptor 2 (HER2) is a biomarker in diagnosis, therapy and prognosis of cancers. PET imaging with HER2 specific agents could provide non-invasive assessment of target expression level with better sensitivity and accuracy. Affibody is a new type of imaging probes because of high affinity and rapid blood clearance. ^{89}Zr exhibits a long half-life, which allows for tracking and quantification biological processes for longer periods. Herein, the ^{89}Zr-labeled modified HER2 affibody, ^{89}Zr-DFO-MAL-CGGGRDN-ZHER$_{2:342}$ (denoted as ^{89}Zr-DFO-MAL-MZHER), were prepared and its biological properties were preliminarily evaluated in tumor models using microPET imaging. *Materials and Methods:* MZHER was conjugated with MAL-DFO and then labeled with ^{89}Zr under mild reaction conditions. The stability of ^{89}Zr-DFO-MAL-MZHER was also determined in PBS and human serum. The HER2 targeting potential and pharmacokinetic profile of the ^{89}Zr labeled tracer were analyzed by in vivo studies in SKOV-3 human ovarian cancer models via small animal PET. *Results:* ^{89}Zr-DFO-MAL-MZHER can be efficiently produced within 20 min.The non-decay corrected yield was greater than 90% and the radiochemical purity was more than 95%.The tracer was stable in PBS and human serum after 120min in vitro incubation. Excellent tumor-to-background contrast were clearly observed at 30min p.i. and kept even at 48h after administration. The uptake values in SKOV-3 cancer xenografts ranged from 6.29 ±1.20 %ID/g at 30min p.i to 3.41±1.31 %ID/g at 48h p.i. respectively. The tumor to muscle uptake ratios were 12.80±3.23 and 30.91±11.56 at the corresponding times. Co-injection of the excess non-labeled ZHER with the probe specifically reduced the SKOV-3 tumor uptake to 1.75±0.53 %ID/g at 1h postinjection. Besides, the tracer showed low liver uptake (~1%ID/g) and high kidney accumulation at the early time points (125.47±23.16 %ID/g at 30min p.i.) then dropped significantly afterward (72.56±15.16 %ID/g at 48 h p.i.), indicating rapid renal clearance. *Conclusion:* ^{89}Zr-DFO-MAL-MZHER is a potential probe for monitoring HER2 receptor expression. Favorable preclinical data showing specific and effective tumor targeting suggest that the further trial should be undertaken to test its diagnostic utility in clinical imaging. ***Research Support:*** This work was supported by National Natural Science Foundation (51473071,81472749,81401450,21401084, 21504034), Jiangsu Province Foundation (BE2014609), Health Ministry of Jiangsu Province Fund (RC2011095,Q201406 and H201529), 333 Project of Jiangsu (BRA2015476).

Excitation function evaluation of ^{63}Zn producing reactions by charged particles

M. Rostampour[1], S. Hamidi[1], **M. Aboudzadeh Rovais**[2], M. Sadeghi[2]; [1]Arak University, Arak, IRAN, ISLAMIC REPUBLIC OF, [2]Nuclear

Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: The ^{63}Zn is a short lived beta emitter, which is very suitable for using in PET. Cyclotron based methods of ^{63}Zn production are investigated by many researchers. There are seven principal routes to produce ^{63}Zn at cyclotrons: ^{63}Cu(p,n)^{63}Zn, ^{65}Cu(p,3n)^{63}Zn, ^{nat}Cu(p, n)^{63}Zn,^{64}Zn (p, n+p) ^{63}Zn, ^{63}Cu(d,2n) ^{63}Zn, ^{62}Ni(α,3n)^{63}Zn, and ^{60}Ni(α,n)^{63}Zn.In the radioisotope production procedure, the nuclear reaction data are mainly needed for respective optimization of production rates. This process involves a selection of the projectile energy range that will maximize the yield of produced isotopes and minimize the radioactive impurities. This study was intended to give a suitable reaction to produce ^{63}Zn via cyclotron. **Method**: In the present study, excitation functions of ^{63}Zn for cyclotron based production methods were calculated by the nuclear model codes, TALYS-1.6 and EMPIRE-3.2.2. The results were compared with the reported experimental data and with the theoretical values obtained from the TENDL-2014 database. And the excitation functions for impurities in different proton induced reactions were calculated. Subsequently, for each reaction stopping power is calculated using SRIM 2013 code. The integral yields for the production of ^{63}Zn via seven reactions were obtained on the basis of cross section values obtained by nuclear model codes and stopping power values calculated by SRIM 2013. **Results and discussion:** Although the cross section for ^{65}Cu(p,3n)^{63}Zn, ^{nat}Cu(p,n)^{63}Zn, ^{64}Zn(p,n+p)^{63}Zn, and ^{62}Ni(α,3n)^{63}Zn reactions are considerable, the isotopic impurities are produced in these reactions. Thus these reactions are not desirable to produce carrier free ^{63}Zn. The energy and intensity of commonly available deuteron beams are low. Therefore, ^{63}Cu(d,2n)^{63}Zn reaction is not practical. There is no isotopic impurity in the ^{60}Ni(α,n)^{63}Zn reaction. Nevertheless, the low natural abundance of ^{60}Ni hinders using this reaction for producing ^{63}Zn. In addition handling of an irradiated ^{60}Ni target has to be performed in highly radiation-shielded cells due to the neutron radiation produced from (α,n) reaction. **Conclusion**: By considering available cyclotrons, the isotopic impurities, and the production yields of seven Cyclotron based methods for producing ^{63}Zn, it has been verified that the ^{63}Cu(p,n)^{63}Zn is an optimal reaction for the cyclotron production of ^{63}Zn. **Keywords**: ^{63}Zn production• Excitation function• Production yield • EMPIRE-3.2.2 • TALYS-1.6•

Myocardial perfusion imaging using dedicated CZT-SPECT: acquisition time optimization

L. Camoni[1], G. Damini[2], A. Fierro[3], G. Zobbio[2], R. Giubbini[1]; [1]Univesity and Spedali Civili of Brescia, BRESCIA, ITALY, [2]Univesity of Brescia, BRESCIA, ITALY, [3]Spedali Civili of Brescia, BRESCIA, ITALY.

Aim: Aim of this study was to evaluate if time reduction of double dose rest acquisition during single day MPI by CZT SPECT can influence the Summed Rest Score (SRS) **Material and methods**: Single-day stress-rest Gated-SPECT with 185+370 Mbq of Tc-labeled compounds wer eperformed using a CZT-based gammacamera (GE D530Alcyone) in 100 patients, randomly selected. The standard acquisition time was 9 minutes for both stress and rest acquisitions. The rest acquisition was retrospectly reconstructed by list-data as a 4 minutes and 30 seconds acquisition. The quantitative data obtained after SPECT reconstructions were evaluated by QPSv2009 using a 17 segment model. The SRS was obtained for the entire LV and from each coronary territory: LAD, LCX and RCA. *Statistical analysis was performed* using SPSS v.21 (IBM Corp., Armonk, NY, USA) by Wilcoxon paired test. **Results**: The data were expressed as means ± standard deviation. The 9 minutes SRS was 2.65±4.4; LAD 1.58±2.9; LCX 0.57±1.6; RCA 0.5±1.3; conversely the 4'30" minutes SRS was 2.81±4.57; LAD 1.67±2.9; LCX 0.58±1.7; RCA 0.6±1.4. p=ns. The SSS was 4,93±5.7 and the SDS for 9 minutes and half-time were respectively 2.59±2.77 and 2.49±2.76. p=ns. **Conclusion**: after injection of 185+370 MBq of Tc-labelled compounds for stress/rest MPI, rest acquisition can be shortened as half time acquisition does not affect SRS and SDS results.

TP057

Comparisons of ejection fractions derived from different preset parameters of count and heartbeat in multiple gated acquisition scan

C. LIN; Taipei Veterans General Hospital, TAIPEI, TAIWAN.

Introduction: The acquisition parameters of presetting count and heartbeat are optional in multiple gated acquisition (MUGA) scan. The study aimed to investigate the ejection fractions (EFs) derived from different preset parameters of count and heartbeat. Materials and methods: Under the in-vivo labeling technique with 20 mCi ^{99m}Tc pertechnetate, 32 consecutive patients (3 males, age 57±12 y/o) received the MUGA scan. To obtain the optimal imaging angle of separating the right and left ventricles, the SPECT mode was applied first. Three groups of MUGA scan data were then serially collected from each patient by Siemens Symbia E Gamma Camera and defined as three groups: Group 1(preset count:8000K), Group 2 (preset count:4000K), Group 3 (preset heartbeat: 500 beats). Images were processed to obtain the following data: EDC (End-diastolic count), EDA (End-diastolic area), ESC (End-systolic count), ESA (End-systolic area) and BGC (Background count/pixel). Left ventricular EFs were then calculated according to three formulas: (1) EF=(EDC'-ESC')/EDC'*100 (2) EDC'=EDC- BGC* EDA (3) ESC'= ESC- BGC* ESA. Comparisons among the EFs from the three groups were evaluated. Correlations between EFs and other variables were also checked, including age, accepted heartbeats, imaging angles, EDC, EDA, and BGC in each group. Results: There were no differences of EFs (Group 1 vs. 2 vs. 3: 67.91±6.34 vs. 67.46±7.44 vs. 67.93±6.01 %, p=ns) among three groups. In each group, there were no correlations between EFs and age, accepted heartbeats, imaging angles, EDC, and EDA. There were positive correlations between EFs and BGC in Group 1(p=0.001), Group 2 (p<0.001) and Group 3(p=0.019), respectively. After excluding the time of rejected heartbeats, the mean acquisition time were 14.26±3.7 min in Group 1, 7.36±2.03 min in Group 2 and 7.14±0.69 min in Group 3. Conclusion: The acquisition parameters of presetting count or heartbeat do not affect the left ventricular EFs in this study. The positive correlation between EFs and background counts indicates that poor efficiency of the in-vivo labeling technique causes higher left ventricular EFs in MUGA scan. Our finding is beneficial for unstable or arrhythmia patients by adjusting parameters to 4M counts or 500 heartbeats to save the acquisition time without changing the EFs in MUGA scan.

TP058

Effect of the Angle of Ventricular Septal Wall on Left Anterior Oblique View in Multi-Gated Cardiac Blood Pool Scan

Y. You, C. Lee, Y. Seo, H. Choi, Y. Kim, Y. Kim, W. Won, J. Bang, S. Lee, T. Kim; Nation Cancer Center, Goyang-si, KOREA, REPUBLIC OF.

Purpose : In order to calculate the left ventricular ejection fraction (LVEF) accurately, it is important to acquire the best septal view of left ventricle in the multi-gated cardiac blood pool scan (GBP). This study aims to acquire the best septal view by measuring angle of ventricular septal wall (θ) using enhanced CT scan and compare with conventional method using left anterior oblique (LAO) 45 view. Subjects and Methods: From March to July in 2015, we analyzed the 253 patients who underwent both enhanced chest CT and GBP scan in the department of nuclear medicine at National Cancer Center. Angle (θ) between ventricular septum and imaginary midline was measured in transverse image of enhanced chest CT scan, and the patients whose difference between the angle of θ and 45 degree was more than 10 degrees

were included. GBP scan was acquired using both LAO 45 and LAO θ views, and LVEFs measured by automated and manual region of interest (Auto-ROI and Manual-ROI) modes respectively were analyzed. Results : Mean ± SD of θ on total 253 patients was 37.0 ± 8.5°. Among them, the patients whose difference between 45 and θ degrees were more than ± 10 degrees were 88 patients (29.3 ± 6.1°). In Auto-ROI mode, there was statistically significant difference between LAO 45 and LAO θ (LVEF 45 = 62.0 ± 6.6% vs. LVEF θ = 64.0 ± 5.6%; P = 0.001). In Manual-ROI mode, there was also statistically significant difference between LAO 45 and LAO θ (LVEF 45 = 66.7 ± 7.2% vs. LVEF θ = 69.0 ± 6.4%; P < 0.001). Intraclass correlation coefficients of both methods were more than 95%. In case of comparison between Auto-ROI and Manual ROI of each LAO 45 and LAO θ, there was no significant difference statistically. Conclusion : We could measure the angle of ventricular septal wall accurately by using transverse image of enhanced chest CT and applied to LAO acquisition in the GBP scan. It might be the alternative method to acquire the best septal view of LAO effectively. We could notify significant difference between conventional LAO 45 and LAO θ view.

TP059

Studies on simultaneous myocardial imaging with dual radionuclides (^{123}I and ^{201}Tl) using cardiac focusing collimator

K. Kunimoto[1], S. Abe[2], N. Fujita[2], Y. Sakuragi[2], T. Odagawa[1], Y. Koshiba[1], M. Honda[1], K. Kato[1]; [1]Nagoya University Graduate School of Medicine, Nagoya, JAPAN, [2]Department of Radiological Technology, Nagoya University Hospital, Nagoya, JAPAN.

Purpose: Recently, a cardiac focusing-collimator (CF)(variable-focus collimator) designed for cardiac studies has been developed and enables to acquire the SPECT data faster than conventional SPECT studies. At present, in simultaneous myocardial imaging with ^{123}I and ^{201}Tl, the conventional parallel-hole collimator has been generally used instead of CF. If CF will be generally used for simultaneous myocardial imaging with ^{123}I and ^{201}Tl, the image acquisition time is shortened and patients' burden is reduced. In this study, we investigated the usefulness of CF in simultaneous myocardial imaging with ^{123}I and ^{201}Tl in the phantom experiment. Materials and Methods: ^{123}I and ^{201}Tl solutions were separately enclosed into the torso phantom, and the SPECT data were acquired using a low-medium energy general purpose collimator (LMEGP) and CF. Using the short-axis images, the crosstalk rate was examined. And both solutions were enclosed in together into the torso phantom and the SPECT data were acquired. The attenuation and scatter corrections were performed. On the short axis images, the accurate counts were determined using crosstalk rate. Using a profile curve obtained in the short-axis images, the full width half maximum (FWHM) was determined. This operation was conducted on the images acquired in each energy window. Results: In the SPECT images of ^{201}Tl, FWHM acquired with CF was better than that acquired with LMEGP. In the SPECT images of ^{123}I, FWHM acquired with CF was improved compared with that before scatter and attenuation corrections, but it did not surpass that acquired with LMEGP. This fact is considered due to the effect of 167 keV gamma rays from ^{201}Tl, and the septal thickness of CF was thin compared with LMEGP. Conclusion: In the SPECT images of ^{201}Tl after scatter and attenuation corrections, FWHM acquired with CF was better than that acquired with LMEGP. In the SPECT images of ^{123}I, however, FWHM acquired with CF did not surpass that acquired with LMEGP even after scatter and attenuation corrections. Further studies will be needed to search for more appropriate acquisition and reconstruction conditions when CF is used.

TP060

Study of Clinical Cases for the Standardization and Unification of the ^{123}I-metaiodobenzylguanidine Heart-to-Mediastinum Ratio

D. Ogura[1], H. Shimada[2], M. Kanou[1], M. Mochiki[1], T. Ino[1], T. Toyama[3], K. Koyama[1]; [1]Gunma Prefectural Cardiovascular Center, Maebashi, JAPAN, [2]Gunma University Hospital, Maebashi, JAPAN, [3]Toyama Cardiovascular Clinic, Maebashi, JAPAN.

[Objectives] Using a simple phantom developed by Nakajima et al., Kanazawa University, the heart-to-mediastinum ratio (HMR) collected and processed differently can be corrected to a specific value so that ratios from different tests can be compared (Nakajima K, et al. J Nucl Cardiol. 2014;21:970-978). In our hospital there are two different devices for imaging. Therefore, correction was required for comparison. Only a few clinical studies have evaluated the use of this phantom, and none using a medium energy (ME) collimator, or where early and delayed values were reported individually. In this study, we used HMRs of the same patient taken with two different imaging devices to calculate the corrected values for standardization and unification. [Methods] PRISM-IRIX (LEHR/MEGP) (Shimadzu) and Infinia 8 Hawkeye 4 (ELEGP) (GE) were used. Early images were taken 15 minutes after ^{123}I-metaiodobenzylguanidine administration, and delayed images after 4 hours. A phantom experiment was conducted for each imaging condition to calculate a transformation coefficient. Imaging was performed using LEHR and ELEGP in 224 heart failure cases, and MEGP and ELEGP in 50 heart failure cases. Using the coefficient, correction values were calculated for the HMRs and compared each other. [Results] Bland-Altman analysis showed the following mean differences with LEHR and ELEGP, respectively: early: -0.60±0.53, delayed: -0.59±0.67 (before correction); and early: -0.24±0.47, delayed: -0.24±0.53 (after correction). The following mean differences were obtained with MEGP and ELEGP, respectively: early: 0.21±0.24, delayed: 0.34±0.36 (before correction); and early: 0.04±0.27, delayed: 0.18±0.34 (after correction). After correction, mean differences were reduced for both early and delayed values, showing a favorable correspondence. [Discussion] As reported previously, Sufficient correction was made for both early and delayed values in either collimator. However, scattered rays frequently penetrated the septum with LEHR; a higher HMR was associated with a greater correction deficiency. Therefore, the use of an iodine-specific or ME collimator seems desirable. HMR variation caused by differences between models by device updating or facility differences could have resulted; it might be improved by standardization. Furthermore, as cutoff values by disease are generated from the hospital's own data, standardization of evaluation criteria is expected to occur between facilities. [Conclusion] Corrected values calculated by a simple phantom experiment were designed to resolve differences between imaging models, collimators, and imaging conditions, and to be adaptable to early and delayed values, respectively. Phantom correction is expected to enable standardization of HMR between hospitals, with subsequent standardization to national and international levels.

TP061

Pharmacological Stress Agents in Myocardial Perfusion Scintigraphy - What to use in clinical practice

D. Teixeira[1], E. Sousa[2]; [1]NHS Greater Glasgow and Clyde, Glasgow Royal Infirmary and Stobhill Hospital, Glasgow, UNITED KINGDOM, [2]Escola Superior de Tecnologia da Saúde de Lisboa, Lisboa, PORTUGAL.

Purpose/Introduction: Myocardial perfusion scintigraphy (MPS) with stress is an effective technique to detect disorders of left ventricle perfusion and function. However, development of new techniques and drugs to perform stress protocols are required to increase specificity, accuracy and sensibility of scans and still make the process simpler and more agreeable for the patients. This work aims to conduct a review about the use of different stress agents in clinical practice, respective advantages/disadvantages, comparison with physical stress and review of combined protocols of stress agents with low level of physical stress. **Subject/Methods:** Bibliographic research was made using "B-On", "PubMed" and "The knowledge network" platforms. The boolean connector "AND" was use combined with words such as "pharmacologic stress", "combined protocols", "myocardial perfusion stress", "adenosine", "dobutamine", "ATP", "dipyridamole" and "regadenoson". **Results/Discussion:** Adenosine, Adenosine Triphosphate (ATP) and dipyridamole are non-specific vasodilators given by infusion with several adverse effects identified in more than 50% of

the cases. Patients with restricted airways cannot be submitted to these agents since they may cause bronchoconstriction. However, regadenoson is a specific vasodilator and can be used safely in these cases, being administered in a standardized single dose. Dobutamine is an adrenergic agonist of the receptors β1 and β2 and is given as an infusion. This product can be used in patients with pulmonary diseases but because it promotes the contractility of the myocardium directly, it is a more dangerous drug and the stress test is a procedure which is harder to control. Secondary effects associated with dobutamine affect around 75% of the patients, however these can be controlled with drugs. Combined protocols work in similar ways for the several agents, combining the pharmacological agent with low level of physical stress. The combined protocols are safe, have reduced side effects and increased the image quality. **Conclusion:** In conclusion all the methods are safe although all have some side effects that can be controlled. Regadenoson should be the drug of choice since it is a vasodilator, used as a single standardized dose with no need for an infusion pump, can be used in the middle of a physical protocol, is safe for patients with pulmonary disease and it is associated with less side effects.

TP062

Reproducibility and reliability of two processing software for Cardiac Gated Scintigraphy

E. Lemos Pereira, M. Fernandes, G. Proença, L. Oliveira; NuclearMed - Hospital Particular Almada, ALMADA, PORTUGAL.

Aim: Several software packages for processing Cardiac Gated Scintigraphy provide more than one processing program. Usually, at the same department, only one is routinely adopted, but results tend to me more accepted if correlated to echocardiogram results. The aim of this study was to evaluate our departments two software for processing Cardiac Gated Scintigraphy. Moreover, we also compared both of our software's with echocardiogram results. Methods: A total of 100 consecutive patients (pt) that performed Myocardial Perfusion Scintigraphy between December 2015 and March 2016 were retrospectively analyzed. Pt characteristics like age, sex, body mass index, clinical indication and cardiovascular risk factors were analyzed. Myometrix™ and ECTollbox™, both Xeleris® software packages, were used do study ejection fraction (EF) and end diastolic and end systolic volumes (EDV and ESV), as well as wall motility. Results were also compared with previous echocardiogram parameters. Data was statistically analyzed with Microsoft Office Excel® and IBM SPSS®. Results: Although preliminary results indicated a good correlation between both gating processing software, as well as with echocardiogram results in the majority of cases, we found that for some pt, great discrepancy on the results was observed. Conclusion: Our results suggest that both cardiac gated processing packages are very reproducible and reliable when compared with echocardiogram. Nevertheless, cardiac gated analysis at Myocardial Scintigraphy must always take in consideration the pt clinical information.

TP063

Gated Myocardial Perfusion Single-Photon Emission Computed Tomography Imaging with Multifocal Collimator

K. Takahashi[1], T. Takeuchi[2], Y. Hosokai[3], H. Odagiri[2], A. Usui[1], H. Saito[1]; [1]Tohoku University, Sendai, JAPAN, [2]Tohoku University Hospital, Sendai, JAPAN, [3]Internatinal University of Health and Welfare, Ohtawara, JAPAN.

Introduction: Combining the functional information of myocardial perfusion single-photon emission computed tomography (SPECT) and the morphological information of computed tomography angiography (CTA) is an established technique for the non-invasive evaluation of coronary artery disease (CAD). Myocardial perfusion SPECT (MPS) using thallium-201 is a 3D-fused SPECT image that is currently combined using non-gated MPS including heart-motion and gated CTA. Gated MPS images are not used owing to insufficient counts available to diagnose CAD. However, a highly sensitive MPS with multifocal collimator, the IQ•SPECT, is available. We aimed to evaluate the optimal reconstruction parameters in gated MPS images using the IQ•SPECT. Methods and Materials: We used a cardiac phantom with a lateral perfusion defect. The left ventricular myocardium, liver, and background were filled with 72, 14, and 7.0 kBq/ml of thallium-201, respectively. The heart rate was set to 60 beats per minute by the ECG checker. Gated SPECT was performed with a dual-head gamma camera equipped with a SMARTZOOM collimator, and the images were acquired with 17 views/detector, 56 beats/view in 8 frames per R-R interval. The gated MPS images were reconstructed by ordered subset conjugated gradient modified (OSCGM) with subset: 1-5, iteration: 1-60. We assessed the image quality using the coefficient of variation (%CV), contrast and the normalized mean squared error (NMSE) to determine the optimal reconstruction parameters. We evaluated %CV with the region of interest (ROI) setting on the anterior, septal, inferior, and lateral walls. Furthermore, we evaluated contrast with ROI setting on the septal and lateral walls. Results: The %CV in the anterior and septal walls converged in update (subset × iteration): 40, while the %CV in the anterior and septal walls in subset: 5 was slightly higher. There was no convergence in the %CV in the inferior and lateral walls. Contrast converged in update: 40 and was slightly lower than that in subset: 5. Iterations at which the NMSE demonstrated a minimum showed a low value with increasing subsets. The minimum NMSE values in subset: 1, 2, and 3 were similar, while subset: 5 was slightly higher. Conclusion: The results of the gated MPS images using IQ•SPECT suggest that the optimal OSCGM reconstruction parameters are subset: 3 and iteration: 14. Gated MPS images with IQ•SPECT may provide improved 3D-fused SPECT images, aiding in the non-invasive evaluation of coronary artery disease.

TP064

Myocardial Perfusion and Sympathetic Activity of the Heart in Professional Deep-water Divers

V. Sukhov, G. Kutelev, A. Chumakov, V. Nikifofov, P. Kirichenko, D. Cherkashin; Military Medical Academy, ST. PETERSBURG, RUSSIAN FEDERATION.

Background and purpose: Currently, state of cardiovascular system in professional deep-water divers is not clear enough. According to several authors, problems with cardiovascular system in divers remain at leading positions: arterial hypertension, neuro-circulatory asthenia, arrhythmias and conduction disturbances, ischemic heart disease, degenerative changes of the myocardium, etc. We need to clarify that. Material and Methods: We examined 20 men (26-42 y.o.) working under increased gas-mixture pressure in water environment. In all of them rest-stress myocardial perfusion and sympathetic activity were assessed using scintigraphy with 99mTc-tetrophosmine and 123I-MBG. Such pathology as myocardial hypertrophy, dilatation of the heart chambers, reduced ejection fraction, myocardial ischemia in these persons were excluded. Results: We found diffusely heterogeneous perfusion at rest and widespread transient decreased of 99mTc-tetrofosmin uptake at stress, and also decline in the heart/mediastinum ratio and negative values of 123I-MIBG washout index. 123I-MIBG and 99mTc-tetrofosmin distribution data were largely concordant. Although all of them showed high tolerance to exercise and aerobic performance, even when compared with non-professional divers. Resume: We suggested retardation of myocardial metabolism, sympatholytic effect at the level of peripheral nerve endings, atherosclerosis of small coronary arteries branches. Coronarospasticeffects, and degenerative changes in cardiomyocytes. Disturbancies in cellular metabolism and sympatholytic effects may be a manifestation of sustainable adaptation of divers' organism to impact of hyperbaric environment factors.

TP065

Comparison between each institution using a 2-Layer Double-Pump Dynamic Cardiac Phantom

R. Hashimoto[1], M. Onoguchi[1], T. Shibutani[1], N. Hara[2]; [1]Department of

Quantum Medical Technology, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, JAPAN, [2]Department of Radiology, Sumitomo Hospital, Osaka, JAPAN.

Purpose: A conventional dynamic myocardial phantom fixed to the size of the outer membrane (epi-cardium) has reported. However, this phantom has the structure that only the inner membrane (end-cardium) can move in the antero-posterior directions. The volume of end-diastolic volume (EDV) and end-systolic volume (ESV) are fixed, and a real movement of the heart is not expressed. Recently, the new myocardial dynamic phantom which can change the myocardium and the left ventricle volume were developed. The aim of this study was to evaluate cardiac function analysis between different institutions whether this phantom can use as the standardization tools. Methods: Tc-99m was filled in the myocardial part of the phantom, and acquired two dual-detector SPECT-CT (Precedence 16; Philips,Symbia T6; Siemens) systems. Acquisition parameters were set on 16 frames per cardiac cycle, main window 140 keV±10%, 64×64 matrix, a rotation angle of 360, 64 projections. Acquisition time was different in each device, but the average count for myocardium was approximately 100 counts per pixel. The phantom fixed heart rates in 60 beats per minute and changed only the stroke width of the left ventricle. Reconstruction was performed with filtered back projection, and the attenuation, scatter and resolution corrections were not performed. The true volume calculated from enhanced CT Images. The ESV, EDV were analyzed using a quantitative gated SPECT (QGS), and the left ventricular ejection fraction (LVEF) were calculated from EDV and ESV. Then those values were compared between each institution. Results: The volume for EDV and ESV were different between each institution, however, the correlation between the true and measured values showed the same tendency to both EDV and ESV. The correlation coefficient for each institution were 0.98 and 0.95 for EDV, 0.87 and 0.95 for ESV, 0.98 and 0.95 for LVEF, respectively. The relative error was less than 30% both EDV and ESV. Conclusion: The calculation value was compared and examined between each institution by the myocardial dynamic phantom which can change the myocardium and the left ventricle volume. It was suggested that the novel myocardial dynamic phantom may be possible to the standardization.

TP066

Clinical usefulness of ^{201}Tl myocardial uptake at stress with ^{201}Tl SPECT-MPI on a Cadmium Zinc Telluride (CZT) camera

R. Matsuda[1], S. Tomiguchi[2], S. Kudo[1], N. Katsuta[3], S. Shiraishi[4], Y. Yamashita[4]; [1]Graduate School of Health Sciences, Kumamoto University, Kumamoto, JAPAN, [2]Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN, [3]Division of Medical Technology, Kumamoto University Hospital, Kumamoto, JAPAN, [4]Department of Diagnostic Imaging, Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN.

Aim/Purpose Measurement of myocardial flow reserve (MFR) on single photon emission computed tomography myocardial perfusion imaging (SPECT-MPI) needs the dedicated SPECT camera. There is the problem in measurement of MBF that a patient's exposure increases with the twice dosage of the radiotracer in case of ^{201}Tl SPECT-MPI. ^{201}Tl myocardial uptake at adenosine stress (^{201}Tl myocardial uptake) is considered to reflect the MFR, because adenosine induces maximum dilatation of coronary arteries. The aim of this study was to evaluate a clinical usefulness of ^{201}Tl myocardial uptake in patients without visually myocardial perfusion abnormalities and to clarify the influence of an attenuation correction (AC) on ^{201}Tl myocardial uptake. **Material and Methods** Forty patients without visually myocardial perfusion abnormalities on stress ^{201}Tl SPECT-MPI were enrolled in this study. They were consisted of 8 without coronary arterial disease (CAD) and 32 with subclinical CAD. Adenosine stress ^{201}Tl SPECT-MPI was performed in all patients using a CZT camera (NM530c, GE). Outlines of the left ventricular myocardium were delineated by the count threshold determined visually. A total count of whole left ventricle (LVC) was then derived from summing counts of all trans-axial myocardial images. Finally, ^{201}Tl myocardial uptake was calculated by dividing the myocardial radioactivity converted from LVC using cross-calibration factor by total injected dose. **Result** Mean value of ^{201}Tl myocardial uptake was 5.1% without AC and 9.2% with AC in 8 patients without CAD, while they were 3.1% without AC and 6.6% with AC in 32 patients with subclinical CAD. Mean value of ^{201}Tl myocardial uptake in patients without CAD is higher than that in patients with subclinical CAD and ^{201}Tl myocardial uptake with AC is higher than that without AC. **Conclusion** ^{201}Tl myocardial uptake is considered to be useful for the diagnosis of subclinical CAD. Further study is necessary for the evaluation of the prognosis to clarify a clinical significance.

TP067

Normal Myocardial Perfusion CZT-SPECT databases comparison

L. Camoni[1], G. Damini[2], A. Fierro[3], G. Zobbio[2], I. Marchina[2], R. Giubbini[1]; [1]Univesity and Spedali Civili of Brescia, BRESCIA, ITALY, [2]Univesity of Brescia, BRESCIA, ITALY, [3]Spedali Civili of Brescia, BRESCIA, ITALY.

Aim: Aim of this study was to evaluate any significant difference in quantitative MPI analysis, using two different commercially available software with different normal databases. **Material and methods**: Single-day stress-rest Gated-SPECT with 150+300 Mbq of Tc-labeled compounds wer eperformed using a CZT-based gammacamera (GE D530Alcyone) in 100 patients, randomly selected. The standard acquisition time was 9 minutes for both stress and rest acquisitions. The quantitative data obtained after SPECT reconstructions were evaluated by QPS v.2009 and Corridor 4DM v.2012 using a 17 segment model. The SSS, SRS and SDS were obtained for the entire LV. Statistical analysis was performed using SPSS v.21 (IBM Corp., Armonk, NY, USA) by Wilcoxon paired test. **Results**: The data were expressed as means ± standard deviation. The QPS v.2009 results were: SSS:4.93±5.7; SRS:2.65±4.4; SDS:2.59±2.77; the Corridor 4DM v.2012 were SSS:6.95±8.5; SRS:5.59 ±7.5; SDS: 2.32±3.44; The statistical analysis was significat for all parameters (p=<0.05) execept for SDS (p=ns) **Conclusion:** Despite presence of significant differences in both SSS and SSR by QPS v.2009 and Corridor 4DM v.2012 there is a substantial overlap in quantification of myocardial ischemia by MPI using widely adopted commercial softwares.

TP068

Quantification of Heart-to-Mediastinum Ratio of I-123-MIBG Scintigraphy in a Cardiac Phantom: influence of collimator choice and of diverse energy window for scatter correction

S. Chaves, A. Faria, T. Vieira, J. Pereira; Centro Hospitalar S. João, Porto, Porto, PORTUGAL.

There is a good tendency of standardization of I-123-metaiodobenzylguanidine (MIBG) cardiac sympathetic imaging in order to become possible to compare different studies. The aim of this work is to compare the value of the Heart-to-Mediastinum ratio (H/M) acquired with different collimators and different energy windows for scatter correction (SC) by comparison with the true H/M in a cardiac phantom. We used a cardiac phantom filled with a I-123 solution. The absolute activity was 10.33 kBq/mL in the heart and 2.16 kBq/mL in the background. SPECT scans were consecutively acquired. For the SPECT/CT (Infinia-Hawkewe 4, GE®) were used LEHR and ME collimators, in L-configuration, rotation of 180°, 60 projections, 30 seconds/projection, 64x64 matrix; 20% energy window (143.1-174.9 KeV) centered on the isotope photopeak (159 KeV). In the acquisitions with LEHR collimators were used six different windows to apply SC by Dual-Energy window (DEW): DEW1=79.6-111.1 KeV; DEW2=111.3-143.1 KeV; DEW3=184-216 KeV; DEW4=174.9-207 KeV; DEW5=174.9-216 KeV; DEW6=DEW2+DEW3. From the first to the fifth, the energy windows were defined with the same width. For all, we used two different multiplication factor (k): 0.8 and 1. OSEM

reconstruction method was adopted and all images were submitted to CT- based attenuation correction. After image reconstruction, an elliptical VOI was drawn around the heart and a cuboid VOI in the background of the phantom (AMIDE®), in order to obtain the total counts (decay correction). We determined the system volume sensitivity using a Jaszczak phantom filled with a uniform concentration of I-123 activity. The H/M ratio was calculated for each SPECT acquired and compared with the true H/M calculated using the calibration factor. It was determined a relative error between true H/M and the calculated H/M. H/M is underestimated by 36% if no SC was applied. DWE1, DEW3, DWE4, DWE5, DWE6 presented high relative error independently of the k used in the SC. DWE2 showed a relative error of - 1% and -8% for k equal a 1 and a 0.8, respectively. Concerning ME collimators the H/M is underestimated by 8%. This research confirm that collimator choice influences the calculation of H/M. When using LEHR collimators SC is needed for I-123-MIBG scintigraphy. The 111.3-143.1 KeV energy window shows better results and a k equals to 1 seems the best.

TP069

Simulation to solve the artifacts and pitfalls myocardial SPECT using data mining

K. Asakura, S. Kazuhiro, K. Miho, O. Akihito; Department of Radiology, Tottori Prefectural Central Hospital, ezu,tottori, JAPAN.

the aim SPECT myocardial perfusion imaging using 99mTc-sestamibi (MIBI) plays a central role in the diagnosis and prognosis of cardiovascular disease. However , there is a possibility that limits the clinical utility by a variety of artifacts and pitfalls. In particular , the filtered-backprojection (*FBP*) reconstruction method is known to produce streak artifacts from very intense area of activity (e.g., the gallbladder). The aim of this simulation is to examine the FBP method which is not affected by the streak artifacts using data mining. **Materials and Methods** MIBI was 7 MBq sealed in the heart part of the phantom (HL20 type) . This normal myocardium was defined as the model A. We acquired SPECT images using a rotating digital gamma camera and a low energy high resolution collimator with an energy window of 141kev ±10% and 64×64 matrix. The images were collected over 360 deg (6 deg every 40 sec) and 60 frames of raw data were generated. Model B was designed on the FBP reconstructed short axis images containing from 1 to 10 times of cardiac radioactivity overlapping with other organs. Further , four types of occlusion model (front wall , bottom wall , side walls , septum) were defined as the model C. The combination of three types of models, we created 81 kind of sinogram as a teacher signal. The sinograms had 32 matrix on the horizontal axis in the channel direction. The vertical axis was arranged in a vertical projection data as the sampling angle . We applied back-propagation-method (BPM) of the artificial-neural-network (ANN) to data mining. As the input data of the ANN, seven directions were used from the sinogram signal which consisted of the samples of 32 directions. Then, short axis images of the myocardium were obtained by the optimal solution of the ANN. In this study, scatter and absorption were not corrected. **Results and Conclusion** Accuracy rate of this technique achieved almost 100%. We confirmed short axis images of the myocardium which is not affected by the streak artifacts in this phantom simulation. However, when this approach without attenuation correction is applied to clinical, some errors may occur. Furthermore, we have to make the ANN learn more teacher signals. If we solve these problem, this method will be useful for clinical.

TP070

The usefulness of Flash 3D Applications to shorten scan time for Gated Myocardial Perfusion SPECT

Y. parlak, D. Goksoy, G. Gumuser, E. Sayit; Celal Bayar University, Manisa, TURKEY.

Inaccurate image reconstruction impacts image quality and can result in both false positives and false negatives. Most reconstructed images are created using algorithms that do not account for the physical characteristics of the image acquisition system. Flash 3D Technology is a sophisticated new SPECT tomographic reconstruction algorithm. Flash 3D adds a post fitler after reconstruction for noise reduction. The aim of this study is to compare rest and stres defects in gated MPS, functional parameters in half time flash 3D and full time Filtered Back Projection (FBP). Twenty patients (mean age: 60±5 years; 11 female, 9 male) were imaged with Siemens Evo Excel gamma camera (Knoxville, USA). Patient preparation, acquisition parameters and reconstruction protocols for all patients were standardized. Half-time (32 projections) and full time (64 projections) SPECT data were acquired for both stres and rest imaging protocol. Full-time data were reconstructed using Standard filtered backprojection reconstruction, whereas half time data were reconstructed using Flash 3D software. The data were evaluated by two Nuclear Medicine especialist blinded to each other. The full-time and half-time data were evaluated and found differences (especially in rest images) in image quality assesed, LV function measured.Statistical analysis were performed between full time FBP and half time Flash 3D. The increased noise in the half-count projections increased the difficulty of assessing on images. We suggest that if we use half time flash 3D in MPS, increased activity should be administered to the patients especially in rest imaging.

TP071

Technical improvement of Continuous Dynamic SPECT in Epilepsy study

P. SUNMYUNG, P. JIN YUNG, Y. JOON HO; SAMSUNG MEDICAL CENTER, Seoul, KOREA, REPUBLIC OF.

Purpose : Epilepsy is a group of neurological diseases characterized by epileptic seizure. During Brain Epilepsy SPECT study, critical factor for proper study with ^{99m} Tc-ECD or ^{99m} Tc-HMPAO is one of the important causes to patent's movement caused by Inter-ictal or Ictal. It causes both improper diagnosis and examination failure. In this study, we evaluated the effect of Dynamic SPECT Acquisition compared to SPECT to raise efficacy and reject the data set with movement, as well as, be reconstructed in certain criteria. Methods: Deluxe Jaszczak phantom and Hoffman 3D Brain phantom were used to find proper standard data set and exact time. SPECT and Dynamic SPECT Acquisition were performed with SymbiaT16. Firstly, Deluxe Jaszczak phantom was filled with $Na^{99m}TcO_4$ 370MBq and obtained in 60 minutes to check spatial resolution compared with SPECT and Dynamic SPECT. The second, the Hoffman 3D Phantom filled with $Na^{99m}TcO_4$ 74 MBq was acquired for 15 Frame/minutes to evaluate visual assessment and quantification. Finally, in the Deluxe Jaszczak phantom, Spheres and Rods were measured by MI Apps program as well as, checking counts with the frontal lobe, temporal lobe, occipital lobe, cerebellum and hypothalamus parts was performed in the Hoffman 3D Brain Phantom. Results: In Jaszczak phantom, Sphere and Background Ratio was measured 0.41 ± 0.0 % with SPECT and 0.36 ± 0.0 % with Dynamic SPECT in 31.8, 25.4 19.1 15.9 mm except for unseen 12.7 mm and 9.5 mm Spheres in Jaszczak phantom which is acceptable differences to use Dynamic SPECT instead of SPECT. And visual evaluation for Rods was also performed and found no differences in 12.7, 11.1, 9.5, 7.9 mm except for 6.4, 4.8 mm in both. In Hoffman 3D Brain Phantom, Approximately the count value of frontal lobe 2660, 2816, temporal lobe 2336, 2720, occipital lobe 3240, 3418, cerebellum 3004, 3290, hypothalamus 1348, 1450 in SPECT and Dynamic SPECT respectively in full acquisition. Removing 8 frame/min in dynamic SPECT was acceptable. However, removing 9frame caused remarkable low image quality and differences. Conclusion : Dynamic SPECT in epileptic seizure condition enhances effects compared to SPECT image. And also is powerful method to reduce reacquisition rate caused by patient movement. The findings further indicate that it suggest rejection limit to maintain clinical value with certain reconstruction factors compared with Tomo data set. Further examination to improve spatial resolution, SPECT/CT should be the answer for that.

TP072

Dynamic supine renal imaging - the importance of standing

M. G. G. Silva, S. Teixeira, A. Canudo, D. Dantas, D. Costa, C. Oliveira, A. Silva; Champalimaud Foundation, Lisboa, PORTUGAL.

Introdution Nephroptosis is a condition in which kidney descends more than 5cm (or two vertebral bodies) between supine and orthostatic (standing) positions. In 10 to 20% of cases it is clinically symptomatic, manifesting frequently with a renal colic. Sometimes, it can be accompanied by excessive rotation of the kidney. **Material and methods** A 78 year old female with a history of right breast carcinoma surgically removed three years before was referred due to pain in her right posterior ribcage. A bone scan was performed in July 2015 screening for secondary bone involvement. There were no osteoblastic bone metastases. However, marked retention of the tracer excretion in the pelvis of the right kidney was observed and prompted the performance of a renogram that was undertaken with MAG3. Previous renal ultrasound (October/2014) had shown both kidneys of normal size and good parenchymal differentiation and no nodular lesions. However, there was marked dilatation of the right pelvis with abrupt transition to the ureter but no definition of an obstructive cause. A pelvic-ureteric junction (PUJ) syndrome was suggested on the right. There were no signs of obstruction despite some retention on the left. Following intravenous administration of 269MBq of ^{99m}Tc-MAG^3 a dynamic renal study was performed supine for 30 minutes. Furosemide was administered 15 minutes within the renal study acquisition. Subsequently, a standing pre-voiding image was obtained and additional standing and supine post-micturition images were acquired. **Results** The renal flow/perfusion was preserved bilaterally. Good concentration of the left kidney and delayed parenchymal transit on the right kidney was recorded. On the left there was pelvicaliceal retention responding promptly to furosemide. On the right there was continuous and progressive accumulation of the radiotracer in the pelvis, with poor and delayed response to diuretic overload, but no obstructive pattern. The left kidney contributed 55% and the right 45% to the total renal function Pre and post-micturition standing images revealed marked ptosis with tilt of the right kidney (around 120° internal rotation of its upper pole). In the supine post-micturition image the right kidney returned to its initial non-ptotic anatomical position. **Discussion/ Conclusion** The herein reported right renal ptosis and internal rotation may explain the right posterior ribcage pain. Standing and not only supine pre and post-void renal images should always be acquired for completion of renogram studies.

TP073

Correlation between parathyroid scintigraphy, size of parathyroid adenomas and biomarkers

S. Sustar[1], S. Rep[1], B. Trebec[1], I. Slodnjak[1], M. Hocevar[2], L. Lezaic[1]; [1]Department for Nuclear Medicine, Ljubljana, SLOVENIA, [2]Department for oncological surgery, Ljubljana, SLOVENIA.

Introduction: Primary hyperparathyroidism is an endocrine disorder that develops as a result of increased and uncontrolled formation of parathyroid hormone. Subtraction scintigraphy and SPECT/CT is the most established method for the preoperative localization of parathyroid adenomas. Most commonly used radiopharmaceutical for the purpose is 99mTc-MIBI. Objective: The aim of the study was 1) to assess diagnostic performance of preoperative localization of parathyroid adenomas in the early and delayed (5 min and 60 min after administration) SPECT/ CT method with subtraction scintigraphy in patients with biochemically proven primary hyperparathyroidism using histology as the gold standard and 2) to determine whether size of parathyroid adenomas, serum PTH, Ca and P are correlated to successful localization. Materials and methods: The study included 41 patients in whom we performed early and delayed SPECT/CT imaging and subtraction scintigraphy (addition of 99mTc-pertechhetate). Correlation between size of the parathyroid adenomas, serum Ca, P and PTH levels was assessed using Spearman correlation coefficient. The volume of surgically removed parathyroid adenomas was calculated as (length×width×height)×π/6. Receiver Operating Characteristic analysis (ROC analysis) were used to express relationship between scintigraphy results and size of the parathyroid adenomas, serum Ca, P and PTH levels. Results: The sensitivity and specificity of early SPECT/CT, delayed SPECT/CT and subtraction scintigraphy was 65.1% and 97.5%, 67.4% and 95.5% and 51.1% and 98.3%, respectively. Combined early and delayed SPECT/CT had the sensitivity and specificity of 74.4% in 95.1%. There was a good correlation (Spearman r=0.828, p<0.05) between iPTH and serum Ca2+ and a fair correlation between the gland volume and serum Ca2+ (Spearman r=0.641, p<0.05) and iPTH (Spearman r=0.606, p<0.05). Conclusion: The most sensitive method of preoperative localization of parathyroid adenomas was combined early and delayed SPECT/CT. There was a good correlation between iPTH and serum Ca2+ and a fair correlation between the gland volume, serum Ca and iPTH.

TP074

A new parameter for the calculation of Thyroid uptake by Thyroid area

S. A. Abdulrasool; Fujairah hospital ,MOH, UAE, Fujairah, UNITED ARAB EMIRATES.

Introduction: Thyroid scintigraphy using Tc-99m is an excellent method of evaluating the function of Thyroid gland and its uptake. A thyroid scan may be ordered by a physician when the gland becomes abnormally large. The scan can be helpful in determining whether the enlargement is caused by a diffuse increase in the total amount of thyroid tissue or by a nodule or nodules. When other laboratory studies show an overactive thyroid (Hyperthyroidism) or an under active thyroid (Hypothyroidism), a Thyroid scan uptake is often used to confirm the diagnosis. A normal scan will show a thyroid of normal size, shape, and position. The amount of radionuclide uptake by the thyroid will be normal according to established nuclear medicine figures. There will be no areas where radionuclide uptake is increased or decreased. Objective & Aims: The objective of this study is to measure the thyroid uptake by area. 1-To calculate the normal range of thyroid uptake by thyroid area (Counts/Pixel) 2-In patients with high Thyroid uptake this parameter will be useful to give an idea wither it is due to Hyperthyroidism or due to big-sized Thyroid gland. Results: Calculation of mean value was carried for all the 500 patients. Results show the following: 1-Normal Range between 6-34 counts/pixel 2-Hyperthyroid patients >35 counts/pixel 3-Hypothyroid patients 4 and counts/pixel was >40 4-Group (3) 100 patients with hypothyroidism, thyroid uptake measured was =<0.2 and counts/pixel was <5-Group (4) 30 patients with thyroid enlargement with thyroid uptake was =>4 high uptake and counts/pixel was between 6-30 which was normal. Conclusion: The thyroid uptake is performed to evaluate the function of the thyroid gland. In Fujairah hospital, we add new, simple and important parameter to thyroid scan by calculating uptake of thyroid. By area (counts per pixel) this useful parameter is applied in all thyroid scan studies. Some cases as a result of large thyroid gland size, the uptake give result higher than the real uptake to know to the real uptake using uptake by area (count per pixel) method.

TP075

Targeting VPAC1 Genomic Receptors for Optical Imaging of Lung Cancer

M. L. Thakur; Thomas Jefferson University, Philadelphia, PA, UNITED STATES.

Objectives: Lung Cancer (LC) accounts for nearly 20% of all cancer deaths in the USA. Low dose CT scan of the chest as a screening strategy for high risk LC subjects has a very high false positive rate and a specific diagnosis of sub-cm lesions is challenging. In recent years, detecting circulating tumor cells (CTC) in liquid biopsy has drawn considerable attention to diagnose primary disease and even to determine effectiveness of therapy and to predict

disease recurrence. VPAC1 receptors are expressed in high density on LC cells at the onset of oncogenesis. The goal of this pilot study is to target VPAC1 using our receptor specific fluorophore TP4303 to optically image LC cells in lung lavage. **Methods**: Routine diagnostic bronchoscopy was performed in patients with suspected lung cancer and a 5-10 ml residual lung lavage sample was cytospun, cells were fixed, incubated with TP4303 (Ex=633mm, Em=754nm), washed and cell nuclei were stained with DAPI (Ex=350nm, Em=470nm). Slides were then read using confocal microscope. The protocol was IRB exempt as no health record was required to be collected. To validate the presence of VPAC1 on LC cells receptor blocking studies were performed, using human LC cell line A549. **Results**: As of this writing, seven lavage samples from seven subjects were analyzed. Histological examinations of lavage led to positive diagnosis for LC in all patients. Cells from 11 patients, under the microscope showed bright orange fluorescence around the cell nucleus, indicating the presence of malignant cells with dense expression of VPAC1 receptors on cell surface. All cells from one patient with Asthma but without LC, were normal without fluorescence. Receptor blocking studies validated the presence of VPAC1. **Conclusion**: The results (100%) of this small (n=11) feasibility study are highly encouraging and warrant studies of sputum obtained non-invasively from patients with known LC and those scheduled for bronchoscopy. Study of the lacrimal glands in Nuclear Medicine

D. Peña Torres, P. Villen Trinado, Y. Said Criado, M. Torres Jimenez, D. Cid Jimenez; COMPLEJO HOSPITALARIO DE JAEN, JAEN, SPAIN.

INTRODUCTION The nasolacrimal duct carries tears from the lacrimal sac into the nasal cavity. The opening of the nasolacrimal duct leads into the inferior nasal meatus and is partially covered by a mucosal fold. Excess tears flow through the nasolacrimal duct, which drains into the inferior nasal meatus. 1. Dacryoscintigraphy is a grossly underutilized nuclear medicine procedure for assessing the patency of nasolacrimal ducts. 2. Nuclear Medicine scan is a means of demonstrating how well tears are cleared from the eyes and drain away OBJECTIVES The aim of the study is to gain and expand professional knowledge in the process of the preparation of radiopharmaceuticals and imaging. MATERIAL AND METHOD We carried out an observational descriptive study analyzing the process regarding the lacrimal glands scintigraphy RESULTS: Lacrimal duct scintigraphy: Preparation of the radiopharmaceutical: load 2 syringes of 1ml, with one drop (about 200μCi/10μl) of sodium pertechnetate Tc solution for injection Recommended for children and adults equally are 0.2 mCi activities in each eye. LEHR collimator Used (Low Energy Hight Resolution) First stage: dynamic acquisition followed by instillation, obtaining a phase of dynamic imaging with 20 shots to 15 seconds per image, creating five simultaneous static shots of 60 seconds per image, with a zoom 2,29 and 64x64 matrix in dynamic and 256 in static. A late phase at 2 hours radiopharmaceutical administration is performed with the same characteristics as the first phase. The gamma camera is placed in upright position to encourage the instillation of radiopharmaceutical. The patient is treated in sitting position, proceeding to the administration of the radiopharmaceutical, taking care to avoid possible contamination that may occur. Therefore a blotter is placed just below the lower eyelid. Then the patient is approximated with its face to the detector centering the field of vision in both eyes. Two factors play an important role for the examination: patient's age and its thus resulting cooperation (to avoid contamination of the work area and image artifacts caused by patient movement) For the examination of children the assistance of their parents might be necessary. CONCLUSIONS After all, top priority for all Specialist Technician in Nuclear Medicine entrusted with the preparation of radiopharmaceuticals is to ensure that their progress benefits the patients, so that the diagnosis of possible functional disorders of the lacrimal duct, which is indicated in suspected functional or partial blockages, can be performed correctly.

TP077

An Semi-liquid Imaging Analysis of Gastric Emptying in Adult Diabetics

Y. Wang; Huashan Hospital, Fudan University, Shanghai, CHINA.

Objective: Diabetes can cause autonomic disorders of the gastrointestinal tract and gastroparesis, so it is of great important to pay more attention to gastric emptying in diabetic patients. Gastric emptying scintigraphy is the gold standard for measuring gastric emptying. This research was to explore the relationship between food and half-time gastric emptying with the method of semi-liquid imaging study. Methods: A retrospective analysis was carried on four diabetic patients with delayed gastric emptying aged 20 to 40 years old and had a history of diabetes over five years. Three cases mixed $^{99}Tc^{m}$-DPTA (2mCi ~ 3mCi) with 500ml yogurt mix, one mixed in a mixture of protein flour (300g) and water (300ml). Patients kept a fast from last night, sat and perched on the probe at the time of acquisition. Dynamic acquisition continued 40 minutes including imaging from the mouth to the gastropyrolic. Started the collection and oral administrated the semi-liquid food mixed with drugs, then drank water (about 500ml) immediately in order to fill the stomach to reach two-thirds. Use First Derivative to speculate gastric emptying time. Results: Patients taking yogurt mixed meal finished in 1 minute, and patient taking protein mixed meal finished in three minutes. Half-time of 3 patients taking stomach yogurt mixed meal were 35min, 37min, 48min respectively and that of patient with stomach taking protein mixed meal half time was 38min after calculated by built-in formula. Conclusion: gastric emptying imaging in patients with diabetic showed that the average half-time of semi-liquid meal was 39.5min. There was no significant difference between the half-time of these two semi-liquid gastric emptying. There were several advantages perched sitting imaging. First, the back can be supported by the probe to ensure long time examination. However, the spine will block part of the count theoretically. Second, it can avoid the risk of pollution probe when eating if faced the probe or partial scan missing. Third, sitting imaging is in line with the human physiological gastric emptying and it avoids the risk of shake and fall. The probe angle can be adjusted in order to obtain a good imaging position when necessary. Although protein mixed meal is more suitable for semi-liquid diet, yogurt mixed meal has a sample preparation and convenient eating and easier measuring of image gastric emptying peak on gastric emptying. It is recommended to use a yogurt mixture in nuclear medicine stomach empty semi-liquid measurement in clinic.

Radiochemical Purity and Stability control in Technescan MAG3

A. PALMIERI[1], C. DAOLIO[1], S. COLA[1], C. CATTINI[2]; [1]SANTA MARIA NUOVA HOSPITAL, REGGIO EMILIA, ITALY, [2]UNIVERSITY OF MODENA AND REGGIO EMILIA, REGGIO EMILIA, ITALY.

Background: Technescan MAG3 Kit for the Preparation of Technetium Tc^{99m} Betiatide (Benzoilmercaptoacetiltriglicina) is a renal imaging agent for use in the diagnosis of congenital and acquired abnormalities, renal failure, urinary tract obstruction, and calculi in adults and pediatric patients. It is a diagnostic aid in providing renal function, split function, renal angiograms, and renogram curves for whole kidney and renal cortex. Aim: The aim is to verify the stability in vitro of Tc^{99m}-MAG3, analyzing the radiochemical purity. **Matherial and Method:** We verified stability for 8 sample of ^{99}Tcm-MAG3 instant kit formulation of Technescan MAG3. Tc^{99m} -MAG3 was prepared using 1 ml of fresh eluate; the activity should not exceed 1110 MBq (30 mCi). The calculated amount of Tc^{99m} was diluted to a volume of 10 ml with saline 0.9%. This volume was added to TechneScan MAG3 vial using a G20 hypodermic needle. The kit was placed in upright position into boiling water bath for 10 minutes. After heating, we cooled the vial in cold water. Tc^{99m} -MAG3 should not be used more than four hours after preparation. We controlled radiochemical purity (RCP)

analysis 4 time: at preparation time and a 4, 5, 6 hours after kit reconstitution. RCP of Tc^{99m} -MAG3 was determined using Thin-Layer Chromatography (TLC) based on instant thin-layer silica gel strips as stationary phase for checking the main impurities, free pertechnetate and reduced hydrolysed 99mTc. The radiochemical purity should not be less than 95% (Ph. Eur). **Results**: Mean of RCP calculated was: 97.95 (+/- 1.42) at preparation time; 96.85 (+/- 1.13) a 4 h; 95.72 (+/- 0.6) a 5 h; 92.07 (+/- 3.36) a 6 h after MAG3 Kit preparation.. **Conclusion:** TLC strip showed adequate RCP with acceptable free and hydrolysed Tc^{99m} percentages until 5 hours after kit reconstitution.

TP079

Comparative Study Of Two Chromatographic Methods For Radiochemical Purity Determination Of 99mTc-HMPAO

Y. Said Criado, D. Peña Torres, P. Villen Trinado, J. Diaz Alarcon, M. Torres Jimenez; COMPLEJO HOSPITALARIO DE JAEN, JAEN, SPAIN.

OBJECTIVE Compare the results of the PRQ (radiochemical purity) of 99mTc-HMPAO obtained by column chromatography versus those obtained by paper chromatography. MATERIAL AND METHODS 17 samples the radiopharmaceutical 99mTc-HMPAO for determination of radiochemical purity by two different chromatographic methods were used: Method 1: Column Chromatography; Stationary phase: Column Sep-Pak®, Mobile phase: Physiological saline Method 2: Paper chromatography; Stationary phase: Whatman™-17 Mobile phase: Ethyl acetate It was calculated mean value and standard deviation of the results of the radiochemical purity (%) of 99mTc-HMPAO by both chromatographic methods. RESULTS Method 1: Mean (average) = 91.50 and Standard Deviation = 2,857 Method 2: Mean (average) = 92.57 and Standard Deviation = 2,249 CONCLUSIONS Similar results are observed by both methods, although by paper chromatography a higher mean (average) and a lower standard deviation is obtained.

TP080

Radioiodinated L-Phenylalanine Conjugated Boron Nitride Nanotubes and In vitro Evaluation of Glioblostoma Cells

O. Kozgus Guldu, 35100, P. Unak, V. Tekin, G. Takan, E. Medine, S. Timur; Ege University, İzmir, TURKEY.

Introduction: Boron nitride nanotubes (BNNTs), isosteres of CNTs with unique physical properties, are inherently noncytotoxic. The ideal properties of Boron Neutron Capture Therapy (BNCT) agents are low toxicity, high brain tumor uptake, rapid clearance from blood and persistence in tumor during the therapy. Therefore, several BNCT agents has developed in 50 years. [(L)-4-dihydroxyborylphenylalanine] (BPA), sodium mercaptoundecahydro-closo-dodecarborate (BSH), sodium salt of closo-$B_{10}H_{10}^{2-}$ (GB-10), β-5-o-carboranyl-2'-deoxyuridine and 3-(dihydroxypropyl-carboranyl-pentyl) thymidine derivative N_5-2OH etc, are most popular agents so far. **Methods**: In this study, we synthesized BNNts by using chemical vapor deposition (CVD) method. Synthesized BNNt/PAMAMs were conjugated with L-Phe compounds using *N*-(3-Dimethylaminopropyl)-*N'*-ethylcarbodiimide hydrochloride/N-Hydroxysuccinimide (EDC/NHS) conjugation method. BNNt/PAMAM/L-Phe nanobioconjugates were radioiodinated with $^{131}I/^{125}I$. *In vitro* biological affinities of characterized nanobioconjugates were investigated on mouse astrocyte brain cells (CRL2541) and human brain glioblastoma cells (U87-MG). 24, 48 and 72 hours toxicities of conjugates on CRL2541 and U87-MG were examined via WST-8 method. Samples at IC_{50} concentration were studied by TUNEL assay to reveal the apoptotic effect of the samples. Time and specific activity dependent cell uptake levels of ^{125}I labeled compounds were determined. Cell binding and uptake affinities of FITC labeled samples were analyzed by fluorescence microscopy. **Results and Discussion**: BNNt's were synthesized via CVD method with a good yield. Radioiodination yields were over 97%. 8 hours was the optimum for time dependent U87-MG and CRL2541 cells uptake and 74 kBq/μg was an optimum radioactivity amount for the experiment. **Conclusion**: As a result, the synthesized BNNt/PAMAM/L-Phe compounds have the potential of being used as a BNCT agent like BPA. When the nanobioconjugate is compared with commercial BPA superior affinity to the glioblastoma cells are obtained. **Keywords**: L- Phenylalanine, Boron Nitride Nanotube, $^{125/131}I$, Radioiodination, Radiolabeling.

TP081

Correlation between two analyses programs for specific binding ratio in 123 I-FP-CIT SPECT in patients with Parkinsonism

T. KIMURA[1], M. Matsuura[2], T. Nakajima[1], I. Fujisawa[1]; [1]Kishiwada City Hospital, Osaka, JAPAN, [2]Saiseikai Noe Hospital, Osaka, JAPAN.

INTRODUCTION: It is known that Parkinson's disease cause reduction in the number of dopamine transporters in the nerve endings. Until recently, there was no practical way to visually assess reduction in intracranial dopamine. However, due to changes in the national healthcare insurance system in 2014 in Japan, 123I-Ioflupane was used. The dopamine transporter imaging by (123)I-N-v-fluoropropyl-2b-carbomethoxy-3b-(4-iodophenyl) nortropane (FP-CIT) SPECT (DaTSCAN) is now an established method for evaluating parkinsonism, detecting presynaptic dopamine neuronal dysfunction. The goal of our research is to consider how the differences in analytic methodology of two DaTSCAN image analysis programs affect the specific binding ratio (SBR). **METHODS**: 45 patients suspected of Parkinson's disease participated in this study from August 2014 to August 2015. We used two types of analysis programs, mask processing (mp) and non-mask processing (non-mp), angle correction (ap) and non- angle correction (non-ap) for non- attenuation processing (non- AC) and attenuation processing (AC). We compared both programs looking at correlation on each data. RESULTS: The correlation of mp and non- mp was good with SBR in non- AC ($r^2 < 0.939$). This was good correlation with SBR in AC ($r^2 < 0.914$). In non- AC, ap and non-ap showed very good correlation with SBR ($r^2 < 0.972$). The correlation of these was good with SBR in AC ($r^2 < 0.970$). CONCLUSIONS: The two DaTSCAN image analysis programs suggested good correlation with SBR on all condition.

TP082

I123 I FP-CIT Reconstruction Software Change in Clinical Practice

M. Hansen[1], C. Turner[2], N. Fullerton[1], R. Jampana[1], C. Santosh[1], A. Nicol[2]; [1]Institute of Neurological Sciences, Glasgow, UNITED KINGDOM, [2]Queen Elizabeth University Hospital, Glasgow, UNITED KINGDOM.

I123 FP-CIT scans are performed at our centre for the evaluation of dopamine transporters in patients with movement disorders or Lewy body dementia. These are currently reconstructed using the Hermes HOSEM Iterative Reconstruction package. This is to change to the new Hermes Hybrid Recon package. Aim: To examine reconstructed images for visual differences between both reconstruction programmes, and to investigate which parameters to set using Hybrid Recon in order to optimise final displayed images available for reporting. Method: 15 patients (7 M, 8 F, mean age 73, age range 55-93) with scans ranging from normal through to grossly abnormal were reconstructed using both HOSEM and Hybrid Recon iterative reconstruction packages. Iteration / subsets numbers were the same for both packages and Chang attenuation correction was used for both. Hybrid Recon images were smoothed using two Butterworth post reconstruction filters (A, B). These reconstructed images were then reviewed

alongside the original HOSEM images by three experienced NeuroRadiologists in a random & blinded manner. The NeuroRadiologists were asked to choose which scans were, in their opinion, the preferred images. Results: All three Neuroradiologists agreed that both data sets A & B would result in the same clinical report as the original data. All three had an overall preference for images reconstructed using post reconstruction filter B. Conclusion: A method has been devised to facilitate the transfer of the reconstruction package for I123 FP-CIT procedures at our centre.

Managing Radium-223 Therapy in patients with Metastatic Castration-Resistant Prostate Cancer - Developing a multiprofessional team

M. Botelho Cruz, D. Aniceto, A. Nunes, C. Mills, V. Lewington, H. Fahim, S. Allen; Guys and St. Thomas NHS Trust, London, UNITED KINGDOM.

Background: The alpha particle emitter Radium-223 dichloride ($^{223}RaCl_2$) prolongs survival in men with bone metastases arising from castration-resistant prostate cancer (CRPC). Unlike other bone targeting radiopharmaceuticals, $^{223}RaCl_2$ is prescribed as a course of 6 monthly injections. In order to manage predicted workload, we developed a new treatment protocol to meet individual patients' clinical needs within a busy nuclear medicine department. A multiprofessional radium team comprising nuclear medicine clinicians, nurse specialists, radiopharmacists, physicists and technologists was created to set up the service. The team discusses individual patients' management before each treatment cycle in a weekly multidisciplinary meeting. A review of the $^{223}RaCl_2$ therapy pathway at our hospital was conducted to assess service efficiency and identify opportunities to streamline workflow 2 years after the introduction of $^{223}RaCl_2$ at our centre. **Method**: Each step of the therapy pathway was analysed from initial referral, to pre-treatment assessment and follow up after each treatment cycle. Options to streamline processes and tailor care to an individual patient's requirements while running an efficient therapy service were reviewed.**Results:** 69 men with metastatic CRPC age range from 49 to 89, received $^{223}RaCl_2$ therapy in our centre. Having analysed each step in the treatment pathway, we developed a flowchart that incorporates all the points of contact with patients and subsequent procedures. This document clearly identifies the requirements of each team member at each contact and is accessible to all members of the therapy team. The weekly multiprofessional team meeting emerged as an important opportunity to pre-empt difficulties in a complex patient population, avoid $^{223}RaCl_2$ waste, ensure staff efficiency and strengthen team collaboration.**Conclusions**: 1. Multiprofessional teamwork is critical to support the development of a routine $^{223}RaCl_2$service for CRPC patients. 2. A flowchart specifying every point of contact with patients undergoing$^{223}RaCl_2$ treatment improves service efficiency and has a positive impact upon demand management. 3. Weekly multiprofessional team meetings ensure that treatment can be adapted to an individual patient's circumstances, to ensure the best care and the optimal outcomes.

TP084

Utility of the SeHCAT Procedure: May Improve de Quality of Life of Patients Affected of Bile Acid Malabsorption?

M. Martínez Sánchez, **A. Ruiz Rodríguez**, M. Negre Busó, I. Trias Davesa, M. Sánchez García, N. Ferran Sureda, X. Aldeguer Mante, A. Rubió Rodríguez; Hospital Josep Trueta Girona, Girona, SPAIN.

AIM: Chronic diarrhea (CD) may have multiple etiologies, both benign and malignant diseases. Different physiopathological mechanisms could produce them, among those are bile acid malabsorption (BAM). In general, patients with CD due to BAM respond well to treatment with bile acid sequestrants (such as cholestyramine) with significant reduction in bowel frequency and a better quality of life. The aim of the study was to verify that SehCAT (radiolabelled bile acid analog) procedure is a simple test for the diagnosis of CD produced by BAM and helps to establish a treatment that improves the quality of life of patients affected. MATERIAL AND METHODS: A prospective study was performed from January 2013 to December 2015. In this period we studied 29 patients with suspicion of BAM. A SeHCAT procedure was done in all of them. The procedure consists in the oral ingestion of a capsule with 0.01 mCi of ^{75}Selenium Tauroselcholic acid, previous fasting of 7 hours. Anteroposterior images of the abdominal region were acquired (300 sec) at 3 hours, 4 days and 7 days, with acquisition of background activity before and after the study, in a dual head gammacamera Philips Forte. From these measurements, the percent abdominal retention (AR) of SeHCAT at 4 and 7 days were calculated. The test was considered positive if AR to 4 days was <25% and AR to 7 days <10%. Clinical follow-up of patients with positive test was made (4 - 6months), assessing if symptoms had improved. RESULTS: Of the 29 patients, 5 were men and 24 women (mean age 62±13.6 years; range of 28 to 78 years). In 10 patients test were negative and in 19 positive (18 women and 1 man). Seventeen patients with positive test began treatment with cholestyramine. At follow-up, 6 manifested asymptomatic and 11 showed a decrease in the number of bowel movement and improved abdominal pain. CONCLUSION: SeHCAT is an easy technique that allows diagnosing BAM as a cause of DC and treat it easily. The treatment improves symptoms, leading to an increase in the quality of life of patients.

TP085

Management of Breast Cancer Patients after a Positive Sentinel Node. In the Road to Avoid Axilla Lymphadenectomy in Conservative and Non-Conservative Surgery

B. PEREZ LOPEZ, R. RUANO PEREZ, M. RAMOS BOYERO, T. RAMOS GRANDE, L. G. DIAZ GONZALEZ, M. P. TAMAYO ALONSO; HOSPITAL UNIVERSITARIO CLINICO DE SALAMANCA, SALAMANCA, SPAIN.

Aim: to evaluate the feasibility of avoiding the axilla clearance in patients with a positive sentinel node (SN) no matter if a conservative or non-conservative surgery of the breast is performed.**Method**: 641 patients with invasive breast cancer and indication of SN biopsy after a clinical and ultrasound axilla examination from 2010 to 2015 were included. The SN evaluation was done with CK19 expression by OSNA (macrometastasis >5.000 copies; micrometastasis 250-5.000 copies). T1 and T2 unifocal or multifocal tumors were analyzed separately. Conservative or non-conservative surgery was considered. Statistical analysis was done with SPSS program.**Results**: conservation of the breast was feasible in 100% T1a-T1b, 80.1% T1c, and 54.3 T2 tumors. In 409 T1 unifocal cancers, SN was positive for macrometastasis in 86 (21.0%), without statistical difference between tumorectomy or mastectomy (p=0.299). Also, axillary clearance was positive in 14/86 (16.3%) without statistical difference (p=0.204). 6/86 (6.9%) classified as pN2. In 54 T1 multifocal cancers, SN revealed macrometastasis in 21 (38.9%), being the axillary clearance positive in 4/21 (19.1%) without difference between tumorectomy or mastectomy (p=0.305). 2/21 (8.0%) classified as pN2. However in T2 tumors, mastectomy was significantly associated with a greater proportion of SN macrometastasis and positive axillary clearance than tumorectomy (p= 0.045). In 118 T2 unifocal cancers, SN was positive for macrometastasis in 42 (35.6%), being the axillary clearance positive in 17/42 (40.5%). 7 of classified as pN2 (16.6%). In 17 T2 multifocal cancers, SN was positive in 8 (47.3%). The axillary clearance was positive in 4/8 (50.0%), 2 (25.0%) of them classified as pN2. **Conclusion:** after a positive sentinel node the remaining tumoral charge in the axilla is greater in T2 than T1 tumors. Up to now, to avoid axillary dissection when mastectomy is performed without planned adjuvant radiotherapy could be considered in invasive T1 tumors but should not be recommended in T2 tumors.

TP086

Patient experience of 18F-FDG-PET/CT in a mask fixation

C. Andersson[1], B. Johansson[2]; [1]Nuclear Medicine & PET, Uppsala University, Uppsala, SWEDEN, [2]Oncology, Uppsala University, Uppsala, SWEDEN.

Objective: The 18F-FDG-PET/CT examination is a valuable diagnostic tool for radiation treatment planning but the knowledge about patients experiences of the examination is scarce. The aim of this study was to explore how patients with known or suspected head- and neck cancer experienced undergoing an 18F-FDG-PET/CT examination in a mask fixation. Methods: A qualitative phenomenology methodology according to Max van Manen and the four existensial; lived space, lived body, lived time and lived relation, a validated method for small sample sizes, was used. A convenience sample of nine patients, seven men and two women ranging in age from 48 to 75 years with known or suspected head- and neck cancer and who were scheduled for an 18F-FDG-PET/CT examination in a fixation mask for the first time was included February 2012 to August 2015. Inclusion criteria were that the participants could speak and understand Swedish, was 18 years or older and outpatients. The patients were asked to participate in the study after the examination was completed. If the patient agreed to participate a conversational interview was conducted either directly after the examination or within one week. The interviews started with the open-ended question "You have now gone through an 18F-FDG-PET/CT examination in a mask fixation. How did you experience the examination?" The interviews were tape-recorded and transcribed verbatim and read through thoroughly and analyzed separately. Results: Different themes regarding the patients' experience of the 18F-FDG-PET/CT examination in a mask fixation and suggestions to improve patient satisfaction was identified. The period during the subsequent uptake phase, PET/CT camera and the time the patient spend in the mask fixation may all be experienced physical and emotional negative. Patients experienced that they were trapped in the mask which caused both physical and mental discomfort. The PET/CT camera was experienced as narrow and uncomfortable. Also feelings of being abandoned were experienced during the time in the camera. Conclusion: To undergo an 18F-FDG-PET/CT examination in a mask fixation may be a physical and emotional negative experience for the head- and neck cancer patient. Improved strategies to prepare the patients for the examination and possibilities to communicate if necessary and reassurance that they are not forgotten may be ways to improve patients' experience of an 18F-FDG-PET/CT examination.

TP087

Briefing for implementation of patient safety in a nuclear medicine service

M. Torres Jimenez, Y. Said Criado, P. Villen Trinado, D. Cid Jimenez, D. Peña Torres; COMPLEJO HOSPITALARIO DE JAEN, JAEN, SPAIN.

AIM: Ensure patient safety by conduction briefing to prevent adverse events. MATERIAL AND MOTHODS: The briefing is informative, short and multidisciplinary meetings where health service professionals, exchange information concerning patient safety. The patient safety is a fundamental principle of health care and a critical component of quality management. At these meetings possible risks to patients or incidents during attendance are discussed. Experiences on patient safety are openly shared, thence the importance of their implementation in any service. In the briefing we do in our service, the topics we discussed are the following, response to the main types of incidents that may occur: Identification of patients and alert to similarities in names., Communication with other services and other hospitals during the patient's transference and derivation., Performance of correct procedure, at the correct organ and in the right patient. Improve communication among professionals responsible for the patient's health., Reduce the risk of falls in patients to position them in the gammacámara, taking special care to elderly and child., Reduce the risk of infection by washing hands., Safe handling and right administration of treatments., Responsibility of all professionals regarding patient., Provide a safety climate to the patients through clear communication., Resource management for grater effectiveness of radiation protection measures. RESULTS: The results of these meetings have been effective in relation to patient safety, reducing the incidence of adverse events. CONCLUSION: The briefings channel the efforts of professionals who care for the patients to ensure their safety.

TP088

A Novel Approach to Radiation Safety Advice for Hospital Staff

L. A. Henderson[1], K. P. Eberhard[1], I. Badr[2]; [1]The London Clinic, LONDON, UNITED KINGDOM, [2]The Radiological Protection Centre, St George's University Hospitals NHS Foundation Trust, LONDON, UNITED KINGDOM.

Aim: Fears and misconceptions surrounding radiation exposure from Nuclear Medicine patients can present a challenge to non-nuclear medicine staff within a hospital setting. In our hospital, patients often attend more than one department during their hospital visit and many non-nuclear medicine staff did not have a good understanding of radiation safety. The objective was to alleviate fear and avoid unnecessary confusion by introducing a clear and effective method of communicating standardised radiation safety precautions to staff who may come into contact with nuclear medicine patients. **Materials and methods:** A traffic light colour coded system of cards was created in line with local legislation, guidelines and 'as low as reasonably practicable' (ALARP) principles. Nuclear medicine studies were categorised into three classifications (red, amber and green) based on the isotope properties and activity reference level of each study. For example; red cards for post Iodine131 therapies, amber cards for F18FDG studies and green cards for Tc04- thyroid studies. Information relating to pregnant staff members as well as recommended distance and time spent with a patient was outlined on the cards as well as a time limit for when the instructions cease to be relevant. The cards were designed for out-patients to take to any other appointments they had within the hospital. More detailed nurse oriented information for in-patients was updated to reflect similar guidance. A thorough roll out of the hospital wide policy was implemented which included training of nuclear medicine and radiology staff, awareness sessions for hospital staff and incorporation into the induction package for new starters. An audit by way of survey on staff understanding will be performed after the policy has been in place for 3 months. **Results**: Initial feedback from staff is very positive. Responses suggest staff feel more confident when dealing with nuclear medicine patients post radioactive administration. Full audit results will be discussed on completion. **Conclusion**: This is a new and simple approach to educating non-nuclear medicine staff in the hospital. Preliminary feedback suggests successful education of hospital staff.

TP089

Implementation of a software ASTRIM for quality assurance management in Nuclear Medicine Department (PET, SPECT and Therapeutic Radiopharmaceuticals) complying with the Italian Current Regulation

C. MALIZIA, C. STEFANO, L. MORA, G. CICORIA, M. MARENGO, S. FANTI, F. LODI; Policlinico S.Orsola Malpighi Bologna, Bologna, ITALY.

Introduction And Purpose ASTRIM software is currently used in many Nucleare Medicine Centres to manage quality assurance of conventional SPECT radiopharmaceuticals. The corrent version is not able to manage the production of PET clinical trials and traditional PET radiopharmaceuticals like FDG. Up-date software ASTRIM was developed in our facility for

management the quality assurance of PET clinical trial and traditional PET radiopharmaceuticals production. Since the Nuclear Medicine Unit of the Bologna S.Orsola performance, about 12000 examinations/year and the new software was necessary to manage the amount of data and and to be compliant with Italian Current Regulation. **Materials And Methods** The change to a computerized management with Software ASTRIM it was possible thanks to the collaboration of all the professional role in Nucleare Medicine such as Nuclear Medice Doctors, Radiopharmacist, Nuclear Medicine Technicians, Nurse, Phisicist together with the Application Technologist of ASTRIM. The change come off for following steps involving every time different professional roles. - Analysis the specific procedures regarding the PET clinic trial and the PET radiopharmaceuticals splitted in several phases to be compliant with the software. - Training of the Nuclear Medicine Staff (50 people). - Routine use of the new developed software. The software implementation work for 10 PET radiopharmaceuticals lasted about six months covering all following phases: 1) storage and registration of devices, isotopes and any other reagent for radiolabelling; 2) preparations of devices for radiolabelling; 3) production of isotopes and preparation of reagents for radiolabelling; 4) radiolabelling; 5) dilution and sterilitazion of the final product; 6)quality control; 7)pre-release of radiopharmaceuticals; 8) fractionation into single dose for patients; 9)release of radiopharmaceuticals. The training of the staff (50 people) continued for about six months and during this time maintaining the management of quality assurance with both the old system and the new software. **Results and Conclusion** The developed ASTRIM Software for quality assurance management allowed to optimize the time especially in pre-release phases of radiopharmaceuticals, becouse of the complexity of the structure with about 80-90 patients daily divided into PET radiopharmaceuticals (3 preparations daily) and SPECT radiopharmaceuticals (5 preparations daily) as well as the radiopharmaceuticals for therapy (one preparation daily) all splitted into 4 PET/TC scanner and 3 Gamma Cameras. Moreover the up-date software allowed better management and monitoring reducing errors, of all the aspect of radiopharmaceuticals preparations, quality control and release.

TP090

4D-PET/CT Imaging Implementation at Oslo University Hospital, Ulleval

J. Ellingsen[1], R. DAGESTAD[1], J. HOLTEDAHL[1], H. L. STOKMO[2]; [1]OSLO UNIVERSITY HOSPITAL, ULLEVAAL, Oslo, NORWAY, [2]OSLO UNIVERSITY HOSPITAL, Oslo, NORWAY.

Introduction Since January this year, we have had a test license for 4D-PET/CT (Siemens Phase-Match) at Oslo University Hospital, Ullevål. ***Hardware:*** Siemens Biograph mCT (40-slice) with Varian Real-time Position Management™ (RPM) Respiratory Gating. With 4D-PET/CT, the breathing cycle is divided into the desired number of phases from amplitude to amplitude. This is done *both* with CT and PET. Each phase of the PET uptake is attenuated with the corresponding phase of the CT. With our current CT-settings this 4D-protocol contributes an additional radiation dose of 2,3 mSv. **Purpose** 4D-PET/CT is a recently acquired technology in Nuclear Medicine. Previously, 3D-PET/CT and 4D-CT have been used in radiotherapy to observe tumour motion and to draw gross target volume (GTV). The former method tends to underestimate the FDG-uptake due to the localization and movement of the tumour. In addition, the FDG-uptake for small lesions are often underestimated and it becomes difficult to delinate the GTV. 4D-PET/CT provides a more accurate semi-quantitation of the FDG-uptake. This is due to a more accurate attenuation correction, as well as a sharper defined lesion. **Implementation / Protocol** A small block with reflectors is placed on the pasient in a location sutiable for detection and recording of breathing movments (e.g. upper abdomen). The movement of the block is registered and infrared light is reflected from the block, and detected and recorded by a camera that is located at the end of the patient table. When the breating registration is completed, the breathing data is exported from Varian RPM to the modality computer for analysis. In our protocol, one static image is generated from the expiration phase. Furthermore, eight phases of attenuated PET uptake are generated. This is played as a cine, so that all the phases of the lesions natural motion are shown on the fused images.

TP091

Operational Strategies and Policies of Nuclear Medicine Departments - Service Managers' view

S. Soares, C. Quintal; Faculty of Economics-University of Coimbra, Coimbra, PORTUGAL.

Introduction:The operational management of a Nuclear Medicine department (NMD) is dependent on factors such as: management style, knowledge and professional experience of the service manager; policies and features of the hospital in which the NMD belongs to. This study will explore the importance that the NMD service managers´ give to their different tasks, and department policies regarding: workflow configuration; service improvement; incorrect preparation of inpatients and managing appointment DNAs.Methods: Semi-structured interviews were conducted with 10 NMD service managers of the NHS, based in the London area.Confidentiality and anonymity was guaranteed. A thematic analysis was chosen to analyse the results, and the dominant themes highlighted. Results:According to the interviewees, providing patient care and safety is their top priority. However, the management of the workload and workflow, staff, budget and resources is crucial for the proper functioning of the departments. Some of the most important and difficult tasks include compliance with the waiting targets and radiation regulations, and having sufficient staff with the necessary skills to perform the required job tasks. All interviewees agree on a semi structural workflow. Workflow configuration can be dependent on: radiopharmaceuticals suppliance and delivery prices; staff and facilities availability; scan duration; ARSAC restrictions and other procedures. This arrangement maximizes the use of the radiopharmaceutical vial, the equipment and all the human resources involved, achieving a smoother workflow (with the inconvenience of generating a disproportional waiting list). Although all interviewees undertook service improvement, only two of them consciously applied process mapping or a lean approach.Interviewees felt that the incorrect preparation of inpatients is mainly due to lack of communication, aggravated by turnover of ward staff. Therefore, assessing the patient beforehand, emphasizing costs involved, and cross charging the wards were methods suggested to minimize this problem. A department choose to outsource work, that requires complex patient preparation, to other Trusts. DNA policies were very similar across departments. Patients with a plausible excuse were re-booked, if not the referral was returned to the referrer. Conclusion: Greater knowledge about service improvement methods may help patient workflow and minimize existing barriers. Optimal strategies vary, and each NMD should adopt methods that best suit its needs. Whilst acknowledging this diversity, the sharing of these results may contribute to wider discussions on best practice.

TP092

Increasing the capacity of MPI IQ-SPECT. Changing the workflow?

M. Dini, N. Weel; Institute Verbeeten, Tilburg, NETHERLANDS.

Aim Over the past few years, the number of patients referred to our institution for myocardial perfusion imaging (MPI) has increased significantly. This year, compared to 2013, the number of studies has increased by more than 20% and further growth is expected. In order to cope with this growth, our department had to critically evaluate and optimize its current workflow process. Our goal was to increase our capacity by 20% in 2016 while maintaining the following conditions: All studies performed within working hours (8:00 - 17:30), With the same equipment, The technicians do not have to work faster **Method** We have visualized the patient-routing throughout an exam. The duration of each step in this process was timed to evaluate were time losses occured (at different points in the process).A distinction was made into 2 major components during the process: a stress test and the examination. We have a stress-test room, a gammacamera, 3 technicians and an additional technician at our disposal. At

each room there were 2 dressing rooms available. We use the IQ-SPECT acquisition method to exam patients. **Results** In the old situation, we could only perform a total of 71 exams (32 stress + 39 rest). In the new situation we are able to perform 92 exams (46 stress + 46 rest). To achieve this we use a rotation system between technicians. 2 technicians work at the camera and 1 is doing the stress test. After 3 patients the technicians rotate. The additional technician (technician 4) places the venflon needle before the stress test. Technician 4 places a venflon needle and puts the patient in a dressing room. Stresstest: Both the doctor and technician 1 stay in the room. This way there is no delay and there is a constant flow of patients. Technician 1 takes the first three charts with him to the scan room. Examination: Technician 2 operates the computer during an exam and technician 3 performs the exam. Technician 3 places the next patient in the dressing room during the CT scan. **Conclusion:** By using a rotation system between technicians the patient sees only 1 person at each step in the exam. In our experience this is very patient friendly. The acquisition time is reduced from 30 min per patient to 20 min per patient.By introducing the rotation system, we've accomplished a *rise* of 25 % of patients.

TP093

Data recording in PET/CT routine research protocols: Could we do better?

C. Baun, T. Nguyen, P. F. Høilund-Carlsen; Odense University Hospital, Odense, DENMARK.

Aim: To examine errors in data recording in a routine PET/CT workflow from which many patients enters into research studies. In our daily work we accept variations of +/- 10% in administered tracer dose and of +/- 5 min in acquisition time point. Such variations influence quantitative PET measurements. Therefore, we identified errors of this type to elucidate the extent of the problem. **Methods and materials:** A retrospective analysis of 201 patients included in five PET/CT research projects performed January 2015 - January 2016. These comprised 158 patients scanned with FDG in a 1h protocol and 24 scanned in a dual-time protocol, 10 patients scanned with sodium fluoride (NaF) in a 45 min and 9 scanned in a 60 min protocol. Recorded data were obtained from handwritten pre-scanning reports, the automatic tracer injection report (when used) and DICOM information from the PET/CT scanner and compared to research protocol requirements regarding tracer type, dose, injection time, and scan time. Basic data regarding patient weight, height, and blood sugar in handwritten reports were compared to registrations typed in by the technologist. **Results**: Among 1h FDG studies, errors were found in 143 cases (91%) and among dual-time FDG scans, in 22 cases (96%). With the two (45 and 60 min) NaF protocols, errors were found in all patient studies (100%). Errors mainly consisted in discrepancies between prescribed and injected tracer dose. This was found in 176 patients (88%). The error range for the FDG dose was -38 - 97 MBq and for the NaF dose -106 - 208 MBq. Errors in registered scan time were seen in 54 patient studies (27%) with a range of 1-59 min. Typing errors in patient height and weight registration were seen in 6 (3%) and 8 (4%) of studies, respectively. Only 4 patient studies had missing information regarding blood sugar. **Conclusion**: The overall absolute accuracy of data registration in routine research protocols appears rather low. Errors mainly concerned administration of correct tracer dose and scan time in accordance to prescribed time points. Although the number of errors is relatively large, it should be taken in consideration that any registration discrepancies regardless of size counted as an error in this study. In the daily routine, a small variation margin is allowed for practical purposes, which, however, reduces the accuracy and reproducibility of quantitative PET measurements. Attention should be taken to optimize reproducibility in routine workflows generating research data.

TP094

Patients not attending, how to reduce them

B. Hoyer Mathiasen, M. Adler, P. C. Holdgaard; Vejle Hospital, Vejle, DENMARK.

Aim: At the Department of Nuclear Medicine, Vejle Hospital, technologists experience a large proportion of outpatients not attending for their appointment. In 2014, 846 of 15471 patients (5,5%) did not attend their appointment. The hypothesis was is was patients in follow up that had received their written information a long time ago that did not attend. We wanted to investigate whether we could reduce the numbers of non-attending patients, who had received their written information more than 90 days by sending the patients a reminder letter. If more patients turn up, it would reduce the waste of resources, shorten waiting lists and improve overall economy. **Materials and methods:** To conduct this study, we registered all patients that had received their written information more than 90 days ago. These patients were sent a reminder letter 14 days prior to their time of examination. The patients not attending recorded. The letter consisted of a text, telling the patients to remember their examination, and referring to information in the original appointment letter, and contact information to our department, in case of any questions. The patients from the same months of 2015 were chosen as a control group. **Results:** 443 patients was included over a period of 3 months in 2016, 18 of these (4,1 %) did not attend and did not cancel their appointment. The control group for the same period in 2015, was 397 patients, 37 of these (9,3 %) did not attend. The results show a significant reduction (p=0,002) in the number of non-attending patients, in the group that received the reminder letter compared to the control group. **Conclusion**: We find that the patients attendance percentage can be strongly improved with a reminder letter prior to the time of the examination, in the patient group that have received their written information more than 90 days prior to the exam date. It has reduced the proportion of non-attending patients by more than 50 %. At the Department of Nuclear Medicine, we will therefore continue to send reminder letters to this patient group, and as of now (April 2016) it has been possible for the patients to subscribe to a reminder SMS.

TP095

Fast tracking of PET research studies that fits in your white coat pocket

E. S. Saxtoft; Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK.

Introduction The Department of Clinical Physiology, Nuclear Medicine & PET performs over 5000 PET/CT scans per year. About a fifth of these are part of highly specialized research projects. Each project has an associated protocol, which is created in collaboration with scientists, project leaders physicians and nuclear medicine technologists. The number of research projects have been increasing in recent years and the need for an electronic project catalog arose. The implementation of an online project catalog has facilitated the management of PET research studies and at the same time some other work processes as the fast track of tracers. The updated easy access to documents has ensured that the quality of research data has increased and we can save time and resources in every day work life. **Materials and Methods** We researched the market for tablets and found a solution that suited our needs. Using a NEXUS 7 Tablet, we have the perfect blend of both technology and mobility in the coat pocket. With a fast connection to the network, we have solved several challenges at once. Fast and useful access to important information and project data as: -Online project catalog -Tracershop overview and tracer release time -Patient transport service follow-up -Netradio for the patients -Mutual activity calendar -Document Management System **Results** We have covered the need to support our own knowledge on the various projects and their study criteria, which benefits the patients, the research studies and the staff on the ward. A clear and user-friendly overview of the various research studies has reduced the possibility of making errors among projects and we can thus feel more secure about the management of project data. The new tablet has contributed to a greater search-experience, as it turns out that the staff can save time and resources by taking the tablet around when the need for quick access to fully updated information is crucial. The tablets are a streamlined solution that is easy to synchronize and ensures that the staff is always working with information that is continuously updated. **Conclusion** The implementation

of the electronic tool benefits primarily the patient studies, quality assurance and the staff. The access to project data and other information on-the- go is probably the best argument for any further development and optimization of the mobile tool. A high specialized department with a large repertoire of project protocols requires an effective tool that can match the demand.

TP096

Do Fasting Hours, Blood Glucose Level and Diabetis Mellitus Influence Uptake of FDG in the Myocardium?

D. Mateo-Navarro[1], A. Sabaté-Llobera[1], M. Cortés-Romera[1], S. Rustarazo-Losada[1], I. Ferrero-Febrer[1], I. Liarte-Trias[1], M. Albadalejo-Castaño[1], A. Cebrián-Leyva[1], D. Coca-Castro[1], L. Gràcia-Sánchez[1], M. Ribas-Sitjas[2], G. Reynés-Llompart[1], C. Gámez-Cenzano[1]; [1]PET Unit, Department of Nuclear Medicine - IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN, [2]Department of Cardiology. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN.

AIM: To correlate myocardial uptake of FDG with fasting hours (FH), blood glucose level (BGL) and diabetes mellitus (DM). MATERIAL AND METHODS: Retrospective evaluation of 208 patients (115 male, mean age 59 years) referred for whole-body FDG-PET/CT. Information about FH and BGL was collected. Fourty-eight patients had DM (23%). One DM patient was excluded due to previous cardiac surgery. Myocardial FDG uptake was analysed semiquantitatively (SUVmax, SUVmean) placing a ROI on the left ventricle, and correlated to FH and BGL. Additionally, patients were divided in 2 subgroups according to FH (<12 and >12 hours), and differences between subgroups were tested. To rule out the potential influence of DM, other 2 subgroups were evaluated (DM and non-DM) and correlated to myocardial FDG uptake. RESULTS: Patients fasted for at least 6 hours (mean 10.3, range 6-20). Mean SUVmax and SUVmean was 5.4 and 3.1, respectively. No correlation was found between FH and myocardial FDG uptake, neither with SUVmax nor with SUVmean (Pearson's r=-0.07 for both parameters). However, higher SUV values were observed with less FH. Analysing the two subgroups (<12 and >12 hours) significant differences were obtained (p=0.022 for SUVmax; p=0.015 for SUVmean); yet, this results could be influenced by the number of outliers and a positively skewed distribution around low fasting times. To have more consistent data, values with SUV>mean+1.9*SD were eliminated. In this setting, we did not find neither correlation between FH and myocardial FDG uptake (r=0.08 for SUVmax and SUVmean), nor differences between subgroups (p=0.962 for SUVmax; p=0.933 for SUVmean). BGL was not available in 8 patients. Mean BGL was 5.6 mmol/L (3.8-12.9). No correlation between BGL and myocardial FDG uptake was observed, neither for SUVmax (r=0.02), nor for SUVmean (r=0.03), though most of the patients (88%) were normoglycemic. Of the hyperglycemic patients, 69.5% had DM. When comparing DM and non-DM patients, no differences regarding FDG uptake in the myocardium were observed (p=0.399 for SUVmax; p=0.424 for SUVmean). CONCLUSION: According to our study, FH and BGL do not seem to influence FDG uptake in the myocardium in standard conditions. However, significant differences appear between patients with <12 and >12 FH, even if they could be influenced by the number of outliers, as higher SUV values are observed in shorter fasting periods. No differences between DM and non-DM were observed, but additional variables may influence the results. Equalizing the number of patients in the subgroups could lead to different conclusions.

TP097

Does an automatic PET infusion system actually deliver the prescribed dose?

J. C. Gam-Hadberg, C. Baun, O. Gerke, P. F. Høilund-Carlsen; Odense Universitetshospital, Odense, DENMARK.

Aim In an effort to reduce the radiation dose to the staff, many departments have implemented the use of automatic infusion systems for PET tracers. In our daily work we accept variations of ±10% in administered tracer dose; errors beyond this limit can have consequences for image quality and influence PET quantification measurements especially in research protocols. Therefore, we aimed to assess the accuracy of our PET infusion system and to elucidate any reduced performance during the years of use. **Materials and methods** Our retrospective analysis included 491 tracer doses delivered to patients by the Intego™ PET Infusion System ((Medrad, Inc., Indianola, PA). Data were obtained from the printed label delivered by the Intego system post injection and comprised 341 delivered doses in 2011 and 150 in 2015. The differences regarding prescribed dose and delivered dose were calculated using Bland-Altman limits of agreement and paired t-tests, also stratified by year. Equivalence testing was performed by the 'two one-sided testing procedure' (TOST), using log-transformation. The equivalence limit was 10%, implicating critical boundaries of 0.9 and 1.11 of a respective 90% CI. **Results** The overall data showed a mean difference between prescribed and delivered dose of 0.22 MBq [95% CI: -0.70 to 1.15], with Bland-Altman limits -20.20 and 20.65 MBq. For the data obtained in 2011 the mean difference was -2.00 MBq [-2.39 to -1.62; p<0.0001], range -9.11 to 5.11 MBq; for data obtained in 2015: 5.27 MBq [2.53 to 8.02; p=0.0002], range -28.12 to 38.66 MBq. Prescribed and delivered doses were found equivalent at the 10% level in both 2011 and 2015. The ratio 'delivered/prescribed dose' was estimated to be 0.999 for both years [90% CI: 0.997 to 1.002]. The Intego performance changed statistically significantly (p<0.0001), but not clinically relevantly from 2011 to 2015. In 2011, 0.6% of doses were beyond the accepted 10% limit by a mean -2.39 MBq, range [-15.34 to 10.56]; for 2015, 4.6% of the doses exceeded the 10% limit by a mean of 23.6 MBq, range [10.84 to 32.01]. **Conclusion** The automatic Intego PET Infusion System delivered the prescribed dose within a 10% equivalence limit, actually within a 5% equivalence limit, although the results suggested that system performance decreased slightly over time. Attention should be paid to ensure accuracy of administered radioactive doses, and performance of automated system should be monitored over time from a quality control perspective.

TP098

Score cards for standardized comparison of myocardial perfusion imaging reports

J. D. Jensen, C. M. Hoff, K. Bouchelouche, N. L. Christensen, M. R. Jochumsen, M. A. Pedersen, L. P. Tolbod; Dept. of Nuclear Medicine and PET-Centre, Aarhus University Hospital, Aarhus N, DENMARK.

Background: When optimizing scan protocols or comparing modalities in myocardial perfusion imaging, it is necessary to compare the current method to the new method This can be achieved by a comparison based on hard numbers such as MBF, summed rest and stress scores, total perfusion deficit etc. However, what is of importance to the patient is the total evaluation of these scores and the weight and confidence ascribed to each by the reporting physician. We suggest a standardized method summarizing the observations and the confidence of the physician in simple scores. We tested the developed score cards in a pilotproject using a training scenario where 3 observers with varying experience (1 month, 5 months and 3 years, respectively) scored static rest/stress Rb-82 PET scans. **Method:** 10 patients with known ischemic heart disease were included. Using the 17-segment AHA cardiac model, each patient will get one or more of the five clinical scores (0) Insufficient pharmacological stress, (1) normal, (2) reversible ischemia, (3) irreversible ischemia and (4) 3-vessel and/or sub endothelial disease. The certainty of the clinical score will be marked as (0) equivocal, (1) probable or (2) certain. Furthermore, the degree of the defect will be defined (0) <10 %, (1) 10-20 %, (2) >20 %. In addition, scan quality will be rated as (1) unacceptable, (2) poor or (3) good. In the test, the scoring process is performed by each observer. **Results**: Summed certainty score was similar for all three observers (15.3±1). A high summed scan quality score was given by the most and least experienced observers (18 and 19

respectively, 20 being the maximum summed score), but lower by the observer with medium experience (15). The average score deviation from the most experienced observer to the least and medium experienced observers was 0.7 and 0.4, respectively. Perfect agreements on extend of defect by medium and most experienced observers, whereas the least experienced observer tended to overestimate defect size. **Conclusion**: The test of the score card in a training situation was successful and results reflected the varying experience of the participating observers. However, deviations on quality score and defect size, illustrate the importance of supplying the observers with clear instructions and definitions. The score card will be used for optimizing cardiac PET protocols in the department.

TP099

First experiences of using segmentation and SPECT SUV tool

B. Mirocha, A. Sackiewicz; Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, POLAND.

Aim of this poster is to present our experiences of using software for SUV calculation for SPEC/CT studies. The use of new software solution for quantitative estimation of radiopharmaceuticals uptake and calculation of concentration in volume of interest (VOI) given in MBq/ml allow us to classify lesion characterization using SPECT SUV. The studies was made with use of GE Healthcare hybrid γ-camera Discovery NM/CT 670 equipped in special software called Q.Metrix. Use of that software for segmentation SPECT/CT studies needs some camera preparation with specific calibration. Studies acquisition data is iterative reconstructed with available corrections (AC, SC, RR) and presented in 3 standard planes (coronal, sagittal, axial). With this software it is possible to do three-dimensional segmentation and spatial localizations based as well on CT or SPECT and further mutual transformation from CT to SPECT and vice versa. At the end system calculate SUV in ROI/VOI and presents it with statistics. Given specification of The Maria Skłodowska-Curie Institute of Oncology and our experience it is possible to predict that Q.Metrix software will be helpful tool in high dose I-131 (3700 MBq) thyroid therapy studies and lesions assessment in follow up studies in bone tumor. Determine the value of SPECT SUV allows to compare statistics of studies in relation to follow up studies or after therapy.

TP100

3d-ssp implementation in nuclear medicine service as tool accessory for interpretation of brain spect 99mtc-hmpao

F. ZELAYA REINQUET, A. Renda Alcalde, J. Outomuro, D. Ruiz Hernandez, M. Castrillon, C. Castillo Berrio, F. Loira, L. Campos, R. Guitian, A. Lopez; Complejo hospitalario de vigo hospital meioxeiro, vigo, SPAIN.

Three-dimensional analysis of stereotactic surface projection(3D-SSP)has been widely used as imaging tool in dementias. It is an analysis method that evaluates cortical perfusion after anatomical standardization by calculating the maximum activity for the corresponding areas of cerebral cortex, assigning a value for each pixel of surface; the algorithm compensates individual differences in cortical thickness and depth of gyri using a standard stereotactic system. OBJECTIVES:1. Determine the degree of concordance of diagnostic interpretation between expert and novice observer with the help of the 3DSSP.2.Determine whether the use of 3DSSP adds value to diagnostic expert and novice observer. MATERIALS AND METHODS: We randomly selected 30 studies of brain perfusion SPECT with 99mTc-HMPAO, done between January and December 2015 at our hospital, with age between 50-79years (determined by the design of the program).Image processing was carried out according e-soft Siemens standardized reconstruction algorithms clinical applications package. Subsequently, the 3D-SSP processing was performed. The images were evaluated by two Nuclear Medicine experts, and nuclear medicine physician in training.The study was divided into two phases.1st phase: Conventional processed image were evaluated, knowing only the reason for the request of the Brain SPECT.2nd Phase: 15 days later, images were reevaluated with help of processed images obtained with 3D-SSP. We delivery to the observer a template with the brain divided into anatomical subregions(prefrontal, orbitofrontal, parietal, frontotemporal, mesial and lateral temporal, and occipital), corresponding to both hemispheres, the observer assigned a value according to the semiquantitative perfusion grade: 0 normal; 1 minor involvement; 2 moderate involvement; 3: severe involvement.For interobserver statistical comparison we use the EPIDAT software, obtaining the Kappa Correlation index between the two interpretations. RESULTS:The kappa coefficient of correlation between the novice and expert observers was as follows:1st phase: 0.8159 with 95% CI (0.7645 to 0.8673).2nd Phase: 0.8860 with 95% (0,8440- 0.9280). CONCLUSION:Our series confirms what has been reported in the literature, 3D-SSP tool helps to improve visual assessment by physician in training. Instead of the 3DSSP contribution provided by the 3DSSP to senior observer is not statistically significant. We believe to train doctors in training is an interesting alternative to implement the training program MIR in the Services tool.

TP101

Standardizing image quality for ^{68} Ga-DOTA-TATE PET/CT

M. Cramer, S. Z. M. van Lierop, C. P. W. Cox, M. Segbers, R. Valkema; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: The European Association of Nuclear Medicine procedure guidelines recommends a dose of at least 100 MBq for ^{68}Ga-DOTA-TATE PET/CT. This poorly defined dose regimen leads to differences in image quality between patients due to body composition and attenuation. Our aim is to propose a dose regimen that standardizes image quality for all patients. Methods: Retrospectively 20 ^{68}Ga-DOTA-TATE PET scans were analyzed. All scans were acquired 58 minutes (± 2.09) post injection (91±14 MBq) on a Siemens Biograph mCT. Time per bed position was dependent on the body mass and varied between 3 and 6 minutes. Iterative image reconstruction was performed using Time-Of-Flight and point spread function recovery (True-X). To assess image quality a volume of interest (VOI) with a diameter of 3 cm was drawn in a homogenous part of the liver. The mean pixel value and standard deviation were measured to calculate the signal-to-noise ratio (SNR). To investigate the relationship between SNR and patient dependent parameters (body mass, length, body mass index (BMI), body mass per body length and lean body mass), the SNR was normalized for variation in injected dose and time per bed position by assuming Poisson statistics for the VOI measurements. The SNR was normalized to 3 min/bed and a dose of 100 MBq which is currently recommended in the EANM guidelines. The relationship between the best correlating parameters and normalized SNR was used to propose an optimized dose regimen. Results: Three patient dependent parameters (Body mass, BMI and body mass per body length) show a significant ($p<0.01$) decreasing linear correlation with the normalized SNR. Pearson r is respectively -0.766, -0.827, -0.823. The normalized SNR is proportional to the square root of the time per bed position and the amount of injected activity. This implies that injected dose or time per bed position should be varied quadratically with one of the patient dependent parameters to achieve standardized image quality. Or a combination of both can be used. Conclusion: Following the current EANM guidelines will result in decreasing image quality for patients with a higher body mass, BMI or body mass per body length. To achieve a standardized level of image quality a quadratic change of the [dose x time per bed position] product with one of these three parameters should be implemented.

TP102

Colonic transit scintigraphy using ^{67}Ga Citrate: establishing a department guideline

D. M. P. S. Neves, B. X. Lourenço, M. Faria Joao; Diaton S.A., Leiria, PORTUGAL.

Introduction: Colonic Transit is defined as the time required to excrete ingested substances that have reached the colon. Measuring colon transit time could be helpful in the evaluation of colonic motility disorders, namely in constipation cases. Radiopaque marker test (radiology), is the most widely used technique, although, colonic transit scintigraphy could represent an alternative. Scintigraphy is based on the oral administration of a non absorbable radiopharmaceutical in the bowel, such as liquid ^{111}In-DTPA, ^{111}In- labeled activated charcoal capsules, or ^{67}Ga-Citrate. To our knowledge, aqueous ^{111}In-DTPA or capsules, aren´t commercially available in Portugal, therefore, ^{67}Ga-Citrate is the plausible option. SNMMI and EANM guideline for small-bowel and colon transit study mention this option, but it isn´t addressed for ^{67}Ga-Citrate use. Additionally, there´s a lack of standardization of this method within the literature. **Aim:** The aim of this work is to present a colon transit scintigraphy guideline using ^{67}Ga-Citrate, established according to our department work. **Material and Methods**: Between 2009 and 2015, 16 patients (12 females and 4 males) were investigated. One patient (normal colon transit) was considered control. All patients were addressed by a surgery consult, with the clinical information of constipation.. After preparation, 5.5 to 7.4MBq (150 to 200 mCi) were orally administered. Images were obtained at AP views, at 4-6 hours, 24 h, 48h, 72h, 96h, and in the 7th day if necessary. Images were all acquired in the same dual-head gama camera. Processing activities included visual analysis, half-clearance time ($T_{1/2}$) calculation, and segmental analysis assessed by geometric center calculation. Results: The average half-clearance time for constipation patients occurred between 72 and 96 hours, and between 24 and 48 hours for the control. According with established interpretation criteria, several image patterns were observed, namely: normal colon transit, generalized slow colon transit, functional rectosigmoid obstruction, and segmental retention. **Conclusion**: The use of ^{67}Ga-Citrate reveled several advantages such as: non absorption in the bowel; price and availability; handling simplicity; good image quality; low administered activity; and suitable physic half-life ($T_{1/2}$=3.3 days), allowing for late imaging if necessary. No secondary effects were reported. The major limitations for it use is the absent standardization and the lack of dosimetry data comparing it with the ^{111}In-DTPA. Data processing was also a challenge. Therefore, in our experience, when other validated radiopharmaceuticals aren´t available, ^{67}Ga-Citrate could be a good option to perform colon transit scintigraphy. Nevertheless, more comparative studies (with 111In-DTPA or/and radiology methods) are needed.

TP103

A Guide to Setting up a Ga68-PSMA PET/CT Service in the United Kingdom

L. A. Henderson[1], R. Pasternicki[1], R. Maria[1], R. T. Meades[2], S. Khan[1], T. D. Barwick[1]; [1]The London Clinic, LONDON, UNITED KINGDOM, [2]Radiological Sciences Unit, Imperial College Healthcare NHS Trust, London, LONDON, UNITED KINGDOM.

Aim: Prostate specific membrane antigen (PSMA) labelled to Ga68 for PET/CT imaging of prostate cancer patients was unavailable in the United Kingdom prior to August 2015. However, due to the success of Ga68-PSMA in Europe demand from urologists was high. The service was setup, with our first patient scanned on the 28/09/2016 and in the following 6 months we successfully scanned 33 patients. Our objective is to summarise our experience of establishing and running this service in the UK to provide other centres with an insight into the challenges and considerations involved. **Method and materials**: Many challenges can arise when trying to implement a new service in a UK nuclear medicine department and for our non-NHS department these were compounded by the fact that the service was not yet offered anywhere else in the country. Availability of the short lived Ga68 isotope was limited and local legislation requires consultant reporting training prior to obtaining a license to use the product. A structured plan was established and executed over the months prior to radiopharmaceutical availability. The separate processes required to setup the Ga68-PSMA PET/CT service included appropriate equipment selection, understanding of regulations, radiopharmaceutical availability, staffing, refining imaging protocols, standard operating procedures, doctor and staff training, referrer education, physics expertise, administration and finance support services. **Results**: Over a six month period 33 patients were scanned and during this time positive feedback was received from referrers. A reference level of 200MBq of Ga68-PSMA using the radiometal chelator HBED-CC was used. Patients were imaged on a Siemens Biograph mCT PET/CT scanner and imaging parameters included uptake period of 1hour. Imaging was performed over a scan range of skull vertex to knees using CT parameters dose reduction software set at a reference level of 70mAs, and a kV at reference level of 120. PET acquisition was performed for 3 minutes per bed, 3 PET reconstructions were created utilising CT for attenuation correction. A pelvis post micturation image was also performed on all patients. Studies were dual reported by Nuclear Medicine trained Radiologists. Challenges were faced to do with radiopharmaceutical availability and the department learned from this by introducing clear patient information to manage expectations. **Conclusion**: We successfully implemented this new service in our department by beginning with a structured and detailed plan. This work has provided a summary of the challenges and considerations experienced in setting up a Ga68-PSMA PET/CT service in the UK.

TP104

Importance of PET TAC Valuation in Oncology

M. Barrera Gonzalez, E. Ariza Cabrera, M. Valderas Montes, A. Benítez Morera, E. López Martínez; Servicio Andaluz de Salud, Cadiz, SPAIN.

Aim: - To implement a data collection system for assessing the patient at baseline. - To establish a protocol to the patient prior information as to the next steps for the diagnosis, evaluation and treatment. -To evaluate the quality of care, ensuring that patients are treated in nuclear medicine for PET procedure are properly prepared, informed, cared for and in a state of comfort. Materials and Methods: We have done an observational, descriptive cross-sectional study, all participating patients and their families. They served a total of 32 patients referred for PET -CT during the months of March and April 2016 in the Nuclear Medicine Hospital Puerta del Mar of Cadiz. To perform this test we used a radiopharmaceutical that it is a derivative of glucose (fluorodeoxyglucose) labeled with fluorine-18 (18F-FDG), which it will study the metabolic activity of the disease process. The gamma camera used is a Siemens PET CT, together with the availability of comfort rooms. We decided to make a collection of data using in an Excel spreadsheet and nursing assessment. Results: According to data obtained from patients seen in the sample, they indicate that 50% are men and the rest are women, the aged are approximately between 45 and 70 years. They have a majority of medical diagnosis of lung cancer, cervical cancer and melanoma. Glycemic indices indicate us that 90% are non-diabetic patients, since not altered capillary glycemia. Conclusion: The creation of this spreadsheet has served as an element of reflection and evaluation of quality in information handling. The deal is personal, one of the qualities that motivates the patient and decreases anxiety. Before the examination, patients have been cared for by nurses and performing a nursing assessment to them, much needed for data collection.

TP105

Local Recurrence in Breast Cancer, Which is the Role of Sentinel Lymph Node Biopsy?

B. PEREZ LOPEZ, R. RUANO PEREZ, T. RAMOS GRANDE, L. G. DIAZ GONZALEZ, F. GOMEZ-CAMINERO LOPEZ, M. RAMOS BOYERO, M. P. TAMAYO ALONSO; HOSPITAL UNIVERSITARIO CLINICO DE SALAMANCA, SALAMANCA, SPAIN.

Objetive: To evaluate the utility of SNB in local recurrence of breast cancer in patients with previous surgery treatment. **Methods**: We reviewed all women with local recurrence from January-2002 until

December-2015. Indication for SNB was preoperative axilla node negative. The exclusion criteria were previous axillary lymph node dissection (ALND) or axillary radiotherapy. Lymphatic mapping was performed by a peri-tumoral intradermal injection of Technetium-labeled (Tc-99m) nanocolloid, considering where was the previous surgical scar. Surgical detection was done with a hand-held gamma probe. ALND was done when SN informed of macrometastasis or not located. **Results**: 59 women with local recurrence were analysed. 23 with previous ALND received no axilla examination. SLNB was not indicated in 4 cases with positive axilla. Also 9 patients directly went to ALND despite SLNB indication because of surgeon decision. Therefore the SLNB was done in 23 patients. Detection was feasible in 15 patients (65.2%), 13 of them had negative SN and 2 presented micrometastasis (13pN0, 2pN1mic) so no ALND was performed in any of them. In the 8 patients without detection of the SN, ALND was done resulting in 6pN0 and 2pN1a (one node). We found no relation between the previous surgical scar localization (external quadrants) and the absence of drainage. In the cases where ALND was directly performed, metastases were found just in the 4 patients with previous clinically suspicious of malignancy. **Conclusion**: SNB in women with local recurrence is technically feasible and permits to avoid axillary clearance. We believe that axillary lymph node dissection should not be performed if sentinel lymph node is not detected due to low probability of axillary lymphatic disease after a correct clinical and ultrasound examination of the axilla.

Is it possible to minimize time of uptake for SeHCAT patients without compromising the diagnosis?

A. Flensborg, G. Zulfovski, J. Nielsen; Bispebjerg Frederiksberg Hospital, Copenhagen, DENMARK.

Introduction: The SeHCAT test for bile acid malfunction is performed differently in different nuclear medicine departments according to time of counting, collimators, background measurement and distance between the patient and the detector(s). In our department we use 10 mins scans for background and measurement of patients using a camera with two uncollimated detectors placed as close as possible to the patient. We decided to find out if it is possible to minimize the measurement time without compromising diagnosis as well as count statistics. **Materials and methods**: Siemens Symbia Gamma Camera with two detectors. The lower detector is shielded with a thin plexiglass plate for protection. 75- SeleniumHomoTauroCholicAcid capsules (GE HealthCare) 20 patients referred to the test. Detectors were placed far from the patient and as close as possible to the patient. Time of measurement was 1, 5 and 10 mins. In addition to the patient tests, background was measured another day while 99mTc and 81mKr was present in the vicinity of the room. **Results and discussion**: There is no significant difference in the retention % whether we use measuring time of 1, 5 or 10 minutes. However, the background counts are lower (approxim. 5, 30 or 60 kcts) when the detectors are placed in the position close to the imaginary patient, while the patient counts are higher when the detectors are close to the patient. This is not surprising, as the background radiation is minimized due to the closeness of the detectors. Background does not vary during the day, and more important: The diagnosis does not vary in any of the setups. This is probably because the only other isotopes used in the department, 99mTc and 81mKr have entirely different gamma energies (140 KeV and 190 KeV), whereas the window is set to 272 KeV, 20% during the SeHCAT-scans, according to one of the 75Se-energy peaks.**Conclusion**: We suggest that the counting time is reduced from 10 mins to 2 mins (The 2 mins count is in order to obtain acceptable background count statistics) and the detectors placed as close as possible to the patient. Background should be measured before the first and after the last patient. This will save time in our busy department and it will also not compromise the count statistics.

GC analysis of radiopharmaceuticals for residual solvents

E. Saksa, O. Solin, T. Viljanen; Turku PET Centre, Turku, FINLAND.

Aim Since there is no therapeutic benefit from residual solvents, all residual solvents should be removed to the extent possible to meet product specifications, good manufacturing practice, or other quality-based requirements. Drug products should contain no higher levels of residual solvents than can be supported by safety data. Testing should be performed for residual solvents when production or purification processes are known to result in the presence of such solvents. The aim of this study was to set up a method for residual solvent analysis of radiopharmaceutical patient injections. **Materials & Methods** The method is based on Agilent USP <467> application note.[1)] We use an Agilent 7820A gas chromatograph with a flame ionization detector (FID), automatic injector, liquid (split) injection and an Agilent DB-624 column. The method is validated for each radiopharmaceutical preparation as different solvents and formulation solutions are used. This is a limit test and therefore parameters to be validated are specificity and limit of detection (LOD). The validation sequence consists of blank, LOD-solution, water and standard solution runs. The concentrations of solvents in the standard solution are added in the concentration maximum limit values. The run time is 20 minutes. After the method validation, radiopharmaceutical sample runs are made. The run sequence consists of two replicate runs from the standard solution, one water run and two replicate runs from the sample. **Results** In validation the resolution factor for all used solvents in the chromatogram were > 1.5 and the LOD calculated from the signal to noise ratio was more than 3:1. Limit of detection is the lowest concentration which can be distinguished from the baseline noise. In radiopharmaceutical samples the concentrations of solvents were under the concentration limit values. **Conclusion** The method is accurate and fast enough to be used in quality control for determination of residual solvents in radiopharmaceuticals with half-lifes longer than ~1h. The method is also useful for process validation. For quality control of carbon-11 radiopharmaceuticals faster run times are needed. [1)] Agilent Technologies, Inc., 2012, 5990-7625EN

Quality, stability and robustness of ^{68}Ga-HBED-CC-PSMA and ^{68}Ga-HA-DOTATATE preparations for nuclear medicine applications using an automated system

R. de Roos, F. F. T. Ververs, B. de Keizer, G. C. Krijger; University Medical Center, Utrecht, NETHERLANDS.

Aim: ^{68}Ga-HBED-CC-PSMA and ^{68}Ga-HA-DOTATATE have been developed as PET tracers to detect (metastases of) prostate and neuroendocrine carcinoma, respectively . The quality, stability and preparation method robustness of these radiopharmaceuticals were studied. Materials and methods: Gallium-68 ($^{68}Ga^{3+}$) was eluted from a registered 1110 MBq ^{68}Ge/^{68}Ga generator and ^{68}Ga-radiopharmaceuticals were prepared with the automated Modular-Lab eazy system and accompanying buffers and cassettes (Eckert & Ziegler, Germany). Radiochemical purity, radionuclidic purity, pH, sterility, endotoxins and yield were determined according to European Pharmacopoeia procedures. The stability in time was analyzed using both ITLC and HPLC. Results: A total of 162 preparations were analyzed within expiration date of the ^{68}Ge/^{68}Ga-generator (1 year). 4 preparations were rejected (technical failure), 2 failed the radiochemical requirements. 156 preparations were released for administration. The mean radiochemical purity of ^{68}Ga-HBED-CC-PSMA was 98.1% ±0,8 and 97.2% ±1.9 using ITLC and HPLC, respectively. For and ^{68}Ga-HA-DOTATATE the mean radiochemical purity was 96.1% ±2.3 and 98.1% ±1.9. All preparations met the required specifications for radionuclidic purity, pH, sterility, endotoxins and radionuclidic purity. Both ^{68}Ga-HBED-CC-PSMA and ^{68}Ga-HA-DOTATATE were sufficiently stable after preparation for 3 hours. Conclusions: The Modular-lab eazy is a stable system for ^{68}Ga-HBED-CC-PSMA and ^{68}Ga-HA-DOTATATE preparations to be used in routine health care and clinical trials.

Financial Management of Nuclear Medicine Departments from their Service Managers' Perspective

S. Soares, C. Quintal; Faculty of Economics-University of Coimbra, Coimbra, PORTUGAL.

Introduction: Many financial and political changes have been affecting the efficiency and organizational structure of the National Health System (NHS) England. In addition, departments have to cope with new technological demands that require investment. The goal of this study is to determine those factors, which service managers feel have the greatest impact on the financial stability of their departments. Methods:14 out of 21 Nuclear Medicine department service managers, London-based and belonging to the NHS, were invited to participate in this study. Individual in-depth interviews were performed with 10 participants. The intention was to evaluate the reality experienced and felt by the service leaders in their midst and according to their perception. The interviews were semi-structured, using the face-to-face model, and analysed by theme. Confidentiality and anonymity was guaranteed.Results: A number of service managers did not have access to departmental budgets or participate in financial meetings. According to the majority of interviewees, changes in the NHS financial model do not affect the quality of the service provided to patients, the way of working or the number of patients. To achieve the Trust Cost Improvement Plan target, service managers are trying to reduce costs and improve the department performance. Common strategies include optimization of appointments, radiopharmaceuticals and equipment usage, as well as extending the working day. Staff organizational structure is also being affected: no overtime payment is allowed and pay bands have been changed. More patients mean more income (especially higher profit examinations: therapies and PET/CT). Increasing the number of low cost examinations and repatriation of work back to the department are all factors that contribute to increased productivity.Conclusion: For some service managers, it is difficult to meet the financial demands. Constant actions to increase income and decrease expenditure need to be taken. However, these actions need to be monitored to not interfere with the service quality provided to the patient. The vast majority of the interviewees did not know which financial model was in operation previously or the characteristics of the current one. To fulfil their responsibilities, service managers should take a greater role in the financial aspects of the department, such as: attending financial meetings, acknowledge of the budget status and having the opportunity to take more financial decisions.

Advanced Practice in Nuclear Medicine: The Changing Role of the Clinical Technologist and Current Practical Problems

M. Casanova Martins[1], R. Bidder[1], P. Davies[2], S. Stace[2], P. Ali[1]; [1]ABMU HB, Swansea, UNITED KINGDOM, [2]Hywel Dda NHS Trust, Swansea, UNITED KINGDOM.

The needs of a nuclear medicine department warrant continuous professional progression and innovation from the clinical technologist, driven by long waiting lists, financial restrictions and lack of staff availability or even deficiency of highly specialized trained people like consultant medical staff. Advanced practice such as cardiac stress testing as part of myocardial perfusion scintigraphy (MPS), or even issuing reports for imaging studies, is therefore beginning to constitute common practice amongst technologists. Working under DAGs (Delegated Authorization Guidelines) to authorise nuclear medicine procedures or to refer patients for additional radiology is also within the scope of advanced practice and is common practice in many departments since IR(ME)R 2000. However, there is a legal requirement for this to be undertaken by registered healthcare professionals. In the UK, there is no statutory register for clinical technologists, which may prevent the full development of their advanced practice responsibilities. Radiographers, on the other hand, are working under the professional guidelines laid down by the HCPC (Health and Care Professions Council) and perform within their technical competencies. Current registration and the various ionising radiation regulations already permit radiographers to undertake these tasks after appropriate training. The aim of this paper is to outline training needs and legal requirements to the safe and high quality delivery of highly specific tasks designated as advanced practice for clinical technologists. The training needs for cardiac stress testing as part of MPS include a thorough training plan which has already been established in 2007 by the BNMS. This training plan comprises, for example, "in house" performance of at least 100 tests using the existing stressing agents (exercise, vasodilators and inotropic tests). Ideally, however, advanced practice training and practice should be certified and accredited. Though, there aren't mechanisms in place for the formal assessment of the advanced practitioner in this field by BNMS/BNCS and/or EANM/ESC. An active involvement of EANM and the ESC would be highly desirable in order to promote standardized training/requirements across Europe. The reporting training for nuclear medicine technologists relies, in the UK, on accredited courses provided by few universities. Involvement of EANM and the ESNM would promote standardization of reporting across Europe, as well as providing robust credibility in achieving a desired professional standard.The legal requirements for advanced practice from clinical technologists are not yet fulfilled or available. Adopting a similar framework to HCPC or the incorporation of clinical technologists within the HCPC could be the solution.

European School of Multimodality Imaging and Therapy ESMIT

Level 1, steered by **Prof. Murat Fani Bozkurt** from Ankara/TR, is the entry level and therefore covers the very **basic** topics. It is 100% **e-learning** based and **free of charge** for all users.

Level 2, the intermediate level led by **Prof. Paola Erba** from Pisa/IT, goes to the heart of **evidence based** teaching, focussed on everyday practice and provided in a mixture of **theoretical and practical** lectures. A key feature of the level 2 programme is the introduction of **Spring and Autumn schools** covering 4 parallel tracks each and bringing together trainees and teachers **from all over Europe** for 3 days of uninterrupted learning in an **academic environment** and at a **low fee.**

Spring School 2017: March 31 - April 2, 2017, Groningen/NL
Autumn School 2017: September 1 – 3, 2017, Cluj-Napoca/RO

Level 3, is a more advanced level, in which knowledge is deepened and expanded for individuals developing **subspecialty areas** of interest. These **high end courses** are held in the EANM Educational Facility in Vienna.
The section is chaired by **Prof. Philip Elsinga** from Groningen/NL.

Each level will be led by the mentioned chairs and working groups consisting of specialists from different backgrounds, including radiologists, clinicians and scientists.
