G. ALEXIOU[1], S. Tsiouris[1], A. Papadopoulos[1], E. Levi[2], A. Fotopoulos[1]; [1]UNIVERSITY HOSPITAL OF IOANNINA, IOANNINA, GREECE, [2]2proACTINA S.A., 20 Delfon St., 15125 Athens, Greece, Athens, GREECE.

Purpose: Treatment of high-grade gliomas involves surgery, radiotherapy and chemotherapy. After treatment, gliomas near always recur. Differentiation of recurrent glioma from treatment induced necrosis (TIN) is not always straightforward. Both entities have the same appearance on MRI. SPECT has the advantage of lower cost and wider availability compared to PET. We set out to investigate the ability of 99mTc-Tetrofosmin (TF) SPECT to detect recurrent glioma. **Material and Methods**: Thirty studies (21 men, 9 women, mean age 61.5 ± 11.1 years) were eligible for the study. All patients had high-grade gliomas, received previous surgery and chemoradiation and during the follow-up period presented with a suspicion of recurrent tumor. On TF SPECT, the portion of the tumor with the highest accumulation was selected as the region of interest (ROI), lesion-versus-normal ratio (LN) was defined as the ratio of average TF counts in the lesion divided by average counts per pixel in normal white matter. **Results:** Twenty-seven patients suffered from glioblastoma, 1 from anaplastic astrocytoma and 2 from anaplastic oligodendroglioma. Histological examinations in 2 cases showed recurrent glioma. Twenty-two cases were considered to have recurrence, whereas 6 were considered to have TIN based on stable neurological symptoms with no sign of massive enlargement of the lesion on follow-up MR after at least 6 months. There was a statistical significant difference in TF uptake between patients with recurrent glioma and TIN (12.29 ± 6.61 vs. 2.37 ± 1.27 respectively; P = 0.002). The L/N cut-off threshold value representatively discriminating the two clinical entities was 4 as indicated by the ROC analysis. **Conclusion:** Brain imaging by TF could offer useful information in the workup of treated gliomas. To validate the technical and diagnostic performance of TF/SPECT, a phase II multicentre clinical trial (EurdraCT No: 2015-005573-21) is ongoing, as part of the clinical development of TF/SPECT for glioma diagnostic imaging. *This project has received funding from EU's Horizon 2020 research and innovation programme, grant agreement No673737. Common malignant tumors of the brain: Can FDG PET/CT aid in differentiation ?

N. C. Purandare, S. Shah, A. Agrawal, C. Bongulwar, T. Gupta, V. Rangarajan; Tata Memorial Centre, Mumbai, INDIA.

Objectives: 1) To study the metabolic characteristics of common malignant space occupying lesions (SOL's) of the brain. 2) To determine the utility of FDG PET/CT in differentiating between the common types of malignant brain SOL's. Materials and methods: All patients with brain SOL's who were referred for a FDG PET/CT scan by a multidisciplinary team were included in this retrospective study. The metabolic characteristics of the brain lesions in the form of SUVmax was obtained and compared with the final diagnosis. Ratios of SUVmax of the primary tumor to that of the contralateral cortex as well as white matter were also calculated. All primary brain lesions underwent a surgical biopsy for histopathological confirmation whereas the diagnosis of metastasis was confirmed by performing biopsy from the primary or other metastatic sites demonstrated on PET/CT. The difference in SUVmax values and tumor to background activity ratios between the various pathologies were compared using non-parametric statistical tests.ROC curve analysis was used to evaluate the optimal SUVmax cut off for Lymphomas. Results: The study included 106 patients (M/F -70/36), median age 55.5 yrs (range 15-78). Glioblastoma multiforme (n=30), lymphoma (n=25) and metastases (n=46) accounted for most of the malignant tumors (95.2%). Majority of patients (66%) had a solitary brain lesion whereas 34% had multifocal disease. Amongst the patients with brain metastases, lung was the commonest site of primary malignancy (n=40).Four patients with brain lymphoma had extracranial disease on FDG PET. Lymphomas showed a significantly high metabolic uptake (median SUVmax-20.3, range 8.1-46.3) as compared to GBM's (median SUVmax-10.3,range 0-21.7) and metastases (median SUVmax-11.5, range 0-19.6) (p=0.00). Tumor to background activity ratios for lymphomas were also significantly higher. There was an overlap in the metabolic uptake of GBM's and metastases with no significant difference between their SUVmax values (p=0.245). A SUVmax $\geq$ 15.5 shows a 84% sensitivity and 80% specificity to diagnose lymphomas (AUC=0.876, p=0.00). Conclusion: 1)PET/CT can be useful in differentiating between the common malignant brain SOL's by virtue of their variable FDG uptake. 2)The high avidity of lymphomas on FDG PET/CT can help differentiate them from GBM's and metastases in majority of cases. 3)The ability of FDG PET/CT to detect primary malignancy in patients with metastatic brain SOL's and extracranial disease sites in patients with brain lymphoma provides additional benefit in their staging work up.

EP026

4′-[methyl-^{11}C]thiothymidine positron emission tomography in patients with newly diagnosed glioma: Comparison with Gd-DTPA enhanced magnetic resonance imaging

Y. Fukuda[1], K. Tanaka[1], Y. Yamamoto[1], T. Hatakeyama[2], N. Kudomi[3], J. Toyohara[4], Y. Nishiyama[1]; [1]Kagawa University Department of Radiology, Kita-gun, JAPAN, [2]Kagawa University Department of Neurological Surgery, Kita-gun, JAPAN, [3]Kagawa University Department of Medical Physics, Kita-gun, JAPAN, [4]Research Team for Neuroimaging, Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN.

Introduction: A novel radiopharmaceutical, 4′-[methyl-^{11}C]thiothymidine (4DST), has been developed as an in vivo cell proliferation marker based on the DNA incorporation method. The purpose of this study was to evaluate 4DST uptake in patients with newly diagnosed glioma and correlate with gadopentetate dimeglumine (Gd-DTPA) enhancement in magnetic resonance imaging (MRI). Methods: 4DST studies in 23 patients with newly diagnosed glioma were retrospectively investigated. In the 4DST PET, metabolic tumor volume as defined as the volume with a threshold of 40 % of the maximum standardized uptake value for tumor (V_{PET}). In the MRI, regions of interest were manually placed over the Gd-DTPA enhancing part of the tumor, avoiding necrotic-appearing areas. The volume of the Gd-DTPA enhancing part of the tumor (V_{MR}) was calculated. Results: 4DST PET detected 20 of 23 gliomas. Three gliomas that were not visualized with 4DST had no Gd-DTPA enhancement. The mean (±SD) of the V_{PET} and V_{MR} was 25.03±31.49 and 14.93±21.24, respectively. A significant correlation between V_{PET} and V_{MR} was found ($r=0.738$, $p<0.0001$). Conclusion: These preliminary results indicate that 4DST PET may be useful for the detection of glioma and the volume of 4DST uptake correlates to that of Gd-DTPA enhancement.

EP027

Correlation of F-18 FDG uptake with Histopathological grading in Meningioma

N. Shuke, C. Miyazaki, T. Kamibayashi, T. Aburano, A. Ando, T. Onishi, O. Saito, T. Inagaki, S. Irie, K. Saito; Kushiro Kojinkai Memorial Hospital, KUSIRO, JAPAN.

Objective: The objective of this study was to investigate the correlation of F-18 FDG uptake with histopathological grading in meningioma. Methods: Eleven patients (pts) with surgically proven meningioma (age 63 ±6, M/F= 5/6), who underwent FDG PET/CT before surgery, were retrospectively studied. As an index of tumor FDG uptake, SUV max was adopted. As histopathological parameters, WHO grade, ki67/MIB-1 labeling index (MIB1LI), and peripheral tissue invasion (brain or bone) were adopted. Bivariate correlations of SUV max of the tumor with WHO grade and MIB1LI were evaluated by rank correlation. Also analyzed was multivariate correlation of SUV max of the tumor with WHO grade (MIB1LI was omitted because of its collinearity with WHO grade) and peripheral tissue invasion (brain or bone) by Hayashi's quantification theory class 1, which is a statistical method to investigate relationship between parametric objective variable and nonparametric explanatory variables. Results: Pathological examination revealed 8 pts had WHO grade 1 meningioma, 2 pts had grade 2, and 1 pt had grade 3. Brain and bone invasion were found in one pt each. Although bivariate rank correlations of SUV max of the tumor with WHO grade or MIB1LI were not statistically significant ($P > 0.05$), multivariate analysis showed significant correlations of SUV max with WHO grade and peripheral tissue invasion ($R^2=0.890$). Partial correlation coefficients of SUV max with WHO grade, bone invasion, and brain invasion were 0.819, 0.910, and 0.318, respectively, indicating significant correlation of SUV max with WHO grade and bone invasion. Conclusion: WHO grade and bone invasion were significantly correlated with degree of FDG uptake by meningioma. Bone invasion might be an independent factor of FDG uptake by meningioma.

EP028

Role of 18F-Fluorocholine PET-CT to improve radiotherapy planning in resected glioblastoma patients

N. Testart Dardel[1,2], M. Zurita Herrera[1], A. Jorques Infante[1], E. Triviño Ibáñez[1], R. Luque Caro[1], M. Pérez Rosillo[1], C. Santos Chamorro[1], M. Gómez-Río[1,2], J. Llamas-Elvira[1,2]; [1]Complejo Hospitalario Universitario de Granada, Granada, SPAIN, [2]IBS, Granada, SPAIN.

OBJECTIVES:Even though major improvements in the treatment of the glioblastoma have occurred in the past few years, the prognosis remains poor. The **aim** of our study is to evaluate the potential role of 18F-Fluorocholine PET/CT to define therapeutic targets prior to radiotherapy and its added value in the delimitation of treatment volumes.PATIENTS AND METHODS:Prospective study of adult patients with resected glioblastoma prior to radiotherapy. The standard protocol for determination of radiation therapy volumes is based on MRi: pre-surgical, early post-surgical (<72h) and delayed post-surgical (4 weeks). The proposed protocol includes the additional information provided by 18F-Fluorocholine PET/CT performed during the week before radiotherapy (integrated PET/CT system following the standard protocol including 6 h fasting, intravenously injection of 185 MBq of 18F-fluorocholine, 15 m resting and acquisition during 30 min; 168 matrix, zoom 2, FWHM 2 mm; reconstruction by iterative algorithm [OSEM, 14 subsets, 4 iterations]). The Nuclear Medicine specialist is asked to estimate the probability of tumour presence to determine treatment targets according to fluorocholine uptake and its relation with Gd-enhanced and/or oedema regions. The definitive radiotherapy target volumes are determined after the analysis of both imaging procedures (MRi and 18F-Fluorocholine PET/CT) separated and fused. A final consensual report is provided to the radiotherapist.RESULTS: Seven patients were included (4 males and 3 females; mean age: 58.7 years [range: 47-71]. In the analysis of fused images in all patients, no significative uptake was appreciated outside the margin of enhanced area in MRi-T1-Gd, neither in the surrounding oedema evaluated by T2F-MRi. In three patients there was total concordance between both image modalities. In 4 patients there were discrepancies between the intensity of the T1-MR-Gd-enhancement and the intensity of fluorocholine uptake: one patient showed a highly intense heterogeneous uptake and in the remaining three the area of fluorocholine uptake was smaller and comprised into the T1-MR-Gd-enhancement area. The planned volumes of treatment were not changed in any patient.COMMENTS:Our preliminary results showed discrepancies in the intensity of MR-T1-Gd-enhanced areas and the intensity of choline uptake. The addition of 18F-Fluorocholine PET/CT in the pre-RT evaluation of these patients has no impact in the expected treatment approach and does not modify the planned volumes for treatment.

EP029

Inter-observer variability of total hemispheric glycolysis ratio obtained at 1-hour and 3-hour FDG-PET/CT imaging in glioma patients

E. A. Segtnan[1,2], C. Constantinescu[1], J. Holm[1], P. Grupe[1], O. Gerke[1,3], P. F. Høilund-Carlsen[1,4]; [1]Odense University Hospital, Odense, DENMARK, [2]University of Southern Denmark, Odense, DENMARK, [3]Centre of Health Economics Research, University of Southern Denmark, Odense, DENMARK, [4]Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, DENMARK.

Aim: Total hemispheric glycolysis ratio (THGr) obtained by FDG-PET/CT may provide predictive value in glioma patients. We performed 1-hour (1h) and 3-hour (3h) time point FDG-PET/CT imaging in glioma patients to examine whether THGr had the same inter-observer variability at late (3h) compared to early (1h) imaging. **Material and methods:** Forty-eight FDG-PET/CT studies were prospectively collected at 1h and 3h after FDG-injection in 5 male and 9 female glioma patients, aged 35-77 (mean 63) years. The PET studies were performed before treatment, after resection/biopsy, after radio-chemotherapy, during and after chemotherapy. Two independent observers applied dedicated software (ROVER; ABX, Radeberg, Germany) for segmentation and calculation of the patients' cerebral(Ce) and cerebellar(Cb) total hemispheric glycolysis ratio(THGr). The two observers obtained IRV results by applying "top-down" procedures, *i.e.* a threshold of either 2 SUVs (T2) or 3 SUVs (T3) below the maximum SUV of Ce or Cb, respectively. The results, therefore represented the brain parenchyma and neurons with the highest level of glucose metabolism, *i.e.* the index of functionality. We also tested

IRV with the "top-down" thresholds 50% below SUVmax (T50), 4 SUVs (T4) and 3 SUVs (T3) below SUVmax, for Ce and Cb, Ce, and Cb, respectively. IRV was calculated with the coefficient of variation and compared to the IRV from 1h scan. **Results:** Cerebrum: IRV for T3-THGr(Ce) was in median 9.5%; Inter Quartile Range (IQR) 4.1-22.3, whereas 1h was 3.3%; IQR 1.9-4.2. IRV for T4-THGr(Ce) was in median 6.0%; IQR 2.3-14.5 , whereas 1h was 2.7%; IQR 1.0-5.0. IRV for T50-THGr(Ce) was in median 3.2%; IQR 0.6-5.0, whereas 1h was 2.3%; IQR 1.0-4.2. Cerebellum: IRV for T2- THGr(Cb) was in median 16.9%; IQR 6-43, whereas for 1h it was 5.9%; IQR 3.0-14.3. IRV for T3-THGr(Cb) was in median 13.7%; IQR 6.8-28.8, whereas for 1h it was 4.5%, IQR 1.8-7.5. IRV for T50-THGr (Cb) was in median 7.3%; IQR 3.4-10.1, whereas for 1h it was 3.5%, IQR 1.7-5.4. **Conclusion:** Only two thresholds had median IRV above 10%. Inter-rater variability when using 3h THGr was lowest with the threshold T50. THGr at 3h had higher IRV than IRV at 1h. The reason for this might be the higher washout of FDG uptake at the 3h time point and, hence, a decrease in metabolic segmented volume and an increased sensitivity of mask delineations. Thus, it appears that high SUV cut-offs should be used with care at 3h time point imaging with FDG.

EP030

Prognostic value of 4'-[methyl-^{11}C]-thiothymidine PET in patients with newly diagnosed glioma

Y. Yamamoto[1], K. Tanaka[1], K. Mitamura[1], T. Norikane[1], Y. Fukuda[1], T. Hatakeyama[1], H. Yamamoto[1], J. Toyohara[2], Y. Nishiyama[1]; [1]Kagawa University, Kagawa, JAPAN, [2]Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN.

A novel radiopharmaceutical, 4′-[methyl-^{11}C]thiothymidine (^{11}C-4DST), has been developed as an in vivo cell proliferation marker based on the DNA incorporation method. The purpose of this study was to evaluate ^{11}C-4DST uptake in patients with newly diagnosed glioma and to correlate the results with proliferative activity and patient prognosis. **Methods:** ^{11}C-4DST PET/CT was investigated in 20 patients with newly diagnosed gliomas. The maximum standardized uptake value (SUVmax), tumor-to-contralateral normal brain tissue (T/N) ratio, and metabolic tumor volume (MTV) were derived from ^{11}C-4DST PET images. Linear regression analysis was used to assess the proliferative activity as indicated by the Ki-67 index in tissue specimens. Kaplan-Meier curves and univariate and multivariate Cox regression were used to analysis of overall survival (OS). **Results:** Median OS was 21.5 months, with 15 survivors at the time of analysis. Linear regression analysis indicated a significant correlation between SUVmax ($r=0.52$, $p<0.03$) and MTV ($r=0.71$, $p<0.001$) using ^{11}C-4DST and the Ki-67 index. In univariable analysis, SUVmax (cutoff 3.0) and T/N ratio (cutoff 5.0) were significant prognostic factors for OS ($p<0.01$ and $p<0.03$, respectively), but these correlations did not hold in multivariate analysis. MTV (cutoff 15) was not predictive for OS ($p=0.58$). **Conclusion:** These preliminary results suggest that ^{11}C-4DST PET/CT may be useful in the noninvasive assessment of proliferation and survival in newly diagnosed gliomas.

EP031

^{18}F-DOPA PET/CT imaging in brain tumors

D. Grigolato, L. Locantore, M. Cucca, M. Zuffante, M. Ferdeghini; Azienda Ospedaliera di Verona, VERONA, ITALY.

AIM: Amino acid transport imaging is a noninvasive imaging technique able to assess metabolic features of brain tumors. We wanted to analyzed the added value of ^{18}F-FDOPA PET when MRI gives uncertain diagnostic results. This study compares visual and semiquantitative analysis parameters for detection of lesions.METHODS: Twenty-one patients, 12 female, 9 male, age range 32 -82 years, underwent ^{18}F-FDOPA PET/CT imaging for suspected tumor recurrences (n.9), for differentiating dysplasia from low grade lesions (n. 8), low grade lesions from ischemic lesions (n. 3), low grade lesions from high grade ones (n. 1). All PET/CT of the brain were acquired at 5 and 60 minutes after radiotracer injection. PET studies were fused with contrast enhanced MR sequences. PET scans were analyzed visually and semiquantitatively: lesion-to-striatum (L/S) and lesion-to-normal brain tissue (L/N) ratios using SUV_{max} in early and delayed images. Uptake parameters were compared and correlated with histology, WHO tumor grade and patient follow-up with conventional imaging.RESULTS: Thirteen PET/CT were positive at DOPA imaging (SUV max range 2.2-8.8), the accuracies for detection of pathological lesions for visual and semiquantitative analysis were similar. Eight of them had higher value of L/S and L/N ratios (range 0.8 - 2.8 and 1.4 - 4.6 respectively): five patients were submitted to surgery with evidence of recurrences; one patient, suspected for ischemic lesion, had high grade astrocytoma; two patients demonstrated progression at MRI and CT. The remaining 5 positive patients had lower values of max L/S and L/N ratios and they were judged having low grade lesions. These patients were stable at a minimum follow up of six months. Eight patients with no or faint DOPA uptake in the suspected regions, even after image fusion with MR, were considered negative. None of them was submitted to surgery and at follow-up they did not evolve. CONCLUSIONS: When MRI is inconclusive DOPA PET/CT imaging can give functional relevant information to clinicians in the complex decision making. It seemed particularly useful in the discrimination between recurrences and radionecrosis/fibrosis. Visual and semiquantitative indices detected brain recurrences and high grade brain lesions with high accuracy. Lesion-to-normal-tissue ratios were the best discriminators.

EP032

Pooled Diagnostic Performance of Static ^{18}F-FET PET Parameters in Differentiating Recurrent Brain Tumours from Nonneoplastic Treatment-related Changes

G. Treglia[1], B. Muoio[2], M. Reinert[3], A. Richetti[2], G. A. Pesce[2], L. Giovanella[1]; [1]Oncology Institute of Southern Switzerland, Nuclear Medicine and PET/CT Center, Bellinzona and Lugano, SWITZERLAND, [2]Oncology Institute of Southern Switzerland, Radiation Oncology, Bellinzona and Lugano, SWITZERLAND, [3]Neurocenter of Southern Switzerland, Neurosurgery, Lugano, SWITZERLAND.

Aim: to assess the pooled diagnostic accuracy of static ^{18}F-fluoroethyl-L-tyrosine positron emission tomography (^{18}F-FET-PET) parameters [maximal and mean lesion-to-background ratios (LBRmax and LBRmean)] in discriminating recurrent brain tumours (BTs) from nonneoplastic treatment-related changes. **Methods**: A comprehensive literature search of published studies on the role of ^{18}F-FET-PET in this setting was performed (from inception up to February 2016) using Pubmed, Scopus and Google Scholar databases. Pooled sensitivity, specificity and diagnostic odd ratio (DOR) of static ^{18}F-FET-PET parameters on a per lesion-based analysis were assessed. The area under the summary receiver-operating-characteristic curve (AUC) was calculated. Sub-analyses were performed whether significant heterogeneity was found ($I^2>50\%$). Pooled weighted mean difference (WMD) of ^{18}F-FET-PET parameters among malignant and benign lesions was calculated. Pooled ROC analysis to assess the best LBRmax and LBRmean cut-off values to discriminate malignant from benign lesions was performed. **Results**: Ten articles including 422 patients with BTs were selected. Pooled sensitivity, specificity, DOR and AUC of static ^{18}F-FET-PET parameters in discriminating recurrent BTs from nonneoplastic treatment-related changes were 84% (95%CI:80-88%), 80% (95%CI:71-88%), 34 (95%CI:15-77) and 0.92, respectively, for LBRmax, and 81% (95%CI:76-86%), 86% (95%CI:76-93%), 30 (95%CI:13-73) and 0.92, respectively, for LBRmean. As significant heterogeneity between the selected studies was found (I2>50%), a sub-

analysis including only patients with high-grade gliomas (HGG) was performed (for LBRmax only). This sub-analysis showed that pooled sensitivity, specificity, DOR and AUC of static 18F-FET-PET in discriminating recurrent HGG from nonneoplastic treatment-related changes were 95% (95%CI:90-98%), 83% (95%CI:68-93%), 44 (95%CI:13-148) and 0.95, respectively, without significant heterogeneity (I2<50%). Pooled WMD among recurrent BTs and treatment-related changes were 0.93 (95%CI:0.6-1.3; p<0.0001) for LBRmax and 0.59 (95%CI:0.3-0.8; p<0.0001) for LBRmean. LBRmax and LBRmean values of 2.2 and 2, respectively, were the best cut-off values to discriminate recurrent BTs from nonneoplastic treatment-related changes at pooled ROC analysis. **Conclusions**: Evidence-based data show that static ^{18}F-FET-PET parameters are accurate in differentiating recurrent BTs from nonneoplastic treatment-related changes, in particular in patients with HGG. Large prospective multicenter trials and cost-effectiveness analyses are needed to substantiate the role of ^{18}F-FET-PET in this setting.

EP033

The Diagnostic Role of FDG PET/CT in Cancer of Unknown Primary Presented with Brain Metastasis

Z. P. Koç, P. Ozcan Kara; Mersin University, Mersin, TURKEY.

Aim: F-18 Florodeoxyglucose Positron Emission Tomography/ Computed Tomography (FDG PET/CT) has an important role in determination of the primary of the patients with cancer of unknown primary (CUP). We investigated the role of this method in a special group of CUP patients presented with brain metastasis. **Materials and Method:** Thirteen patients (5M, 8F; mean: 57,7 ±12,9 years old) with diagnosis of brain metastasis according to histopathology and/or MRI were included into this retrospective study. **Results:** The patients presented with hypermetabolic (mean SUVmax:8,6±1,14) or hypometabolic brain lesions with additional metastatic sites in 7 patients (mean SUVmax:5,91 ±3,5). Two of these patients were documented to have benign brain disease. The primary tumor was determined by FDG PET/CT in 9/11 patients (69%) (lung (n=5), primary brain (n=3), renal cell carcinoma (n=1)) and two patients with suspicious primary site (colon (n=1), nasopharynx (n=1)) were determined. Seven of thirteen patients were out of follow up. Four patients had documented primary site which we pointed out in FDG PET/CT. **Conclusion:** Previous studies report 20-50% detection rate for identification of primary tumor in patients with CUP. However new generation multislice scanners may provide higher detection ratio's. The detection rate of FDG PET/CT might be higher than previously reported according to this study however prospective studies in large series are warranted. **Key Words:** Unknown primary, brain, metastasis, FDG.

EP034

Hypoxic volume of malignant glioma by ^{18}F-fluoromisonidazole PET: a comparison with ^{11}C-methionine PET and Gd enhanced MRI-based tumor volume

K. KIRII, M. Kanoto, Y. Sugai, T. Hosoya; Yamagata university faculty of medicine, Yamagata city, JAPAN.

OBJECTIVE: In malignant glioma, few reports have examined a correlation between PET-based metabolic volume and hypoxic volume. The objective of this study was to assess hypoxic volume of malignant glioma by comparing between hypoxic tissue assessed by ^{18}F-fluoromisonidazole (FMISO), metabolic tumor volume by ^{11}C-methionine (MET) PET and morphological tumor volume by Gd enhanced MRI. **MATERIALS AND METHODS:** Eighteen patients with newly diagnosed glioblastoma multiforme(GBM) who had a pretreatment MET-PET, FMISO-PET and Gd-enhanced MRI were retrospectively reviewed. Metabolic tumor volume and hypoxic volume was estimated using an adaptative threshold-based automatic method on MET (MET-volume) and FMISO (FMISO-volume) PET. Morphological tumor volume was delineated on the gadolinium (Gd) enhanced T1 weighted MRI (Gd-volume). **RESULT:** Mean MET-volume (42.6cm^3) was not significantly different from mean Gd-volume (35.3 cm^3), mean FMISO-volume was (23.4 cm^3) was significantly smaller than MET-volume and Gd-volume. Each MET-volume and FMISO-volume showed a strong correlation with Gd-volume(r=0.81 and r=0.78, respectively). FMISO-volume also showed a strong correlation with MET-volume(r=0.78, p<0.01). The percentage of FMISO-volume in Gd-volume was large at 63.4%. **CONCLUSION:** Hypoxic volume by FMISO-PET was different from metabolic volume and MRI-based tumor volume in GBM. However hypoxic volume was large depending on the metabolic volume.

EP035

Evaluation of recurrent primary brain tumors by 11C Methionine PET/CT and 99m Tc Methionine SPECT/CT A comparative analysis

N. Seniaray, Sr.[1], A. Jaimini[1], M. D'Souza[1], D. Kumar[1], P. Panwar[2], A. Mishra[2], R. Sharma[1]; [1]Department of PET Imaging, Institute of Nuclear Medicine and Allied Sciences (INMAS), New Delhi, INDIA, [2]DCRS, Institute of Nuclear Medicine and Allied Sciences (INMAS), New Delhi, INDIA.

Introduction: 11C Methionine is an amino acid tracer which has been widely used for evaluation of recurrent primary brain tumors. However, 11C Methionine is a cyclotro produced radiopharmaceutical with a short halflife of 20 min, which increases the cost and limits its availability. 99m Tc Methionine can overcome these limitation and can be used as an alternative tracer to 11C Methionine in the evaluation of brain tumors suspected of residual or recurrence .We review our experience of 11C Methionine and 99m Tc Methionine in detection of recurrent primary brain tumor. Materials and Methods: 20patients (12 males, 8 females) age 35-55 years' post therapy were sent for recurrence evaluation. All patients underwent 11C Methionine PET/CT and 99m Tc Methionine SPECT/CT scans on two different days. Results: 11C Methionine images were assessed visually and by SUV calculation. 99m Tc Methionine images were visually assessed and tumor to background ratio calculated. Both were found to show tracer accumulation at sites of residual/recurrent tumor in all cases. Conclusion: Our study reveals that 99m Tc Methionine can be used as an alternative tracer to 11C Methionine in the evaluation of brain tumors suspected of residual or recurrence.

EP036

Influence of different attenuation correction approaches on dynamic [18F]FET PET/MRI of recurrent glioma

I. Rausch[1], A. Haug[1], R. Aghamohammadi-Sareshgi[2], M. Fenchel[3], M. E. Mayerhoefer[1], T. Beyer[1], T. Traub-Weidinger[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]General Hospital of Vienna, Vienna, AUSTRIA, [3]Siemens Healthcare GmbH, Magnetic Resonance, Erlangen, GERMANY.

Aim: To evaluate the influence of different attenuation correction approaches in positron emission tomography (PET)/magnetic resonance imaging (MR) on clinical evaluation of dynamic [18F]FET imaging. **Methods:** Up to date, 12 patients who underwent a 40 min (0-40 min post injection) dynamic PET/MR (Siemens Biograph mMR) examination following the injection of 250 MBq [18F]FET were included in this ongoing study. Dynamic PET data was reconstructed using an OP-OSEM algorithm (3 iterations, 21 subsets, 3mm FWHM Gaussian post filtering) into 8 frames of 2x2 min, 4x4 min and 2x10 min using four different attenuation correction methods: (A) Standard implemented Dixon-based AC, (B) Standard implemented UTE-based AC, (C) a

model-based post-processing approach incorporating spatially variant bone attenuation values into the attenuation map from (A) (non-commercial prototype software by Siemens Healthcare) and (D) CT-based AC. For each reconstruction, a threshold-based volume of interest (VOI) was segmented using a threshold of 90% of the maximum pixel in the respective lesion on summed images (20-40 min). An additional spherical background VOI was placed on the contralateral side to calculate a lesion-to-background ratio (LBR). The VOIs were copied to the different timeframes to calculate the time activity curves (TAC). From the last time frame, volumes of the VOIs and LBR were extracted. An experienced reader with 5 y of experience in dynamic [18F]FET imaging assigned each TAC to two curve patterns: 1) constantly ascending or peaking followed by a plateau and 2) peaking followed by a descent. The volumes and LBRs were compared, and differences to (D) were calculated. For the TAC patterns, changes in assignments relative to the pattern found in (D) were investigated. **Results:** Extracted VOI volumes changed on average by (A): -14±29%, (B) -7±38% and (C) 0±23% relative to (D). LBR were in general similar for all AC methods with an average difference to (D) of (A): -2±2%, (B) -2±5%, and (C) 0±3%. The assignment of the TACs to the different uptake patterns changed for 2/12 cases for (A) and for (B). For (C), no change in uptake pattern assignment could be observed. **Conclusion:** The use of different AC methods in PET/MR can influence the clinical diagnosis in dynamic [18F]-FET glioma imaging. This is mainly attributed to changes in the segmentation of VOIs when using threshold-based segmentation approaches. Nevertheless, LBR seems to be comparable for all evaluated AC approaches.

EP037

Total hemispheric glycolysis ratio by FDG-PET/CT in gliomas; Evaluating diaschisis and potential prognostic information

E. A. Segtnan[1,2], P. Grupe[3], O. Gerke[3,4], J. O. Jarden[5], S. B. Christlieb[3], C. Constantinescu[3], J. E. Pedersen[3], S. Houshmand[6], S. Hess[3,7,8], M. Zarei[9], A. Gjedde[10], A. Alavi[6], P. F. Høilund-Carlsen[3,8]; [1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]University of Southern Denmark, Odense, DENMARK, [3]Department of Nuclear Medicine, Odense University Hospital, odense, DENMARK, [4]Centre of Health Economics Research, Odense, DENMARK, [5]Department of Neurology, Herlev University Hospital, Copenhagen, DENMARK, [6]Division of Nuclear Medicine, Department of Radiology, Perelman School of Medicine, Hospital of the University of Pennsylvania, Philadelphia, PA, UNITED STATES, [7]Department of Radiology and Nuclear Medicine, Hospital of Southwest Jutland, Esbjerg, DENMARK, [8]Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, DENMARK, [9]National Brain Mapping Centre, Shahid Beheshti University (Medical and General Campus), Tehran, IRAN, ISLAMIC REPUBLIC OF, [10]Department of Neuroscience and Pharmacology, Panum Institute, University of Copenhagen, Copenhagen, DENMARK.

Aim: Diaschisis denotes brain dysfunction remote from a focal brain lesion. We quantified diaschisis using cerebral and cerebellar hemispheric glycolysis ratios and tested the claim that these ratios have prognostic value in glioma patients. **Material and methods:** Fifty FDG-PET/CT studies collected prospectively in 5 male and 9 female glioma patients, aged 35-77 years, were compared to scans from 10 healthy controls, aged 43-75 years. Dedicated 3D-segmentation software (ROVER, ABX, Germany) provided "total hemispheric glycolysis" (THG), i.e., the product of segmented metabolic volume and SUVmean in each hemisphere. The hemisphere of likely diaschisis (i.e., the ipsilateral cerebral and the contralateral cerebellar hemisphere) was normalized to the opposite hemisphere to provide the "total hemispheric glycolysis ratio" of cerebrum and cerebellum, i.e., THGr(Ce) and THGr(Cb), respectively. Receiver operating characteristics (ROC) provided optimal cut-offs for these variables. Two independent observers obtained data for reproducibility analysis, and quantitative scores were compared with visual interpretation done by a PET neuroimaging specialist. **Results:** The coefficient of variation for the two independent observers' calculation of THGr(Ce) had a median of 3.3%(interquartile range (IQR) 1.9-4.2) and one of median 5.9%, (IQR 3.0-14.3) for THGr(Cb).Visual analysis confirmed cerebro-cerebellar diaschisis in 100% of glioblastoma PET studies performed within one year until death. Diaschisis was not observed in healthy controls, who had mean values of THGr(Ce) and THGr(Cb) that significantly exceeded those of patients, i.e., p= 0.0007 and p=0.02, respectively. Median THGr(Ce) averaged 0.62, 0.71, 0.88 in patients surviving less than one year, one to three years, and more than three years, respectively, versus 0.98 in healthy controls. Median THGr(Cb) averaged 0.74, 0.88, 1.01, and 0.96, respectively. The finding of a low THGr (Ce<0.62 or Cb<0.84) agreed almost completely with the presence of diaschisis by visual assessment of cerebrum or cerebellum, i.e., in 16/17 (94%) and 25/26 (96%) of PET scans, respectively. The combination of THGr(Ce) <0.62 and THGr(Cb) <0.84 had a 100% sensitivity and a 78.6% specificity with regard to survival of less than one year for the glioblastoma patients. **Conclusion:** We present a novel and feasible quantitative approach for detection of diaschisis in glioma patients. THGr could demonstrate diaschisis in both cerebrum and cerebellum, and optimized cut-off values for THGr(Ce) and THGr(Cb) had a high sensitivity and fair specificity for prediction of survival of less than one year for these glioma patients. The presented semi-automated quantitative approach may allow comparison of similar data obtained at different institutions.

EP038

Towards early detection and personalized treatment monitoring of glioma: [68Ga]-DOTA-A2B1, a promising prognostic surveillance agent

H. Chiu, 333[1], W. Chang[1], S. Hsu[1], Y. Chung[1], Y. Lin[1], F. Huang[2], T. Yen[1,3], C. Huang[1]; [1]Center for Anvanced Molecular Imaging and Tranlation, Chang Gung Memorial Hospital, Taoyuan, TAIWAN, [2]Department of Biochemical Science and Technology , National Taiwan University, Taipei, TAIWAN, [3]Department of Nuclear Medicine, Chang Gung Memorial Hospital, Taoyuan, TAIWAN.

Purpose: Despite recent advances in diagnostic tools and aggressive surgery followed by adjuvant chemotherapy, the clinical outcome of patients with glioblastoma multiforme (GBM) remains dismal. The overexpression of integrin $\alpha2\beta1$ has been associated with increased radioresistance and chemodrug-resistance in glioblastoma, making it a promising surveillance biomarker for not only early malignant glioma detection but also subsequent treatment effect monitoring. **Methods:** To prospectively verify the prognostic value of integrin $\alpha2\beta1$, the *in vitro* western blot was performed to validate the integrin $\alpha2\beta1$ expression level of human glioblastoma (U87MG) cells and its dose-dependent escalation after adding doxorubicin. The PET/MR hybrid brain tumor imaging were performed with novel integrin $\alpha2\beta1$ targeting PET tracer ([68Ga]-DOTA-A2B1) in orthotopic U87MG glioma xenograft mice (n=5) and the tumor regions of interest (ROIs) was determined by manually 50% of maximum minus minimum tumor activity. The follow-up PET/CT scans were performed just after 6 hours of the administration of effect dose of doxorubicin (5mg/Kg) in U87MG tumor-bearing animal to validate the treatment respond capability of [68Ga]-DOTA-A2B1 PET tracer. The average radioactivity accumulation within a tumor or an organ was further analyzed in accordance with the pathologic data. **Results:** Extremely high expression level of integrin $\alpha2\beta1$ of glioblastoma U87MG cell correlated with its high tumorigenic potential in western blot results justifies its role as a potential prognostic marker. The [68Ga]-DOTA-A2B1 PET tracer longitudinally demonstrated prominent tumor uptake in orthotopic U87MG xenografts along with the steady growth of tumor size monitoring with MR imaging. The tracer uptake in malignancies

were 0.30+/-0.05, 0.34+/-0.05 and 0.58+/-0.11 (%ID/g) at day 7, day 14 and day 21, respectively. Furthermore, due to the low normal brain uptake background, the tumor contrast ratio of tumor/contralateral region increased significantly from 2.22 (day 7) to 2.80 (day 14) and 3.11 (day 21), which can achieve precise whole brain tumor localization for preoperative planning and delineate the tumor margins with high sensitive and high spatial resolution from con-registered PET/MR imaging data. After administration of effect doxorubicin dose (5mg/Kg) in tumor bearing animals, the two-fold increase of [68Ga]-DOTA-A2B1 tracer uptake was observed in the tumor lesions, making treatment respond monitoring is possible. **Conclusion:** These results suggest that there is significant uptake in [68Ga]-DOTA-A2B1 accumulation along with the tumor growth monitoring by MR imaging. The specific uptake might offer a critical diagnostic imaging criterion in the identification of aggress phenotype of gliomas.

EP039

Added value of SPECT/CT in patients with equivocal bony metastasis from breast cancer

D. BEN SELLEM, L. ZAABAR, B. DHAOUADI, B. LETAIEF, M. F. BEN SLIMENE; University of Tunis El Manar, Faculty of Medicine of Tunis, Salah Azaiez Institute, Department of Nuclear Medicine, Tunis, TUNISIA.

Aim: Planar bone scintigraphy lacks specificity. But single photon emission computed tomography/computed tomography (SPECT/CT), by clarifying anatomic localization of lesions in 3D and correlating to CT aspects, allows accurate diagnosis. The purpose of our study was to investigate the value of SPECT- CT in the assessment of solitary foci of increased bone metabolism classified as indeterminate on whole-body planar scintigraphy in patients with breast cancer. **Material and Methods:** Our prospective study included 100 patients aged 28 to 83 years (mean ± SD = 53.4±10) followed for breast cancer. All these patients underwent planar whole-body scintigraphy 2-3 h after intravenous injection of a mean activity of 740 MBq (20 mCi) 99m technetium- methylene diphosphonate (^{99m}Tc-MDP). Immediately after acquisition, these images were analyzed by a board-certified nuclear medicine physician. All of them had at most two indeterminate increased uptake on planar scintigraphy and therefore they underwent SPECT/CT scan and among them 80 (80 %) had solitary focus. We performed our studies on the same hybrid camera combining a dual-head γ-camera with a dual-slice spiral CT scanner installed within the same gantry (Symbia T2; Siemens Medical Solutions). Afterwards, the corresponding SPECT/CT images were analyzed and the findings previously considered as indeterminate were classified either as definitely benign, indeterminate, or definitely malignant. **Results:** SPECT-CT allowed us to classify these indeterminate lesions as malignant in 40 % of cases (48 foci) and benign in 51.7 % of cases (62 foci). However, 10 (8.3 %) remained indeterminate. This technique detected over them, 12 additional metastatic bone foci included in the field of SPECT exploration that were invisible on planar scan. In two other patients, spine lytic metastases were multiple. SPECT-CT was able so to clarify 91.7 % of planar findings classified as indeterminate, modifying the final report in 90 % of our patients. **Conclusion:** Our study highlighted the higher diagnostic value of SPECT-CT over planar skeletal scintigraphy in clarifying more than 91 % of solitary indeterminate lesions in oncologic patients. Thus, this technique modified the final report for almost 90 % of our patients, allowing early adequate therapeutic management.

EP040

Variations of FDG PET/CT SUV and textural indices in breast cancer according to lymph node status

S. Boughdad[1], C. Nioche[2], F. Orlhac[3], L. Champion[1], J. Alberini[1], I. Buvat[2]; [1]Institut Curie-Hôpital René Huguenin, Saint-Cloud, FRANCE, [2]IMIV CEA, Inserm, CNRS, UnNiv Paris Sud, CEA-SHFJ, Orsay, FRANCE, [3]IMIV CEA, Inserm, CNRS, UnNiv Paris Sud, CEA-SHFJ, IGR, Orsay, FRANCE.

Introduction: Breast cancer (BC) is a very common cancer and lymph node (LN) involvement is an important prognostic factor. The aim of our study is to identify variations of SUV and textural indices (TI) in BC according to the LN involvement status and also as a function of the grade and the Ki 67 expression.Method: We studied a population of 76 women who underwent a F18-FDG-PET/CT in our institution for initial staging of biopsy proven BC. Two groups of patients were defined: N+ (LN involvement) and N- (no LN involvement), according to the current guidelines: either cytology proven or on approved imaging techniques (MRI or F18-FDG-PET/CT). Volume (mL), SUV (max, mean and peak), TLG (total lesion glycolysis, mL) and TI (homogeneity, entropy, LRE, SRE, LGZE and HGZE) were measured in each VOI obtained using a threshold method (40% of SUVmax) and exceeding 1.5 mL in volume. We used a Mann-Whitney test to determine whether Volume, TLG, SUV and TI were significantly different in the VOI between the N+ and N- groups. We also compared the groups according to Ki 67 expression using a cut-off of 20% and the grade (grade I-II vs III).Results: Eighty VOI were drawn in our BC population: 43 VOI in 40 patients in the N- group and 37 VOI in 36 patients in the N+ group. Three N+ pts and one N- pt had a multifocal BC. There was no significant difference in SUV and TI between N+ and N- patients ($p > 0.05$) but there were significant differences in the volume between N+ and N- pts ($p=0.003$). When we compared N+ and N- pts in subgroups created from the Ki 67 expression and the grade, there were still significant differences in the volume (cf table) but no significant difference was found for SUV or TI. Besides, according to the metastatic status when comparing N+ patients according to the metastatic spread (M+ or M-), the only significant difference found was once again the volume (p 0.04).Conclusion: Our study did not show any significant difference in SUV or TI between N+ and N- patients in our BC population. The only significant difference was the tumor volume. This difference remained when we analyzed subgroups according to the grade and Ki 67 expression. Tumor volume appeared to be a strong prognostic factor at initial staging.

EP041

Is F-18-FDG-PET/CT usefull to stage or predict progression-free survival in breast cancer patients?

M. Sollini[1], B. Zangheri[2], L. Calabrese[2], M. L. Di Paolo[3], A. Versari[3], M. Gasparini[4]; [1]Humanitas University, Rozzano, ITALY, [2]IRCCS MultiMedica, Sesto San Giovanni (MILAN), ITALY, [3]IRCCS Ospedale Santa Maria Nuova Reggio Emilia, Reggio Emilia, ITALY, [4]IRCCS Multimedica Sesto S. Giovanni, Sesto San Giovanni, ITALY.

Aim: Breast cancer (BC) is the most commonly diagnosed cancer among women. The role of F-18-FDG-PET/CT in the management of BC is increasing. We aimed to evaluate the role of PET/CT to stage and to predict outcome in BC. Methods: 62 female (one bilateral) with histology proven BC who performed FDG-PET/CT during the staging were retrospectively analysed. FDG upatke in primary tumor (T), lymph node(s) (N) or distant (M) metastases was considered. According to PET/CT results patients were divided in group 1 (uptake in N and/or M, any T) and group 2 (negative N and M, any T). According to immunoistochemical characteristics, patients were grouped as A (any ER/PgR, Her2 - and Ki67<14%), B (any ER/PgR, Her2+ and

Ki67>14%), C (ER/PgR/Her2 all negative) D (ER/PgR - with Her2+), E (any ER/PgR, Her2 - and Ki67>14%). Histology was used as reference standard for FDG-PET/CT in all pre-operative cases for T/N parameters, in the post-surgical setting imaging and clinical follow-up (FU) were used. Progression-free survival (PFS) was calculated. Differences for variables were assessed by Chi-square test (or Fisher test); differences for survival were studied by Kaplan-Mayer curves with log rank test. P-value <0.05 was considered significant. Results: patient were followed for 745 ±854 days. PFS was 635±440 days. Forty-four patients had no evidence of disease, 16 patients had progressive disease (group 1=13, group 2=3), while in 2 cases bone metastases (detected by PET/CT at diagnosis) were stable according to the RECIST criteria. FDG-PET/CT resulted positive and negative in 57/62 and 15/62 patients, respectively. FDG uptake was seen only in T and in N in 18 and 3 patients, respectively; in T + N in 14 cases, in T + M in 2 cases, in T + N + M in 8 patients, and in N + M in 2 cases. According to final diagnosis PET/CT resulted TP=41/63, TN=12/63, FN=10/63 and TP=26/63, TN=25/63, FN=11/63, FP= 1/63 for the T and the N status, respectively. PET/CT resulted positive for M in 12 cases (10 TP and 2 FP). PET/CT results did not differ significantly among categories A-E (p=0,263). Groups 1 and 2 significantly differed in terms of outcome (p = 0,005). Survival significantly differed in group 1 and group 2 (p=0.002). Conclusion: PET/CT resulted useful to stage and predict outcome in BC, supporting its clinical use. Staging PET/CT allows, in addition to having a more accurate and early diagnosis, an ever greater customization of therapy.

EP042

FDG PET parameters on primary tumor are prognostic factors of progression free survival for patients with initial metastatic breast cancer

L. Delcroix, A. Maillez, A. Olivier, E. Tresch, A. Oudoux, **H. Kolesnikov-Gauthier**; Oscar Lambret Center, Lille, FRANCE.

Aim: This study was performed in order to evaluate the prognostic relevance of ^{18}FDG PET/CT in patients with breast cancer who had distant metastasis at the diagnosis.Materials and methods: Between September 2011 and December 2015, 66 metastatic breast cancer patients underwent ^{18}FDG PET/CT at the time of initial diagnosis and before any treatment.Histological and clinical prognostic factors were reviewed. Different PET parameters such as maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were retrospectively measured on primary tumor (t). A 3D isocontour at 41% of the maximum pixel value was used to determine a volume of interest (VOI) for each lesion. We analyzed the relationship between these PET parameters and the progression-free survival (PFS). Univariate and multivariate analyses were performed with Cox and Kaplan-Meier hazards models. Optimal cutoff values (maximizing the log-rank test) were determined for variables which were significantly correlated with PFS. Results: Median age was 60 years (range: 33-88). According to clinical examination and mammography results, tumours were T1 (n=3), T2 (n=30), T3 (n=14), T4 non-d (n=8), T4d (n=11). Among the 66 patients, 12 had triple negative breast cancer, 9 a lobular invasive carcinoma and 26 visceral metastasis. Forty-nine patients (74%) progressed or died during the follow-up, (mean follow-up: 31 months; range: 2.8-50 months). Mean PFS was 10 months (range: 6.8-12.4 months). tSUVmax, tMTV and tTLG, were identified by univariate analysis as prognostic factors for PFS (p<0.01). We determined optimal cutoff values of tSUVmax (≤9.7 vs >9.7), tMTV (≤42.8 vs >42.8), tTLG (≤380 vs >380) for predicting PFS. Multivariate analysis revealed that tSUVmax [HR=2.9; IC95%: 1.5-5.6], tMTV [HR=5.0; IC95%: 2.2-11.2] and tTLG [HR=6.3; IC95%: 2.8-13.8] independently predicted PFS. Conclusion: tSUVmax, tMTV and tTLG values determined on initial ^{18}FDG PET/CT are independent prognostic factors for PFS in patients with metastatic breast cancer.

EP043

Role of prone high resolution PET CT in breast cancer

A. Baassiri, G. Berjawi, M. Abusamra, K. Gharzeddine, L. Nassar, M. Hourani, **M. Haidar**; American University of Beirut Medical Center, Hamra - BEIRUT, LEBANON.

Objective: The goal of this study is to determine if patient staging for breast cancer patients differs between prone position and supine position. **Methods:** Thirty three patients had undergone a supine position PET/CT at standard resolution that was followed by a prone position PET/CT at high resolution acquisition. Images acquired in both positions of the same patient were compared. **Results:** We had a total number of 33 patients; 29 of them presented for staging and 4 for restaging. One patient had presented for restaging where both PET/CT positions had detected one axillary lymph node lesion with no primary breast lesion. The average value of SUVmax of the primary breast lesions detected on prone position PET/CT was 7.63 and in Supine position PET/CT the average value of SUVmax was5.95. One case of classical invasive lobular carcinoma had been missed in the supine position but detected in the prone position. Axillary lymph nodes were detected in 20 out of 33 cases by prone position PET/CT while the supine position PET/CT detected them in 18 cases. The minimum number of lesions detected per case was 1 and the maximum was multiple (more than 10) for both PET/CT positions. The average value of SUVmax of the axillary lymph nodes detected on prone position PET/CT was 7.00, and for supine position the average value of SUVmax was 5.74. As for comparison between both PET/CT positions, in one case the prone position image detected multiple axillary lymph nodes while none of them were detected in the supine position. Internal mammary lymph nodes were detected in 3 cases in total. The prone position detected them all while the supine positionmissed one case. In this case, one lymph node had been detected in the prone position but missed in the supine position. Supra clavicular lymph nodes were detected in 3 cases in the prone position while they were detected in a single case in the supine position. No mediastinal lymph nodes were detected in either PET/CT positions in any of our patients. Bone lesions were detected in 3 cases out of 33 by both PET/CT positions. All three were osteolytic lesions. **Conclusion:** Our preliminary results showed that the high resolution prone position is a promising technique to detect primary breast lesions and metastatic lymph nodes which may be missed by traditional acquisition (supine position) which can lead to change in patient staging and management.

EP044

FDG PET-CT evaluation of the contralateral breast in patients with recently diagnosed breast cancer

R. Kumar, A. Mukherjee, M. Nadig, C. Bal; All India Institute of Medical Sciences, New Delhi, INDIA.

Objectives: Although breast cancer is one of the most common cancers in women, bilateral breast cancer is uncommon. Contralateral breast cancer can be synchronous and/or metachronous in patients with cancer of one breast. The present study evaluated the role of PET-CT in detecting contralateral breast cancer in patients with known breast cancer undergoing PET/CT scan for restaging. **Methods:** Data of 2197 breast cancer patients referred for PET-CT at our department were analysed over a period of eight year. **Results:** Incidence of bilateral breast cancers was 10.6% (233 of 2197 patients). Mean age of these patients was 46.1 ± 11.4 yrs (range 25-72 yrs). Out of 233 patients Synchronous tumors were found in 109 (47%) patients of which 66 (61%) were known to have bilateral tumors before being referred for PET and in rest 43 (39%) patient contralateral breast tumor was confirmed after noting abnormal FDG uptake in the other breast. Metachronous tumors were found in 124 patients (53%). Average time period between detection of 2nd lesion in this group was

18 months (range 8 months- 72 months). In this group 72 patients (58%) had been treated for cancer in one breast and presented with clinically or mammographically suspicious lump in the contralateral side and referred for further evaluation by PET/CT. Increased FDG uptake was seen in all of these lesions which were confirmed by histopathology later on. The remaining 52 (42%) patients suspicion of tumor was raised after noting abnormal intense 18F-FDG uptake in the other breast during follow-up study and confirmed by further evaluation. Thus 18F-FDG PET/CT detected unsuspected contralateral breast tumour in 4.3 % (95/2197) of patients and accounted for 40.7 % (95/233) of the bilateral breast tumors in this series. **Conclusions:** FDG PET-CT play important role in detection of cancer in contalateral breast in patients of known breast cancer.

EP045

Can PET/CT Volumetric Data Be Useful As Biomarkers Predictive Of Pathological Response To Neoadyuvant Treatment In Patients With Locally Advanced Breast Cancer?

M. Martinez de Bourio, A. Jiménez-Ballvé, O. Salsidua Arroyo, A. Serrano-Palacio, M. García García-Esquinas, C. Rodríquez-Rey, A. Ortega-Candil, J. A. García-Saénz, M. E. Fuentes Ferrer, J. L. Carreras-Delgado; HOSPITAL CLINICO SAN CARLOS, MADRID, SPAIN.

Objective: To investigate whether the different PET indexes, measured in the initial staging PET/CT scan, can be able to predict the pathological response to neoadyuvant treatment in patients with locally advanced breast cancer (LABC). Materials and methods: A retrospective study from January/2010 till March/2016 was performed. One hundred women (mean age 49 years old, range 25-75 years) with LABC treated with neoadyuvant chemotherapy (NAC), were included. 18F-FDG PET/CT scan for initial staging was performed prior undertaking neoadyuvant treatment, analysing different metabolic parameters: SUVmax, SUVmean, metabolic tumour volume (MTV) and total lesion glycolysis (TLG) in the primary tumour (T), in local metastatic nodes (N) and all lesions. The histological response was analysed in the surgical specimen, and it was classified as pathological complete response when there was no evidence of tumour and non pathological complete response in the opposite case. Results: From all of the patients included in this study, twenty-nine per cent (29/100) showed pathological complete response whereas seventy-one per cent (71/100) showed non pathological complete response. From the different metabolic parameters measured in the initial staging PET/CT scan, only MTV in the primary tumour was related to pathological response, being higher in patients who did not show a pathological complete response compared to those who showed a pathological complete response (7.8 cm^3 vs. 4.9 cm^3; p=0.046). Differences observed in SUVmax, SUVmean and TLG values (in the primary tumour, local metastatic disease and all lesions), as well as in MTV value (in local metastatic disease and all lesions), were not significantly correlated with response to NAC. In the ROC curve analysis, the best cut-off point of MTV in the primary tumour to predict a pathological complete response was $\geq$ 6.8 cm^3 (sensitivity 61% and specificity 59%). Conclusions: In our study, the only PET parameter able to predict the pathological response in patients with locally advanced breast cancer who undergo neoadyuvant treatment, is metabolic tumour volume measured in the primary tumour. These results suggest that the inclusion of this parameter to clinical data could identify those patients who will have a better response to neoadyuvant treatment.

EP046

Prognostic value of primary tumor SUVmax on F-18 FDG PET/CT compared with semi-quantitative tumor uptake on Tc-99m sestamibi breast-specific gamma imaging in invasive ductal breast cancer

J. Yoo, H. Yoon, B. Kim; Ewha Womans University School of Medicine, Seoul, South Korea, Seoul, KOREA, REPUBLIC OF.

Objectives: This study aimed to evaluate the prognostic value of F-18 FDG PET/CT in comparison with Tc-99m breast-specific gamma imaging (BSGI) and previously established clinical prognostic parameters of invasive ductal breast carcinoma (IDC). Methods: We retrospectively included 149 female IDC patients (mean age: 49.1 years, range: 29-78) who underwent PET/CT and BSGI. Maximum standardized uptake value (SUV_{max}) and tumor-to-normal ratios (TNR) of primary tumor was measured on PET/CT and BSGI, respectively. Univariate and multivariate survival analysis was performed to evaluate the prognostic value of measured parameters and other clinical prognostic factors: pathologic tumor size (pTS), axillary nodal status (ANS), nuclear grade, histologic grade, hormonal receptor status of estrogen (ER) and progesterone receptor (PR) and C-erb-B2 expression. Results: Among 149 patients, recurrence occurred in 15 patients (10.1%). In univariate analysis, pTS ($p < 0.001$), ANS ($p < 0.01$), nuclear grade ($p < 0.05$), histologic grade ($p < 0.01$), ER status ($p < 0.01$), C-erb-B2 status ($p < 0.01$), primary tumor SUV_{max} ($p < 0.001$), and TNR ($p < 0.001$) were significant predictors of recurrence. Among them, pTS ($p < 0.05$) and primary tumor SUV_{max} ($p < 0.01$) were independent prognostic factors in multivariate regression analysis. Conclusions: In IDC patients, high primary tumor SUV_{max} of PET/CT and high TNR of BSGI were poor prognostic factors and especially primary tumor SUV_{max} was an independent prognostic factor along with pTS. (This research was supported by grants from the National Research Foundation (**2015R1C1A1A02037051, 2012M3A9B6055379**) of South Korea.)

EP047

Dual-time-point FDG-PET/CT: prognostic value of total metabolic tumour volume in patients with recurrent breast cancer

C. B. Petersen[1], M. G. Hildebrandt[1], O. Gerke[1], C. Baun[1], K. B. Falch[1], A. Alavi[2], P. Høilund-Carlsen[1]; [1]Odense University Hospital, Odense C, DENMARK, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, UNITED STATES.

Aim: The purpose was to examine the prognostic value of total lesion glycolysis (TLG) and metabolic tumour volume (MTV) measured by 18F-FDG-PET/CT in women with recurrent breast cancer. Material and methods: Twenty-two women (aged 37-76 years) diagnosed with disseminated recurrent breast cancer underwent dual-time-point (1h and 3h) FDG-PET/CT. The scans were evaluated using dedicated quantification software (ROVER®, ABX, Radeberg, Germany), with an iterative algorithm and threshold of 40% of maximum. Whole body MTV, TLG and TLG corrected for partial volume effect (cTLG) were calculated. Differences in mean values of measured variables between survivors and non-survivors were recorded. ROC analyses of these variables were made to find cut-off points for high and low risk of death and to serve as basis for Kaplan-Meier curves. Multiple COX-regression analyses were made to test for correlation between PET variables and baseline characteristics and survival during a follow-up period of 17-43 months, (mean 20 months). Results: Eleven of the 22 patients died during the follow-up period. Median MTVs for survivors and non-survivors at 1 h imaging were 26.7 cm^3 (range: 8.1-372.3) and 83.0 cm^3 (4.4-744.7), respectively; at 3 h 18.9 cm^3 (6.4-393.6) and 58.3 cm^3 (4.8-747.7), respectively, (all p-values < 0.05). No statistically significant difference was found for any of the other PET measures. ROC analyses showed that values below cut-off points of 44.1 and 34.7 for MTV at 1 h and 3 h imaging, respectively, were associated with longer survival. Multiple COX-regression analyses showed modest, but statistically significant, hazard ratios of 1.00346, 1.000708, and 1.000409, respectively, for MTV, TLG, cTLG at 1 h imaging and of 1.000506 for TLG at 3 h imaging. Conclusion: Significantly higher metabolic active tumour burden was found in non-surviving compared to surviving women with systemic recurrent breast cancer. Thus, semi-quantitative PET measures might be independent prognostic factors. Due to the limited number of patients, our results should only be seen as hypothesis generating. The potential clinical value of these measures needs to be documented in larger samples of patients.

EP048

Clinical significance of FDG uptake in invasive duct carcinoma of the breast - correlation with histopathological prognostic markers

L. PUSHPALATHA SUDHAKAR, S. Praveen, P. Amber, M. Sailaja reddy, P. Raghuram; KRISHNA INSTITUTE OF MEDICAL SCIENCES, SECUNDERABAD, INDIA.

Aim: To evaluate the prognostic value of FDG uptake in Invasive Duct Carcinoma (IDC) of the breast in correlation with histopathological factors such as tumor grade ,nodal involvement , immune histochemical (IHC) markers including estrogen receptor (ER), progesterone receptor (PR) , and HER2 / neu status. Materials & Methods : Study included 40 patients with surgically proven IDC. Maximum standardized uptake values (SUV max) for the primary lesions were evaluated retrospectively on preoperative F18 FDG PET - CT scans. Histopathology factors including tumor grade, lymph nodal involvement , ER , PR & HER2/neu receptor status were analyzed. SUV max was correlated with these factors. p values of less than 0.05 were considered statistically significant. Results:The average SUV max of forty lesions was 12.75 (SD±8.30). Grade 2 tumor was seen in 18 and grade 3 in 22. Lymph nodal involvement was seen in eighteen patients (45%). The mean SUV max value of ER + and ER - lesions were 12.45 ± 8.24 and 13.70 ± 8.88 respectively .Mean SUV max of PR+ was 13.32 ± 8.85 and PR - was 10.00 ± 4.20 .HER2/neu + had mean SUV max of 12.23 ± 7.10 and HER2/neu - had 13.00 ± 8.91. The mean SUV max of grade 2 was 9.83 ±7.74 and grade 3 was 15.04±8.16 .The lymphnodal involvement showed mean SUV max of 15.61±7.29. Statistically significant correlation was noted between SUV max and the lymph nodal involvement as well as the tumor grade (p value less than 0.046). However there was no correlation between SUV max and ER, PR & HER2/neu status. Conclusion: Our study highlights the statistically significant correlation between FDG uptake and nodal involvement & tumor grade . SUV max can be used as one of the prognostic factor in nodal involvement and high tumor grade.However no correlation between the uptake and ER, PR , HER2/neu receptor status was found in our study.

EP049

New era of PET/CT in breast cancer: High resolution acquisition

A. BASSIRI, G. Berjawi, M. Abusamra, K. Gharzeddine, L. Nassar, M. Hourani, **M. Haidar**; American University of Beirut Medical Center, HAMRA- BEIRUT, LEBANON.

Objective: The aim of this study is to determine the role of high resolution PET/CT in staging and management of breast cancer patients. ***Methods:*** 25 patients with breast cancer had undergone a supine position PET/CT at standard resolution that was reconstructed to high resolution acquisition. ***Results:*** According to the pathology results, we had 20 lesions of invasive ductal carcinoma, one lesion of granulation tissue, two cases of invasive mammary carcinoma, and a case of invasive mucinous carcinoma. The 25 breast lesions detected on PET/CT had an average size of 1.96 cm. The average value of SUVmax of the primary breast lesions detected on high resolution PET/CT was 5.83 versus 4.57 in standard acquisition. All these lesions were better characterized and visualized in high resolution acquisition. Axillary lymph nodes were detected in 13 out of 25 cases by both PET/CT resolutions. The intensity of uptake was higher with high resolution acquisition lead to better visualization of lymph node and decrease the grey zone. No internal mammary, supraclavicular, or mediastinal lymph nodes were detected by either PET/CT resolutions. Bone lesions were detected in 2 cases out of 25 by both PET/CT positions. All lesions were osteolytic lesions. No osteoblastic lesions were detected by either PET/CT positions. ***Conclusion:*** Our preliminary results showed no change in patient staging in any of the patients between both PET/CT resolutions but high resolution Images lead to be more comfortable for localization and decrease the number of grey zone lesion especially for the axillary lymph node.

EP050

Variations of FDG PET/CT SUV and textural indices in breast cancer according to metastatic status

S. Boughdad[1], C. Nioche[2], F. Orlhac[3], L. Champion[1], J. Alberini[1], I. Buvat[2]; [1]Institut Curie-Hôpital René Huguenin, Saint-Cloud, FRANCE, [2]IMIV CEA, Inserm, CNRS, UnNiv Paris Sud, CEA-SHFJ, Orsay, FRANCE, [3]IMIV CEA, Inserm, CNRS, UnNiv Paris Sud, CEA-SHFJ, IGR, Orsay, FRANCE.

Introduction: Breast cancer (BC) is a very heterogeneous disease and the metastasis stage is of poor prognosis. We investigated whether SUV and textural indices (TI) in BC differed as a function of the metastatic status and also of the Ki 67 expression, grade and molecular subtype. Method: We studied a population of 122 women who underwent a F18-FDG-PET/CT in our institution for initial staging of biopsy proven BC. Two groups of patients were defined: M+ (metastatic spread) and M- (no metastatic spread), according to the current guidelines (biopsy proved or on approved imaging technique: MRI or F18-FDG-PET/CT). Volume (mL), SUV (max, mean and peak), TLG (total lesion glycolysis, mL) and TI (homogeneity, entropy, LRE, SRE, LGZE and HGZE) were measured in each VOI obtained using a threshold method (40% of SUVmax) and exceeding 1.5mL in volume. We used a Mann-Whitney test to determine whether Volume, TLG SUV and TI were significantly different in the VOI between the M+ and M- groups. We also compared the groups according to Ki 67 expression using a cut-off of 20%, grade (SBR II vs III) and the breast molecular subtype (classification of 2010). Results: We drew 132 VOI in our BC population: 84 VOI in 76 patients in the M- group and 48 VOI in 46 patients in the M+ group. There was no significant difference in SUV and TI between M+ and M- patients ($p > 0.05$). When limiting the analyses to patient subgroups based on a 20% cut-off for Ki 67 expression, or based on the grade or according to the luminal B subtype, SUV and TI were still not significantly different for M+ and M- patients. However, there were significant differences in TLG between M+ and M- patients: 101.8±181.3 mL in M+ vs 53.3±97.9 mL in M- ($p=0.028$), and the volume (mL) was also different ($p<0.05$). We also found significant differences in volume in the 2 subgroups based on the Ki 67 expression:$p=0.016$ between M+ and M- in the Ki 67 >20% subgroup including 33 M+ and 53 M- pts. Similarly, volumes and TLG were significantly different between the 30 M+ and 50 M- pts with Luminal B tumors: 30 M+ vs 50 M- pts ($p=0.00$: volume and $p=0.048$: TLG). Conclusion: The only significant differences found between M+ and M- patients in our BC population were in the TLG and the tumor volume which remains a strong prognostic factor in BC.

EP051

The role of (18)F-Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (PET/CT) in patients with breast cancer recurrence: a comparison to conventional imaging (CI) techniques and clinical impact on patient management

S. Panareo[1], I. Santi[1], I. Rambaldi[1], S. Taralli[1], A. Frassoldati[2], C. Cittanti[1]; [1]University Hospital - Nuclear Medicine Unit, FERRARA, ITALY, [2]University Hospital - Oncology Unit, FERRARA, ITALY.

AIM: The aim of this study was to evaluate the impact of PET/CT on clinical management in patients with breast cancer recurrence and compare PET/CT data with CI data (US, ceCT, MR).METHODS: we observed 70 consecutive patients (age 60.25 ± 6.2 yo) addressed to PET/CT scan from January 2015 to April 2016 for suspected recurrence of previously staged and treated breast cancer. All patients were studied with the same high performing PET/CT scanner with innovative image reconstruction algorithm (integrating parameters derived from "Point Spread Function" and "Time Of Flight" calculations). PET/CT findings were compared with CI data on a patient

basis. RESULTS: in 21 patients (30.0%) PET/CT revealed recurrence of breast cancer in the region of the primary tumor; CI detected local recurrence in 16 patients (22.9%) [p=ns]. In 2 cases (2.8%) PET/CT showed a focal radiotracer uptake in the contralateral mammary gland (final histology showed malignant tumor involvement). In 21 patients (30.0%) PET/CT showed lymph node metastases in the primary breast tumor ipsilateral axilla, while CI managed to do so in 15 (21.4%) [p<0.35]. Furthermore PET/CT showed lymph node disease relapse in other basins in 39 patients (55.7%) while CI in 23 (32.8%) [p<0.1]. Bone metastases were detected by PET/CT in 28 patients (40%) while by ceCT in 12 (17.4%) [p<0.01]. Lung involvement was detected by PET/CT in 17 cases (24.2%) while by ceCT in 15 (21.4%) [p=ns]. PET/CT showed liver metastases in 9 cases (12.8%) while CI in 8 (11.4%) [p=ns]. Adrenal metastases were seen on PET/CT in 6 cases (8.5%) while on CI in 3 (4.2%) [p<0.106]. In 22 patients (31.4%), PET/CT detected additional lesions not visible on CI. PET/CT had an impact on clinical management in 37 patients (52.8%) by detecting more extensive loco-regional disease or distant metastases. In 21 patients (30.0%) extensive surgery was not undertaken and treatment was changed (CHT and/or RT). The sensitivity, specificity, accuracy, positive and negative predictive values of PET/CT were respectively 97%, 92%, 95%, 94% and 96%. CONCLUSIONS: PET/CT proved to play an important role in restaging patients with breast cancer recurrence since its results changed the clinical management in a large percentage of patients. PET/CT showed better performance than CI in all evaluated recurrence sites -although the difference was mainly not statistically significant- therefore it could potentially replace conventional imaging in restaging patients with breast cancer recurrence -especially concerning bone involvement- to optimize diagnostic timing and even costs.

EP052

Correlation of hypoxia inducible transcription factor in breast cancer and SUVmax of F-18 FDG PET/CT

Y. Jeong, J. Jung, Y. Cho, S. Park, H. Oh, **S. Kang**; Catholic University of Daegu School of Medicine, Daegu, KOREA, REPUBLIC OF.

Background Tumor hypoxia induces the expression of several genes via the hypoxia-inducible transcription factors alpha (HIF-1α), which is associated with the prognosis of several cancers. We studied the immunohistochemical expression of HIF-1α in patients with invasive ductal breast cancer (IDC) and the possible correlation with SUVmax of the primary tumor (pSUVmax) as well as other biological parameters. Prognostic significance of pSUVmax for the prediction of progression-free survival (PFS) was also assessed. **Materials and Methods** Two-hundred seven female patients with IDC who underwent pretreatment F-18 FDG PET/CT were enrolled. The pSUVmax was compared with clinicopathological parameters including ER, PR, HER2, axillary lymph node (LN) metastasis, stage and HIF-1 α. The prognostic value of pSUVmax for PFS was assessed using the Kaplan-Meier method. **Results** pSUVmax was significantly higher in patients with HIF-1α≥2 compared to patients with HIF-1α<2 (5.2±4.5 vs. 3.7±3.1, P=0.008). pSUVmax was also significantly higher in higher stage (P<0.000001), ER-negative tumors (P<0.0001), PR-negative tumors (P=0.0011) and positive LN metastasis (P=0.0013). pSUVmax was significantly higher in patients with progression compared to patients who were disease-free (6.8±4.4 vs. 4.1±3.7, P=0.0005). A receiver-operating characteristic curve demonstrated a pSUVmax of 6.51 to be the optimal cutoff for predicting PFS (sensitivity; 53.6%, specificity; 86.0%, P<0.0001). **Conclusions** pSUVmax on pretreatment F-18 FDG PET/ CT reflects expression of HIF-1 α and can be used as a good surrogate marker for the prediction of progression in patients with IDC. The amount of FDG uptake is determined by the presence of glucose metabolism and hypoxia in breast cancer cell.

EP053

Dual-time-point FDG Uptake Correlates with Prognostic Factors of Invasive Breast Cancer: Clinical Usefullness of Early Delayed Scanning

H. Song; Jeju National University School of Medicine, Jeju-si, KOREA, REPUBLIC OF.

Purpose This retrospective study investigated the correlation between FDG uptake on tumours assessed by modified dual-time-point FDG PET/CT and clinical, histopathologic, and immunohistochemical prognostic parameters of invasive breast cancer. **Subjects & Methods** Thirty-two women were enrolled. All the patients underwent mastectomies and pre-operative FDG PET/CT by modified dual-time-point scanning for invasive breast cancer. They underwent standard FDG PET/CT (PET1) followed by the early delayed acquisition (PET2) without repositioning and additional CT scanning. Maximal standardized uptake values on PET1 (SUV1) and PET2 (SUV2) were evaluated, and the percentage changes between SUV1 and SUV2 (retention index) calculated. Clinical factors (age, body mass index, and blood glucose level at the time of FDG injection) and pathologic features (tumour size, number of metastatic lymph nodes, and TNM stage) were assessed. Biologic prognostic parameters (histologic grade; tubular differentiation; nuclear pleomorphism; mitotic count; and expression of estrogen receptor (ER), progesterone (PR), HER-2, p53, epidermal growth factor receptor (EGFR), CK56, Ki-67, and E cadherin) were evaluated from primary tumours after mastectomy. Statistical analysis was performed to find the correlation of clinical features, pathologic factors, and biologic prognostic parameters with retention index. **Results** PET2 scans were conducted 17.7 ± 1.5 min after PET1 without repositioning and additional CT scanning. Retention index showed a moderately positive relationship with the degree of Ki-67 expression ($p < 0.001$, rho = 0.629). Significant statistical differences between histologic grade (1 to 3, P = 0.016), nuclear pleomorphism (1 to 3, P = 0.002), mitotic count (1 to 3, P = 0.01) and ER (positive and negative, P= 0.023) were observed around the mean retention index. **Discussion & Conclusion** This modified dual-time-point FDG PET/CT has advantages including a low radiation exposure to patients and a shortened scanning time compared to a conventional dual-time-point FDG PET/CT (delayed acquisition on 120-180 min after FDG injection). This study demonstrated that retention index correlated with well-known biologic prognostic factors of invasive breast cancer and that early delayed scanning could possibly substitute for a conventional dual-time-point FDG PET/CT.

EP054

Dynamic uPAR-PET/CT imaging of breast cancer patients for establishing optimal scan time following injection of ^{68}Ga-NOTA-AE105

D. Skovgaard[1], M. Persson[2], N. Kroman[1], T. Tvedskov[1], A. Loft[1], A. K. Berthelsen[1], M. Brandt-Larsen[1], J. Madsen[1], L. Hojgaard[1], **A. Kjaer**[1]; [1]Rigshospitalet, Copenhagen, DENMARK, [2]Curasight ApS, Copenhagen, DENMARK.

Introduction Overexpression of urokinase-type plasminogen activator receptors (uPAR) represents an established biomarker for poor prognosis in many common malignant diseases including breast cancer. Accordingly, uPAR is an important target both for new therapeutic and diagnostic strategies. In a recent *first-in-human* uPAR PET study using the tracer ^{68}Ga-NOTA-AE105, which is based on the high affinity uPAR peptide antagonist AE105, we found high uptake in both primary breast cancer and lymph node metastases. However, no dynamic scans were performed in that study and accordingly, the best image contrast, i.e. tumor-to-background ratio, following injection of ^{68}Ga-NOTA-AE105 remains to be established. The aim of the present study was therefore to determine the optimal time to perform PET/CT following injection of ^{68}Ga-NOTA-

AE105 in breast cancer patients. *Materials and methods* Five patients with histologically confirmed breast cancer scheduled for lumpectomy/mastectomy underwent 60 minutes of dynamic PET and low dose-CT of the breast region starting at the time of injection of ^{68}Ga-NOTA-AE105 (≈200 MBq). PET data was reconstructed into 5-minutes time frames, resulting in 12 consecutive frames in total. Time activity curves were created for tumor lesions, background organs (muscle and normal breast tissue) and blood pool. Tumor-to-background ratios were calculated for all time frames. In addition, experienced readers evaluated the images for best visual tumor-to-background contrast. *Results* The primary tumors of all 5 patients and several bone metastases in one patient were clearly visualized on the ^{68}Ga-NOTA-AE105 PET/CT at all time frames (average SUV_{max} 3.7; range 1.9-5.1). Tumor-to-background ratio were higher than 2 across all time points (average $SUV_{max\ (tumor)}/SUV_{mean\ (background)}$: muscle 6.8; range 3.8-10.3 and normal breast 5.4; range 2.1-18.5). Due to an initial high blood pool activity, the tumor-to-blood pool ratio reached a level >1 at the time frames between 15-25 minutes. By visual judgment, tumor-to-background contrast was found to be best between 15-25 min. *Conclusion* Based on tumor-to-background ratios as well as visual judgment, the optimal time for conducting uPAR PET/CT imaging following injection of ^{68}Ga-NOTA-AE105 is suggested to be approximately 20 minutes.

EP055

Hybrid PET-MR imaging for accurate nodal staging prior to neoadjuvant chemotherapy in breast cancer patients - preliminary results

S. Vöö, B. Goorts, M. L. Smidt, T. J. van Nijnatten, J. Wildberger, M. B. Lobbes, F. Mottaghy; Maastricht University Medical Center, Maastricht, NETHERLANDS.

Purpose: To assess the clinical value of hybrid FDG PET-MR imaging for nodal staging prior to neoadjuvant chemotherapy (NAC) in breast cancer patients. **Methods and Materials:** In this prospective study, patients with primary invasive breast cancer with at least cT2 and/or a histopathologically confirmed lymph node metastasis undergoing NAC were included. A hybrid PET-MR breast protocol was performed before NAC. MR images were evaluated independently by one dedicated breast radiologist, PET images independently by one dedicated nuclear physician. Afterwards a combined PET-MR report was made. The number and localization of lymph nodes suspicious for metastases on PET-MR was compared to conventional nodal staging methods, i.e. ultrasound with core needle biopsy and MRI-only. The percentage of patients with a modified treatment plan based on PET-MR was studied. **Results:** In this ongoing study, 25 patients were included so far. In 16% (4/25) of the included cases, treatment plan altered based on PET-MR findings. In two patients, PET-MR showed an enlarged internal mammary lymph node with high FDG-uptake. One patient had five axillary lymph nodes suspicious for metastases on PET-MR, whereas initially only two where seen on ultrasound and none on MRI-only. For these three patients radiotherapy plan was extended. One patient had three axillary lymph nodes suspicious for metastases on PET-MR compared to more than three on ultrasound and MRI-only, resulting in a reduced radiotherapy plan. **Conclusion:** Pre-NAC hybrid PET-MR changed treatment plan in 16% of patients. Consequently, PET-MR might be more accurate for nodal staging, compared to conventional imaging.

EP056

The Prognostic role of Skeletal Tumor Burden on ^{18}F-Fluoride PET/CT in Metastatic Breast Cancer

A. E. Brito, C. Mosci, A. Santos, S. Q. Brunetto, C. D. Ramos, E. Etchebehere; University of Campinas, Campinas, BRAZIL.

Introduction Skeletal tumor burden determined by ^{18}F-Fluoride PET/CT has been shown to have a prognostic role in prostate cancer patients treated with Ra-223. **Objectives** This study aimed to correlate skeletal tumor burden determined by ^{18}F-Fluoride PET/CT with clinical outcomes in patients with breast cancer. **Methodology** Patients with breast cancer that underwent a ^{18}F-Fluoride PET/CT whole-body image for investigation of bone metastases were retrospectively analyzed. ^{18}F-Fluoride PET/CT PET images were quantified using METAVOL® software. Skeletal tumor burden was calculated using the threshold SUVmax ≥ 10. to exclude normal bone. Abnormal sites not related to metastases (ex. urinary bladder, degenerative processes, etc) were manually excluded. The parameters total volume of fluoride avid bone metastasis (FTV_{10}), the total uptake of fluoride-avid bone metastasis (TLF_{10}), the highest SUV_{max} among all the metastases, and the mean SUV_{max} were calculated. The primary endpoint was overall survival (OS), established from the date of ^{18}F-Fluoride PET/CT until death or last follow-up. Secondary aims were time to progression (TTP), time-to-bone event (TTBE) and progression free survival (PFS). The tumor characteristics Ki-67, HER-2, Histology and nuclear grades were correlated with skeletal tumor burden. **Results** Twenty-eight female patients with breast cancer (25 invasive ductal carcinomas), ages 60.6 ± 11 years were studied. Median follow-up was 13.9 months (2 -31 months). At the end of follow-up, the mean TLF_{10} and FTV_{10} of patients that were alive was three times lower than of patients that were dead. Furthermore, the mean TLF_{10} and FTV_{10} was five times greater for patients that progressed when compared to those who did not progress. TLF10 and FTV10 values were shown to be highly correlated (p0.95; P<0.0001). FTV_{10} was significantly associated with OS and TTP on univariable (P<0.0001) and multivariable analyses ($p < 0.05$). There was no significant association between TLF_{10}, FTV_{10}, mean SUV_{max} or SUVmax with TTBE and PFS. The tumor characteristics (Ki-67, HER-2, histology and nuclear grades) were not independent predictors of survival. **Conclusion** These preliminary results show that TLF_{10} seems to be an independent prognostic imaging biomarker of OS and TTP in breast cancer patients. The analysis of a larger population can confirm these results.

EP057

Utility of Single-Photon Emission Computed Tomography (SPECT/CT) in selective Sentinel Lymph Node Biopsy (SLNB) in patients with melanoma

M. Pedrera-Canal, A. Ortega-Candil, M. J. Pérez-Castejón, C. Riola-Parada, A. Serrano-Palacio, O. Salsidua Arroyo, A. Jiménez-Ballvé, L. Lapeña-Gutierrez, J. L. Carreras-Delgado; HOSPITAL CLINICO SAN CARLOS, MADRID, SPAIN.

Objective: The aim of the study was to investigate the role of Single-Photon Emission Computed Tomography (SPECT/CT) in selective Sentinel Lymph Node Biopsy (SLNB) in patients with melanoma. Material and Methods: This is a retrospective study between April/2011 and November/2015. We consecutively included 44 patients affected of cutaneous melanoma (23 female and 21 male) with a mean age of 61,5 years old. Location of primary lesion was: head and neck (13.6%), trunk (43.2%), upper extremities (20.5%) and lower extremities (22.7%). All patients had indication for SLNB procedure. Initially all patients underwent primary excisional biopsy. Both SLNB and margins enlargement surgery were performed the same day. Dynamic images were acquired immediately after ^{99}Tc-nanocolloidal albumin peri-scar injection, secondly planar images of the injection-site 30 and 60 minutes post-injection were performed and finally SPECT/CT scanning was acquired (Low dose CT, 140 Kv, 2,5 mAs). SLNs excision was undertaken 3-6 hours after injection with a gamma probe and a portable gammacamera**.** Results: SLNs detection rate reached 95.4% (42/44 patients) using planar images and SPECT/CT. The mean number of radiotracer deposits visualized in the planar images and SPECT/CT was the same (2.51 deposits, range 0-6). We did not find significant differences between both images

(p= 0.136), with a good Kappa Index (0.767). The radiotracer did not migrate in 4.5% (2/44) patients, whereas, in 65.9%, lymphatic drainage was only in one nodal station and in 22.7% patients drainage reached two or more nodal stations. Migration distribution was ipsilateral to the primary lesion in 85.7% (36/42) patients and bilateral in 14,3% (6/42). A mean of 2.81 sentinel nodes were removed (range 0-10). In 71.4% (30/42) patients, SLNs were negative for malignancy and their Breslow Thickness (BT) mean value was 1.99 mm. However, in 28.6% (12/42) patients, SLNs were positive for malignancy, obtaining a BT mean value of 3.58mm. Surgeons considered SPECT-CT images very useful for a better anatomical localization. Conclusion: In our sample, planar lymphoscintigraphic and hybrid SPECT/CT imaging presented the same ability to detect SLNs. However SPECT/CT was very useful for surgeons to improve the correct anatomical localization, especially in those cases with more than one lymphatic drainage station and bilateral distribution.

EP058

SPECT-CT with 99m-Tc-MIBI in diagnosis of non-sentinel lymph node invasion by breast cancer

P. Krzhivitskiy, S. Novikov, S. Kanaev, P. Krivorotko, O. Ponomareva, L. Jukova, A. Chernaya, E. Turkevich; N.N. Petrov Institute Oncology, St Petersburg, RUSSIAN FEDERATION.

Purpose: to evaluate accuracy of SPECT-CT with 99m-Tc-MIBI in diagnosis of non-sentinel lymph node (LN) involvement in patients with early breast cancer (BC). **Material and methods:** 184 patients with clinically early (T1-3 N0 M0) BC were included in this study. All of them underwent SPECT-CT examination on Symbia-T16 scanner which is consists of dual head gamma-camera combined with 16 slices diagnostic CT. SPECT-CT was performed 15 min after i/v injection of 740-860 MBq of 99mTc-MIBI. Experienced radiologist and specialist in nuclear medicine separately reported on CT and SPECT-CT data. The signs of metastatic lymph node involvement were: short axis more than 10mm, cortical thickness more than 4mm, solid structure (absent hilum), intensive tracer uptake (70% above background and more), more than 2 abnormally LN. All LN with tracer uptake on the level of background or less than 70% above background uptake were considered as normal or nonspecific LN. The size of primary tumor also was taken into consideration - more than 20mm. Final interpretation of the data was done according to histological verification of removed sentinel and non-sentinel LN. **Results:** In total 62 (34%) of 184 evaluated patients had axillary LN metastases on final histology: in 37 cases we revealed involvement of only sentinel LN and in remaining 25 patients (14%) - sentinel and non-sentinel LN. We determined high accuracy (88%) and sensitivity (96%) and moderate specificity (55%) of SPECT-CT in diagnosis of non-sentinel LN invasion. **Conclusion:** Our data demonstrated high sensitivity (96%) of SPECT-CT with 99mTc-MIBI in diagnosis of non-sentinel LN involvement by BC. At the same time we must also take into consideration high false positive rate (38%) of this test.

EP059

The preliminary study of 18F-FES PET/CT in predicting postmenopausal patients with ER/PR+, metastatic breast cancer receiving combination treatment of fulvestrant and docetaxel

Z. Yang, Y. Sun, J. Zhang, B. Wang, S. He, Y. Zhang, X. Xu, H. Yuan, Y. Zhang; Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim: To investigate the clinical value of 18F-FES PET/CT in predicting postmenopausal patients with ER/PR+, metastatic breast cancer receiving combination treatment of fulvestrant and docetaxel. Methods: Postmenopausal patients with pathology confirmed ER/PR+, metastatic breast cancer were prospectively enrolled and randomly divided into two groups (D: docetaxel and D+F: docetaxel + fulvestrant). Each patient underwent FES and FDG PET/CT before and after two cycles of treatment. SUVmax of all the metastatic lesions were measured. Patients were followed every 2 cycles for at least 1 year. Tumor response was evaluated according to RECIST 1.1 Criteria. The ER changes in different groups were performed by x2 test. The difference of SUVmax in two groups of various PFS (>1 year and <1 year) was validated by two-tailed t test. Results: Thirteen patients in group D and 9 patients in group D+F have been consecutively enrolled. However, 4 patients in group D were lost during follow up due to various reasons and they were not further analyzed for PFS; additionally, 2 patients in group D+F suffered from adverse effect in cycle 1 and quitted from our study, and another patient failed to undergo FES PET/CT. The ratio of PFS>1 year in group D and D+F were 4/9 and 4/6, respectively. FES PET/CT detected 7 patients with ER upgraded and 6 patients with ER downgraded in group D; nevertheless, all 6 patients were confirmed to be ER downgraded in group D+F. There was statistical difference between these two groups (p=0.044). In group D+F, SUVmax of FES in patients with PFS>1 year decreased significantly than those with PFS<1 year (>1 year: 79.5±26.3%, <1 year: 8.5±2.1%, p=0.023) after 2 cycles. However, there was no obvious change by FDG results (>1 year: 57.0±55.0%, <1 year: 15.0±87.7%, p=0.495). Besides, no statistical difference of both FES and FDG were detected in group D+F. Conclusion: Several preclinical studies demonstrated that fulvestrant could significantly reverse the ER mediated chemoresistance in vivo. Our preliminary study showed ER downgrade in all patients receiving combination treatment of fulvestrant and docetaxel by FES PET/CT. We might use the changes of SUVmax in predicting patients' outcome; therefore, individualized treatment strategy could be referred.

EP060

^{18}F-FDG PET/CT versus ^{18}F-Fluoride PET/CT for Detecting Bone Metastases in Patients With Breast Cancer and Equivocal Bone Scan

A. E. Brito, R. G. Almeida, C. Mosci, M. C. L. Lima, B. J. Amorim, A. O. Santos, T. F. Souza, S. Q. Brunetto, E. C. Etchebehere, C. D. Ramos; UNICAMP, Campinas, BRAZIL.

Introduction Whole-body bone scintigraphy (BS) is a sensitive procedure for diagnosis of bone metastasis (BM) in patients with breast cancer; however, it presents low specificity and significant rate of equivocal results. **Objectives** This study aimed to compare ^{18}F-FDG-PET/CT and ^{18}F-fluoride-PET/CT for detection of BM in patients with inconclusive BS. **Methods** We prospectively studied 18 female patients with breast cancer and no BM previously diagnosed (33-78 years of age, mean: 57±12 years). All patients had BS performed for staging or restaging purposes with inconclusive findings and were submitted to true whole-body ^{18}F-FDG-PET/CT (4.5MBq/kg) and ^{18}F-fluoride-PET/CT (3.7MBq/kg) acquisitions, with a time interval of 20±17 days between the procedures, without treatment. All abnormalities identified on BSs were compared with their appearance on both ^{18}F-FDG and ^{18}F-fluoride images. Inconclusive lesions on BSs and additional lesions on PET/CT images were classified as BM or not. The lesions defined as BMs were also classified as lytic, blastic, mixed or without any anatomical changes, according to their appearance on CT images. The final diagnosis of BM was defined by follow-up (clinical and imaging procedures) and established at least 1 year after the PET/CT studies. **Results** The final diagnosis after follow-up defined that 12/18 patients had BMs and 6/18 patients had only benign lesions. ^{18}F-fluoride-PET/CT identified all 12 metastatic patients, whereas ^{18}F-FDG-PET/CT identified only 9 (sensitivity 100% and 75%, respectively, for patient analysis). Thirty-three of the 50 inconclusive lesions on BSs were defined as BM. ^{18}F-fluoride-PET/CT identified 30/33 and ^{18}F-FDG-PET/CT 19/33 of these BMs (sensitivity of 91% and 58%, respectively, for lesion analysis). ^{18}F-fluoride-PET/CT detected 26 additional lesions in 5/12 metastatic patients and ^{18}F-FDG-PET/CT 48 additional BM in only 2 patients; therefore, the methods detected a total of 101 BMs. On CT images, 26/101 BMs were classified as blastic, 19/101 lytic, 4/101 mixed and 52/101 without anatomical changes (most of these in only one patient) and the sensitivity for these types of BMs were respectively 85%, 68%, 75% and 55% for ^{18}F-fluoride-PET/CT

and 42%, 68%, 50% and 88% for ^{18}F-FDG-PET/CT. **Conclusion** ^{18}F-fluoride-PET/CT is more sensitive than ^{18}F-FDG-PET/CT to detect BM in patients with breast cancer and inconclusive BS. ^{18}F-fluoride PET/CT is more sensitive than ^{18}F-FDG-PET/CT to identify blastic and mixed blastic/lytic lesions. The sensitivities of both procedures for pure lytic lesions were similar in the present study. Interestingly, ^{18}F-FDG-PET/CT was more sensitive than ^{18}F-fluoride PET/CT to detect lesions without anatomical changes found in one patient.

EP061

Locally Advanced Breast Cancer: Utility Of Volumetric Parameters In 18F-FDG PET/CT Scans To Predict Recurrence And Overall Survival

M. Martinez de Bourio, A. Jimenez-Ballvé, O. Salsidua Arroyo, A. Serrano-Palacio, A. Ortega-Candil, C. Rodriguez-Rey, M. García García-Esquinas, J. A. García-Saénz, M. E. Fuentes Ferrer, J. L. Carreras-Delgado; HOSPITAL CLINICO SAN CARLOS, MADRID, SPAIN.

Objective: To evaluate the ability of PET volumetric parameters, such as metabolic tumour volume (MTV) and total lesion glycolysis (TLG) compared to Standardized Uptake Value (SUVmax and SUVmean) in the initial staging ^{18}F-FDG PET/CT performed in patients with locally advanced breast cancer (LABC), to predict the recurrence risk and overall survival. *Materials and methods:* This is a retrospective study of 100 LABC women who were treated with neoadjuvant chemotherapy from January/2010 till March/2016. We measured SUVmax, SUVmean, MTV and TLG in the primary tumour and MTV and TLG in all lesions (the sum of the primary tumour and lymph node metastases). *Results:* The median follow up was 52.5 months, 13% (13/100) presented recurrence, local disease (n=2), distant metastasis (n=10) and both (n=1), and 5% (5/100) died, all of them with recurrence. The only parameter related to recurrence was MTV in the primary tumour, which was higher in those patients with recurrence compared to those without it (20.5 cm^3 vs 6.8 cm^3; p=0.048). TLG in the primary tumour was also higher in the group with recurrence, almost reaching statistical significance (91.1 g vs. 24.5 g; p=0.079). We found statistical association between MTV, measured in the primary tumour and all lesions, and overall survival (31.3 cm^3 vs. 7.1 cm^3; p=0.003; and 36.2 cm^3 vs. 8.7 cm^3; p=0.006, respectively). Likewise, TLG in the primary tumour and all lesions was higher in those patients who died (126.9 g vs. 25.5 g; p=0.007 and 164.6 g vs. 33.8 g; p=0.009). However, neither SUVmax nor SUVmean in the tumour and all lesions were able to predict recurrence and overall survival significantly (p>0.05). In the ROC curve analysis, the best cut-off points of MTV in the primary tumour to predict recurrence and overall survival were: ≥ 9.35 cm^3 (sensitivity 62 % and specificity 61%), and ≥ 27 cm^3 (sensitivity 80 % and specificity 88%) respectively. *Conclusions:* Metabolic tumour volume in the primary tumour could be useful to predict both recurrence risk and overall survival in patients with locally advanced breast cancer. Other parameters associated with overall survival are metabolic tumour volume in all lesions, as well as total lesion glycolysis in the primary tumour and all lesions.

EP062

Fludeoxyglucose (^{18}F) PET/CT in breast cancer patients: evaluation of patient based diagnostic performance and of impact on patient management

L. Kaliska[1], M. Zacharovska[1], M. Vereb[2], S. Balogova[3]; [1]Institute of Nuclear and Molecular Medicine, Agel Diagnostic, Banska Bystrica, SLOVAKIA, [2]Praxis für Radiologie, Nuklearmedizin und Strahlentherapie, Kassel, GERMANY, [3]Nuclear Medicine Clinic, St. Elisabeth Cancer Institute Hospital, Bratislava, SLOVAKIA.

Aim: Breast cancer (BC) has a high prevalence among malignancies in woman. Prognosis and management of BC patients depends on both, histopathologic characteristics and spread of the tumour. Early diagnosis of recurrence is also important to allow appropriate treatment. The aim of this study was to prospectively assess the value of FDG PET/CT in terms of diagnostic performance and impact on patient management in various clinical situations of BC. Material and Methods: 434 patients were referred for a FDG PET/CT in following clinical situations: Initial staging: 1. Initial staging (n=8), 2. Staging after resection of primary tumour (n=6); Evaluation of primary curative treatment and systematic follow-up: 3. Evaluation at the end of treatment (n=12), 4. Systematic follow-up in asymptomatic patients (n=62); Localisation of recurrent BC: 5. Clinical suspicion from recurrence (n=21), 6. Suspicion of recurrence on conventional imaging (n=72), 7. Raise in serum tumour markers levels (n=98), 8. Restaging of BC (n=14); and Evaluation of palliative treatment: 9. Evaluation of effect of palliative treatment (n=141). The standard of truth for evaluation of diagnostic performance was either histology (45/434=10%) or follow-up more than 6 months (398/434=90%). The impact of FDG PET/CT on patient management was considered as major (change between main clinical modalities) or minor (within intended modality). Results: The patient based sensitivity, specificity and diagnostic accuracy of FDG PET/CT were 196/209=94%, 199/229=88% and 395/434=91% respectively. Overall the impact on patient management was observed in 194/434=45% of cases. The major impact was observed in 98/194=51%, minor impact in 95/194=49% patients. The most frequent impact on management was observed in group 9, 6 and 7. In a group of patients referred for systematic follow-up FDG PET/CT (group 4), the impact of FDG PET/CT on patient management was observed in 8/62=13% cases (Table 1). Conclusion: Our results show that FDG PET/CT plays a substantial role in the management of breast cancer patients, having considerable impact rate on the clinical management particularly in patients referred for localistaion of recurrent disease in case of clinical, biochemical or imaging suspicion if recurrent disease.

EP063

PET/MRI in Staging of Breast Cancer: Correlation with Histological Findings

D. Franceschi, K. Airola, R. Matthews, R. Chimpiri, K. Yaddanapudi, N. Relan; Stony Brook University Hospital, Health Sciences Center, STONY BROOK, NY, UNITED STATES.

INTRODUCTION: F-18 FDG positron emission tomography (PET) combined with magnetic resonance imaging (MRI) is a new hybrid technology used in cancer imaging. We retrospectively evaluated its utility in the initial staging of patients with breast cancer and correlated with histological findings. MATERIAL AND METHODS: We identified 64 FDG PET/MRI studies performed in patients with breast cancer in period from January, 2014 to May, 2016. In 12 patients imaging was done for staging purposes, due to locally advanced cancer or postoperatively due to positive sentinel node surgery. Studies were reviewed by radiologist and nuclear medicine physician. RESULTS: In 10 patients histology was invasive ductal carcinoma and 2 patients had invasive lobular carcinoma. All 12 patients had hypermetabolic lymph nodes reflecting metastatic adenopathy. In 6 patients additional satellite hypermetabolic breast lesions and in 4 patients distant hypermetabolic lesions representing metastases are identified. Average SUV was 11.4 in ductal carcinoma ranging up to 31.8, and low SUV of 1.4 and 3.0 was found in patients with lobular carcinoma. One patient with lobular carcinoma had metastasis in the uterus without evidence of hypermetabolic activity. CONCLUSIONS: PET-MRI proved to be a feasible and effective modality in staging of patients with breast cancer capable of accurate primary lesion, metastatic adenopathy and distant metastasis identification.

EP064

Clinical efficacy of extensive and dual-time-point ^{18}F-FDG PET/CT for breast cancer

t. hamada[1], t. komori[1], y. tanaka[1], n. sato[2], y. narumi[1]; [1]osaka medical hospital, takatsukishi, JAPAN, [2]hokusetsu general hospital, takatsukishi, JAPAN.

Purpose: Since there are siginificant false positives and false negatives in metabolic imaging with FDG, it has been attempted to improve diagnostic accuaracy devising imaging acquisition. In case of breast cancer, although there are several reports on clinical efficacy of dual-time-point ^{18}F-FDG PET/CT, only few extensive and dual-time-point are included in the studies. Our study is to verify the additional information acquired by delayed images (2 hour after) comparing with the early images (1 hour after FDG injection) in 77 case with 96 examinations. Subjects & Methods: 77 cases of breast cancer patient (age;36-84 years old) have undergone ^{18}F-FDG PET/CT scan (GE Discovery-ST and 710Q.Suite Vision) with dual-time-point scan (early PET/CT (1hour after FDG injection) [E] and delayed thoracicoabdominal area (2 hour) [D]). The injection dose was 185-250Mbq. The total number of examination was 96. This study performed from May 2007 through December 2015. We compared the diagnostic accuracy between early and delayed images. Results: Both E and D were positive in 36 cases, but one case of those was benign pulmonary granuloma. Diagnosis was changed in 13 cases at D. These were; three cases of increase in number of lymph node metastasis, three cases of increase in number of liver metastasis, two cases of increase in number of bone metastasis, and five cases of localized intestinal tract accumulation to physiological accumulation. This study showed that the sensitivity, specificity, and accuracy of E were 0.855(47/55), 0.854(35/41), and 0.854(82/96) respectively, whereas those of D were 1(55/55), 0.976(40/41), 0.99(95/96) respectively. D had better sensitivity, specificity, and accuracy than E (p=0.0047, p=0.0253, and p=0.0008 respectively). Conclusion: In breast cancer patient, dual-time-point ^{18}F-FDG PET/CT improves diagnosis precision.

EP065

Accuracy of imprint cytology for intraoperative diagnosis of axillary sentinel node in Breast Cancer

M. Luna, M. Solà, M. Fraile, J. Julian, E. Castellà, A. Mariscal, I. Pascual, J. Navines, A. Fernández, M. Framis; Hospital Germans Trias, Badalona, SPAIN.

Objective: The study aim was to establish Sensitivity, Specificity, Positive Predictive, Negative Predictive, and Accuracy Values of both imprint cytology (IC) and the OSNA assay for intraoperative assessment of axillary sentinel node (SN) involvement in breast cancer patients and if there were potential differences related to specific clinicopathological variables. We wished to find out if true positive and false negative results of imprint cytology in axillary limphadenectomy (ALND) were associated to CK19 copy numbers. Also, we adressed a comparative cost analysis between techniques. **Methods**: 244 patients treated for breast cancer in the Breast Unit of Hospital Germans Trias i Pujol from March 2011 to May 2015 were prospectively included. A transversal, consecutive design was applied to assess the diagnostic test (IC) compared to the reference test (OSNA). Inclusion criteria were: T1 and T2 tumors with negative nodes, both clinical and on axillary US/FNA. Excluded wre patients on neoadjuvant chemotherapy. **Results**: sensitivity of imprint cytology for macrometastases was 70% with an AUC 0,84. Considering all patients in whom ALND is not to be performed as true negative cases (negatives plus isolated tumour cells or micrometastases), the negative predictive value of IC was 95,75%. Accuracy of IC reached 96,12%. No significant differences in clinicopathological variables were detected between true positives and false negatives of IC. The false negative rate was acceptably low (3.87%). The release time of results for OSNA doubled that of IC. In the comparative cost analysis, it was observed that OSNA was associated with an increased cost of € 370, wich added to the axtra surgical time required. **Conclusions**: IC makes a good technique for intraoperative sentinel node diagnostic as it has high sensitivity, high negative predictive value, and low false negative rate compared to the OSNA assay. It allows keeping the whole node tissue and thus the possibility of improved histopathological evaluation, which can be useful for adjuvant. Furthermore, IC offers the advantage of being less time consuming. Cost analysis shows a higher cost for OSNA , which may exceed the potential benefit of sorting out false negatives from IC.

EP066

The additional prognostic information of FDG PET/CT when added in pre-operative and post-operative setting of patients with high risk breast cancer

L. Evangelista[1], V. Guarneri[2], T. Saibene[3], S. Michieletto[4], P. Conte[2]; [1]Nuclear Medicine and Molecular Imaging Unit, Veneto Institute of Oncology IOV - IRCCS, PADOVA, ITALY, [2]Oncology Unit 2, Veneto Institute of Oncology IOV - IRCCS, PADOVA, ITALY, [3]Brast Surgery Unit, Veneto Institute of Oncology IOV - IRCCS, PADOVA, ITALY, [4]Breast Surgery Unit, Veneto Institute of Oncology IOV - IRCCS, PADOVA, ITALY.

Introduction. The aim of this study was to assess the prognostic information providing by 18F-FDG PET/CT in patients with high risk breast cancer, either before and after surgical approach. **Materials and methods.** Between 2011 and 2013, we prospectively enrolled 275 patients (age: mean±standard deviation=53±12 years) with a high risk breast cancer (stage I-III; triple negative and HER2 positive cancer). One-hundred forty-nine (54.2%) patients underwent 18F-FDG PET/CT before neoadjuvant therapy and 126 (45.8%) after surgery and before any additional adjuvant therapy. The patients were followed for a median period of 79 (2-157) months. The effects of PET/CT findings and prognosis was assessed by using Kaplan-Meier analysis, separately for each group of patients (pre-operative and post-operative setting, respectively) and by Cox-regression analysis for the identification of the predictors of poor prognosis. A statistical significance was set for a $p<0.05$. **Results.** During the follow-up period, 4 patients were lost at follow-up. Forty patients had a recurrence of disease and 28 died (14.5% and 10.2%, respectively). A total of 46 events occurred. In pre-operative setting, the rates of recurrence and death were higher in patients with a positive PET/CT finding other than the site of primary cancer, although only the rate of recurrences were significantly different between patients with a positive than negative scan (27.4% vs. 0%; p<0.05). Conversely, in the post-operative setting, any significant difference was found between positive and negative PET/CT results, neither for recurrence and death, (11.4% vs. 5.6% and 11.4% vs. 8.9%, respectively). After 120 months, in the pre-operative setting, at Kaplan-Meier analysis 95% of patients with a negative PET/CT other than the site of primary cancer were still alive, as compared to only 75% with a positive scan. Interestingly in the same length of time, 100% of patients with a negative scan were free of disease-recurrence. Unfortunately, any significant difference, in terms of survival curve was found in the post-operative setting. Similarly, at multivariate Cox-regression analysis, a positive PET/CT resulted a significant predictive factor of a poor prognosis (all events; HR: 0.117; p=0.036), in patients in pre-operative setting. The significance was lost in the post-operative setting. **Conclusions.** In the pre-operative setting, PET/CT is able to provide additional prognostic information, being able to better stratify those patients who will develop a recurrence or die for breast cancer, from those who will be a long survivor. Conversely, PET/CT in post-operative setting did not add any prognostic value.

EP067

The new perspective of PET/CT for axillary node staging in breast cancer patients according to ACOSOG Z0011 trial

E. Kong, K. Chun, I. Cho, S. Lee, S. Kang, J. Choi; Yeungnam University Hospital, Daegu, KOREA, REPUBLIC OF.

Purpose: According to the results of the ACOSOG Z0011 trial, the use of sentinel lymph node (SLN) dissection alone did not result in inferior survival compared with axillary lymph node dissection (ALND) in patients with limited SLN disease treated with breast-conserving surgery (BCS). We investigated the diagnostic performance of FDG PET/CT with respect to one or two ALN metastasis from three or more. Methods: We retrospectively analyzed preoperative contrast enhanced PET/CT images taken from Jan 2010 to June 2012. The patients had clinical T1-2 primary invasive ductal cancer without palpable adenopathy and was underwent BCS with ALND within 2 weeks from scan. We excluded the patients with neoadjuvant chemotherapy or distant metastasis at initial work up. We counted the number of suspicious LN, considering FDG avidity with morphologic change; Image analysis was as follows: FDG PET evaluation for any focally increased PET signal, then a morphologic evaluation was done. Images were considered positive if areas in the axillary basin took up more FDG than the surrounding tissues. The criteria for abnormal lymph nodes on CT included a round/ovoid, or cortical thickening with contrast enhancement. The sizes of the lymph nodes did not directly enter the final PET/CT finding criteria. Results: Fifty-three women (27-72 y-0) were enrolled and their mean tumor size was 2.09 (1.2-4.2 cm). All the patients had axillary metastasis: 1 or 2 (n=42; limited group), 3 or more (n=11; extended group). Four women had recurrence during follow up period. The mean tumor size was 2.19 in limited group and 2.07 in extended group. The mean SUVmax for tumor was 7.16 in limited group and 7.20 in extended group. PET/CT correctly predicted 41/42 in limited group and 7/11 in extended group. The diagnosis for extended group was 63.6% in sensitivity, 97.6 in specificity, 87.5 in PPV and 91 in NPV. Regarding 4 false negative patients, 5.89 in tumor SUVmax and 2.33 in tumor size. Regarding 4 recurred patients, 10.16 in tumor SUVmax and 2.1 in tumor size, the tumor SUVmax showed an evident trend (p=0.158) Conclusion: Preoperative PET/CT scan predict 3 or more positive ALN metastasis with high specificity and have evolving role to treat plan in patients with clinical T1-2 IDC and no palpable adenopathy.

EP068

Meta-analysis of 99mTc-Sestamibi Imaging for Neoadjuvant Chemotherapy Response in Locally Advanced Breast Cancer: More Consistent Results by Incorporating Standardized Quantification, SPECT/CT and Tumour Subtypes?

A. Collarino[1], E. J. de Koster[2], R. A. Valdés Olmos[1,3,4], L. M. Pereira Arias-Bouda[1,5]; [1]Nuclear Medicine Section, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, [2]Department of Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, [4]Department of Nuclear Medicine, The Netherlands Cancer Institute –Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [5]Department of Nuclear Medicine, Alrijne Ziekenhuis, Leiderdorp, NETHERLANDS.

Aim: In recent years ^{18}F-FDG has displaced ^{99m}Tc-Sestamibi as radiotracer for breast cancer functional assessment. However, results of ^{18}F-FDG PET/CT in early prediction of neoadjuvant chemotherapy (NAC) response in locally advanced breast cancer (LABC) remain contradictory and appear to be strongly influenced by breast tumour subtypes. The purpose of this meta-analysis was to determine whether and how ^{99m}Tc-Sestamibi has been evaluated to predict NAC response in LABC. **Materials and Methods:** The literature search was updated up to February 15th, 2016. Studies with at least 10 women with LABC evaluating ^{99m}Tc-Sestamibi for NAC response with planar imaging, SPECT, and/or SPECT/CT taking histopathology and/or radiological imaging as reference standard were included. Meta-analysis was performed using Meta-DiSc, statistical software version 1.4. **Results:** Out of 162 references 17 studies concerning 588 women, were selected; 14 studies evaluated ^{99m}Tc-Sestamibi with conventional planar scintimammography and 3 with dedicated gamma cameras for breast imaging. No articles evaluating SPECT or SPECT/CT and tumour subtypes were found. Pooling of all studies was inappropriate because of heterogeneity in methodology and patient selection. Therefore, only the 14 studies with planar ^{99m}Tc-Sestamibi were analysed. Overall pooled sensitivity for correct prediction of tumour presence was 70% (95% CI 64-76%) and specificity for correct prediction of tumour absence was 77% (95% CI 70-83%). In relation to the timing of ^{99m}Tc-Sestamibi only two articles were found concerning in total 88 patients with sensitivities of 94-95% and specificities of 85-90% when assessment was effectuated early during NAC. **Conclusion:** Only conventional planar ^{99m}Tc-Sestamibi scintimammography has been used to predict tumour response in LABC with relatively low sensitivity and specificity. Preliminary results using ^{99m}Tc-Sestamibi early during NAC appear to be more sensitive but experience is limited. Other important factors, not or insufficiently evaluated, like SPECT/CT imaging, tumour subtypes and standardized ^{99m}Tc-Sestamibi quantification and timing need to be further investigated.

EP069

Cardiotoxicity Related To Trastuzumab In Breast Cancer: Influence Of Cardiovascular Risk Factors And Basal Cardiac Study With Multiple Gated Adquisition Ventriculography

M. Garrido Pumar, Sr., M. Pombo Pasin, V. Pubul Núñez, S. Nieves Maldonado, B. Aradas Cabado, S. Argibay Vázquez, M. Fierro Alanis, A. Ruibal Morell; Clinic Universitary Hospital of Santiago de Compostela, Santiago de Compostela, SPAIN.

OBJECTIVE: Cardiotoxicity is an important adverse efect in the treatment of breast cancer. Cardiotoxicity from the monoclonal antibody Trastuzumab, used in HER2-positive breast cancer differs from the cardiotoxicity caused by anthacyclines because the myocardial damage caused by trastuzumab is no dosage-dependent and it is reversible if detected in an early stage. Monitorizing the carcdiac function, usually by measuring the eyection fraction of the left-ventricle (LVEF) is extremely important to prevent tha cardiotoxity caused by trastuzumab. In this study we intend to analyze the influence of cardiovascular risk factors and the hemodinamic factors measured by a basal study with multiple gated adquisition ventriculography (MUGA), in patients that begins to receive trastuzumab for threatment of early breast cancer. METHODS: We studied 258 women with HER2-positive breast cancer that performed a basal MUGA and consecutive controls of LVEF during the therapy with trastuzumab. Cardiovascular risk factors included age, obesity, hypertension, diabetes, dyslipidemia, anemia and previous cardiopathy. Basal MUGA parameters include sistolic data: LVEF, telesistolic and telediastolic volumes (TSV and TDV) and diastolic data: Peak filling rate (PFR) and time to peak filling rate (TPFR). We consider positive a study with a decline of LVEF <50% during the threatment with tastuzumab. RESULTS: 43 women had a <50% decline of LVEF during the trastuzumab administration. There were no significant relation with the presence of any cardiovascular risk factors and the decline of LVEF. The basal MUGA study however showed relation with lower values of basal LVEF (58 [55-62] vs 66 [62-71] p<0.001), VTS (45 [42-52] vs 34 [29-40) p<0.001], VTD (112 [97-139] vs 104 [91-118] p 0.019) and PFR (139 [112-168] vs 124 [111-152] p 0.31). In the group of 43 women with a significant decline of LVEF, 32 showed a recovery of LVEF after the modificatios/suspension of the therapy, and 4 developed clinical cardiac

insuficiency. CONCLUSION: Potential trastuzumab cardiotoxiciy is a frequently observed during treatment and reversible in most cases if we made a good control of patients. The cardiovascular profile does not allow a stratification of the patients at risk. The basal study of cardiac function however showed that patients with lower basal sistolic and diastolic function are more related to develop a significant decline of eyection fraction. The perform of a basal cardiac study if highly recommended in the treatment of breast cancer with trastuzumab.

EP070

Clinical-diagnostic implication of incidental mammary 18F-FDG uptake during PET/CT performed for other pathology

S. Panareo[1], I. Santi[1], I. Rambaldi[1], S. Taralli[1], P. Carcoforo[2], M. Rollo[3], P. Querzoli[4], C. Cittanti[1]; [1]University Hospital - Nuclear Medicine Unit, FERRARA, ITALY, [2]University Hospital - Radioguided Surgery Unit, University of FERRARA, ITALY, [3]University Hospital - Senology Section, FERRARA, ITALY, [4]University Hospital - Pathology Section, University of FERRARA, ITALY.

AIM: to investigate the clinical-diagnostic meaning of accidental breast uptake of 18F-FDG during PET/CT performed for other pathology, mainly cancer, correlating with radiological imaging and histopathology. **METHODS AND MATERIALS**: we retrospectively selected 43 patients (7 male, 36 female, mean age 66.28±14.7y/o) investigated for breast uptake of 18F-FDG, successively examined with mammography (MMX), UltraSound (US) and, if necessary, Magnetic Resonance (MR). Cases suspected for breast malignancy were studied with US-guided macro-biopsy (USMB). Patients were primitively affected by lung cancer (15), NHD (8), melanoma (4), head-neck cancer (2), other diseases (13) as well as ampullary cancer, Burkitt's lymphoma, CUP Syndrome, esophageal cancer, GIST, T lymphoma, occult tumour, sarcoma, thyroid cancer, tonsil cancer, rectal cancer, vasculitis. A correlation between PET/CT (SUV), radiology (imaging and BI-RADS classification), age, histopathology was done. PET/CT images were interpreted by one radiologist and one nuclear physician together. **RESULTS**: Of 43 patients analyzed, 19 performed US and MMX, 11 performed only US, 13 did not perform nothing because they did not carry on the follow-up. Of 11 patients who performed US, 6 did not perform USMB because unnecessary. Eight patients of 30 who carried out the study of the radiological findings on mammary gland did not show morphological abnormalities. Histopathology of 22 eligible patients showed: 9 infiltrating ductal carcinomas, 4 lymphomas (including 1 skin), 1 adenoidcystic cancer, 1 carcinomatous mastitis, 6 fibroadenomas and 1 phyllodes tumour. About 22 patients studied, we found 7 with SUVmax >2.5 and 15 with SUVmax <2.5 (average SUV= 2.0233±2:38SD). There was not statistically significance (p=0.361) between SUVmax and histology. The incidence of malignancy was 68.2%. The incidence of benignity was 31.8%. We did not found a significant correlation (p< 0.106) between SUVmax and radiological imaging. We did not see a significant correlation (p<0.356) between patient age and tumour characterization. BI-RADS classification did not correlate with final histology. In 8 cases PET finding was not confirmed radiologically for the occurrence of artifacts from breast movement during PET or physiological distribution of 18F-FDG in the mammary gland related to menstrual cycle. **CONCLUSIONS**: The identification of an accidental mammary uptake during PET may represent an "*alarm bell*" inducing to deepen PET findings. It seems to have a clinical implication because the change of patient treatment. The diagnostic anticipation would have a favorable prognostic value and lead to a significant reduction in costs. Data must be confirmed in a more large casuistic.

EP071

Usefulness assessment of single photon emission tomography/computed tomography for localisation sentinel lymph node in breast cancer patients

A. Giżewska[1,2], A. Mazurek[1], Z. Stembrowicz-Nowakowska[1], M. Koza[2], M. Dziuk[1,2]; [1]Military Institute of Medicine in Warsaw, Warsaw, POLAND, [2]Affidea, Warsaw, POLAND.

Introduction Planar SLN scintigraphy yields functional data while hybrid SPECT/CT imaging provides information on both function and anatomy of the lymph node. **Aims** The aim of the study was to verify whether the routine performing of SPECT/CT in addition to planar imaging increases the SLN detection rate and yields more accurate SLN localization details in patients with early-stage breast cancer. The primary aim of the study was to compare diagnostic accuracy in SLN detection of SPECT/CT and planar imaging. **Materials and methods** There were 153 early-stage breast cancer patients referred to the Department of Nuclear Medicine of the Military Institute of Medicine in Warsaw for sentinel lymph node scintigraphy in years 2007-2013. Patients with T1-2N0M0 breast cancer were included - the primary tumor was ≤5 cm in diameter, the axillary lymph nodes were non-palpable and invisible in conventional imaging studies. Planar and SPECT/CT lymphoscintigraphy were performed on the day prior to the operation, 1.5-2 hours after periaeolar injection of 74-111 MBq (2-3 mCi) of 99mTc-Nanocoll or 99mTc-Nano-albumon. Both planar and SPECT/CT examinations were performed using hybrid gammacameras. **Results** SPECT/CT identified SLN in 119/153 patients and planar scintigraphy in 114/153 patients which yielded an identification rate of 77,7% and 74,5% respectively. Lymph node assessment performed intraoperatively identified SLN in 76/126 patients with an identification rate of 60,3%. SPECT/CT identified SLN in more than one region in 17 patients. All the SLN with metastases were identified in SPECT/CT (n=22). They were localized in the axilla (95,5%) and by the sternum (4,5%). Metastatic SLN were also found in planar imaging (n=19) and during intraoperative lymph node detection procedure (n=18). Planar imaging yielded 170 uptake foci which were interpreted as SLN. Most of the foci were located in the axillar region (90%, n=153). Sensitivity and specificity of each assessed method was calculated basing on the results of histopathological examination. Sensitivity and specificity of SPECT/CT, planar imaging and intraoperative SLN detection were as follows: 91% and 93%, 62% and 55% and 46% and 61%. SPECT/CT sentinel lymph node detection yielded the highest positive and negative predictive values - they were 78% and 97% respectively. **Conclusions** 1. Hybrid SPECT/CT lymphatic mapping yields high SLN detection rate in patients with early-stage breast cancer and provides precise lymph node localization details. 2. SPECT/CT identifies more SLNs compared to planar imaging and intraoperative SLN detection. 3. SPECT/CT imaging is particularly recommended when the planar imaging is difficult to interpret or inconclusive.

EP072

Brown Fat In Breast Cancer Patients: Analysis Of Serial ^{18}F-PET/CT Scans

A. GONZALEZ JIMENEZ, **R. SANCHEZ SANCHEZ**, A. C. REBOLLO AGUIRRE, N. TESTART DARDEL, E. M. TRIVIÑO IBAÑEZ, J. M. LLAMAS ELVIRA; Hospital Virgen de las Nieves, GRANADA, SPAIN.

AIM Brown adipose tissue (BAT) is present in at least a significant fraction of human adults; however its physiological importance requires further investigation. Recent studies suggest that BAT may play a key role in breast cancer progression. ^{18}F-FDG Positron emission tomography/computed tomography (PET/CT) enables the study of metabolic active tissues on glucose substrates. The aim of this study is determine the prevalence of BAT in breast cancer

patients and to analyze whether a correlation exists between presence of BAT in ^{18}F-PET/CT and the different characteristics of this patient population. MATERIAL AND METHODS We retrospectively analyzed data from breast cancer patients who had ^{18}F-PET/CT scan between January-June of 2015. Data on distribution (bilateral upper neck, supraclavicular and paraspinal regions) of active BAT were evaluated by two nuclear physicians, blinded to the clinical history. ^{18}F-PET/CT scan were considered positive when diffuse, symmetrical, abnormal BAT uptake was detected. No SUVmax threshold value was set to define a positive BAT. Statistical analysis to determine whether correlation exists between ^{18}F-PET/CT results and the different characteristics of this population was done. RESULTS A total of 180 patients were included. The patient characteristic were: mean age (years)-56.95, Invasive ductal carcinoma-76.1%, Invasive lobular carcinoma-13.3% and other histology-10.5%, Grade of differentiation (G): GI-19.4%, GII-50.4%,GIII-30.2%, Molecular type: Luminal A-27.3%, Luminal B-54%, HER2-8.1% and Basal like-10.6%, Initial malignant tumor size (cm): <2 cm-35.7%, 2-5 cm-46.4%,>5 cm- 17.9%, 74.4% of patients had initial nodes metastases and 55.3% distant metastases. A total 180 of PET/CT images were analyzed. Nine scans (5%) showed abnormal BAT uptake. Abnormal BAT uptake was present on uncorrected and attenuation-corrected images. Statistical analysis showed that correlation exist between positive BAT in PET/CT and younger age (<40 years) (p=0.002) and the absence of initial distant metastases (p=0.042). CONCLUSION Our retrospective clinical data provide support to pursue prospective clinical and translational studies to further define the role of BAT in breast cancer development and progression.

EP073

Comparison of subareolar Injection lymphoscintigraphy with the 1 day and the 2 day protocol for the detection of sentinel lymph nodes in patients with breast cancer

J. Seok, E. Lee; Chung-Ang University Hospital, Seoul, KOREA, REPUBLIC OF.

Objectives: Lymphoscintigraphy and sentinel node biopsy were used for the detection of axillary lymph node metastasis in breast cancer patients. We compared the results of subareolar injections on the day of surgery (1 day protocol) with injections the day before surgery (2 day protocol). **Methods:** This study included 880 breast cancer patients who underwent surgery between 2001 and 2016. For the 1 day protocol 0.8 ml of Tc-99m Tin-Colloid (37MBq) was injected in 549 patients in the subareolar region on the morning of the surgery. For the 2 day protocol 0.8 ml of Tc-99m Tin-Colloid (185MBq) was injected in 331 patients on the afternoon before surgery. Lymphoscintigraphy was performed in the supine position and sentinel node identification was performed by hand-held gamma probe during surgery. **Results:** Among 549 patients with the 1 day protocol, 519 cases (94.5%) were identified by sentinel node lymphoscintigraphy, and 522 cases (95.1%) were identified by gamma probe. Among the 331 patients, in the 2 day protocol, 308 cases (93.1%) had the sentinel node identified by lymphoscintigraphy, and 298 cases (90.0 %) had the sentinel node identified by the gamma probe. There was no significant difference in the identification rate of the sentinel node between the 1 day and 2 day protocol by lymphoscintigraphy and the gamma probe. **Conclusions:** The results of the identification of the sentinel node according to 1 day or 2 day protocols showed no significant differences. Because the 2 day protocol allows for an adequate amount of time to perform the lymphoscintigraphy, it is a more useful protocol for the identification of sentinel nodes in patients with breast cancer

EP074

Value of FDG PET/CT in stage IV breast cancer

J. Duch, L. Del Carpio, T. Ramón y Cajal, A. Flotats, M. Estorch, D. López, A. Moral, I. Carrió; Hospital de la Santa Creu i Sant Pau, Barcelona, Barcelona, SPAIN.

Aim: The prognosis in patients with stage IV breast cancer is heterogeneous, including patients with only distant node metastasis diagnosed by FDG PET/CT. We aimed to compare the prognosis of this patients compared to the rest of stage IV breast cancer patients. Methods: Between january 2012 and june 2015 we retrospectively studied pacients with locally advanced breast cancer (LABC) with FDG PET/CT. For prognosis stratification, in stage IV breast cancer we differentiated pacients with only bone metastasis, with visceral metastasis and with only distant node metastasis. We compared progression free survival (PFS) and overall survival (OS) in these groups of patients. Results: We recruited 188 pacients with LABC being 43 of these in stage IV (mean age 68). Baseline performance status (PS) was 0-1 in 81% and presurgical PS was 0-1 in 93%. 16 patients were T1, T2 or T3. In 9 patients (21%) FDG PET/CT only found distant node metastasis, in 16 patients (37%) only bone metastasis and in 18 patients (42%) visceral metastasis. No significant differences were found in progression free survival (PFS) and overall survival (OS) between group of only distant node metastasis (PFS 18 months; OS 35 months), only bone metastasis (PFS 28 months; OS 32 months) and visceral metastasis (PFS 24 months; OS 35 months). Conclusions: FDG PET/CT is useful in staging locally advanced breast cancer. If stage IV is found, the presence of only distant node metastasis (hardly diagnosed with procedures other than PET/CT) has the same prognostic value as the rest of stage IV.

EP075

^{99m}Tc MIBI SPECT as a Tool for Effectiveness of Neoadjuvant Chemotherapy Evaluation

A. Medvedeva[1,2], V. Chernov[1,2], I. Sinilkin[1,2], R. Zelchan[1,2], Y. Belevich[1], S. Chizhevskaya[1], E. Slonimskaya[1], O. Bragina[1,2], E. Choynzonov[1,2]; [1]Tomsk Cancer Research Institute, Tomsk, RUSSIAN FEDERATION, [2]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Purpose: assessment of the role of SPECT with 99mTc-MIBI of neoadjuvant chemotherapy response prediction in patients with cancer. Materials and methods: The study included 27 breast cancer patients and 20 patients with cancer of the larynx and laryngopharynx. SPECT studies were carried out 20 minutes after the injection of 740 MBq of 99mTc-MIBI using ECAM-180 gamma-camera (Siemens), studies was conducted before treatment and after two courses of neoadjuvant chemotherapy. The imagines were quantitatively assessed using the tumor/background index (T/B index) for patients with breast cancer and indices tumor / submandibular salivary gland (T/SSG index) and tumor / parotid gland (T/PG index) for patients with cancer of the larynx and laryngopharynx. Indices were compared with clinical effect which was assessed by RECIST scale. Results: Partial response was registered in 20 (74%) patients with breast cancer and stable disease was observed in 7 (26%) patients by RECIST scale. After neoadjuvant chemotherapy T/B index decreased from 3.5 ± 1.7 to 1.6 ± 0.7. Decreasing of T/B index more than 30% was observed in 24 (89%) breast cancer patients and no considerable change in 3 patients (11%). Partial response was registered in 12 (60%) patients with cancer of the larynx and laryngopharynx and stable disease was observed in 8 (40%) patients by RECIST scale. After neoadjuvant chemotherapy T/SSG index decreased from 0.49 ± 0.15 to 0.34 ± 0.12 and T/PG index from 0.51 ± 0.12 to 0.39 ± 0.1. Decreasing of indexes more than 30% was observed in 15 (75%) patients with cancer of the larynx and laryngopharynx and no considerable change in 5 patients (25%). Conclusion: Thus, the present study demonstrated that SPECT with 99mTc-MIBI may be regarded as a method of assessing the state of malignant neoplasm of breast cancer, larynx and laryngopharynx during neoadjuvant chemotherapy. The T/B index is the most beneficial in response of breast cancer neoadjuvant chemotherapy evaluation and T/SSG and T/PG indices are useful in response of larynx and laryngopharynx cancer neoadjuvant chemotherapy estimation.

EP076

Comparison of the efficiency for Tc-99m Tin-colloid and Tc-99m Phytate in sentinel node detection in breast cancer patients

J. Seok, E. Lee; Chung-Ang University Hospital, Seoul, KOREA, REPUBLIC OF.

Objectives: Lymphoscintigraphy and sentinel node biopsy has become a standard method for detection of axillary lymph node metastasis in breast cancer patients, but the standard radiopharmaceutical was not prepared. About detection of axillary lymph node metastasis by lymphoscintigraphy and sentinel node biopsy in breast cancer patient, we compared the results of Tc-99m Tin-colloid and Tc-99m Phytate by subareolar injection. **Methods:** This study included 880 breast cancer patients who were performed operation during 2001-2016. Four hundred twelve patients were injected 0.8 ml of Tc-99m Tin-colloid (37-185 MBq) by subareolar injection. Four hundred sixty eight patients were injected 0.8 ml of Tc-99m Phytate (37-185 MBq). Lymphoscintigraphy was performed in supine position and sentinel node localization was performed by hand-held gamma probe in operation. **Results:** Among 412 patients by Tc-99m Tin-colloid, 374 cases (90.8%) were localized the sentinel node by lymphoscintigraphy and 367 cases (89.1%) were localized by gamma probe. Among 468 patients by Tc-99m Phytate, 453 cases (96.8%) were localized by lymphoscintigraphy and 453 cases (96.8%) were localized by gamma probe. The detection rate by lymphoscintigraphy and gamma probe was superior for Tc-99m Phytate compared to that for Tc-99m Tin-colloid, with a statistically significant difference. ($p<0.05$, $p<0.05$) **Conclusions:** Tc-99m Phytate is a better choice for localization of sentinel node than Tc-99m Tin-colloid in breast cancer patients

The value of ^{18}F-FDG PET/CT and CEA among patients with colorectal carcinoma in detecting disease recurrence

A. Barrenechea, **I. Bandong**, F. Estrada; St. Luke's Medical Center-Quezon City, Quezon City, PHILIPPINES.

Surveillance for colorectal carcinoma recurrence in patients who have undergone surgery and adjuvant treatment with chemotherapy or radiotherapy is usually initiated with elevated serum carcinoembryonic antigen (CEA) levels. Previous studies have shown, however, that elevated CEA is less sensitive in detecting recurrence as recurrence is also seen in patients with normal CEA levels. We evaluated the utility of FDG-PET/CT in patients with suspected recurrence of CRC by comparing PET/CT performance to CEA levels. **METHODS:** An ambispective cross-sectional design was done on 183 adult patients diagnosed with colorectal adenocarcinoma and who had previous surgical resection, with or without chemotherapy or radiotherapy, and who underwent PET/CT using ^{18}F-FDG from July 2013 to September 2015 at a PET center of a local tertiary hospital. Eighteen patients (10 males, 8 females, with ages ranging from from 28 to 87 years and a mean age of 63.72 years) were included as these patients were the only ones who had histopathologic confirmation or clinical follow-up proving disease recurrence. **RESULTS:** The FDG-PET/CT study yielded a true positive in detecting recurrence in 11 (61%) out of the 18 patients, a true negative in 5(28%) patients, a false negative in 0 (0%) patients and a false positive in 2(11%) patients. The sensitivity, specificity, and positive predictive value (PPV) of the FDG-PET/CT study for establishing recurrence were 100, 71 and 85%, respectively. In contrast, these parameters were 82, 29 and 64%, respectively, for CEA levels. No significant association was noted between CEA levels and PET/CT scan as well as $SUV_{max.}$ **CONCLUSIONS:** FDG PET/CT is a highly sensitive and specific tool for detecting recurrence in patients with colorectal carcinoma when compared to CEA and is able to provide a more accurate diagnosis even in patients that show a negative CEA on surveillance.

EP078

Prognostic value of initial and post-chemoradiotherapy FDG-PET in patients with anal carcinoma

A. TESTARD[1], C. Guillerminet[1], L. Campion[2], M. Lacombe[1], S. Girault[1], O. Morel[1]; [1]ICO Paul Papin, Angers, FRANCE, [2]ICO Gauducheau, Nantes, FRANCE.

AIM : The objective of this study was to evaluate the prognostic value of FDG-PET-CT before and after definitive chemo-radiotherapy in patients with anal canal cancer. MATERIALS AND METHODS : This retrospective study included 31 patients treated for anal canal cancer with curative radiotherapy (+/- chemotherapy). Constitutive parameters (sex, age), T and N stage (TNM stage) evaluated on staging conventional imaging (CT, echography, +/-MRI) and N evaluated on initial PET-CT were recorded. Primary tumor SUV max, MTV (metabolic tumor glycolysis), TLG (total lesion glycolysis) were measured on the 31 pre-treatment PET and on the 25 post-treatment PET, and their percentage change were calculated. A visual metabolic response assessment was also performed. We correlated these different parameters (clinical and quantitative) with the event free survival (EFS). An event was a residual disease, a local recurrence or distant metastasis. RESULTS : Pre-treatment PET : univariate analysis showed that the male sex ($p=0.011$), lymph node involvement on PET ($p=0.006$) and TLG (using a 41% and a 35% SUV max threshold) had a worse impact on EFS. On multivariate analysis, only nodal status on PET was statistically significant, the 2-year EFS was 100% for patients without lymph node involvement and 56% for patients with lymph node involvement ($p=0.0147$). Post-treatment PET : univariate analysis showed that male sex ($p=0.011$), SUV max ≥ 5 ($p=0.04$), response index $\leq 67\%$ ($p=0.04$), MTV $\geq 3{,}5$cc ($p=0.016$), TLG ≥ 10 ($p=0.037$) and δTLG (difference between pre-treatment TLG and post-treatment TLG) had worse impact on EFS. On multivariate analysis, only SUVmax was significantly correlated with EFS, the 2 year EFS was 89% for patients with SUV max < 5 on post-treatment PET and 22% for patients with SUV max ≥ 5 ($p=0.0006$). CONCLUSION : At initial staging, the nodal status evaluated by PET was the only independent predictor factor of EFS. After treatment, only SUV max (with cutoff at 5) calculated on PET was correlated with EFS on multivariate analysis. At our knowledge, it's the first study which presented that metabolic parameters calculated on post radiotherapy PET, were predictive of patient outcome.

EP079

The role of FDG PET-CT in the detection of local recurrence of rectal cancers

Z. Kandemir, 06608, E. Özdemir, S. Yılmaz Aksoy, M. Keskin, N. Yıldırım, &. Kılınc Vicdan, S. Türkölmez; Ankara Atatürk Training and Reasearch Hospital, Ankara, TURKEY.

Aim: Fluorine-18 fluorodeoxyglucose positron emission tomography /computed tomography (18F FDG PET/CT) is an important and useful imaging method in the evaluation of colorectal cancers (CRC). It can be used for detecting recurrence during follow-up after primary treatment and restaging. In this study, we aimed to evaluate the role of PET/CT in patients with presacral soft tissue density to detect local recurrence. **Materials and methods:** A total of 80 patients with diagnosis of rectum tm (52 male, 28 female, mean age: 59,1 [28-95]) who had soft tissue density during follow-up and referred for PET/CT between July 2010 and September 2015 were included in this study. PET/CT examinations were retrospectively analyzed. Final diagnosis was made by histopathologic analysis, serial CEA measurement or clinical-radiological work-up. **Results:** PET/CT detected recurrence in 49 of 80 (61,25%) patients. CEA levels were available in all patients. Sixty-seven patients also underwent CT imaging and 13 patients underwent MR imaging. PET/CT was performed 2 times in 6 patients and 3 times in the other 6 patients. Seven patients had histopathological

correlation. The sensitivity, specificity, negative predictive value (NPV) and positive predictive value of FDG PET/CT in differentiating a *fibrotic presacral* mass from *recurrent* disease were 92.8%, 71%, 64.2%, 78% and 82.5%, respectively. **Conclusion:** FDG PET/CT which give both metabolic and anatomic information, can effectively differentiate between fibrotic masses and soft tissue recurrences in patients with rectum tm. Hence, it helps early diagnosis of the disease allowing proper management.

EP080

Evaluation of FDG PET/MR in the restaging of colorectal cancer

S. Djelbani[1], C. Comtat[1], T. Aparicio[2], P. Wind[3], B. Helal[1], I. Buvat[1], **M. Soussan**[1]; [1]IMIV, CEA-Inserm, Univ Paris Sud, CNRS, Université Paris Saclay, Orsay, France, Orsay, FRANCE, [2]APHP, Avicenne Hospital, department of gastroenterology, Bobigny, FRANCE, [3]APHP, Avicenne Hospital, department of digestive surgery, Bobigny, FRANCE.

Objectives: FDG-PET/MR might be a powerful tool for restaging colorectal cancer (CRC), because it combines the excellent accuracy of liver MR for liver metastasis and the sensitivity of PET for extra-hepatic lesions. The aim of this study was to compare the detection rate and diagnostic confidence of PET/MR imaging with PET and liver MR alone for the restaging of CRC. METHODS: Eighteen patients with CRC underwent FDG-PET/MR (Signa, GE Healthcare) for restaging. FDG-PET/MR parameters were: head to mid-tight scan, 4MBq/kg, 3-6 min/bed position, time-of-flight OSEM reconstruction with 2 iterations/28 subsets, 5 mm post-reconstruction filter. MR sequences consisted in a Dixon sequence for attenuation correction, a thin section axial T2-weighted sequence from head to mid-tight, and diffusion-weighted (DWI) and post-contrast multiphase T1W sequences for liver imaging. Three image sets were analyzed: PET (read with only low resolution Dixon sequence for anatomical localization purpose), liver MR and PET/MR. A radiologist and a nuclear medicine physician independently assessed liver MR and PET, respectively. Double reading was performed for PET/MR. Metastatic lesion was defined on PET as a pathological increase of FDG uptake. On liver MR, lesions were rated as metastases when at least two of the three sequences (T2W, DWI, post-contrast T1W) were compatible with the diagnosis. Detection rate, lesion conspicuity (0=not visible, 1=barely visible, 2=clearly visible) and diagnostic confidence (1=uncertain, 2=rather certain, 3=very certain) were compared between the three sets of images. RESULTS: Detection rate of liver metastasis was the highest with PET/MR (n=34) compared to PET (n=28) and MR (n=32). For liver metastasis, lesion conspicuity increased in PET/MR (rate of grade 2: 97%, 33/34) and MR (88%, 30/34), compared to PET (74%, 25/34); diagnostic confidence increased in PET/MR (rate of grade 3: 94%, 32/34) and MR (97%, 31/32) compared to PET (82%, 23/28). PET detected 39 extra hepatic lesions: 20 lung nodules, 16 lymph nodes, 2 carcinomatosis nodules and 1 bone metastasis. Enhanced FDG uptake was present in measurable targets seen in T2W in 85% of extra hepatic lesions (33/39). In particular, T2W imaging identified 90% (18/20) of hypermetabolic lung nodules. CONCLUSIONS: PET/MR with full liver imaging is feasible in CRC restaging in less than 45 minutes. Although its precise role in the patient management still needs to be established, our preliminary results suggest that it might be a valuable option for a one-stop shop comprehensive patient assessment.

EP081

Association between FDG-PET/CT Findings and Tumor Markers in Patients with Colorectal Carcinoma

A. Hassanzadeh-Rad, M. Eftekhari, A. Kafshgar, A. Fard-Esfahani, B. Fallahi, A. Emami-Ardekani, D. Beiki, M. Saghari; Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Patients with Colorectal Carcinocma (CRC) are followed up by serum tumor markers (i.e Carcinoembryonic Antigen (CEA) and CA19-9). FDG-PET/CT scans are often asked by the referring physician for staging, restaging or evaluation of response to treatment. We aim to correlate serum tumor markers levels with FDG-PET/CT findings to better delineate pathophysiology of CRC and relationship between tumor markers and metabolic activities of tumoral lesions. **Patients and Methods:** Patients with pathologically documented CRC who are referred to our center for FDG-PET/CT study and have results of recent CEA and CA19-9 tests (performed within 3 months of scan), are enrolled in the study. After injection of 6-12 mCi of FDG, fasting patients are asked to wait for 1 hour till PET/CT acquisition. PET/CT is performed using Siemens Biograph T6 ® device. CT electrical current and voltage are set for 30 mA and 120 kV respectively. Processing of tomographic data are done by iterative reconstruction method. Manufacturer's software is used for visualization of PET-CT images. Quantification part of the software is applied for drawing Regions Of Interest (ROIs) and calculating maximum Standardized Uptake Values (SUVmax) of lesions. All patients have been followed up for at least 6 months after the study. **Results:** Preliminary data consist of 40 patients with CRC (25 male and 15 female, Age= 58.32± 12.27 years). PET/CT results were negative in 6 (15 %) and positive in 34 (85 %) of the patients. Follow ups reveal True Positive and True Negative results to be 97.1 % and 83.3 % respectively. In patients with true positive results, there was a statistically significant positive correlation between CEA serum levels and maximum SUVmax of all tumoral lesions (r= 0.52, p-value= 0.003). No significant correlation was found between CA19-9 levels and SUVmax of the lesions. There were no significant correlations between tumor markers and number or anatomical locations of metabolically active lesions either. **Conclusion:** Statistically signicant positive correlation between CEA and maximum SUVmax of tumoral lesions in patients with CRC can better delineate association between tumor markers and metabolic activity of tumoral cells. By increasing number of patients in this study, a linear or non-linear relationship between SUVmax of tumoral lesions and CEA levels maybe proposed which can be used as an aid to visual interpretation of FDG-PET/CT scans in patients with CRC.

EP082

Demonstration of the effectiveness of neoadjuvant chemotherapy and radiotherapy by ^{18}F-FDG PET-CT and MRI in patients with colorectal cancer

S. S. Gül[1], S. Rahatlı[2], G. Güler[3], F. Sönmezgöz[4], Z. Hasbek[5]; [1]Gaziosman Pasa University School of Medicine, Department of Nuclear Medicine, TOKAT, TURKEY, [2]Gaziosman Pasa University School of Medicine, Department of Internal Medicine, TOKAT, TURKEY, [3]Gaziosman Pasa University School of Medicine, Department of Radiation Oncology, TOKAT, TURKEY, [4]Gaziosman Pasa University School of Medicine, Department of Radiology, TOKAT, TURKEY, [5]Cumhuriyet University School of Medicine, Department of Nuclear Medicine, Sivas, TURKEY.

AIM: Colorectal cancer is one of the most common tumors of the gastrointestinal tract. It is more common in males with a peak age at the 5th decade. The primary treatment for colorectal cancer is surgery. The adjuvant therapy selected according to the stage and location of the disease affects the prognosis. Postoperatively administered radiotherapy and chemotherapy is effective on local and systemic recurrences, respectively. In our study, the effectiveness of preoperative chemotherapy and radiotherapy in patients with colorectal cancer was evaluated by using ^{18}F-FDG PET-CT and MRI. **METHODS:** Twelve patients with a diagnosis of colorectal adenocarcinoma were included in the study (5females/7males; mean-age:68.1±11.8years). Patients were treated with concomitant chemotherapy and radiotherapy before the surgery. Preoperative and postoperative ^{18}F-FDG PET-CT and MRI images were obtained. PET-CT

images were used to determine the tumor size, area and volume with the SUVmax and were compared to the tumor size, area and volume on MRI. **RESULTS:** All patients had the diagnosis of adenocarcinoma. Chemotherapy regimen of capacitamine 825 mg/m^2 two times daily for 5 days/week was given to 8 patients and 5-Fluouracil 225 mg/m^2 with an infusion pump for 7 days was given to the remaining 4 patients. Simultaneous radiotherapy included a total of 45 Gy with a fractioned dose of 1.8 Gy/day to the areas with standard risk and a total of 50 Gy with a fractioned dose of 2 Gy/day to the high-risk areas. Preoperative and postoperative ^{18}F-FDG PET-CT and MRI images were obtained (Figure1). Both imaging methods revealed a significant decrease in the tumor size, volume and area after the treatment (Table1). In addition, PET-CT images showed a significant decrease in SUVmax. **CONCLUSION:** Effect of perioperative chemotherapy and radiotherapy on survival rate is an important research area in terms of adjuvant therapy with no available clear conclusions. Results of the present study suggest that chemotherapy and radiotherapy given before the surgery is an effective treatment method resulting in a significant decrease in tumor size which was shown in both PET-CT and MR images. In conclusion, ^{18}F-FDG PET-CT is considered to be a good alternative for conventional MRI. **Table 1.** Comparison of the decrease in tumor size after the neoadjuvant chemotherapy and radiotherapy by using MRI and PET-CT in patients with colorectal cancer. **Figure 1.** The decrease in tumor size (white arrow) on transaxial and sagittal 18F-FDG -PET-CT images obtained before and after the surgery in patients with colorectal cancer.

EP083

Features of 18 FDG PET application for recurrence detection and staging during radiation therapy planning and its effectiveness monitoring in patients with tumors of the anorectal localisation

O. Solodyannikova[1], A. Ashumkhin[2], Y. Kmetiuk[2]; [1]Institute of Oncology AMS of Ukraine, KIEV, UKRAINE, [2]Ukrainian Radiosurgery Center of Clinical Hospital "Feofanyia", KIEV, UKRAINE.

Background. Experience of 18f-FDG PET/CT clinical application confirms the usefulness of this imaging in oncology, namely: for the differential diagnosis, staging before surgery or radiation therapy, restaging after treatment. Also 18-FDG PET/CT showed high sensitivity for the efficacy monitoring of chemotherapy and radiotherapy. The numerous studies on the use of 18-of FDG PET/CT images for further dynamic control and radiotherapy planning proved higher results' accuracy of systemic and loco-regional staging compared with conventional CT and MRI techniques. It was found that the macroscopic tumor volume determined by PET/CT is statistically significantly larger in the CT MPO with mean difference of 25%. **Materials and methods**. Between 11/2011 and 01/2016 the 18 FDG PET/CT was performed in 277 patients with colorectal cancer. Of them men were 154, women - 123; patients age was from 24 to 82 years. In overall 388 examinations were performed in 277 patients, including 94 without contrast and 294 with contrast. Average activity per injection was 373.98 MBq; in men - 402.75 MBq, in women - 332.62 MBq. We used Cyclotron Siemens Eclipse RDS for obtaining radiopharmaceuticals 18-FDG; and PET/CT Scanner Siemens Biograph 64. **Results.** Functional 18-FDG PET/CT images were used during planning of radiotherapy for rectum and anal canal carcinomas. It is found that the PET/CT by sensitivity and specificity is more informative compared with conventional structural imaging techniques. Mean sensitivity and specificity of 18-FDG PET/CT for the main focus were 83% and 91%, respectively, while the corresponding indices for the basic CT method were respectively 64% and 74%. The sensitivity of lymph node involvement evaluation using CT method was 65% and PET/CT - 53%. It should also be taken into account the risks of false-negative results of PET/CT for lesions in the lungs less than 1.0 cm, small lesions in the upper sections of liver, located predominantly subcapsularly, and in histological tumor type - mucinous adenocarcinoma. It was found that applying PET/CT for staging caused changes of the treatment tactics in 55.4% of patients, of them in 15 - due to higher disease stage, and in 5 - scheduled surgery was not performed. **Conclusions**. The 18 FDG PET/CT possesses significant advantages concerning the disease recurrence detection and restaging in the cases when CT and MRI data are inconclusive. It was proved that by sensitivity and specificity the PET/CT method is more informative for planning radiotherapy compared with conventional structural imaging techniques.

EP084

Prevalence of malignant and premalignant lesions on incidental focal colorectal uptake with dual time point (18)F-FDG-PET/CT images

A. G. GÓMEZ-GRANDE, P. Pilkington Woll, A. Hernandez Martinez, P. Sarandeses Fernandez, S. Ruiz Solis, J. Marroquin, M. Tabuenca, A. Saviatto, J. Estenoz Alfaro; HOSPITAL UNIVERSITARIO 12 DE OCTUBRE, MADRID, SPAIN, MADRID, SPAIN.

Aim: Analyze the prevalence of malignancy or pre-malignancy of incidental colorectal focal uptakes detected by 18F-FDG-PET/CT, using additional delayed images. Materials and methods: Retrospective analysis of 3264 PET/CT studies carried out consecutively in the Nuclear Medicine Department of our hospital from January 2015 to March 2016. The Inclusion criteria were patients with incidental focal colorectal uptake. Patients suspected of colorectal carcinoma were excluded. Finally, a total of 61 patients were included in the analysis. Colonoscopy was recommended based on the persistence of the focal colorectal uptake in the delayed images, which were acquired approximately two hours post-injection. Colonoscopy with biopsy was established as a gold standard. The SUVmax value and histopathological results in these patients were evaluated. Results: In 44 of the 61 patients colonoscopy and biopsy was performed, confirming malignant or non-malignant pathology in 42 of these (95%). Eleven of these 42 patients (26%) were diagnosed of a primary unsuspected colorectal carcinoma (10 adenocarcinomas y 1 GIST), while 25 patients (60%) had premalignant lesions with different degree of dysplasia (11 tubular Adenoma, 12 tubulovillous adenoma, 1 serrated adenoma, 1 adenomatous polyp and 1 juvenile (retention) polyps). The remaining 6 patients (14%) had inflammatory findings (2 diverticulitis, 1 cytomegalovirus (CMV)-associated colitis, 1 lymphoid hyperplasia, 1 ulcerative colitis and 1 hemorrhoid). In all these cases focal uptake persisted on delayed images and SUVmax increased in most of them. Nevertheless, the SUVmax increase was not statistically different between malignant, pre-malignant and inflammatory/infectious lesions ($p<0.05$). The remaining 2 cases had a negative colonoscopy. SUVmax was ≤ 5 and decreased in the delayed images. The SUVmax average value was 17,10 for malignant lesion (carcinomas and high-grade dysplasia), 11,78 for premalignant lesion and 7,53 for inflammatory and infectious lesions. During the time of this analysis, the prevalence in the FDG-PET/TC imagine of malignant lesion, including adenoma with high grade dysplasia, was 36%. Conclusion: Presence of incidental focal colorectal uptake on a PET/CT justifies a colonoscopy to detect malignant and premalignant lesions. The dual time point images could help to confirm and better characterize these incidental findings. This protocol let early detection and treatment of malignant and premalignant lesions.

EP085

Fluorodeoxyglucose-PET/CT in locally advanced head and neck cancer can influence the stage migration and nodal radiation treatment volumes

R. Mazzola[1], P. Alongi[2], F. Richetti[1], A. Fiorentino[1], S. Fersino[1], N. Giaj-Levra[1], U. Tebano[3], M. Salgarello[4]; [1]Division of Radiation Oncology, Sacro Cuore Don Calabria Cancer Care Center, Negrar (Verona), ITALY, [2]Unit of Nuclear Medicine, San Raffaele G.Giglio Institute, Cefalù, ITALY, [3]School of Radiation Oncology, University of Padova, Padova, ITALY, [4]Division of Nuclear Medicine, Sacro Cuore Don Calabria Cancer Care Center, Negrar (Verona), ITALY.

Aim: Although [18F] fluorodeoxyglucose (FDG) positron emission tomography (PET/CT) is effective for the staging of locally advanced head and neck cancer (HNC), its role on patient management remains controversial. Present study analyzed the impact of PET/CT in the radiotherapy (RT) planning-strategy in HNC, focusing on neck-nodes treatment planning and correlating CT-scan and PET/CT performances. **Materials and Methods:** Inclusion criteria of this retrospective analysis were: age > 18 years old, histologically proven squamocellular HNC, patients candidate to curative RT ± chemotherapy, evaluation of stage of disease by means of PET/TC and CT-scan performed at our Institution. PET/CT scans were visually reviewed by experienced readers blinded to clinical data. Visual assessment was used to define the presence of primary lesion, local lymph node and distant recurrences. All cases in which a stage migration was recorded, in terms of differences in nodal involvement between CT and PET/CT, were discussed with the Nuclear Medicine Physician and Radiologist. Only in case of discrepancies of imaging interpretation between them it was discussed with the patient the utility of a fine needle aspiration cytology (FNAC). **Results:** sixty patients treated between October 2011 and February 2016 were included in the analysis. Primary tumor site was represented as follows: Nasopharynx in 8 patients (13%), Oropharynx in 25 (42%), Oral Cavity in 19 (32%) and Larynx non-glottic in 8 (13%). Oral cavity tumors revealed to be at particular risk of nodal stage migration, occurring in 21% of cases (5/19). PET/CT findings caused changes in the management of RT volumes in 10% of patients. In one case of nasopharynx cancer, it was detected the primary tumor previously unknown at CT-scan, in 5 cases of oral cavity tumors neck-nodes PET/CT positive from one side and/or the other (not detected at CT-scan) were included in the high-risk volumes and in 2 cases of oropharyngeal cancer RT was avoided because of distant metastases detection. **Conclusion:** Present findings showed that PET/CT images could be a guide in HNC in order to individualize the RT-curative strategy. Further investigations are advocated to evaluate if this strategy could impact on long-term outcomes in HNC.

EP086

Application of an Adaptive Thresholding Algorithm for ^{18}F-FDG PET Head and Neck Lesion Segmentation

L. L. Vigna, M. Paolini, E. Puta, L. Deantonio, R. Matheoud, G. Loi, M. Krengli, M. Brambilla, G. Sacchetti; A.O.U. Maggiore della Carità, Novara, ITALY.

AIM: ^{18}F-FDG PET is used in radiation oncology for the delineation of gross target volumes (GTV) in the treatment planning. The aim of this work was to implement on the treatment planning system and to use in a clinical context an adaptive thresholding algorithm (ATA), previously derived and validated on a phantom. MATERIAL AND METHODS: forty-one patients (12F,29M) that underwent radical intensity modulated radiation therapy with simultaneous integrated boost (IMRT-SIB) for head-and-neck squamous cell carcinoma (3 oral cavity, 11 nasopharynx, 20 oropharynx, 6 hypopharynx and 1 larynx lesions), were included in the present analysis. 33/41 pts received concurrent radio-chemotherapy and 37/41 were in a locally advanced stage. Median age was 64 years (range 38-76 yrs). For all the patients FDG-PET/CT was performed in RT treatment position with patients immobilized with a customized thermoplastic mask. The lesions were outlined by means of ATA implemented on the iTaRT workstation (Tecnologie Avanzate, Italy). This algorithm uses calibration curves specific for each PET/CT scanner that depend on lesion-to-background ratio (LB) and amplitude of reconstruction smoothing filter (FWHM). The biological target volume segmented by means of ATA (BTV_{ATA}) was compared with the mean value of the gross tumour volume manually drawn by 2 expert radiation oncologists (GTV_{RO}) on the basis of the anatomical information provided by the simulation CT or pre-treatment MRI. The reproducibility of ATA in volume estimation was determined evaluating the volume overlap of multiple segmentation of the same lesions by different operators. RESULTS: lesion LB was in the range (4-30) and SUV mean (sd) was 14.8(9.5), respectively. Mean (sd) BTV_{ATA} and GTV_{RO} were 13(6) cm^3 and 18(4) cm^3, respectively. ATA thresholding values were in the range (39-51)%. Results showed high reproducibility (98%) of the algorithm implemented on workstation, with some limitations in the estimation of small volumes. CONCLUSIONS: the proposed adaptive threshold algorithm resulted robust and reproducible. The ATA used in the present study allows routine GTVs delineation on PET images clinically feasible. At present [^{18}F]FDG-PET is routinely available and of interest also for focused dose escalation. A IMRT-SIB with dose painting by contours with a boost on BTV_{ATA} drawn by our algorithm can be feasible.

EP087

Variatioins in target volume definition and dose to normal tissue using anatomic biological imaging in the treatment of bone metastases

D. Berwouts[1], K. De Wolf[1], W. De Neve[1], L. Olteanu[1], B. Lambert[1], I. Goethals[1], I. Madani[2], P. Ost[1]; [1]Ghent University Hospital, Ghent, BELGIUM, [2]University Hospital Zurich, Zurich, SWITZERLAND.

Purpose: To report the impact on target volume delineation and dose to normal tissue using anatomic versus biological imaging (^{18}F-FDG-PET) for bone metastases. *Material and methods:* Patients with uncomplicated painful bone metastases were randomized (1:1:1) and blinded to receive either 8 Gy in a single fraction with conventionally planned radiotherapy (arm A) or 8 Gy in a single fraction with DPBN (dose range between 6 and 10 Gy) (arm B) or 16 Gy in a single fraction with DPBN (dose range between 14 and 18 Gy) (arm C). The primary endpoint was overall pain response at 1 month. Volumes of the gross tumor volume (GTV) - both biological (GTV_{PET}) and anatomical (GTV_{CT}) -, planning target volume (PTV), dose to the normal tissue and maximum standardized-uptake values (SUV_{MAX}) were analyzed (secondary endpoint). *Results:* Sixty-three percent of the GTV_{CT} volume did not show ^{18}F-FDG-uptake. On average, 20% of the GTV_{PET} volume was outside GTV_{CT}. The volume of normal tissue receiving 4 Gy, 6 Gy and 8 Gy was at least 3x, 6x and 13x smaller in arm B compared to arm A and Arm C ($p<0.05$). Conclusions: PET-information potentially changes the target volume for bone metastases. DPBN between 6 and 10 Gy significantly decreases dose to the normal tissue compared to conventional radiotherapy.

EP088

Usefulness of 18F-choline PET/CT in treatment of oligometastatic prostate cancer recurrence using Stereotactic Body Radiation Therapy (SBRT)

A. Franceschetto[1], A. Bruni[2], L. Massi[1], B. Lanfranchi[2], V. Rossetti[1], F. Lohr[2], N. Prandini[1]; [1]Azienda Ospedaliero-Universitaria di Modena – Policlinico, Dipartimento ad Attività Integrata di Oncologia ed Ematologia, Struttura Complessa Medicina Nucleare, Modena, ITALY, [2]Azienda Ospedaliero-Universitaria di Modena – Policlinico, Dipartimento ad Attività Integrata di Oncologia ed Ematologia, Struttura Complessa Radioterapia Oncologica, Modena, ITALY.

Aims: Currently the detection of oligometastatic prostate cancer (Ol-PCa) recurrence is common in clinical routine due to imaging innovations, such as the 18F-/11C-choline PET. In these patients (pts) the use of aggressive local treatment, as radiotherapy, may be potentially justified rather than a systemic approach. We report clinical experience of a small group of pts with Ol-PCa recurrence and treated with SBRT on positive lesions at 18F-choline PET/CT (18F-CH). **Matherials and Methods:** From 2011 to September 2015, 18 pts with Ol-PCa recurrence at 18F-CH, were treated with SBRT on PET-positive lesions (mean age: 69 years; range: 56-81). All pts underwent radical prostatectomy at time of first diagnosis and 11 of them also received adjuvant/salvage radiotherapy (RT). At staging, we found 3 high-risk PCa, 9 very high-risk PCa, and 1 intermediate-risk PCa; Gleason Score (GS) was less than 7 in 1 pts, equal to 7 in 8 pts, and exceeding 7 in 9 pts. Median time to clinical relapse after primary treatment (surgery +/- RT) was 26.2 months (range: 3-141). Nine pts received one or more lines of androgen deprivation therapy (ADT) before RT. Mean and median PSA before SBRT was 3.01 ng/ml and 1.9 ng/mL (range: 0.69-14.9), respectively. SBRT was delivered on 18F-CH positive nodal recurrence (N-MTS) in 16 pts, and in 2 pts with positive bone metastases (B-MTS); it was delivered in association with ADT in 6 pts, while the treatment was exclusive in the other 13 pts. We analyzed outcomes in terms of local control (LC), progression free survival (PFS) and overall survival (OS). **Results:** All pts were alive at a mean and median follow-up (15.5 and 18.3 months, respectively) (range: 2,5-58). Fourteen pts were treated with SBRT to 1 site (abdominal node: 12 pts; bone lesion: 2 pts), while 4 pts were treated to 2 different sites (all nodal). One-Year OS was 100% while mean and median PFS were respectively 19.7 and 13.1 (CI95% 5.3-21) months. One-year PFS were 52.7%, while LC was 100%. In terms of PFS, we have not found significant statistical prognostic factors: only adiuvant ADT and no concomitant treatments (SBRT exclusive) seemed to have a positive impact on PFS with a 1-year PFS of 60.0% for hormone-naive pts. **Conclusions:** In pts with Ol-PCa recurrence, 18F-CH has proved to be useful in plannig SBRT, a non invasive loco-regional approach, with the aim of reducing side effects of more invasive treatments.

EP089

18F-FDG PET/CT-guided SBRT planning in stage I-II unresectable NSCLC: a clinical experience

A. Franceschetto[1], A. Bruni[2], L. Massi[1], B. Lanfranchi[2], V. Rossetti[1], F. Lohr[2], N. Prandini[1]; [1]Azienda Ospedaliero-Universitaria di Modena – Policlinico, Dipartimento ad Attività Integrata di Oncologia ed Ematologia, Struttura Complessa Medicina Nucleare, Modena, ITALY, [2]Azienda Ospedaliero-Universitaria di Modena – Policlinico, Dipartimento ad Attività Integrata di Oncologia ed Ematologia, Struttura Complessa Radioterapia Oncologica, Modena, ITALY.

Aims: Positron emission tomography computed tomography with 18F-FDG (FDG-PET/CT) has proven to be a valuable diagnostic and staging tool for non-small-cell lung cancer (NSCLC). FDG-PET/CT has also been shown to have a significant impact on the treatment of these patients (pts), and, particularly, on radiation therapy target volume definition. We report our experience in a small group of pts with early-stage NSCLC treated with Stereotactic Body Radiation Therapy (SBRT) for coexisting diseases instead of standard surgery. Matherials and Methods: From 2008 to 2014, 15 pts with stage I-II NSCLC were treated with SBRT exclusively on lung lesions on the basis of FDG-PET/CT and CT simulation using same immobilization devices for both studies. At staging, mean age was 73 years (range: 52-83); the histology was adenocarcinoma (ADK; 11 pts), squamous cell carcinoma (SCC; 3 pts), and large cell carcinoma (LCC; 1 pt). The pts follow-up was carried out by FDG-PET/CT and by chest and abdominal CT scans. We analyzed outcomes in clinical terms, and of progression free survival (PFS) and overall survival (OS). Results: At basal FDG-PET/CT, we found a mean SUVmax of 5.71 (median: 4; range: 1.8-17) in ADK, of 4.1 (median: 2.8; range: 2-7.5) in SCC, and a SUVmax of 10.9 in the LCC. A lung toxicity due to SBRT was reported in 5 pts, one of whom required hospitalization. All but 8 patients were alive at mean and median follow-up, respectively of 22.3 and 23.8 months (range: 3.7-48.4). Mean time to TC and/or FDG-PET/CT relapse after SBRT was 19.5 months (median: 20.4; range: 3.6-45.5), while metastases appeared at a mean time of 20.8 months (median: 18.6; range: 1.4-45.5) only in 4 pts with ADK (lung: 3 cases; bone with liver: 1 case). One year after treatment, OS and PFS were respectively 67% and 60%, while overall mean and median PFS were both 18.4 months. Analyzing our population in statistical terms, no prognostic factors were found as statistical significant. Conclusions: In patients with early-stage unresctable NSCLC, FDG-PET/CT plays a important role in defining the radiotherapy planning ad giving them a valid alternative to surgery.

Uterine cervical cancer: Diagnostic performance of F-18 FDG PET/CT for preoperative examination of regional lymph-node metastasis based on MR diagnosis of local staging

M. Nakabayashi[1], M. Nogami[1], T. Hashimoto[1], A. Kogiku[1], S. Hirabayashi[2], D. Takenaka[1], S. Adachi[1]; [1]Hyogo Cancer Center, Akashi, JAPAN, [2]Institute of Biomedical Research and Innovation, Kobe, JAPAN.

PURPOSE: The purpose was to evaluate the diagnostic performance of F-18 FDG PET/CT for preoperative examination of regional lymph-node metastasis in patients with uterine cervical cancer based on the interpretation of local extent on MRI. MATERIALS AND METHODS: Fifty-four consecutive patients with pathologically confirmed as squamous cell carcinoma of the uterine cervix and clinically diagnosed as T1b-2b N0 underwent PET/CT and pelvic MRI before operation. The SUVmax and size in short-axis of detected regional lymph nodes on PET/CT were separately measured on the workstation in 8 lymph-node regions in the pelvis. The primary lesion was also evaluated by SUVmax, SUVpeak, metabolic tumor volume (MTV), total lesion glycolysis (TLG) on PET/CT and by tumor size and extent on MRI. The reference standard of the regional lymph nodes was acquired histopathologically from lymph node dissections in the operation. To evaluate the relationship between PET/CT and/or MR findings and histopathological results, the logistic regression test was performed. The ROC analysis was performed to determine the diagnostic performance of PET/CT for regional lymph node metastasis. RESULTS: Eight (30 lymph-node lesions) in 54 patients were confirmed to be positive for regional lymph node metastasis histopathologically. The logistic regression test showed the SUVmax of the regional lymph node significantly correlated with pathological results(odds ratio 6.12, p=0.0023), whereas no correlation was found with the other parameters regarding primary lesion and lymph nodes. The diagnostic performance by SUVmax of the lymph node (Area under the curve (AUC) 0.81, sensitivity 66.7, specificity 90.0, cut-off SUVmax 1.8) was significantly higher than that by size (AUC = 0.54) in patients with T2 on MRI, however, there was no significant difference between SUVmax and size in patients with T1 on MRI and in overall subjects. CONCLUSIONS: In patients with T2a-b cervical cancer on MRI, diagnostic performance of SUVmax for the regional lymph-node metastasis is significantly higher as compared with T1b on MRI, suggesting diagnostic ability of PET/CT for regional lymph node metastasis is variable depending on the local extent evaluated by MRI.

EP091

Detection of pelvic lesions in patients with endometrial cancer with fused PET/MRI. Compared to PET/CT or MRI

H. Juri, T. Komori, T. Hamada, Y. Tanaka, A. Higashiyama, G. Nakai, Y. Narumi; Osaka Medical College, Takatsuki, JAPAN.

Purpose: To evaluate the fusion image from pelvic magnetic resonance imaging (MRI) and ^{18}F-fluorodeoxyglucose positron emission tomography (FDG-PET) for detecting lesions in patients with endometrial cancer. **Materials and Methods:** Forty-eight patients with endometrial cancer underwent PET/computed tomography (CT) and pelvic MRI for staging. Two readers evaluated lymph node metastases, peritoneal disseminations, and other malignant lesions in the pelvis with PET/CT, MRI, and fusion images from PET and MRI (fused PET/MRI). The area of lymph nodes was divided into eight areas, consisting of common iliac, external iliac, internal iliac, and obturator area on the right or left sides. The final diagnosis were obtained by histopathological examinations or radiological imaging follow-up. Sensitivity, specificity and accuracy for detecting lesions were determined by comparing the results of consensus readings with the final diagnosis as per lesion analysis, and differences between each group were evaluated using McNemar test. **Results:** Sensitivity, specificity and accuracy for detecting lymph node metastases were 45.5% (5/11), 99.7% (372/373) and 98.4% (378/384) on PET/CT, 36.4% (4/11), 99.7% (372/373) and 98.2% (377/384) on MRI, and 36.4% (4/11), 99.7% (372/373) and 98.2% (377/384) on fused PET/MRI, respectively, and there was no significant difference between each group. Sensitivity, specificity and accuracy for detecting peritoneal disseminations were 42.9% (3/7), 100% (42/42) and 91.8% (45/49) on PET/CT, 28.6% (2/7), 100% (42/42) and 89.8% (44/49) on MRI, and 42.9% (3/7), 100% (42/42) and 91.8% (45/49) on fused PET/MRI, respectively, and there was no significant difference between each group. Sensitivity, specificity and accuracy for detecting other malignant lesions in the pelvis were 87.5% (7/8), 97.6% (40/41) and 95.9% (47/49) on PET/CT, 87.5% (7/8), 100% (41/41) and 98.0% (48/49) on MRI, and 87.5% (7/8), 97.6% (40/41) and 95.9% (47/49) on fused PET/MRI, respectively, and there was no significant difference between each group. Fused PET/MRI does not improve detection of all lesions in the pelvis in patients with endometrial cancer compared to PET/CT. Althouth fused PET/MRI improve detection of two lymph node metastases compared to MRI, it is not significantly different. **Conclusion:** Fused PET/MRI does not improve detection of lesions in the pelvis in patients with endometrial cancer compared to PET/CT or MRI.

EP092

FDG-PET/CT in early stage uterine cervical cancer: can SUVmax discriminate between malignant and benign lymph nodes?

J. Holm, M. G. Hildebrandt, A. Thomassen, O. Gerke, P. F. Høilund-Carlsen; Odense University Hospital, Odense C, DENMARK.

Aim: The frequency of lymph node metastasis in early stage uterine cervical cancer is low. If positive pelvic lymph nodes are detected by the diagnostic FDG-PET/CT-scan, further staging by laparoscopic lymph node dissection is performed before radical hysterectomy or other treatment is initiated. Unfortunately, this set-up often drags out the staging process. PET specialists are urged to improve the segregation between lymph nodes suspected of true malignancy and those regarded as merely reactive to recent cervical conization, portio biopsy, or other benign causes. We retrospectively examined whether the distinction between true positive, false positive, and true negative lymph nodes could be assessed by SUVmax alone. **Materials and methods:** A total of 134 patients aged 25-81 years (median 42) with early stage cervical uterine cancer, FIGO stage 1A or 1B, who had undergone preoperative FDG-PET/CT during the period 2009-2015 were retrospectively included. The scan result was compared to histopathology obtained by lymph node dissection. SUVmax was measured in PET-avid pelvic lymph nodes in the right side, left side or at the midline, and each assigned a separate SUVmax-value. The differences between the true positive, false positive and the true negative reactive lymph nodes were assessed by one-way analysis of variance, using Bonferroni's adjustment for multiple testing. **Results:** Thirty women had 44 lymph nodes with increased PET activity. Eight (18%) lymph nodes were true positive, twenty-five (57%) false positive, and eleven (25%) true negative, reactive nodes. The corresponding mean SUVmax values ± SD were 3.1±0.89, 3.4±0.78 and 2.1±0.84, respectively. We found a statistically insignificant difference of 0.3 ($p=0.96$) in SUVmax between the true positive and false positive group, but significant differences of 1 ($p=0.034$) between true positive and true negative nodes and of 1.3 ($p<0.0001$) between true negative and false positive nodes. **Conclusion:** SUVmax values obtained by preoperative FDG-PET/CT imaging in early stage uterine cervical cancers cannot discriminate PET-positive metastatic from non-metastatic lymph nodes. Diagnostic laparoscopic lymph node dissection should be performed in all lymph node PET-positive patients. The SUVmax of reactive lymph nodes was significantly lower than that of both true and false PET-positive lymph nodes. Nevertheless, correct PET/CT lymph node diagnostics in early stage cervical cancer remains a complex combination of several parameters, and the SUVmax value cannot stand alone.

EP093

Can preoperative PET/CT be used as an efficient tool in planning extent of surgical lymph node dissection in endometrial cancer patients?

B. E. AKKAS[1], **H. EFETURK**[1], B. B. DEMIREL[1], G. UCMAK[2,3]; [1]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL, DEPARTMENT OF NUCLEAR MEDICINE, ANKARA, TURKEY, [2]HITIT UNIVERSITY ÇORUM RESEARCH AND TRAINING HOSPITAL, DEPARTMENT OF NUCLEAR MEDICINE, ÇORUM, TURKEY, [3]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL, DEPARTMENT OF NUCLEAR MEDICINE, Ankara, TURKEY.

Aim: The most important prognostic factor in endometrial cancer (EC) patients is lymph node metastasis. The primary therapeutic approach to EC is surgery. To avoid intraoperative complications and morbidity, lymphadenectomy (PPLND) is perfromed in selected patients. The aim of this study was to assess the role of preoperative PET/CT in detecting lymph node metastasis in EC patients and to assess its contribution to tailoring surgical therapy of patients. Materials and methods: Preoperative PET/CT was performed in 72 EC patients. Presence of lymph node (LN) positivity on PET/CT was compared to postoperative histopathology results. The FDG uptake in LN was evaluated according to visual uptake compared to background and was marked as present or absent. A true positive (TP) lesion was a LN detected on PET/CT and also found to be positive on histopathology; a false positive (FP) lesion was a LN detected on PET/CT but not positive on histopathology; a true negative (TN) lesion was a LN not detected on both PET/CT and histopathology and a false negative (FN) lesion was a LN not detected on PET/CT but positive on histopathology. Sensitivity, specificity, positive predictive value, negative predictive value and accuracy of PET/CT was calculated on a patient based criteria. Results: Of 72 patients 9 (12%) had histopathologically confirmed LN metastasis. PET/CT detected pelvic/paraaortic LN in 14 patients with positive FDG uptake. Of these, PET/CT was TP in 8, FP in 6 patients, PET/CT did not reveal any hypermetabolic LN in 58 patients. Of these 57 were TN, whereas 1 patient has a metastatic pelvic LN. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy was calculated as 88%, 90%, 57%, 98% and 90% respectively. The low PPV was attributed to inflamatuary LN. The average size of TP LN's

was 0.7 cm (0.5-1 cm) and the average size of FP LN's was 0.7 cm (0.6-1 cm). There was no significant difference between SUVmax of TP and FP LNs. Conclusion: Our study showed high sensitivity, specificity, NPV and accuracy. These values show that PET/CT can successfully detect patients without LN metastasis. We considered that although PET/CT has a significant limitation in distinguishing metastatic LN from inflammatory processes in patients with EC, PET/CT is a valuable method to successfully select patients in whom extended surgery with lymphadenectomy, which may increase surgery based morbidity, can be avoided.

EP094

Predicting response for locally advanced cervical cancer

b. vendel; umcg, groningen, NETHERLANDS.

Purpose. Being able to identify noninvasively, prior to therapy, those patients with cervical cancer at highest risk of recurrence or compromised survival, allows for targeting this high risk population with more aggressive therapy, such as adjuvant chemotherapy or participation in a clinical trial. Additionally, the prognostic information offered by the PET-based prognostic nomograms could be used for risk stratification in clinical trials. The problem is that most nomograms are developed in a single institution following different local protocols. For this feasibility study, we evaluate the use of a previously developed FDG-PET-based prognostic nomograms for locally advanced cervical cancer assessed on pretreatment FDG-PET for predicting recurrence-free survival (RFS), disease-specific survival (DSS), and overall survival (OS) in the Netherlands. Patients and methods. The preliminary study included 20 cervical cancer patients, FIGO stage Ib1-IVa, treated with definitive radiation or chemoradiation therapy in the period 2010-2016. All patients underwent FDG-PET/CT at diagnosis, from which cervical tumor volume, SUVmax, SUV peak, SUV Mean, SUV min,tumor volume and LN status were recorded. Using the prognostic nomogram developed by Kidd et al 2012 RFS, DSS, and OS, were calculated. Results. 65 percent of patients had FDG-avid LN on PET; the highest level of nodal involvement was pelvic in 11, para-aortic in 2, The average cervix tumor SUVmax was14,05 (range, 5.15-21.97) SUVpeak 12,43, SUV mean 8,48, SUV min 5,62 and PET tumor volume average was 52.89 cm3 (range, 6.38-253.6 cm3). PET LN status had the greatest influence on outcome. The average calculations were: RFS 1 year 0,78, RFS 3 year0,62, DFS1 year 0,89, DFS 3 year 0,72 OS 1 year 0,87 OS 3 year 0,68. The patients who developed a recurrence in the first 2 years had an average RFS3 year of 0,58. Conclusions. Pretreatment FDG-PET LN status, cervical tumor SUVmax, and tumor volume combined in a nomogram create good models for predicting cervical cancer RFS, DSS, and OS. In the final study a larger cohort of 300 patients will be analyzed to establish the prognostic value of new SUV measurement and develop a new predicting model.

EP095

Assessment of nodal status by 18F-FDG PET/CT in early stage vulvar cancer

P. Guglielmo[1], C. Crivellaro[2], C. Dolci[3], L. Baratto[1], F. Elisei[4], L. Guerra[4], A. Buda[5], L. Montanelli[1], E. De Ponti[6], C. Landoni[2]; [1]University of Milan Bicocca, Milan, ITALY, [2]Nuclear Medicine Department, ASST - San Gerardo, Monza; Nuclear Medicine, University of Milan Bicocca, Milan, ITALY, [3]Tecnomed Foundation, University of Milan Bicocca, Milan, ITALY, [4]Nuclear Medicine Department, ASST - San Gerardo, Monza, Monza, ITALY, [5]Gynecology Department, ASST - San Gerardo, Monza; Gynecology, University of Milan Bicocca, Milan, ITALY, [6]Medical Physics Department, ASST Monza, Monza, ITALY.

Objectives In early stage vulvar cancer (clinical stage I-II) the involvement of regional lymph nodes (LN) is one of the most important prognostic factor. A non-invasive imaging modality that allows an accurate LN staging could improve preoperative assessment and consequently therapeutic approach. Aim of this study was to evaluate the performance of 18F-FDG PET/CT in nodal staging of patients (pts) affected by early stage vulvar cancer. Methods 25 pts (mean age 68 years; range 51-83) with an apparent clinical early stage vulvar cancer underwent preoperative 18F-FDG-PET/CT scan followed by radical vulvectomy and bilateral (or monolateral in case of tumour > 2 cm from midline) inguinal lymphadenectomy. PET/CT images were analyzed by three examinators in consensus and correlated to histopathological findings according to a pt-based and a lesion-based analysis. Furthermore the highest SUVmax of the nodal uptake of each inguinal area (if present) has been calculated.Results PET/CT scan resulted negative at inguinal LN level in 15 pts (7 true negative -TN-, 8 false negative -FN-) and positive in 10 pts (5 true positive -TP-, 5 false positive -FP-). Mean number of dissected LNs was 12 per pt. Incidence of LN metastases resulted 52% (13/25), in particular with low-volume metastases in 23% of cases. On pt-based analysis, sensitivity, specificity, accuracy, negative and positive predictive value of PET/CT in detecting LN metastases were 38%, 58%, 48%, 47%, 50% respectively. On a lesion-based analysis, considering 46 LN-sites overall, these values were 42%, 80%, 67%, 73%, 53% respectively. The average value of SUVmax was 4.1 (range 0.7-9.3) for sites of metastatic LNs, whereas 1.6 (range 0.7 - 5.4) for site with negative LN at histology (p=0.007); however in 47% of nodal metastatic sites, a low FDG uptake (SUVmax less than 2.5) was observed.Conclusions In clinical early stage vulvar cancer patients, 18F-FDG PET/CT was not an accurate tool for the nodal status assessment. Although the average value of SUVmax in metastatic sites resulted higher, nodal metastases could occur also in sites with absent or low uptake. Sensitivity of PET/CT resulted low (38%) probably related both to the presence of low-volume or low glycolytic activity/necrotic lesions. In addition, FP findings may occur because inguinal LNs frequently undergo reactive changes.

EP096

Risk Stratification of Endometrial Cancer Patients into clinical Low-Risk or High- Risk Groups Based on Preoperative FDG PET/CT Parameters

H. EFETURK[1], B. E. AKKAS[1], B. B. DEMIREL[1], S. DEMIRTAS[2], G. UCMAK[2,3]; [1]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, ANKARA, TURKEY, [2]HITIT UNIVERSITY ÇORUM RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, ÇORUM, TURKEY, [3]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, Ankara, TURKEY.

Aim: Endometrial cancer is the most common gynecologic malignancy and the eighth leading cause of death from malignancy in women. Postoperative risk assessment for recurrence is generally based on prognostic factors determined by surgical and pathological staging which forms the basis of postoperative adjuvant therapy planning and follow-up. Functional imaging and quantification of 18-flourodeoxyglucose positron emission tomography-computerized tomography (PET/CT) parameters of the primary tumor may have prognostic implications. The aim of this study was to determine whether metabolic PET/CT parameters can be used as a potential preoperative imaging modality to improve risk classification and guide a tailored surgical approach and therapeutic strategy. **Materials and methods:** Preoperative FDG PET/CT was performed in 72 women with endometrial cancer. 52 patients had stage I, 5 patients had stage II, 10 patients had stage III and 5 patients had FIGO stage IV disease. Tumors were classified as high or low-risk carcinomas postoperatively. Patients with FIGO stage I, endometrioid histology, histological grade 1 or 2 and invasion of less than half of the myometrium were included in low-risk group. The remaining patients were included in the

high-risk group. Maximum standardized uptake values (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of the primary tumor were compared to postoperative histopathology in order to evaluate whether these metabolic parameters can predict high-risk patients preoperatively. Receiver operating characteristics (ROC) curve analysis was performed to examine which metabolic parameters were able to differentiate high-risk from low-risk endometrial cancer. **Results:** SUVmax (15±6.6 vs. 18.8±7, p:0.02) , MTV (7.8±5.7 vs. 28.4 ±37.6, p:0.006) and TLG (80.7±85.6 vs. 355.5±453.4, p:0.001) were significantly higher in high-risk patients compared to low-risk group. The areas under ROC curves (AUCs) for distinguishing low-risk patients from high-risk groups were 65% for SUVmax, 75% for MTV and 73% for TLG. When metabolic indices were compared to FIGO clinical stages, both MTV and TLG were significantly correlated with higher FIGO stage (p:0.02). We did not observe correlation between SUVmax and FIGO stage in our patient group. **Conclusion**: Our study showed that a prognostic estimate can be obtained prior to surgery with metabolic parameters obtained by preoperative PET/CT. All SUVmax, MTV and TLG were found successful to predict high-risk patients. However, we found that TLG, which considers both the metabolic activity and tumor burden, was a stronger parameter that can be used to distinguish high-risk patients and may guide the surgeon deciding the extent of the surgical procedure preoperatively.

EP097

The Experience of ^{99m}Tc-Al_2O_3 Using for the Detection of Sentinel Lymph Nodes in Cervical Cancer Patients

V. Chernov[1,2], I. Sinilkin[1,2], A. Medvedeva[1,2], R. Zelchan[1,2], A. Lyapunov[1], O. Bragina[2], A. Chernyshova[1], L. Kolomiets[1], V. Skuridin[2]; [1]Tomsk Cancer Research Institute, Tomsk, RUSSIAN FEDERATION, [2]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

The purpose of the study was to evaluate the feasibility of using the new radiopharmaceutical, based on technetium-99m-labeled gamma-alumina (^{99m}Tc-Al_2O_3), for the detection of sentinel lymph nodes in cervical cancer patients. Materials and methods. Nanocolloid ^{99m}Tc-Al_2O_3 with size of nanoparticles 80-100nm coated with organic covering was studied. During passage through the lymphatic way nanoparticles lose organic coating and strongly accumulate in the sentinel lymph nodes without redistribution. The study included 23 patients with cervical cancer $T_{1a}N_xM_x$ - $T_{2b}N_xM_x$ stage. The day before surgery, four submucosal injections of ^{99m}Tc-Al_2O_3 at a dose of 20 MBq per quadrant were made in each quadrant around the cervical tumor. SPECT study was performed at 18 hours after injection, intraoperative detection was executed by gamma probe at 20 hours after injection. Patients were then underwent iliac-pelvic lymph node dissection. After lymphodissection, the removed lymph nodes were re-examined with gamma probe to detect SLNs missed during intraoperative examination. Results.In all patients 27 SLN were identified by SPECT and 34 SLN by gamma probe. Accumulation of ^{99m}Tc-Al_2O_3 in SLN was 3%-12% (average - 7%) by SPECT and 17%-29% (average - 24%) by gamma probe (in compare to spot of injection).The most common site for SLN detection was the external iliac region (57%), followed by the internal iliac, obturator, presacral and retrosacral regions (they amounted to 14%, respectively), and the parametrial region (1%). The excised SLNs were evaluated by imprint cytology with subsequent routine histological examination. All lymph nodes including SLNs and non-SLNs were metastasis-negative, there by indicating that there was no phenomenon of "jumping" nodal metastases. Conclusions. The clinical study of ^{99m}Tc-Al_2O_3, a new radiopharmaceutical agent, have shown that the studied nanocolloid has high uptake level in SLN and can be successfully used for visualization of SLN in patients with cervical cancer. SPECT and intraoperative gamma probe-guided identification performed after paratumoral injection of ^{99m}Tc-Al_2O_3 enable the detection of SLNs with 79 and 100% sensitivity, correspondently.

EP098

Sentinel lymph node biopsy in endometrial cancer in early stages: evaluation of results

J. Cordero Garcia, C. López de la Manzanara Cano, A. Palomar Muñoz, M. Talavera Rubio, M. Tello Galán, V. Poblete García, F. Pena Pardo, A. García Vicente, Á. Soriano Castrejón; Hospital General de Ciudad Real, CIUDAD REAL, SPAIN.

Objective: To evaluate the results of the application of the technique of sentinel lymph node (SLN) in endometrial cancer in early stages. Material and methods: Prospective study (research project with public funding PI-2009/31) which included 66 patients with endometrial adenocarcinoma, at presurgical clinical stage I, excluding the upper clinical stages and those patients diagnosed with endometrial sarcoma. To identify the SLN, 2 mCi of 99mTc-Nanocoll were injected in two opposite points of the uterine cervix (total: 4 mCi), obtaining planar images and SPECT-CT of the pelvis at 30 min, and delayed planar images at 16 h when necessary. The SLN was identified intraoperatively using a conventional gamma-probe. All patients were treated with pelvic lymphadenectomy, hysterectomy and oophorectomy. The SLN were studied by conventional histology (H & E), as well as those lymph nodes obtained from the lymphadenectomy Results: In 58 patients at least one SLN was identified both in the scintigraphic and in the intraoperative study (detection rate 88%). In 8 patients was not possible to find a SLN neither scintigraphically nor surgically. One SLN was found in 25 patients, 2 SLN in another 17, and 3 or more in the remaining 16. During the operation a total of 104 SLN were identified (median 1, mean 2). Histological study showed that only 2 of the patients had lymph node involvement, both by micrometastases (3.1%), and in both of them the SLN was the only affected node (100% true positives, 100% sensitivity). Conclusions: SLN identification in endometrial cancer in early stages is a simple and reliable technique with a good detection rate and histological correlation. Therefore, it may be considered as an alternative to systematic pelvic lymphadenectomy in these patients.

EP099

Lymphatic metastasis correlates with metabolic tumor burden detected by PET/CT in patients with endometrial carcinoma

B. E. AKKAS[1], **H. EFETURK**[2], B. B. DEMİREL[2], G. UCMAK[3,4]; [1]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL, ANKARA, TURKEY, [2]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL, DEPARTMENT OF NUCLEAR MEDICINE, ANKARA, TURKEY, [3]HITIT UNIVERSITY ÇORUM RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, ÇORUM, TURKEY, [4]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL, DEPARTMENT OF NUCLEAR MEDICINE, Ankara, TURKEY.

The presence of lymph node (LN) metastasis in endometrial cancer is well accepted to have a negative effect on prognosis. In this study, we investigated the association of clinical parameters and metabolic indices such as metabolic tumor volume (MTV), standardized uptake value (SUVmax) and total lesion glycolysis (TLG) with the presence of surgically proven LN metastasis in patients with primary endometrial carcinoma. A total of 72 patients with endometrial carcinoma, who were referred to our clinic for 18F-FDG PET/CT imaging for initial staging and pretreatment evaluation were enrolled in this retrospective study. 59 patients had endometrioid type tumor, whereas 13 patients had non-endometrioid subtypes. All patients underwent surgical staging including hysterectomy, bilateral salphingo-oopherectomy, abdominal exploration and selective lymphadenectomy. 52 patients had FIGO stage 1, 5 patients had stage II, 10 patients had stage III and 5 patients had stage IV disease. The

presence of LN metastasis was correlated with metabolic parameters such as SUVmax, MTV and TLG. Results: Nine patients had surgically proven LN metastasis. Six of 10 (60%) patients amongst stage III patients, and 3 of 5 (60%) patients amongst FIGO stage IV patients had LN metastasis. Apart from clinical stage, 6 of 13 patients (46%) with non-endometrioid type tumor had LN metastasis. Patients with LN metastasis had significantly higher MTV (68.4±56.3 cm^3 vs. 14.2±17 cm^3, p:0.0001) and TLG (810±651 vs. 160±228.4 grams, p:0.001) compared to non-metastatic patients. On univariate analysis, the presence of LN metastasis was significantly correlated with non-endometrioid histology, advanced FIGO stage, high MTV and high TLG of the primary tumor. Conclusion: Non-endometrioid tumor type and advanced FIGO stages are known poor prognostic factors which are clinically associated with lymphatic involvement in patients with endometrial cancer. In addition to these well known clinical parameters, we observed that metabolic indices that considers metabolic tumor burden also correlate with LN metastasis in endometrial cancer. These findings support the use of PET/CT as a complementary approach to FIGO staging in the pre-treatment work-up of patients with endometrial cancer.

EP100

Comparison of integrated ^{18}F-FDG PET/contrast-enhanced CT and contrast-enhanced CT for pretreatment staging of epithelial ovarian cancer

M. Mayoral, P. Paredes, A. Saco, L. Buñesch, M. C. Sebastià, S. Martínez-Roman, A. Fernandez-Martinez, J. Ordi, J. Pavia, J. Pahisa, F. Lomeña; Hospital Clinic Barcelona, Barcelona, SPAIN.

AIM: Contrast-enhanced CT (ceCT) is the procedure of choice for preoperative staging of epithelial ovarian cancer (EOC). This study aimed to evaluate the diagnostic performance of integrated ^{18}F-FDG PET with ceCT (PET/ceCT) in comparison with conventional ceCT. **MATERIALS AND METHODS:** Thirty-two patients with suspected or newly diagnosed EOC underwent pretreatment PET/ceCT. An experienced nuclear medicine physician evaluated PET/ceCT and the ceCT component was interpreted by a radiologist separately. For each study, findings other than the primary tumour were categorized into four groups: peritoneum, abdominopelvic lymph nodes, supradiaphragmatic disease and metastasis in other organs. Histopathological findings, whenever possible, were the reference standard to determine the final diagnosis of disease status. The diagnostic performance of PET/ceCT and ceCT was calculated on a site-based analysis. For extra-abdominal areas not resectable during surgery, the agreement of the two imaging modalities was compared with the kappa coefficient. McNemar test was used to determine the significance of differences between both techniques. **RESULTS:** The median age was 62 years old (range 19-83 years). Papillary serous adenocarcinoma was the most common histological subtype, being present in 24/32 (75.0%) cases. The mean value of CA-125 serum levels was 1057.1 U/mL (standard deviation 1162.4 U/mL). Peritoneal biopsies were obtained from 21 patients and histopathology showed tumoral involvement in 19 (90.5%) patients. The two imaging modalities detected peritoneal implants in all these cases. Abdominopelvic lymph nodes status could be histologically evaluated in 15 patients, 6 (40.0%) of which had metastasis. The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of PET/ceCT to detect abdominopelvic adenopathies was 83.3%, 77.8%, 71.4%, 87.5% and 80.0%. For ceCT, these values were 66.7%, 66.7%, 57.1%, 75.0% and 66.7%, respectively. PET/ceCT detected supradiaphragmatic disease in 13/32 (40.6%) patients and ceCT in 5/32 (15.6%) patients, all of them also detected by PET/ceCT. These differences between both techniques were statistically significant (p=0.008). The agreement between both techniques to detect supradiaphragmatic disease was fair (κ=0.271). PET/ceCT detected metastasis in other organs in 6/32 (18.8%) patients and ceCT in 4/32 (12.5%) patients. These differences were not statistically significant (p=0.5). The agreement between both techniques to detect metastasis in other organs was substantial (κ=0.684). **CONCLUSION:** PET/ceCT was superior to conventional ceCT for the detection of supradiaphragmatic disease and abdominopelvic lymph nodes. Thus, integrated PET/ceCT is a more accurate imaging modality for staging EOC than ceCT.

EP101

Prognostic role of 18F-FDG PET parameters in preoperative phase of endometrial carcinoma

E. Incerti[1], P. Mapelli[1], A. Bergamini[2], P. Rancoita[3], A. Bonazzi[4], F. Fallanca[1], E. Rossi[2], M. Petrone[2], E. Rabaiotti[2], A. Dell'Acqua[2], G. Mangili[2], L. Gianolli[1], M. Picchio[1]; [1]IRCCS San Raffaele Scientific Institute, Nuclear Medicine, Milan, ITALY, [2]IRCCS San Raffaele Scientific Institute, Obstetrics and Gynecology, Milan, ITALY, [3]University Centre of Statistics in the Biomedical Sciences, Vita-Salute San Raffaele University, Milan, ITALY, [4]University Of Milano-Bicocca, Milan, ITALY.

Aim: To explore the prognostic value of preoperative 18F-FDG PET/CT in endometrial cancer by using 18F-FDG PET-specific semi-quantitative tumour parameters. **Methods:** Preoperative 18F-FDG PET/CT was performed from August 2009 to March 2015 in 32 women (mean age: 63 years, range: 49-81 years) with endometrial cancer. Mean and maximum standardized uptake values (SUVmean - max), metabolic tumour volume (MTV) and total lesion glycolysis (TLG) of primary tumours, at different thresholds of 40%, 50%, 60% (40-50-60), were retrospectively evaluated and compared with anatomical and pathological features. All 18F-FDG PET-specific semi quantitative tumour parameters measured have been evaluated to assess their diagnostic performance in terms of differentiation of low-risk disease (pT1 or International Federation of Gynecology and Obstetrics - FIGO Stage I) from high-risk disease (pT2-pT3 or FIGO Stage II-III-IV). The Receiver Operating Characteristics (ROC) curve analysis was used to investigate the performance of PET parameters in predicting the tumour status. For each PET parameters, the optimal cut-off was derived using a standard method, consisting in choosing that value corresponding to the point on the ROC curve nearest to the upper left corner of the ROC graph. Logistic regression analysis was used to assess whether the PET parameters categorized with the optimal cut-off were able to predict the tumour status and only those which reached a statistical significance were reported (P-value <0.05). **Results:** MTV40 and TLG40-50-60 were significantly related to FIGO Stage I versus FIGO Stage II-III-IV (P =0.0157, P =0.0246, P =0.0474, P =0.0474, respectively). The optimal MTV40 cut-off value of 8.9, determined by ROC analysis, was found to have 70% sensitivity and 77% specificity for risk stratification. The optimal cut-off values of 85.6, 58.0, 40.0, for TLG40-50-60, determined by ROC analysis, respectively, were found to have 60%, 60%, 60% sensitivity, respectively, and 82%, 77%, 77% specificity for risk stratification, respectively. **Conclusions:** MTV40 and TLG40-50-60 of primary endometrial cancer show correlations with anatomical and pathological features, being more useful for differentiating low-risk from high-risk disease than SUVmean-max parameters that could not reach a statistical significance in our series. 18F-FDG PET-specific semi-quantitative tumour parameters may represent a clinically valuable tool for preoperatively predict endometrial carcinoma.

EP102

Preoperative metabolic indices of FDG PET/CT correlate with deep myometrial invasion in clinical FIGO Stage I endometrial carcinoma

B. E. AKKAS[1], H. EFETURK[1], B. B. DEMIREL[1], G. UCMAK[2,3]; [1]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, ANKARA, TURKEY, [2]HITIT UNIVERSITY ÇORUM RESEARCH AND TRAINING

HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, ÇORUM, TURKEY, [3]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, Ankara, TURKEY.

The prognosis of patients with FIGO Stage I endometrial cancer is favorable after radical surgery. Depth of myometrial invasion (MI) is one of the clinically significant prognostic factors in patients with endometrial cancer. In addition, prior knowledge of MI depth is important for surgical planning. Curative tumor resection is possible in superficial MI (<50% of myometrium), while patients with deep MI (> 50% of myometrium) may benefit from extended surgery with pelvic and/or paraaortic lymphadenectomy. The aim of this study was to evaluate the value of FDG PET/CT for estimating MI in endometrial cancer. Method: 52 patients with FIGO stage I endometrial cancer were included in this study. All patients underwent FDG PET/CT imaging prior to surgery. Standardized uptake values (SUV), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were calculated on the PET image. All patients underwent total hysterectomy and bilateral salpingo-oophorectomy (THBSO). Extended surgery was considered based on intra-operative findings and frozen section results. Metabolic data was compared to post-operative histopathology obtained from the surgical specimen. Results: The surgical stage was IA in 32 and IB in 20 patients. Nineteen patients (63.5%) had deep MI, 33 had superficial MI. SUVs in patients with deep MI were significantly higher than those with superficial MI (20.2±6.8 vs. 14±6.4, respectively, p:0.001). The area under ROC curves (AUCs) for distinguishing patients with deep MI from those with superficial MI was 77% for SUVmax. The best compromise between sensitivity (84%) and specificity (73 %) was reached at a cut off value of SUVmax:15.6. MTV in patients with deep MI was significantly higher than those with superficial MI (15.4±9.2 vs. 9.4±9.7, respectively, p:0.01). AUC for predicting patients with deep MI for MTV was 75% and a cut off value was calculated as 9.9 cm^3 with a sensitivity of 72% and specificity of 73%. AUC for TLG was calculated as 77% which was higher than both SUVmax and MTV. The cut off for TLG was found as 108 grams with a sensitivity of 72% and specificity of 76%. Conclusion: Our study showed that all metabolic parameters obtained from preoperative PET/CT are successful to predict deep MI in patients with clinical stage I endometrial cancer. We considered that, after confirmed by larger prospective studies, SUVmax greater than 15.6, MTV greater than 9.9 cm^3 and TLG greater than 108 grams can be applied preoperatively for risk stratification and deciding upon the optimal surgical therapeutic strategy.

EP103

The role of maximum standardized uptake value and minimum apparent diffusion coefficient of the primary tumor for predicting clinicopathological characteristics in endometrial cancer

F. AYDIN[1], E. SURER BUDAK[1], T. TOPTAŞ[1], A. ONER[2], C. CEVİKOL[1], T. ŞİMŞEK[1]; [1]AKDENIZ UNIVERSITY, ANTALYA, TURKEY, [2]KOCATEPE UNIVERSITY, AFYON, TURKEY.

Abstract Objective: To investigate relationships of maximum standardized uptake value (SUV_{max}) and minimum apparent diffusion coefficient (ADC_{min}) of the primary tumor to clinicopathological features, and to compare their predictive ability in patients with endometrial cancer (EC). **Methods:** A prospective case-series with planned data collection was conducted in a total of 45 patients who underwent staging surgery following a preoperative evaluation with ^{18}F-fluorodeoxyglucose positron emission tomography combined with computed tomography (^{18}F-FDG PET/CT) and diffusion-weighted magnetic resonance imaging (DW-MRI). Relationships between variables were analyzed using the multiple linear regression analysis. **Results:** The mean ADC_{min} and SUV_{max} were 0.72±0.22 and 16.54±8.73, respectively. In univariate analysis, while the potential factors associated with ADC_{min} were age, myometrial invasion (MI), and lymphovascular space involvement (LVSI); the potential factors associated with SUV_{max} were age, stage, tumor size, MI, LVSI and number of metastatic lymph nodes. However, only MI remained to be an independent variable associated with ADC_{min} (P=0.007) as well as SUV_{max} (P=0.024) after adjustment for other confounders in multivariate analysis. Optimal cutoff values of ADC_{min} and SUV_{max} for predicting deep MI were found to be ≤0.77 [93.7% sensitivity, 48.2% specificity, and 93.0% negative predictive value (NPV)] and >20.5 (62.5% sensitivity, 86.2% specificity, and 81.0% NPV), respectively; although the comparison of two diagnostic tests revealed no significance (P=0.266). **Conclusions:** MI is the sole clinicopathological feature independently associated with SUV_{max} as well as ADC_{min}. However, predictive performances of both parameters are not high enough to support the routine use of ^{18}F-FDG PET/CT or DW-MRI.

EP104

Value of (18)F-fluorodeoxyglucose PET/CT in the diagnosis of local recurrence uterine cancer: comparison with CT and MRI

S. Panareo[1], I. Santi[1], I. Rambaldi[1], S. Taralli[1], A. Stefanelli[2], C. Cittanti[1]; [1]University Hospital - Nuclear Medicine Unit, FERRARA, ITALY, [2]University Hospital - Radiotherapy Unit, FERRARA, ITALY.

AIM: To evaluate the accuracy of (18)F-fluorodeoxyglucose (FDG) PET/CT (PET/CT) in the diagnosis of suspected uterine cancer local recurrence after treatment (surgery, chemotherapy and/or radiotherapy) and to assess the impact of PET/CT findings on clinical management, compared with contrast enhanced CT alone and MRI. METHODS: we retrospectively studied 64 women (mean age 72±5.2 yo) who underwent treatment for histopathologically proven uterine cancer. For the clinical-diagnostic suspect of local cancer recurrence, all patients underwent PET/CT examination at least 3 months from the end of treatment. PET/CT results were correlated to contrast enhanced CT alone and MRI. Lesion status was determined on the basis of histopathology, radiological imaging and clinical follow-up for longer than 6 months. Differences among the three imaging modalities were tested using the Cochran Q test, followed by multiple comparisons using the McNemar test with Bonferroni adjustment. RESULTS: Patient-based analysis showed that PET/CT confirmed a local disease relapse in 35 patients (54.6%) out of 64. PET/CT data were confirmed by clinical-diagnostic and surgical follow-up. On the other hand CT alone showed a local recurrence of disease in 22 patients (34.3%). On the other hand MRI showed a relapse disease in 25 patients (39 %). The sensitivity, specificity, and accuracy of PET/CT were, respectively, 91%, 93%, and 92%; whereas those of contrast enhanced CT alone were, respectively, 68%, 87%, and 78%. Finally, sensitivity, specificity and accuracy of MRI were, respectively, 82%, 91% and 90%. PET/CT findings resulted in a change of management in 21 of 64 patients studied (32%). CONCLUSION: PET/CT is a more accurate modality for assessing recurrence of uterine cancer and more appropriate than contrast enhanced CT alone in the restaging of patient with suspected uterine cancer recurrence. MRI seems to be better then contrast enhanced CT for the restaging of local recurrence of uterine cancer but not performing like PET/CT. PET/CT done at least 3 months from the end of treatment allows to differentiate between after treatment local inflammation and tumour recovery. The change of treatment management gives a better prognostic stratification and restraint of costs. Data must be confirmed in a more large casuistic.

EP105

The effect of dual phase PET/CT imaging on Standardized Uptake Value, Metabolic Tumor Volume and Total Lesion Glycolysis of the primary tumor in endometrial cancer patients

B. E. AKKAS[1], G. UCMAK[2,3], H. EFETURK[1], I. KERIMEL[1], B. B. DEMIREL[1]; [1]ANKARA ONCOLOGY RESEARCH AND

TRAINING HOSPITAL, DEPARTMENT OF NUCLEAR MEDICINE, ANKARA, TURKEY, [2]HITIT UNIVERSITY ÇORUM RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, ÇORUM, TURKEY, [3]ANKARA ONCOLOGY RESEARCH AND TRAINING HOSPITAL DEPARTMENT OF NUCLEAR MEDICINE, Ankara, TURKEY.

Aim: It is known that fluorodeoxyglucose (FDG) uptake continues to rise for several hours after the injection of radiotracer in various malignancies. Dual phase positron emission tomography/computed tomography (PET/CT) imaging has been shown to have impact on the differentiation of malignant lesions from benign inflammatory processes. Our aim was to evaluate the effect of dual phase PET/CT imaging of the primary tumor on the functional metabolic parameters that reflect metabolic tumor burden such as maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in patients with endometrial cancer and to investigate their role in risk stratification. Methods: Preoperative PET/CT results and postoperative histopathology results were retrospectively analyzed in 72 patients with endometrial cancer. Dual-phase pelvic imaging was performed on 16 of these patients. Clinical FIGO stages were as follows; stage I (n:5), stage II (n:5), stage III (n:4) and stage IV (n:2). Early imaging was done 1 hour after and delayed imaging was done approximately 2 hours after FDG injection. The SUVmax, MTV and TLG values were obtained from the primary lesion in the uterus in both early and delayed images. MTV was measured inside the tumor with margin thresholds set as 40% of SUVmax. Results: We observed a significant increase in tumor SUVmax on delayed image. The average of SUVs of the primary tumor were 17.2 ±6.8 on the initial image whereas 20.8±7.6 on delayed image (p:0.002). MTV ranged between 3.5-130 cm^3 and TLG ranged between 25-1800 g in the patient group. We found no significant difference in MTV and TLG of the primary tumors with dual phase imaging. Conclusion: Dual-phase FDG PET offers information about the dynamics of glucose metabolism. We observed that, although malignant tumors continue to accumulate FDG over time, indices reflecting metabolic tumor burden are not affected by dual-phase PET imaging in this study of limited number of patients. We considered that both MTV and TLG are stable metabolic parameters that are not affected by timing of acquisition in patients with endometrial cancer.

EP106

Incidence and clinical Significance of bone metastasis detected using F-18 FDG PET/CT in Patients With Gynecologic Malignancy

S. Yoon; Dankook University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Objective: Usually bone metastasis is rare in the gynecologic malignancy, therefore bone scan is not indicated. The prognosis of gynecological cancer patients with bone metastasis is poor. We performed F-18 FDG PET/CT for staging and evaluation of metastasis in 4242 patients with gynecologic malignancy. Therefore we evaluated the incidence of bone metastasis using F-18 fluorodeoxyglucose positron emission tomography (FDG-PET) in the patients with the gynecologic cancer patients. Material and method: Between 2009 and 2015, we retrospectively analyzed PET/CT scans with pathological-proven gynecologic malignancies including cervix cancer(3040 patients), endometrial cancer(805 patients) and ovarian cancer(397 patients). Bone metastases were proved by MRI following FDG PET-CT or clinical follow up. Results: Incidence of metastatic bone metastasis in all 4242 patients with gynecologic malignancy was 18 patients(0.4%). Eight patients (33%) among 24 patients with bone metastasis were pathologically diagnosed cervical carcinoma. Three endometrial and seven ovarian carcinoma showed bone metastases. Five patents (28%) among 18 patients showed only single bone metastasis on the PET CT. The most common type of gynecologic malignancy with bone metastasis by incidence was ovarian carcinoma (1.8%=7/397patients) compared with cervical carcinoma (0.3%= 8/3040patients) and endometrial carcinoma (0.4%=3/805patients). Conclusions: We found that the incidence of bone metastases in the gynecologic malignancy were very low (0.4%). The most common type of gynecologic malignancy with bone metastasis by incidence was ovarian carcinoma more than four to six times compared with cervical carcinoma and endometrial carcinoma. Although some article reported the incidence of bone metastasis secondary to endometrial cancer was 6 to 15% through very long follow up including autopsy, usually bone metastasis is rare in the gynecologic malignancies.

EP107

Correlation of ^{18}F-FDG uptake on PET/CT with Ki67 immunohistochemistry in pretreatment epithelial ovarian cancer

M. Mayoral, P. Paredes, A. Saco, A. Fernandez-Martinez, P. Perlaza, A. Tapias, P. Fusté, M. C. Sebastià, J. Ordi, J. Pavia, J. Pahisa, F. Lomeña; Hospital Clinic Barcelona, Barcelona, SPAIN.

AIM: Metabolic tumor volume (MTV) and total lesion glycolisis (TLG) from ^{18}F-FDG PET/CT are emerging prognostic biomarkers in various solid neoplasms. These volumetric parameters and the maximum standardized uptake value (SUVmax) have shown to be useful criteria for disease prognostication in preoperative and post-treatment epithelial ovarian cancer (EOC) patients. On the other hand, Ki67 is another known prognostic biomarker in EOC associated with tumour aggressiveness. The aim of this study was to evaluate the association between ^{18}F-FDG PET/CT measurements (SUVmax, MTV and TLG) and Ki67 in pretreatment EOC to determine whether PET/CT parameters could non-invasively predict tumour aggressiveness. **MATERIALS AND METHODS:** Fifteen patients with suspected or newly diagnosed EOC underwent pretreatment PET/CT. Two nuclear medicine physicians assessed the images. The highest SUVmax among all the malignant lesions and volumetric parameters MTV and TLG with a threshold of 30% and 40% of the SUVmax were obtained. The sum of the MTV of every lesion was the whole-body MTV (wbMTV) and whole-body TLG (wbTLG) was the summation of the MTV of each lesion multiplied by its SUVmean. On the other hand, proliferative activity as indicated by the Ki67 index was estimated in tumoral tissue specimens. Mean and hotspot Ki67 were obtained. Immunohistochemical findings were correlated with PET parameters using linear regression analysis. Previously, Shapiro-Wilk test was used to determine if the variables under study followed a Normal distribution. **RESULTS:** In this group of 15 patients with pretreatment EOC, the median age was 60 years old (range 19-74 years). Serous cancer was the most common histological subtype, being present in 11/15 (73.3%) patients. The median values of SUVmax, wbMTV 30%, wbMTV 40%, wbTLG 30% and wbTLG 40% were 14.79 (range 4.33-24.42), 572.22 mL (range 171.14-1548.59 mL), 406.42 mL (range 130.28-1176.26 mL), 2468.29 g (range 389.96-7418.11 g) and 2027.61 g (range 326.61-6013.27 g), respectively. The median values of mean and hotspot Ki67 were 33.60% (range 5.60-79.00%) and 54.41% (range 22.5-95.9%), respectively. All variables under study followed a Normal distribution. A weak correlation was observed between PET parameters and Ki67. The highest correlation was obtained between mean Ki67 and SUVmax (r^2=0.198). **CONCLUSION:** SUVmax, wbMTV and wbTLG measured by ^{18}F-FDG PET/CT were weakly correlated with Ki67. Thus, PET parameters do not seem to be predictors of tumour aggressiveness in patients with pretreatment EOC.

EP108

Comparison of 18F-FDG PET/CT or PET and CT in the diagnosis of metastatic lymph nodes in cervical cancer patients: a meta-analysis

H. Zhou; West China Hospital, Chengdu, CHINA.

Purpose: The study aims to perform a meta-analysis to compare the diagnostic performance of 18F-FDG PET/CT or PET and CT for detection of metastatic lymph nodes in cervical cancer patients. Methods: Articles of 18F-FDG PET/CT and CT on PC published in English from January 1990 to September 2016 was searched in the PubMed, EMBASE, Cochrane Library, Web of Science, and EBSCO databases to identify eligible studies on PET/CT or PET or CT of metastatic lymph nodes in cervical cancer patients. QUADAS was used to evaluate the methodological quality of the included studies. Pooled sensitivity, specificity, and diagnostic odds ratios (DOR) were calculated both on a per-patient basis. Summary receiver operating characteristic (SROC) curves were also drawn to obtain the area under curve (AUC) and Q* value. Results: 33 articles were included in the analysis. On a per-patient basis, the pooled sensitivity of PET/CT or PET (88%) was significantly higher than that of CT (62%), and the pooled specificity of PET/CT (92%) was higher than that for CT (89%). Conclusions: This meta-analysis indicated that FDG PET/CT or PET was better than CT on a per-patient basis for diagnosis of metastatic lymph nodes in cervical cancer patients.

EP109

FDG-PET/CT in the primary assessment of operability of women with ovarian cancer - experiences with incidental findings

S. E. Sponholtz[1], **M. G. Hildebrandt**[1], P. F. Høilund-Carlsen[1], O. Mogensen[2], P. T. Jensen[1]; [1]Odense University Hospital, Odense, DENMARK, [2]Karolinska University Hospital, Stockholm, SWEDEN.

Aim: The aim was to assess the clinical impact of pre-operative FDG-PET/CT in women with ovarian, fallopian tube, and peritoneal cancer (abbreviated to: OC) with special focus on consequences of identifying incidental findings (IFs). **Material and methods:** Pre-operative FDG-PET/CT scans in women with OC performed from January 2011 - December 2012 at our hospital were reviewed. All IFs were registered, and at the first succeeding multidisciplinary team conference it was decided whether an IF needed further examination or not. Subsequent procedures were tracked via medical records. The result of additional examination and the consequent delay in planned treatment was registered. **Results:** Of 209 included women, aged 16-95 years, 46 (22%) presented with one or several IFs. Further examination was recommended in all 46 and was actually performed in 35 (76%). Malignancy was identified in 12 (34%) of the 35 women, revealing metastases from OC (9 women) or a synchronous primary cancer (3 women). The identified metastases from OC were localized in lungs, uterus, colon, vagina, and breasts. Further investigation in the remaining 23 women with IFs, who underwent further examination, revealed two benign lesions and one pre-malignant lesion; no abnormality was found in 16 women, and findings were considered inconclusive in four. A significant delay in time until treatment of median four days (range 1-83) was found when an IF led to further examination ($p < 0.004$). **Conclusion:** About 1/5 to 1/4 of FDG-PET/CT scans detected IFs. Further examination led to a malignant diagnosis in about 1/3 of these cases, most often as metastases from OC, indicating that FDG-PET/CT may be considered a valuable tool in assessing metastases with rare locations in women with OC. Further examinations as a consequence of IFs delayed the time to treatment by median four days; the clinical implications of this must be balanced against the gain by detecting unrecognized malignancy in 12 of 209 patients (6%).

EP110

Incidence and clinical Significance of Neck Node metastasis in Patients With Gynecologic Malignancy : Tumor Marker vs PET/CT Correlation in 4242 patients with gynecologic malignancy

S. Yoon; Dankook University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Objective: Usually node metastasis in the neck region is rare in the gynecologic malignancy, We performed F-18 FDG PET/CT for staging and evaluation of metastasis in 4242 patients with gynecologic malignancy. Therefore we evaluated the incidence of neck node metastasis using PET/CT in the patients with the gynecologic cancer patients. PET/CT finding correlated with tumor marker. **Material and method**: Between 2009 and 2015, we retrospectively analyzed F-18 FDG PET/CT scans with pathological-proven gynecologic malignancies including cervix cancer(3040 patients), endometrial cancer(805 patients) and ovarian cancer(397 patients). Neck node metastases were proved by sono guided biopsy of the neck nodes or clinical follow up. We compared the tumor marker according to the multiplicity of FDG uptakes outside of the neck and only single uptake in the neck. **Results**.: Incidence of metastatic neck node in all 4242 patients with gynecologic malignancy was 24 patients(0.6%). Fifteen patients (75%) among 24 patients with pathological proven neck node metastasis were cervical carcinoma. Three endometrial and six ovarian carcinoma were diagnosed as neck node metastases. Six patents (25%) among 24 patients showed only single uptake in the neck on the PET CT. Four patients among six single node metastasis was cervix carcinoma. Tumor marker of 5 patients (83%) among 6 patients with only single uptake and metastasis in the neck were within normal range. While, only 2 patients (11%) among other multiple focal FDG uptakes including neck node uptake showed the normal tumor marker. The most common type of gynecologic malignancy with neck node metastasis by incidence was ovarian carcinoma (1.5%= 6/397patients) compared with cervical carcinoma (0.5%=15/3040patients) and endometrial carcinoma(0.4%= 3/805patient). **Conclusions**:We found that the incidence of neck node metastases in the gynecologic malignancy were very low (0.6%). Sensitivity of tumor marker in patient with single neck node metastasis was very low (17%). The most common type of gynecologic malignancy with neck node metastasis by incidence was ovarian carcinoma more than three times compared with cervical carcinoma and endometrial carcinoma. We should rule out the neck node metastasis in case of neck node uptake on the PET/CT even though very lower incidence of neck node metastasis and normal tumor marker in gynecologic malignancy.

EP111

The Role of F-18 FDG PET/CT Scan in Evaluation of the Patients with Vulvar and Vaginal Cancers

I. AK SIVRIKOZ[1], E. VARDARELİ[2], H. ONNER[1], S. OZALP[3]; [1]ESOGU SCHOOL OF MEDICINE DEPARTMENT OF NUCLEAR MEDICINE, ESKISEHIR, TURKEY, [2]ACIBADEM UNIVERSITY SCHOOL OF MEDICINE DEPARTMENT OF NUCLEAR MEDICINE, ISTANBUL, TURKEY, [3]ESOGU SCHOOL OF MEDICINE DEPARTMENT OF GYNECOLOGIC ONCOLOGY, ESKISEHIR, TURKEY.

Aim: The use of FDG-PET/CT in patients with vulvar cancer is unclear. There are a few reports suggesting that these tumors are FDG avid, however there is very little published data addressing the diagnostic impact of PET/CT in vulvar and vaginal cancers. The aim of this study was to assess the diagnostic yield of F-18 FDG PET/CT in the management of patients with vulvar and vaginal cancers. **Material and methods:** We retrospectively analyzed the data of 34 consecutive patients underwent F-18 FDG-PET/CT study for a known primary or suspected/recurrent vulvar/vaginal cancer from our institution and another centre had same PET/CT scanner. All patients underwent a staging evaluation with history and physical examination, routine laboratory studies, vulvar/vaginal biopsy, CT of the thorax, abdomen and pelvis, and whole-body F-18 FDG PET/CT scan (Siemens Medical Solutions, Biograph 6, Chicago, IL, USA). **Results:** A total of 34 patients with vulvar carcinoma (n= 28 patients) and vaginal carcinoma (n=6 patients) enrolled to the study. The mean age of the patients was 68.2 ± 2,18 years (range 45-91 years). Twenty four FDG PET/CT studies were from patients with a new diagnosis (70%) and 10 from patients with suspicion of recurrence due to previous vulvar/vaginal cancer (30%). The histological types of

the tumours were the Squamous cell ca in 29 patients, Malign Melanoma in 4 patients and Adenocarcinoma in one patient. F-18 FDG PET/CT scan was performed on pre-operative period in 18 of 24 patients. All of them showed increased FDG uptake at primary tumour localization (18/18). There were no sign of pelvic nodal involvement or distant metastatic disease in 7 of these 18 patients. However, inguinal/iliac lymph node involvements and distant metastasis (lung, liver and bone) were seen in 9 of 18 patients and in 2 of 18 patients, respectively. The PET/CT scan was performed in 6 patients after the excision of vulvar lesion for staging of diseases. There was no pathologic FDG uptake for suggesting nodal/distant metastatic involvement on whole body study. There were positive FDG results for only local recurrence and/or iliac/inguinal lymphatic involvements in 2 of 10 patients (10/34) with suspicion of recurrence due to previous vulvar/vaginal cancers. In remaining 8 patients, there were positive FDG results for distant metastasis (lung, bone, liver and adrenal gland). **Conclusion**: F-18 FDG PET/CT is postulated as a useful imaging modality for the management of vulvar/vaginal cancers, mainly in the identification of nodal metastases.

EP112

Standardizing SUV Measurements and Comparing With Other Parameters to Predict Treatment Failure of Cervix Carcinoma

L. A. Güner, E. Ozyar, B. Sahin, B. Atalar, T. Aksoy, E. Vardareli; Acibadem University Maslak Hospital, Istanbul, TURKEY.

There are reports of different SUV based measures estimating prognosis of cervix carcinoma. Since body weight normalization is only one of the approaches with its own shortcomings, we proposed further normalizations that may provide additional or more robust information for tumor characteristics that may be related to disease prognosis. Methods: We prospectively evaluated 41 patients referred to our department for chemoradiotherapy. 23 of 41(56%) patients had pelvic and/or FDG avid abdominal lymph nodes before treatment. During follow up (median 21 months), 14/41 had recurrence(34%) of which 11/41 had distant recurrence (27%), 5/41(12%) had local/regional recurrence, 2/41 had both. Using the pretreatment staging FDGPET scans, we calculated SUVmax of primary lesion, SUVmean, SUVmax normalized to cerebellum mean (SUVnormcerebellum), SUVmax normalized to liver mean (SUVnormliver), metabolic tumor volume of 40% of maximum FDG uptake, metabolic tumor volume of >2.5SUV, total lesion glycolysis (tlg), tlg normalized to cerebellum, tlg normalized to liver, standard deviation of primary lesion as a surrogate for heterogeneity and visual evaluation of heterogeneity (Hvisu). Results: Of all the parameters calculated, versus recurrence (local/distant) only SUVnormliver was significantly correlated (p=0.047). Versus only distant-recurrence, again only SUVnormliver was significant (p=0.05). When we analyzed the subgroup of patients with FDG-avid abdominal lymph nodes before treatment, none of the variables held significance. When patients without FDG-avid abdominal lymph nodes were selected, again none of the variables were significantly correlated, although p-value for SUVnormliver was 0.08. When plotted in a ROC curve, SUVnormliver of 7.2 was the optimal cutoff point for predicting recurrence (with 71% sensitivity and 50% specificity). For this threshold, odds ratio of having a recurrence was 2.1. On the other side, with a pretreatment FDG-avid abdominal lymph node, the odds ratio of having recurrence was 1.9. These two parameters; pelvic lymph node positivity and SUVnormliver were correlated (p=0.027) and ROC analysis showed SUVnormliver of 7.6 was optimum cutoff value (65% sensitivity, 79% specificity for pelvic lymph node). Conclusion Among the mentioned parameters of tumor burden, heterogeneity or metabolic activity, only SUVmax normalized to liver was predictive of treatment failure. When subgroup analysis was performed for node-negative disease, this parameter was weakly correlated, though still better than others. Node positivity is already established for predicting recurrence. Other SUV based parameters should be avoided, as our results show no correlation to recurrence. SUV normalized to liver may still have value in node negative subgroup. Larger sample sizes are required to establish its value.

EP113

Sentinel node biopsy in early endometrial cancer: preliminary results

A. Caresia Aróztegui, L. Ribot Luna, J. Martin Marimon, Q. Sun Lin, A. Rodríguez Revuelto, I. Costa Trachsel, B. Morillas Oliveras, Y. García García, J. Antoni Vives, L. Bernà Roqueta; Hospital Parc Tauli, Sabadell, SPAIN.

AIM: This study aims to evaluate our experience implementing sentinel lymph node (SLN) mapping in early stage endometrial cancer. MATERIALS AND METHODS: We included 22 patients with early stage endometrial cancer (preoperative FIGO stage Ia (n=7), Ib (n=14), and II (n=1)) on laparoscopic staging between 2010 and 2016. The SLN mapping technique included cervical injection of 99mTc-nanocolloid, preoperative lymphoscintigraphy (24 h before intervention), and intraoperative laparoscopic gamma probe SLN detection. After surgical removal of the SLN, all patients underwent systematic laparoscopic pelvic lymph node dissection. Ultrastaging of SLN was performed with haematoxylin and eosin stain (H&E) and immunohistochemistry (CAM 5.2). Lymphadenectomy samples were studied by conventional histopathological analysis with H&E. We calculated the detection rate and descriptive statistics for node- and patient-based analyses. RESULTS: The SLN mapping technique failed in two patients (1 without SLN drainage and 1 with intraperitoneal nanocolloid uptake); the SLN detection rate was 90% (20/22). A total of 29 SLNs were detected (mean, 1.45 per patient); 69% in the interiliac region (20/29) and 31% in the internal iliac region(9/29). One SLN had macrometastases, four had micrometastases, and two had isolated tumour cells. At lymphadenectomy, a mean of 14.8 nodes were dissected; all non-SLNs dissected were negative (0% false-negative rate). Of the 20 patients, 4 had positive SLN (1 macrometastases and 3 micrometastases). Ultrastaging of SLNs revealed lymph node metastases in 2 patients undetected by conventional histopathological analysis. In the patient-based analysis, the sensitivity was 100% and the negative predictive value was 100%. CONCLUSIONS : SLN surgical biopsy in early endometrial cancer is a feasible and useful technique for detecting metastatic node involvement. The high negative predictive value in our preliminary results suggests that it could be incorporated into routine clinical practice.

EP-07 – Sunday, October 16, 2016, during Exhibition hours, e-Poster Area

EP114

The role of oropharyngealoesophageal scintigraphy in the evaluation of swallowing function in nasopharyngeal and oropharyngeal cancer treated by radiotherapy: short-term results of a prospective study

E. Fiasconaro[1], M. Grosso[1], E. Tardelli[1], G. Aghakhanyan[1], B. Fattori[2], G. Puccini[1], M. Gennaro[1], R. Boni[1], F. Guidoccio[1], R. Raschillà[1], S. Ursino[3], I. Paglianiti[1], D. Volterrani[1]; [1]Department of Nuclear Medicine, University Hospital S. Chiara, Pisa, PISA, ITALY, [2]Otorhinolaryngology-Audiology-Phoniatric Unit, University Hospital Cisanello, Pisa, PISA, ITALY, [3]Department of Radiation Oncology, University Hospital S. Chiara, Pisa, PISA, ITALY.

Aim To report the initial results of a prospective trial aimed to assess instrumental deglutition function (Videofluoroscopy, OroPharyngealEsophageal and Fiberoptic Endoscopic Evaluation) for sparing the swallowing organ at risk in nasopharyngeal and oropharyngeal cancers after radio or chemoradiotherapy using intensitymodulated radiotherapy (IMRT). **Patients and Methods** Since 2012 to 2014, we enrolled 23 patients affected by Nasopharynx (7) or Oropharynx (16) cancer (Stage II-IVA), ECOGP 0-2. Instrumental assessment of swallowing function included VFS, FEES and OPES at baseline, 1, 6 and 12 months after radiotherapy. The scores of dysphagia parameters, such us pre-deglutition penetration, aspiration, pharyngeal transit time (PTT) and hypopharyngeal retention index (HPRI), were

calculated after each assessment both with liquid (L) and semiliquid (SL) bolus intake.**Results** The examination of the relationships between the pre and post-treatment changes in HPRI score was found to be statistically significant both at FEES-L (p=0,021) and SL (p=0,02) and at VFS-L (p=0,008) and SL (p=0,005) and OPES-SL (p=0,028). In particular we found a SLHPRI worsening scores from the baseline to 1 month after treatment. Besides, a total of 12 (55%), 21 (95%) and 14 (62%) patients experienced poorer scores at FEES-L, VFS-L and OPES-L. All patients showed a poorer HPRI score at VFS-SL and OPES-SL, as well as 14 (70%) at FEES-SL. PTT resulted not significantly affected by RT at the three different exams both after L and SL bolus intake. Furthermore, the pre-deglutition penetration at 1 month was detected in only 1 patient at FEES-L and SL while aspiration at 1 month was detected in 1 only patient by OPES-L and FEES-SL. Finally, aspiration was observed in only 2 patients (10%) at OPES-L. **Conclusions** Our preliminary data seem to confirm a low percentage of major instrumental dysfunction (pre-deglutition penetration or aspiration) after IMRT and lack of severe side effects (PEG positioning or clinical aspiration). IMRT significantly limits acute severe deglutition sequelae in HN cancer treated patients compared to literature reports. Thus, the dysphagia assessment using solid bolus might show a higher percentage of HPRI worsening due to the requirement of a stronger muscular propulsion in this cohort. Indeed, longer follow-up and greater sample size are needed to further evaluate wether increase of HPRI by instrumental methods such as OPES, would be related to a high risk of developing late aspiration (6 and 12 months).

EP115

Sentinel lymph node procedure in squamous cell carcinoma of the oral cavity, comparison with subsequently performed elective neck dissection

D. Lobeek[1], W. L. J. Weijs[1], C. Coppen[1], A. I. J. Arens[1], M. C. van Rijk[1], M. Rijpkema[1], E. P. Mijnheere[1], J. Honings[1], M. A. W. Merkx[1], H. Ghaeminia[1], S. C. van den Bosch[1], O. C. Boerman[1], W. J. G. Oyen[1,2], R. P. Takes[1]; [1]Radboud University Medical Center Nijmegen, Nijmegen, NETHERLANDS, [2]Institute of Cancer Research, Royal Marsden NHS Trust, London, UNITED KINGDOM.

AIM: Several studies have been performed to study the feasibility and clinical applicability of the sentinel lymph node (SN) procedure in oral cavity squamous cell carcinoma (OCSCC). The SN-procedure is gaining more acceptance as a viable alternative to the conventional elective neck dissection (END) in T1-2N0 OCSCC. To introduce this SN-procedure in our institution, we performed a SN-procedure prior to the END to evaluate the feasibility of this procedure. MATERIAL AND METHODS: The day before surgery, 80 MBq ^{99m}Tc-nanocolloid was administered as four peritumoral injections in patients clinically classified as T1-2N0 OCSCC. The injection was followed by dynamic lymphoscintigraphy. Additional planar and SPECT/CT images were obtained 2-4 hours after injection. Pre-operatively, all images were used to identify the tumor draining lymph nodes and to discriminate them from second echelon nodes. These SNs were marked on the skin. During surgery the marked SNs were identified using a handheld gamma probe and excised. The SN-procedure was immediately followed by END and tumor resection. RESULTS: Sixteen patients with a cT1-2N0 OSCC (buccal mucosa (n=2), tongue (n=10), floor of the mouth (n=4)) were recruited from August 2015 till April 2016. In each patient, one to five SNs were identified pre-operatively. 82% (37/45) of all SN foci could be localized and resected, of which 22% (8/37) revealed metastasis. With the END a total of 374 nodes were excised. 1.9% (7/374) of the nodes in the END specimen, not identified and removed as SN, showed accumulation of ^{99m}Tc-nanocolloid, but did not contain metastasis. 0.53% (2/374) nodes of the END in two patients revealed metastasis at histology. One patient showed metastases in an ipsilateral node level III of a lateral tongue tumor and the other showed metastases in a level II node of a floor of the mouth tumor in the midline. Both patients were within the first six of the performed procedures and in which not all SNs were harvested during the SN biopsy. The SNs found in these two patients did not contain metastasis. CONCLUSION: One to five nodes per patient were identified as SNs, but not all were identified and excised during the SN-procedure. For adequate SN-procedures, a close cooperation of all involved disciplines is essential. Also, a learning curve should be taken into account to identify, mark, and find SNs adequately. To intercept possible mishaps of the SN-procedure, the SN-procedure should be introduced while continuing the END in the first couple of patients.

AIM Medullary thyroid carcinoma (MTC) is a rare calcitonin and carcinoembryonic antigen (CEA)-secreting tumor of the parafollicular C cells of the thyroid. Calcitonin is the principal serum tumor marker. The aim of this study was to investigate the potential use of FDG-PET/CT in localizing MTC residual, recurrent or metastatic disease in patients with elevated calcitonin +/- CEA levels. MATERIAL AND METHODS From our database between 2003 to 2015 we retrospectively included 59 FDG-PET/CT studies in 44 patients with MTC. Final selection criteria with total thyroidectomy and elevated calcitonin levels resulted in 51 FDG-PET/CT scans in 44 patients. Serial follow-up scans (7) were included when there was an increase in calcitonin level by at least 20% and the prior study was negative or when positive after surgical resection of FDG-avid lesions in the interim and the calcitonin level did not normalize. PET/CT findings were classified as positive or negative on the basis of visual interpretation of the scan. Maximum Standardized uptake values (SUVs) were also calculated. FDG-PET/CT findings were confirmed by histopathological results, when available, or other imaging studies and clinical follow-up (mean 4 years, range 1-12). RESULTS The 51 FDG-PET/CT scans were classified as: 23 true-positive, 3 false-positive, 14 true-negative and 11 false-negative. The overall sensitivity specificity, positive predictive value and negative predictive value were 68%, 82%, 88% and 56% respectively, with a diagnostic accuracy of 72%. Calcitonin levels ranged from 49 to 28.000 pg/ml (mean in positive FDG-PET/CT scans of 3521 and in negative ones of 521). We found statistical differences on calcitonin levels between positive and negative FDG-PET/CT scans (p<0,05). The mean SUVmax of all lesions with FDG uptake was 4,7 g/ml (range 3-11; mean in metastatic disease: 5,6 and in locoregional disease: 3,5). There were statistical differences on SUVmax values between patients with locoregional and metastatic disease (p<0,05). CONCLUSIONS FDG-PET/CT can detect residual, recurrent or metastatic MTC with a reasonable sensitivity of

68% and diagnostic accuracy of 72% in patients with elevated calcitonin levels. The probability for disease detection is higher in patients with higher calcitonin levels. FDG-PET/CT has a therapeutic impact because of its high positive predictive value (88%). However, in negative FDG-PET/CT scans a strict clinical, serological, and radiological follow-up is mandatory because of the negative predictive value of the technique (56%).

EP117

Usefulness of ^{18} F-FDG-PET-CT in Searching for the Primary in Cancer of Unknown Primary (CUP) of Head and Neck

C. Sampol[1], S. Rubí[1], A. Moll[2], M. Villar[3], M. Toscano[3], M. Oporto[1], C. Peña[1]; [1]Hospital Universitario Son Espases. Nuclear Medicine Department., Palma de Mallorca, SPAIN, [2]Hospital Universitario Son Espases. Radiology Department., Palma de Mallorca, SPAIN, [3]Hospital Universitario Son Espases. Radiopharmacy Department, Palma de Mallorca, SPAIN.

AIM To analyze the usefulness of the ^{18}F-FDG-PET/CT in detecting CUP of the head and neck after a malignant anathomopathologic result in a biopsy of a cervical lymph adenopathy as the only finding. METHOD Included 49p, all of them diagnosed with malignancy of head and neck lymphadenopathy. A CT with intravenous contrast and an endoscopic examination were done, without detecting any lesion suspicious of primary tumor. A ^{18}F-FDG-PET/CT was performed on patients. Afterwards we proceed to confirm the results of the images by biopsy or by clinical follow-up. RESULTS Out of 49p included, median age 60yo, 42 were Squamous cell carcinoma,4 Undifferentiated, 2 adenocarcinomas and 1 lymphoepitelioma. The PET-CT showed primary tumor in 24p,22 located in head and neck (8 in base of tongue, 7 in amygdala, 2 in nasopharynx, 2 in piriform sinus and 3 in hipopharynx), and 2 located outside of head and neck (metastatic prostate cancer and lung). 3/24p were false positive: 2 amygdala and 1 hipopharynx,with negative biopsy result. The detection rate of primary tumor with PET-CT was 42.8%(21/49). In 25p PET-CT was negative of any focus suspicious of primary tumor, being negative the biopsy in 23(1p was diagnosed with metastasic parotideal node of a cutaneous malignancy and 3p showed distant metastasis);2/25p were false negative result of the image finding positive biopsy in left nasopharinx and lateral wall of hipopharinx. Out of 19p without primary tumor diagnosis, no tumor was detected or distant metastasis by any other technique during follow-up (average 24m).The PET/CT detected distant metastasis in 5p(bone, lung, brain and adrenal gland), as well as extracervical lymph nodes in 14p (12 of the supraclavicular).A second primary tumor was detected by PET in 2p, both in the colon (1p died the following moth because of a perforation).One of the patients with Undifferentiated tumor result an anaplastic lymphoma on the finally anathomopathologic result after functional lymphadenectomy. The PET/CT in the detection of the primary tumor in CUP of head and neck showed a S, E, PPV, NPV of 91%, 88%, 87.5% and 92%, respectively. In 35% of cases thanks of PET/CT,the treatment strategy was modified. CONCLUSION The ^{18}F-FDG PET/CT demonstrates a very strong capability in detecting primary tumor of head and neck CUP in patients with cervical lymph adenopathies that induces an important change in the therapeuthic approach of this patients. It should be used as a guide of biopsy in the clinical handling of these patients.

EP118

Similar image of FDG PET-CT in lesion of palatine tonsils: in primary tonsillar cancer, Non Hodgkin Lympoma and Chronic tonsislit-three cases

T. Y. P. Yordanova, Anelia Klisarova, Pavel Bochev, Borislav Chaushev,Zhivka Dancheva; MBAL St Marina, Varna, BULGARIA.

Aim: The aim of this study is to assess the usefulness of 18 F-FDG PET/CT in lesion of palatine tonsils and cervical lymphadenopathy. F-FDG PET/CT has been used for the evaluation of various tumors. PET/CT is used to identify primary or synchronous secondary primary tumor of the Head and neck through changes in F-FDG uptake. However, both physiologic and abnormal lesions increase F-FDG uptake. Methods: We presented three cases of patients with biopsy confirmed various primary malignancies (Non-Hodkyn's Lymphoma, Oropharyngeal carcinoma and Lung carcinoma). The whole body T/CT scan presented similar image in head and neck in all of them- high FDG in palatine tonsil and increase glucose metabolic activity in regional lymph node. Methods: Before whole-body PET/CT two of patients had histological confirmation of primary malignancy of palatine tonsils (Non-Hodkyn's Lymphoma, Oropharyngeal carcinoma). The third patient has histological conformation of primary lung carcinoma and PET/CT detected high metabolic activity in palatine tonsil (SUVmax 7.9) and high FDG uptake in regional lymph node(SUVmax 3.5), which was suspicious for synchronous secondary primary tumor of Head and neck. In the patient with Non-Hodgkin's Lymphoma, PET/CT showed high 18F-FDG uptake in tonsil (SUVmax 3.8) and in regional lymph node (SUVmax 2.5). In patient with Oropharyngeal carcinoma PET/CT demonstrated very high FDG uptake in palatine tonsil (SUVmax 10.7) similar like those with primary lung carcinoma and incidental finding of high FDG accumulation in tonsil SUVmax 7.9 (which was suspected for synchronous secondary primary tumor of Head and Neck). Both patients presented with remarkable FDG uptake in palatine tonsil (SUVmax 10.7/ 7.9) and high glucose metabolism in regional lymph node (SUVmax 2.5/ 3.5). In third patient after tonsillectomy of the suspected malignant lesion the histology report revealed inflammation (chronic tonsilite). The PET/CT result was false positive. Conclusion: 18F- FDG is not tumor specific marker. We presented three cases with various tumors: primary tonsillar lymphoma, primary oropharyngeal carcinoma (involved tonsil) and Lung carcinoma with chronic inflammation in palatine tonsil. The whole body T/CT scan presented similar image in head and neck in all of them- high FDG in palatine tonsil and increase glucose metabolic activity in regional lymph node. Our three cases illustrated that PET-positive lesions not always present malignancy (regardless of the degree of glucose metabolism SUVmax), and a tissue biopsy is mandatory to confirm the diagnosis.

EP119

Laryngeal tuberculosis mimicking laryngeal carcinoma on F-18 FDG PET/CT imaging

A. Cengiz[1], S. Göksel[1], Y. Başal[2], S. Taş Gülen[3], Y. Yürekli[1]; [1]Adnan Menderes University, Medical School, Department of Nuclear Medicine, Aydin, TURKEY, [2]Adnan Menderes University, Medical School, Department of Otorhinolaryngology, Aydin, TURKEY, [3]Adnan Menderes University, Medical School, Department of Chest Disease, Aydin, TURKEY.

Aim: Laryngeal tuberculosis is an infrequent manifestation of extrapulmonary tuberculosis but it is the most common granulomatous disease of the larynx**.** Usually, it is seen as a complication of pulmonary tuberculosis but sometimes only laryngeal involvement is possible. Clinical, laryngoscopic and radiological findings of laryngeal tuberculosis have a tendency to mimic laryngeal cancer. F-18 FDG PET/CT findings of extrapulmonary tuberculosis are not specific and also mimic malignancy. We present a case of laryngeal tuberculosis who had underwent F-18 FDG PET/CT imaging with prediagnosis of laryngeal carcinoma. **Case report:** A 51 year old women was referred to our otolaryngology clinic with history of cough, hoarseness and sore throat. Laryngoscopy revealed diffuse swelling and a lesion involving both arytenoids and the marginal portion of the epiglottis suggesting carcinoma of the larynx. Her prior medical history was unremarkable. Histopathological examination of lesion demonstrated necrosis and suspicious for malignancy and a second biopsy was recommended. Contrast-enhanced computed tomography (CT) scan of the neck

demonstrated an edema and asymetria of **epiglottic vallecula. Thorax CT showed multipl nodules which resembling pulmonary metastasis on both lungs. Patient underwent** F-18 FDG PET/CT imaging for diagnosis and staging. PET/CT imaging showed hypermethabolic focus on left aryepiglottic fold and interarytenoid area (SUVmax:8.9) which was not accompanied by anatomical finding. In addition, there were multipl hypometabolic nodules and hypermetabolic infiltrations (SUVmax:6) on both lungs and mildly hypermethabolic milimetric cervical lymph nodes. Second larengeal biopsy revealed a necrotising granulomatous inflammation suggesting tuberculosis. Mycobacterium tuberculosis PCR assay was also positive. Patient diagnosed lung and larengeal tuberculosis and antituberculosis medication was started. **Conclusion:** As a whole body scanning method, 18F-FDG PET/CT facilitates the dedection of extrapulmonary tuberculosis. Although it is a rare condition, extrapulmonary tuberculosis in head and neck should be kept in mind in differential diagnosis.

EP120

Role of 18F FDG PET-CT in restaging of patients with malignant salivary gland tumors: - experience at a tertiary care hospital

D. Malik, T. K. Jain, R. Kumar, A. Bhattacharya, A. Sood, B. R. Mittal; Post graduate institute of medical education & research, Chandigarh, INDIA.

Objective: Salivary gland tumors are rare neoplasms comprising about 0.5% of all malignancies and about 5% of head and neck cancers that have not been studied extensively with FDG PET/CT. The aim of present study was to assess the clinical utility of 18F-Fluorodeoxyglucose (^{18}F-FDG) positron emission tomography-computed tomography (PET-CT) for restaging patients with malignant salivary gland tumours.**Methods:** In this retrospective study we evaluated the data of 25 patients (Age: 44.9±23.2 years; male/female: 17/8) with histopathological proven malignant salivary gland tumor, who underwent ^{18}F-FDG PET-CT for restaging between August 2008 and September 2015. After restaging ^{18}F-FDG PET-CT majority of patients received chemotherapy (85%), followed by radiotherapy and surgery.^{18}F-FDG PET-CT images were reviewed by two nuclear medicine physicians in consensus who were blinded to all details except for primary diagnosis. Clinical/imaging follow up (minimum-12 months) with histopathology were taken as reference standard. **Results:** Of the 25 patients, 18 patients were presented with primary parotid tumors while 7 with submandibular gland tumours. All 25 patients underwent FDG PET/CT for restaging and found 19 (76%) were positive and 6 (24%) were negative for disease. FDG PET/CT detected locoregional disease in 18 (72%) patients and distant metastasis in four (16%) patients. In all four patients with distant metastasis, the lesions distribution was lung in 2/4 (50%) patients and brain and skeleton in one patient each. Seventeen FDG PET/CT were true positive, 5 were true negative, two were false positive and one was false negative. The overall sensitivity of ^{18}F-FDG PET-CT was 94.7% [95% CI: 73.9-99.8], specificity was 71.4 % [95% CI: 29.0-96.3], positive predictive value 90.0% [95% CI: 68.3- 98.7] negative predictive value 83.3% [95% CI: 35.8- 99.6] and accuracy was 94%. Additionally FDG PET/CT detected 2nd primary malignancy in two patients (lung and larynx in one each). **Conclusions:** We concluded that 18F-FDG PET/CT had high diagnostic accuracy for residual/recurrent disease in malignant salivary gland tumor patients and also useful in detection of additional metachronous second primary.

EP121

Efficacy of 11C-MET-PET/CT in the restaging of adenoid cystic carcinoma of head and neck

F. SCALORBI[1], A. Matti[1], G. Lima[1], S. Diodato[1], A. Iannalfi[2], M. Bonora[2], B. Vischioni[2], P. Castellucci[1], S. Fanti[1]; [1]S. Orsola-Malpighi Hospital-University of Bologna, Bologna, ITALY, [2]Centro Nazionale Adroterapia Oncologica, Pavia, ITALY.

Aim: The aim of this retrospective study was to evaluate the role of 11C-MET-PET/CT (MET-PET) in the restaging of adenoid cystic carcinoma (ACC) of head and neck, after primary treatments (surgery, radiotherapy or both). **Materials and Methods:** Eleven patients (6 female, 5 male, mean age 60.5 years, range 23-79 years) underwent MET-PET, between May 2013 to November 2015, within 3.3 months from the last treatment (range 1-4; only one patient performed MET-PET after 14 months). Four of eleven (36%) were treated with Hadron Therapy, two (18%) with surgery and five (46%) with both therapies (surgery + Hadron Therapy). All the findings were validated by means of imaging and/or clinical follow up (FU) (mean value 9.8 months, range 3-20 months). MET-PET were evaluated visually by two experienced nuclear medicine physicians. MET-PET results were classified as positive, negative or doubt. SUV max was calculated but not used to achieve the final diagnosis. **Results:** MET-PET was positive in six (55%) of eleven patients, negative in four (36%) and doubt only in one case (9%). All the six positive cases were confirmed to be true positives (TP) by clinical and/or radiological FU. MET-PET Positive Predictive Value (PPV) was 100% for the localization of local relapse and for the detection of lateral-cervical lymph-nodes metastasis. In one of these cases MET-PET showed an increased uptake in temporal lobe, that was confirmed to be positive during FU. Four cases were negative on MET-PET, two of these were True Negative and two were False Negative (FN). The first FN case had local progression of disease after one year of FU. We consider this as typical long-term evolution that characterized this disease. The second FN patient showed faint uptake misinterpreted as post-actinic reaction but consistent with progression of disease, as confirmed three months later by FU. MET-PET was doubt in one patient, were it was not possible to distinguish between post surgical changes and persistence of disease. Finally we would like to underline that, in our small population, we didn't note any correlation between time elapsed from the end of primary treatment and the accuracy of MET-PET. **Conclusions:** MET-PET showed an excellent PPV (100%) and a low NPV (50%) to restage ACC. This is partially in contrast with what is generally observed in other head and neck tumors. Further studies are needed in order to assess the potential clinical impact of MET-PET to restage ACC.

EP122

A novel, objective interpretation method for dual-phase Technetium 99m-sestamibi parathyroid scan, measuring the degree of asymmetric parathyroid activity on bilateral thyroid beds, aids preoperative localization of single parathyroid adenoma for minimally invasive parathyroidectomy

D. Kim, J. Rhodes, J. Hashim, L. Rickabaugh, D. Brams, E. Pinkus, Y. Dou; Lahey Hospital and Medical Center, Burlington, MA, UNITED STATES.

Aim: Primary hyperparathyroidism affects approximately 1 in 1,000 people in the general population. Approximately 80% of these cases can be attributed to solitary parathyroid adenoma. Given this high incidence of solitary adenoma, surgical and imaging communities have searched for an accurate preoperative localizing test to select patients for minimally invasive parathyroidectomy (MIP) in lieu of traditional four-gland exploration. We hypothesized that Tc99m sestamibi scan interpretation incorporating numerical measurements on the degree of asymmetrical activity on bilateral thyroid beds can be useful in localizing single adenoma for MIP. **Materials and Methods**: We devised a novel two-step interpretation method for dual-phase Tc99m sestamibi scan, based on the degree of asymmetrical activity on early phase images and dichotomized interpretation of washout on delayed images. To measure asymmetrical activity on early phase images, the numerical ratio value of each scan was obtained by dividing the number of counts from symmetrically drawn regions of interest (ROI) over bilateral thyroid beds. To validate our new method, 109 sestamibi scans–previously performed for primary hyperparathyroidism–were reinterpreted and correlated with their final

pathology. **Results**: Among the 109 cases, there were 85 instances of non-ectopic single adenoma (78.0%), 2 ectopic adenoma (1.8%), 11 hyperplasia (10.1%), 2 multiple adenoma (1.8%), 2 parathyroid carcinoma (1.8%), and 3 normal parathyroid glands (2.8%). Using the ratio values obtained for each scan as above, an empirical Receiver Operating Characteristic curve was obtained and the area under the curve (AUC) was calculated to be 0.71 (p=0.0032), validating this method as a diagnostic tool. Using Youden indices, the optimal cut-off point with maximal combined sensitivity and specificity was found with a corresponding sensitivity of 67.45% (56.48% to 77.16%, 95% CI) and a specificity of 76.2% (52.83% to 91.78%, 95% CI). An additional higher cut-off with higher specificity and minimum possible sacrifice on sensitivity was also selected, yielding a sensitivity of 27.91% (18.77% to 38.62%, 95% CI) and a specificity of 90.48% (69.62% to 98.83%, 95% CI). The addition of delayed phase information also improved the specificity for localization, but to a lesser degree than the degree of asymmetrical activity on the initial phase. **Conclusion**: Our results demonstrated that more asymmetrical activity on the initial phase corresponded with greater success in the localization of single parathyroid adenoma on sestamibi scans. Using high cut-off ratio value obtained from initial phase sestamibi scan images, we were able to select patients for minimally invasive parathyroidectomy with 90% specificity.

EP123

Increased Tc99m-labelled Somatostatin Analogue Uptake in a Lymph Node Metastasis of Squamous Cell Carcinoma in the Head and Neck Region. Presentation of an Unusual Case

Z. Varga[1], L. Jorgov[1], É. Remenár[2], M. Gödény[2], E. Takács[1], I. Szilvási[1], G. Dabasi[1]; [1]Semmelweis University, Budapest, HUNGARY, [2]National Institute of Oncology, Budapest, HUNGARY.

In our case report we present intensive uptake of Tc99m-EDDA/HYNIC-TOC in a histologically verified lymph node metastasis of squamous cell cancer in the neck region. This is a very rare finding. To our best knowledge only one similar case report has been published up to now. Case report: A 70 year old male patient was admitted because of recent enlarged lymph node without any inflammatory changes on the right side of the neck. MRI revealed abnormal soft-tissue mass on the neck close to the right submandibular gland. US guided FNA was inconclusive. Based on MRI examination diagnosis of a glomus tumor was suspected. We performed Tc-99m-HYNIC-EDDA-TOC scintigraphy using SPECT/CT. Increased uptake of radiopharmaceutical was seen in the soft tissue mass with a diameter of 30x27x25 mm without any other abnormal uptake on the whole body scan. After a repeated MRI examination surgical excision biopsy was performed in July 2013. Histological finding was lymph node metastasis of grade III basaloid type of planocellular cancer. By immunohistochemistry chromogranin, synaptophysin, S100 were negative. Looking for the primary tumor MRI and contrast-enhanced CT of the head and neck, thorax, contrast-enhanced CT of the abdomen, pelvic region and FDG PET/CT examinations, biopsy from the tongue root and from the right tonsil were performed. No primary tumor was found. Based on the decision of the onco-team, regional radiotherapy was applied to the right neck region. In the follow up of the patient until February 2015 no recurrence or any sign of progression were observed by repeated imaging methods. The primary tumor remained unknown. Discussion: To our best knowledge there are just a few report on abnormally increased uptake by somatostatin receptor scintigraphy in squamous cell carcinoma and only one report has been published in a patient with squamous cell cancer of the head and neck region. Up to present, basaloid cancer has not been on the indication list of somatostatin receptor scintigraphy. We plan to start a prospective study to evaluate the possible clinical usefulness of Tc99m-EDDA/HYNIC-TOC scintigraphy in patients with squamous cell tumors of the head and neck region.

EP124

Diagnostic and prognostic values of 18F-FDG PET-CT in the management of adenoid cystic carcinoma of salivary glands

G. Bera, R. De Laroche, G. Hervé, C. Bertoia, M. Bandini, M. Habert, A. Giron, C. Bertolus, A. Kas; Groupe Hospitalier Pitié-Salpêtrière, PARIS, FRANCE.

Aim Adenoid cystic carcinoma of salivary gland is the most commonly reported malignant tumor of the minor salivary glands and one of the most common cancers of the major salivary glands. The difficulty in its management lies on its unusual relentlessly growing characterized by perineural invasion and multiple local recurrences. Moreover, in contrast to regional node metastases, hematogenous spread is common especially to lung, bone and liver. Solid or high-grade histological type is considered to be more aggressive with relatively poor survival. Only one publication has reported the prediction of distant metastasis based on pretreatment SUV_{max} of the primary tumor. The purpose of this study is to demonstrate the diagnostic and prognostic values of PET-CT in the management of this tumor. **Methods** 14 patients (5 parotides, 2 sub-mandibulars, 7 minor salivary glands) including 5 high-grades had initial pretreatment PET-CT. SUV_{max}, MTV and TLG were measured on the primary tumor by 2 reviewers. Patients were classified into 2 groups reflecting their status, *better prognosis* (without any recurrence, n= 6) or *lower prognosis* (at least one recurrence to related death, n=8). Histological grading, status at last follow-up and follow-up duration were taken as gold-standard. **Results** Median follow-up period was 25 months (3-258). All PET-CT detected primary tumor and distant metastasis (n=6). Median time to first recurrence was 20 months (range 18-156) for 4 patients. Only 4 patients had nodal metastasis, 2 of them were not identified by PET-CT nor MRI and concerned a lymph-node fused to the tumor. SUV_{max} (median 5, range 2.8-14) was positively correlated with grading (high vs low cut-off 6.4, $p<0.001$) and the presence of a solid pattern tumors > 30% (cut-off 5.4, $p<0.0002$). MTV (median 6.6, range 1.7-89) and TLG (median 31.5, range 3.6-206) separated correctly the 2 groups, cut-off 6.1 ($p<0.01$) and 19.6 ($p<0.05$) respectively and showed a non significant trend to negative correlation with follow-up duration ($p=0.07$). The distinction between *better prognosis* group and patients dead of disease (n=3) was in particular well defined with MTV and TLG, cut-off 16.8 ($p<0.0007$) and 45.4 ($p<0.003$) respectively. **Conclusion** This study supports the high diagnosis value of 18F-FDG PET-CT for adenoid cystic carcinoma of the salivary glands by detecting primary tumors and metastasis in all cases, with only 2 false negative findings for lymph-nodes fused to the primary tumor. In addition PET parameters of primary tumors such as SUV_{max}, MTV and TLG could be used as prognostic factors.

EP125

Functional vs morphological imaging in nasopharyngeal carcinoma : What agreement ?

S. Touil, H. Bendaoud, Y. Shimi, J. Benouhoud, H. Aschawa, A. Guensi; CHU IBNOU ROCHD OF CASABLANCA, Casablanca, MOROCCO.

Morocco is a country with intermediate risk of nasopharyngeal cancer with an incidence of 5 cases per 100,000 inhabitants per year. The diagnosis is often delayed in our context. Indeed locally advanced and metastatic forms represent 66.5% of cases according to the register of the cancers of Casablanca of 2007. The positron emission tomography (PET-CT) is now the investigation of choice for their staging .We conducted a prospective study spread from January 2013 to December 2015 for 19 patients followed for nasopharyngeal cancer T3 T4 N +,who having benefited PET-CT: 10 in the initial balance sheet and 9 at the time of local

recurrence. The aim of our study was to evaluate the correlation between PET-CT and morphological imaging (MRI and / or nasopharyngeal CT; Assessment of extension including thoraco-abdominal CT and bone scan) in the determination of the lymph node and metastatic status and its impact on the therapeutic strategy.70% of patients who underwent PET during the initial assessment had nodal involvement (10% N1, 50% N2 and N3 10%) against 60% in morphological imaging (20% N1, N2 30% and 10% of N3) .For the evaluation of distant metastasis, 10% of patients were metastatic at PET (lung metastases) versus 0% on morphological imaging.Among the nine patients who underwent a PET with local recurrence, 55.6% had cervical lymph node recurrence associated (against 22.2% for MRI nasopharyngeal) and 22.2% distant metastasis. No patient received thoraco-abdominal CT at the recurrence.PET-CT allowed the change of the therapeutic strategy concerning the lymph node status in 37% (14% in the initial assessment and 59.5% in local recurrence). It must be applied routinely before each recurrence of nasopharyngeal carcinoma and before all locally advanced tumors at the initial evaluation time

EP126

FDG PET/CT in staging of head and neck carcinoma and for detecting synchronous tumors and distant metastases

T. Yordanova, Anelia Klisarova, Pavel Bochev, Borislav Chaushev,Zhivka Dancheva; MBAL St Marina, varna, BULGARIA.

im: The role of PET-CT imaging in head and neck squamous cell carcinoma during pre-treatment staging, radiotherapy planning, treatment response assessment and post-therapy follow-up is reviewed with focus on current evidence, controversial issues and future clinical applications. Second primary tumors are notably the first cause of death with a decisive impact on overall survival rates of early stage HNSCC patients. In staging, the role of ^{18}F-FDG PET-CT is well recognized for detecting cervical nodal involvement as well as for exclusion of distant metastases and synchronous primary tumors. Accurate diagnosis of tumor extent is important. It is real advantage of early detection of distant metastases in asymptomatic patients. Materials: We describe a case of 54 years old man with pain in his throat from several months. After clinical examination, endoscopy and biopsy in the left region of oropharynx, the histopathology report revealed squamous cell carcinoma. The patient came in our department for pre-tretment staging before radiotherapy. Methods:^{18}F-FDG PET-CT performed at pre-treatment staging a patient with carcinoma of left tonsil and root of the tongue. Whole body PET-CT shows intense ^{18}F-FDG uptake of the primary tumour as well as lot of lateral cervical lymph nodes. PET/CT demonstrated a tumor mass in the left kidney with high uptake and osteolitic lesion with soft tissue component in proximal femur with high glucose metabolism in the surrounded muscles. The conventional contrast CT of abdomen founded a tumor on the left kidney. After one week the patient underwent orthopedic surgery of right femur- hip replacement. Histopathological report establish metastasis in bone and femoral muscles from renal cell carcinoma. Then the patient was scheduled for surgery on the kidney and followed radiotherapy of the primary tumor in head and neck. Conclusion: Second primary tumours (SPTs) can occur in 5-10% of HNSCC patients and are more frequent in the head and neck region, oesophagus and lungs. We presented an interesting clinical case in patient with HNSCC and second primary tumor of the renal. In this context, a high accuracy of ^{18}F-FDG PET-CT for detection of distant metastasis and synchronous tumors, has been clearly demonstrated. Moreover, in approximately 13% of cases the improvement in detection of distant lesions leads to a change of management with important consequences for patient survival.

EP127

Diagnostic Value of 18F-FDG PET/CT in Patients with Cervical Lymph Nodes Metastases of Unknown Primary

J. A. Marroquín Gálvez, A. Saviatto, E. Martínez Albero, A. C. Hernandez Martinez, J. P. Pilkington Woll, S. Ruiz Solis, P. Sarandeses Fernandez, A. Gomez Grande, J. M. Estenoz Alfaro; 12 de Octubre University Hospital, Madrid, SPAIN.

OBJECTIVE 18F-FDG PET/CT is an essential tool in the initial and post-treatment evaluation of head and neck tumors, with an important role in the detection of occult primary tumors. The aim of this study was to determine the diagnostic value of 18F-FDG PET/CT in patients with cervical lymph node metastases of unknown primary. **METHODS** Retrospective study of patients with cervical lymph node metastases of unknown primary after endoscopic/physical examination and/or CT (contrast-enhanced CT of neck, thorax and abdominal was performed in 14/20 patients), in which 18F-FDG PET/CT was performed, between October 2009 and March 2015. A total of 20 patients were included, 18 men and 2 women, with age ranging from 45-80 years (mean 63.35 ± 9.77), history of smoking (18/20) and alcoholism (11/20). Pathological study of cervical lymph nodes were consistent with squamous cell carcinomas (17) and undifferentiated carcinomas (3). **RESULTS** The primary tumor detection rate of 18F-FDG PET/CT was 40%, finding the primary tumor in 8/20 patients: hypopharynx 4, nasopharynx 2, supraglottis 1 and oropharynx 1. In one patient PET/CT was false positive in the nasopharynx, without evidence of malignancy on the biopsy. PET/CT was negative in 11/20 patients, in 2 of these the primary tumor was detected during follow-up (cutaneous squamous cell carcinoma in pinna and bladder urothelial carcinoma). Finally 10 patients remained with diagnosis of unknown primary tumor. 18F-FDG PET/CT change the N staging in 6/14 patients with contrast-enhanced CT of neck: N1 to N2b (2), N2b to N2c (1), N2b to N3 (2) and N2c to N3 (1). PET/CT did not detect distant metastases in any patient, but found two synchronous tumors (colonic adenocarcinoma and carcinoma of the gastroesophageal junction). The obtained sensitivity, specificity, positive predictive value, negative predictive value and accuracy rates for the detection of the primary tumor were: 80%, 90%, 88.89%, 81.82% and 85%, respectively. **CONCLUSIONS** 18F-FDG PET/CT is a valuable tool in the detection of primary tumors in patients with cervical lymph node metastases of unknown origin. Its ability to improve node staging and detect distant metastasis or synchronous tumors can influence treatment management.

EP128

Hypertrophic osteoarthropathy linked to pulmonary metastasis secondary to undifferentiated nasopharyngeal carcinoma, an insight from bone scintigraphy and 18F-FDG PET/CT imaging

E. Fiasconaro[1], G. Aghakhanyan[1], E. Biasco[2], E. Papucci[1], C. Malvezzi[1], I. Paglianiti[1], M. Grosso[1], L. Galli[2], D. Volterrani[1]; [1]Regional Center Nuclear Medicine, PISA, ITALY, [2]Oncology Unit 2, University Hospital of Pisa, PISA, ITALY.

AIM Secondary hypertrophic osteoarthropathy (HO), also known as Pierre Marie-Bamberger syndrome, is a rare condition commonly associated with broncogenic malignancies. Extrathoracic causes are less frequent. Periostitis is the hallmark of HO and is accompanied with burning pain, swelling of limbs and clubbing of distal phalanges. The bone scan and clinical manifestations usually unveil the HO, nevertheless, atypical presentations my occur. Herein, we presented a rare case of HO due to progression of pulmonary metastatic disease secondary to nasopharyngeal carcinoma that underwent into comprehensive diagnostic work-up with bone scintigraphy and whole-body18F-FDG PET/CT imaging. MATERIALS AND METHODS A 69-years old woman referred to our center for bone scintigraphy due to diffuse pain in her upper and lower extremities last 8 weeks. Patient had a history of undifferentiated

nasopharyngeal carcinoma (cT3N1M1), treated 3 years ago with radiotherapy. Despite initial good response and post-treatment remission, two years follow-up revealed radiological and histopathological evidence of the disease dissemination with pulmonary and mediastinal lymph-nodes metastases. A chemotherapy has been initiated. The response evaluation one month post-treatment revealed metastatic disease progression. The patent developed overt pain involving the extremities and light clubbing. A bone scan using technetium hydroxymethane diphosphonate (99mTc-HDP) was performed. To restage the disease and corroborate the scintigraphic finding a whole-body 18F-FDG PET/CT was obtained. RESULTS The 99mTc-HDP bone scan showed bilateral patchy linear uptake along cortical margins of diaphysis of tubular bones both upper and lower extremities ("tramline" sign) with increased periarticular uptake on both sides. Whole-body 18F-FDG PET/CT, in comparison to previous PET study, revealed multiple new pulmonary mass lesions and widespread mediastinal lymphadenopathy with no recurrence of primary disease. Moderately increased periosteal FDG uptake was observed in the long bones of the upper and lower extremities. In line with mild soft tissue swelling in distal portion of the fingers (clubbing), the patient was diagnosed with secondary HO. CONCLUSION The intrinsic features of HO, such as clubbing, pain and periostitis of the long bones are well known, nonetheless, the pathogenesis of HO is still unclear. We reported a case of secondary HO in a patient with history of undifferentiated nasopharyngeal carcinoma, which draws a causal link between development of secondary HO and progression of pulmonary metastatic disease, but not with primary tumor. Occasionally, the bone scan might be misleading in atypical presentations or advance stages of underlying disease, thus 18F-FDG PET, elucidating the inflammatory nature of HO, may assist in diagnostic controversies.

EP129

Parathyroid Carcinoma: Clinical Cases with a favourable Outcome

S. Kusacic Kuna, H. Tomic Brzac, G. Horvatic Herceg, D. Huic; Clinical Department of NUclear Medicine, Zagreb, CROATIA.

OBJECTIVES: Parathyroid carcinoma is a rare endocrine malignancy which usually secrete parathyroid hormone (PTH), thereby producing hyperparathyroidism. The majority of carcinomas are sporadic, but rare forms of genetic hyperparathyroidism-jaw tumor syndrome with mutations in the *HRPT2* gene are also reported. The etiology of cancer remains unknown, it could be associated with a history of neck irradiation, but some autors suggest long-standing secondary hyperparathyroidism as a provoking factor of disease. PATIENTS AND METHODS: The aim of report is to present a cases of a patients with favourable outcome of parathyroid cancer, with comparing the clinical and pathohistologic findings of each patient. The study included three female patients (mean age 51 years) with primary hyperparathyroidism due to parathyroid carcinoma managed at the Clinical Department of Nuclear Medicine during 5 years. All of them exibit symptomatology of hypercalcemia at presentation with high levels of PTH, and two of them have previous anamnesis of multinodular goiter. All of them had renal impairment with significantly reduced bone density, and one of them has typical „brown" tumours involving the long bones of the extremities. Patients underwent to surgery after improving of calcium laboratory results with adequate hydration, diuretics and bisphosphonates administration and after the amelioration of the general state. Preoperative imaging techniques such as neck ultrasound and 99mTc sestamibi scan help to localize disease, ultrasound-guided fine needle-aspiration biopsy (US-FNAB) revealed suspected cells in two of patients, but the definitive diagnosis was established only on the basis of patohistological preparations. The imaging material with a demographic data and histopathological features of the tumor are presented. RESULTS: All of patients experienced long-term remission after the surgery with normalization of laboratory parameters as serum PTH and calcium levels. The brown tumors in one patient required no additional surgical treatment. CONCLUSION: A parathyroid carcinoma is a rare form of endocrine cancer that sometimes could be difficult to diagnose preoperatively due to clinical features shared with benign causes of hyperparathyroidism. Complete surgical resection is the recommended treatment and offers the best chance of cure, although persistent or recurrent disease occurs in more than 50% of patients.

EP-08 – Sunday, October 16, 2016, during Exhibition hours, e-Poster Area
Clinical Oncology: Liver, Upper GI & Pancreatic Cancer

EP130

Ultra-High Definition Digital PET for Hepatic Malignancies and Metastases

J. Zhang[1], C. L. Wright[1], A. Siva[1], P. Bhatia[1], K. Binzel[1], C. Tung[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Philips Healthcare, Cleveland, OH, UNITED STATES.

Purpose: To evaluate if FDG PET imaging of the liver can be qualitatively improved within whole-body acquisitions by using an ultra-high definition (UHD) reconstruction approach with 1mm^3 voxel volume enabled by digital PET technology and compare the findings to current clinical reconstruction, standard definition (SD) of 64 mm^3 voxel volume PET. **Materials and Methods:** Imaging was performed on a pre-commercial release, digital photon counting PET/CT system (Vereos, Philips) (dPET). 12 clinical patients receiving ^{18}F-FDG whole-body dPET with a target dose of 480 MBq that had demonstrated hepatic lesions were included in this evaluation. A total of 79 hepatic lesions were identified and included in this assessment. dPET imaging was reconstructed in both traditional SD 4mm voxel length and investigational UHD 1mm voxel length using the 3D OSEM TOF algorithm. While the system default OSEM number of subsets was 29, we performed reconstructions with a range of subsets (S=1, 5, 9, 13, 17 and 25) leaving the number of iterations fixed at 3. ROIs were placed on normal liver background and the hepatic lesions. SUV, SNR and normal liver parenchyma uniformity were quantitatively measured with penalty scores from 1-10 being assigned based on noise levels. Blinded image reviews were performed by experienced readers. **Results:** Refining the reconstruction from the traditional SD 4mm to the investigational UHD 1mm led initially to increased noise in normal liver parenchyma with visible blobby liver texture when the default number of subsets was used. Subsequently, the assessment found that the optimal number of subsets was 17 for 4mm SD reconstruction and 9 for 1mm UHD. With the reduced number of subsets the overall image quality improved and led to an increased confidence level for lesion detection. The quantitative assessment showed that liver background noise was reduced by 56±8% for the UHD recon when changing from S=29 to S=9. Correspondingly, normal liver parenchyma uniformity was improved by 60±8%, while lesion SUV_{max} remained equivalent ($p<0.01$) and a significantly improved SNR by about 2x. We found a variability that led to the concept of a BMI adaptive # of subset approach where (BMI>28) benefited from even lower # of subsets (S=7). **Conclusion:** Ultra-high definition reconstruction was demonstrated to be feasible for FDG dPET after optimization and appears capable of considerably improving the detectability and characterization of hepatic lesions as well as the diagnostic confidence.

EP131

Role of FDG-PET/CT in Suspected Gallbladder Cancer: Preliminary Results

A. Sabaté-Llobera[1], L. Gràcia-Sánchez[1], J. Mestres-Martí[1], G. Reynés-Llompart[1], J. L. Vercher-Conejero[1], E. Llinares-Tello[1], L. Lladó-Garriga[2], T. Serrano-Piñol[3], E. Ramos-Rubio[2], C. Gámez-Cenzano[1]; [1]PET Unit, Department of Nuclear Medicine - IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona),

SPAIN, [2]Department of Surgery. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN, [3]Department of Pathology. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN.

AIM: Gallbladder cancer is an uncommon, fatal malignancy, sometimes found incidentally in image examinations. Our objective was to evaluate the additional information from FDG-PET/CT in patients with suspected gallbladder cancer based on clinical presentation, tumor markers (CA19-9) or conventional imaging (CT and MRI). **MATERIAL AND METHODS:** Whole-body FDG-PET/CT was performed in 22 patients (12 men, median age 68.5 years) with clinical/radiological suspicion of gallbladder cancer. FDG uptake in the gallbladder was assessed both visually (positive when higher than liver activity) and semiquantitatively (SUVmax and lesion-to-normal-hepatic-activity ratio (L/NHA)). We analysed the correlation between semiquantitative parameters and CA19-9 with definitive diagnosis (benign/malignant) based on histopathological findings or follow-up (9-40 months). **RESULTS:** Histopathology and CA19-9 levels were available in 15/22 and 20/22 patients respectively. Globally, median SUVmax and L/NHA in the suspected lesion were, respectively, 3.7 (1.1-15.3) and 1.14 (0.34-6.12). Visually 10/22 patients (45%) were PET-negative, with median SUVmax 1.8 and median ratio L/NHA 0.53, and were interpreted as benign findings. In the 12/22 PET-positive patients (55%), median SUVmax and L/NHA ratio were 8.5 and 2.66, respectively; all except one were interpreted as malignant. Surgery was performed in 15/22 patients (68%); 7 patients were not operated and follow-up confirmed bening lesions (adenomyomatosis). Of the 11 patients interpreted as benign, four were operated: 3 showed chronic cholecystitis and one an adenocarcinoma; the remaining 7 patients had adenomyomatosis. The 11 patients interpreted as malignant in the PET/CT were all operated: 10 had neoplastic lesions, while one had chronic inflammation. Sensitivity, specificity, positive and negative predictive values, and accuracy of FDG-PET/CT are 91%. In 5/20 patients (25%) CA19-9 levels were increased (72.3-3060 U/ml), all with histologically proven malignant lesions. However, 6/11 (54%) patients with gallbladder cancer had normal CA19-9 (<37 U/ml). Malignant lesions had significantly higher SUVmax and L/NHA ratio than benign disease (p<0.05). When correlating the ratio L/NHA with histological results, logistic regression showed a perfect segregation (100% specificity) between benign and malignant pathology at a cut-off of 1.2. When analysing the correlation SUVmax-histopathology we found a cut-off of 5.4 to distinguish between benign and malignant lesions (probablility of 90%). Moderate-low correlation was observed between CA19-9 levels and histopathology (φ=0.53). **CONCLUSIONS:** Despite the small number of patients, FDG-PET/CT seems to be a good technique to differentiate between benign and malignant lesions of the gallbladder. The ratio L/NHA shows better results than SUVmax, and both metabolic parameters have a better correlation with histology than CA19-9.

EP132

Clinical Impact of PET/MRI Dosimetry after Radioembolization

P. J. Parikh, N. Maughan, A. Weiner, K. Fowler, R. LaForest, N. Saad; Washington University School of Medicine, Saint Louis, MO, UNITED STATES.

Aim: To measure clinical changes in management after the implementation of Y-90-PET dosimetry Methods: Patients were scanned on the Biograph mMR (Siemens, Erlangen, Germany) within 36 hours of Y-90 radioembolization based on patient and scanner convenience. 20-40 min of PET data were acquired in a single station to cover the liver. Key MR sequences used were a 2-point DIXON for attenuation correction, dynamic arterial post-gadolinium contrast VIBE for hypervascular lesions, and delayed post-gadoexetate contrast VIBE for hypovascular lesions. PET images were reconstructed with 3 iterations, 21 subsets, 172 x 172 matrix, post-processing Gaussian filter of 5 mm in full width at half maximum, and with resolution recovery, resulting in a voxel size of 4.17 x 4.17 x 2.02 mm. Individual lesions were segmented on the appropriate MR image, and then lesion specific dosimetry was calculated on a commercial software package with the dose-point kernel method (SurePlan, MIM Software, Cleveland, Ohio). Dosimetry was calculated on a per-voxel basis, and the Davg (average dose to the tumor) and the D70 (dose to 70% of tumor) were calculated off the dose-volume histogram for each segmented lesion. Results: 12 reports have been generated for 11 patients with primary or metastatic liver cancer since January 2016. Seven patients received resin microspheres (.8-1.5 GBq, body surface area calculation) and 4 patients received glass microspheres (107-309 Gy, infused volume calculation). Two patients, with greater than 20 metastatic lesions from neuroendocrine or colorectal cancer, did not have the dosimetry completed due to the workload required. 29/42 lesions in the remaining patients showed adequate D70 or Davg based on recent publications in Y-90 PET dosimetry. Dosimetric results prompted changes in therapeutic management in 4 patients. Three patients (2 colorectal cancer, 1 hepatocellular carcinoma) received immediate salvage radiation therapy to 1-3 unexpected under-dosed lesions in the area of the radioembolization. The 4th patient received radioembolization by an experienced interventional radiologist (> 100 cases) to the left lobe for biphenotypic liver cancer. The catheter tip was in the left hepatic artery on radiograph prior to administration. However, post-treatment PET/MRI noted most of the dose going to the right lobe. This patient is being observed for liver toxicity and further liver directed therapy is postponed. Conclusion: Post-treatment radioembolization dosimetry resulted in changes to patient management in a third of patients, both in detecting lesions that are under-dosed and with a significant administration change as compared with intended treatment.

EP133

Quantitative FDG-PET parameters for the assessment of patients with oesophageal and gastrooesophageal carcinoma

E. Cong[1], M. Lee[1,2,3], A. Chicco[4], M. Lin[1,4,2], J. Yap[5], P. Lin[1,5,2], T. Tran[3], I. Ho-Shon[1,5,2]; [1]University of New South Wales, Sydney, AUSTRALIA, [2]Western Sydney University, Sydney, AUSTRALIA, [3]Cancer Therapy centre, Liverpool Hospital, Sydney, AUSTRALIA, [4]Department of Nuclear Medicine and PET, Liverpool Hospital, Sydney, AUSTRALIA, [5]Department of Nuclear Medicine and PET, Sydney, AUSTRALIA.

Aim: To assess the prognostic value of quantitative FDG-PET parameters collected before and after definitive or neoadjuvant radiotherapy and/or chemotherapy in patients with newly diagnosed oesophageal or gastro-oesophageal junction carcinoma. *Methods:* Ninety seven patients with endoscopically confirmed oesophageal or gastro-oesophageal junction carcinoma treated with definitive or neoadjuvant therapy received pre-treatment FDG-PET/CT scans, and of these, sixty seven received post-treatment FDG-PET/CT scans. Quantitative parameters (maximum standardized uptake value: SUVmax, mean standardized uptake values: SUVmean, metabolic tumour volume: MTV, and tumour lesion glycolysis: TLG) were obtained for both pre and post-treatment scans which were then used to derive absolute and percentage changes in these parameters. Cox regression was used to analyse the relationship between parameters and survival. ROC curves and log-rank analysis were used to identify optimal thresholds. *Results:* On multivariate analysis all post-treatment and percentage changes in quantitative FDG-PET/CT parameters were significant prognostic factors for overall survival (OS) and progression free survival (PFS) (e.g. post-treatment SUVmean, HR = 2.231, $p < 0.001$ for OS; percentage change in MTV, HR = 1.003, $p = 0.013$ for OS) whilst no pre-treatment parameters were significant prognostic factors. Patients with post-treatment SUVmean < 3 had median OS of 53.3 months

compared to 15.2 months for SUVmean >= 3 and patients with a reduction in MTV of 96% or more had median OS of 56 months compared to 15.1 months for patients with a reduction in MTV of less than 96%. *Conclusion:* Post-treatment quantitative parameters can be used to assess prognosis in patients with oesophageal or GOJ cancer undergoing curative therapy. Percentage change in parameters can be used to potentially assess for treatment response to guide subsequent management.

EP134

Potential prognostic value of ^{18}F-FDG-PET/CT imaging in patients with esophageal cancer using metabolic and anatomical parameters—exploratory analysis of retrospective data from 40 patients

T. S. Nakuz[1], B. Wallner[1], W. Wadsak[1], P. Anner[1], B. Fueger[2], A. Haug[1], M. Hacker[1], G. Karanikas[1]; [1]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Vienna, AUSTRIA, [2]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Radiology, Vienna, AUSTRIA.

Aim of the study: The objective of this study was to determine the prognostic value of relative changes in SUV_{max} , HU, size of the primary lesion by tumor length, and wall thickness obtained by ^{18}F-FDG-PET/CT to predict overall survival in patients with esophageal cancer. **Materials and Methods:** In this retrospective study, 40 patients (33 males and 7 females) 30 to 80 years of age (mean age, 61 years) were included. All patients underwent a pre-treatment ^{18}F-FDG-PET/CT-scan and a second scan before esophagectomy. For statistical evaluation, the median decrease in SUV_{max}, HU, length, and wall thickness of the primary lesion in patients was dichotomized using the median observed value. Overall survivals were computed by Kaplan-Meier method and then compared between the two groups. The significance of prognostic variables for outcome was calculated by the log-rank test. **Results:** The average timespan between the two scans was 89 days (42 to 286 days). Twenty-nine patients received chemotherapy, nine received radio-chemotherapy, and two received radiotherapy. The median decrease of SUV_{max} was 37% (range, an increase of 94% to a decrease of 89%). The two-year overall survival showed a significant difference for patients with a less than 37% decrease in SUV_{max}, at 55%, than for patients with a greater than 37% decrease, at 80% (p=.005). For HU, the median decrease was 4%; thus, the two-year overall survival for patients with a decrease under 4% was 60%, and for patients with a HU decrease higher than the median, 73.7% (p=.340). The median decrease in the length of the primary tumor was 8%. The two-year survival of patients with a lower than median decrease was 47.4% and 83.3% with a higher than median decrease (p=.014). The median decrease in the thickness of the primary tumor was 30%. The two-year overall survival for patients was 55% with a less than 30% decrease in the thickness, and 80% for patients with a greater than 30% decrease (P=.084). **Conclusion:** Based on our results, a combination of a functional variable, represented by SUV_{max}, and an anatomical variable, such as the length of the primary tumor, could provide an even more precise prognostic appraisal of outcome for patients with esophageal carcinoma.

EP135

Whole body 18F-FDG PET/TC in comparison with CECT in the TNM evaluation in patients with suspected esophageal carcinoma recurrences

C. Altini, **A. Niccoli Asabella**, A. Di Palo, V. Lavelli, V. Loseto, C. Ferrari, G. Rubini; Nuclear Medicine Unit, D.I.M. – University of Bari "Aldo Moro", Bari, ITALY.

Aim: To evaluate the role of whole body 18F-FDG PET/CT and CT with contrast enhancement (CECT) in the TNM evaluation of patients (pts) with suspected recurrent esophageal cancer. Materials and Methods: 33 18F-FDG PET/CT were performed in 33 pts (27 males and 6 females; median age 58 years old, range 45-80 years). 22/33 pts previously underwent surgery and chemotherapy, 6/33 pts underwent only surgery and 5/33 pts underwent chemotherapy and radiotherapy. Both the techniques were performed at least 6 months after the end of therapy. All CECT were performed within 30 days from the 18F-FDG PET/CT. The results of 18F-FDG PET/CT and CECT were compared with clinical and instrumental follow-up of at least six months and with histology in pts who underwent subsequent surgery. Sensitivity (Se), specificity (Sp), diagnostic accuracy (DA), Positive Predictive Value (PPV) and Negative Predictive Value (NPV) of the two methods were calculated. The two techniques were compared with the McNemar test. Results: Concerning the T parameter, 18F-FDG PET/CT and CECT resulted positive both in 10/33 (30.3%) pts. Se, Sp, DA, PPV and NPV of 18F-FDG PET/CT and CECT were respectively 82%, 95%, 91%, 90%, 91% and 73%, 91%, 85%, 80%, 87%; no statistical difference between the two techniques was observed (p=0.723). Concerning the N parameter, 18F-FDG PET/CT resulted positive in 9/33 (27.3%) pts and CECT resulted positive in 6/33 (18.2%) pts. Se, Sp, DA, PPV and NPV of 18F-FDG PET/CT and CECT were, respectively, 100%, 89%, 91%, 67%, 100% and 50%, 89%, 82%, 50%, 89%; no statistical difference between the two techniques was observed (p=0.505). Concerning the M parameter, 18F-FDG PET/CT resulted positive in 8/33 (24.2%) pts and CECT resulted positive in 9/33 (27.3%) pts. Se, Sp, DA, PPV and NPV of 18F-FDG PET/CT and CECT were respectively, 75%, 92%, 88%, 75%, 92% and 75%, 88%, 85%, 67%, 92%; no statistical difference between the two techniques was observed (p=1.000). Conclusions: The two techniques demonstrated an optimal performance in whole body staging of patients with suspected esophageal cancer recurrence. Even if there is not differences statistically significant between them, 18F-FDG PET/CT resulted better then CECT especially in the T parameter evaluation. Analysis of more numerous samples is necessary to refine these results.

EP136

Recommendations for radioembolization after liver surgery using yttrium-90 resin microspheres: an international consensus panel report

M. Samim[1], L. M. van Veenendaal[1], M. N. G. J. Braat[1], R. van Hillegersberg[1], S. Gómez-acebo[2], Y. Kao[3], D. Liu[4], J. D. Louie[5], D. Y. Sze[5], S. C. Rose[6], D. B. Brown[7], H. Ahmadzadehfar[8], E. Kim[9], M. A. A. J. van den Bosch[1], M. G. E. H. Lam[1]; [1]University Medical Center Utrecht, Utrecht, NETHERLANDS, [2]Clinica Universidad de Navarra, Pampola, SPAIN, [3]Cabrini Hospital, Melbourne,, AUSTRALIA, [4]Vancouver General Hospital, Vancouver, BC, CANADA, [5]Stanford University Medical Center, Stanford, CA, UNITED STATES, [6]University of California, San Diego, San Diego, CA, UNITED STATES, [7]Vanderbilt Cancer Center, Nashville, TN, UNITED STATES, [8]University Hospital Bonn, Bonn, GERMANY, [9]Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES.

Introduction: For radioembolization (RE) using yttrium-90 (^{90}Y) resin microspheres (SIR-Spheres®, Sirtex, Sydney, Australia), the Body Surface Area (BSA) method is commonly used for calculation of the prescribed activity. Guidelines on how to adjust activity in patients with a history of liver resection are lacking. The primary aim of this study was to draw recommendations on activity planning for resin microsphere RE in patients with a previous history of liver surgery, based on clinical data and expert consensus. Material and Methods: Patients with a history of liver surgery undergoing ^{90}Y RE with resin microspheres between February 2009 and July 2015 were selected. Data on patient, disease and procedure characteristics were collected from the electronic medical records. The

mean absorbed dose across the target arterial territory (D_{Target}) was retrospectively calculated for each patient. In case of an available post-treatment ^{90}Y-PET/CT scan, the absorbed dose in the healthy liver tissue (D_{HL}) was also calculated. The dose-toxicity correlations were investigated for D_{Target} and D_{HL}. For evaluation of current expert opinion in activity reduction in the context of prior liver surgery, six representative post-surgical patients were selected and presented to ten international experts in the field of ^{90}Y RE. Results: A total of 43 patients were included. Activity reduction (range 20-50% decrease or target dose of 50 Gy) occurred in seven patients (16%), with surgery reported as a reason for dose reduction in five out of seven. There was a significant correlation between D_{Target} and D_{HL} (R^2=0.293; P=0.004), but a dose-toxicity correlation was only found for D_{HL} (R^2=0.408; P=0.001). Recommendations on activity reduction for the six presented patients were highly variable between the members of the expert panel. Across all presented cases, the desired D_{Target} advised by the expert panel members varied between 18-55 Gy. Activity reductions were recommended by the expert panel 40 times (67%); small liver remnant volume was the most common reason for recommending activity reduction (24 times, 37%). Conclusion: Although resin microsphere ^{90}Y RE could be safe in the majority of post-surgical patients, caution should be taken when using the BSA method for activity prescription because it does not account for the decreased remnant liver volume. Alternatively, a possible approach might be to use D_{Target} ≤50 Gy as an interim guide, until dose-toxicity relationships using D_{HL} have been explored in further radiobiological detail.

EP137

Restaging of pancreatic cancer: clinical and prognostic value of FDG PET/CT

P. Alongi[1], D. Familiari[2], V. Trono[3], S. Pulizzi[1], R. Gentile[4], S. Russo[2], A. Ruggeri[2], M. Fornito[2], M. Midiri[5]; [1]San Raffaele G.Giglio Institute, Cefalù, ITALY, [2]A.R.N.A.S GARIBALDI - Nesima, Catania, ITALY, [3]University of Milano-Bicocca, Milano, ITALY, [4]University of Messina, Messina, ITALY, [5]University of Palermo, Palermo, ITALY.

Aim: The aim of this retrospective study, through a collaboration between San Raffaele G.Giglio Institute (Cefalù,Italy) and ARNAS Garibaldi (Catania,Italy), was to evaluate the clinical and prognostic impact of FDG-PET/CT in the restaging process of pancreatic cancer. **Materials and Methods:** data from 52 patients (pts) treated for primary pancreatic cancer, who underwent FDG-PET/CT for suspicious of recurrent disease were collected. Accuracy was assessed employing conventional diagnostic procedures, multidisciplinary team case notes, further PET/CT scans and/or follow-up. ROC curve and likelihood ratio (LH+/-) analysis were used for completion of accuracy definition. Progression-free survival (PFS) and overall survival (OS) were assessed by using Kaplan-Meier method. The Cox proportional hazards model was used to identify predictors of outcome. **Results:** sensitivity, specificity, positive predictive value, negative predictive value and accuracy of FDG-PET were 85%, 84%, 90%, 76%, 84%. AUC was 0.84 (95%IC 0.72-0.96; p<0.05). LH+ and LH- were 5.3 and 0.17 respectively. FDG-PET/CT findings influenced significantly the therapeutic management in 30% of pts revealing new metastatic foci in 5 pts and excluding suspicious lesions in 11 pts. Analysis of PFS revealed FDG-PET/CT positivity to be associated with a worse cumulative survival rate over a six months (6m) and 12 months (12m) period in comparison to FDG-PET/CT negativity (6m-PFS 63% vs 95%, p<0.05; 12m-PFS 43% vs 85%). Moreover, a negative study was associated with a significantly longer OS than a positive one (73% vs 14% after 2 years, p<0.05). In addition, a positive PET scan was associated with an increased risk of disease progression (HR=3.4; p<0.05) and an increased risk of death (HR:2.5 (p<0.05). **Conclusion:**FDG-PET/CT showed high diagnostic accuracy for restaging process of pancreatic cancer, proving also its potential value in predicting clinical outcome after primary treatment.

EP138

Added diagnostic and prognostic value of FDG PET/CT in assessment of nodal metastasis in high risk patients with GIST

E. El-kholy[1], G. El-Hennawy[1], H. Fathy[1], H. Moustafa[2], M. Maher[3]; [1]Nuclear medicine unit, National cancer Institute (NCI) Egypt, Cairo, EGYPT, [2]NEMROCK center, Cairo University, Egypt, Cairo, EGYPT, [3]Medical oncology departement, National cancer Institute (NCI) Egypt, Cairo, EGYPT.

Aim: to evaluate the role of FDG PET/CT in detection of nodal metastases in GIST and to assess its response pattern to imatinib therapy and prognosis. **Materials and methods:** 47 patients (23 female, 24 male, mean age: 49.2±12.7) with pathologically proven GIST in whom FDG PET/CT scan were retrospectively assessed. Nodal lesions analysis in total 66 PET/CT studies (18 pre-therapy and 48 follow up) scans during imatinib therapy were conducted in comparison to diagnostic CT. Pathological and clinical/radiological follow-up for 3-15 months duration served as standards of reference. **Results:** Lymph node (LN) metastasis is reported in 9 patients (19%), their mean age was 53.6±13.8. Stomach was the site of primary in 66.7% and spindle cell pathology was found in 7 among 9 patients (77.7%).The mean SUVmax value and size was 6.7 ± 4.5 and 2.7 cm (range,1-9 cm), respectively. All 9 patients had double and triple site of metastases (liver and/or peritoneal deposits). A total of 40 lymph nodes (29 abdominal and 11 mediastinal), (19 ones at pre-therapy staging) were detected. FDG PET/CT had higher sensitivity, specificity, and accuracy of 97%, 71%, and 93% versus 82%, 57%&78%; for diagnostic CT, with P-values of 0.35, 0.03 and 0.03; respectively. FDG PET/CT was true positive in 32 lesions (80%), compared to 27 lesions (67.5%) in diagnostic CT. FDG PET/CT showed false positive results in 2 nodal lesions (5%) that proved inflammatory in follow up. Finally 7 out of 9 patients with nodal metastases (77.7%) showed disease progression (1 patient died), compared to 3/13 patients (23%) with liver and/or peritoneal deposits without nodal metastases. **Conclusion:** In an incidence of 19%, lymph nodes metastasis is believed to be an adverse prognostic factor in patients with GIST. FDG PET/CT seems to be superior to diagnostic CT in nodal detection and assessment response to Imatinib therapy. **Key words:** FDG PET/CT, GIST, nodal metastases, Imatinib therapy, prognosis.

EP139

Differentiation of physiologic and pathologic uptake in histological proven pancreatic neuroendocrine tumours using 68Ga-DOTA-TOC PET/CT

A. Kroiss, C. Uprimny, L. Scarpa, L. Geraldo, L. Gruber, B. Neururer, I. Virgolini; Nuclear Medicine, INNSBRUCK, AUSTRIA.

Purpose We wanted to establish the range of ^{68}GaDOTATOC uptake in pancreatic neuroendocrine tumours (NET). This would allow differentiation between physiological uptake and tumourrelated somatostatin receptor (SST) expression in the pancreas (including the uncinate process). *Methods* 115 ^{68}GaDOTATOC PET/CT studies were performed in order to detect or exclude SST-expressing malignancy. Histopathology confirmed NET of the pancreas in 15 patients who underwent surgery after positive ^{68}GaDOTATOC PET/CT scan. Results: SUV_{max} (mean +/- standard deviation) values of ^{68}Ga-DOTA-TOC were 33.2 +/- 15.1 in three NET of the uncinate process, 57.9 +/- 67.6 in three NET of pancreas body and 47.2 +/- 39.7 in nine NET of the pancreas cauda. Significant differences in SUV_{max} between nonmalignant and malignant tissue was found for the pancreas cauda (p<0.03). At a cutoff value of 17.1 the specificity and sensitivity for differentiating tumors in the uncinate process were 92.0% and 100% (p<0.0001) and 92.5% and 88.9% (p<0.0001) for the cauda at a cutoff value of 12.0, respectively. A cutoff value of 14.4 was evaluated for the pancreas body, resulting in a specificity and sensitivity of 100%

($p<0.0001$), respectively. *Conclusion* ^{68}GaDOTATOC is an excellent tracer for the imaging of pancreatic NET expressing SST on the tumour cell surface. The noninvasive PET/CT approach by measurement of regional SUV_{max} offers important clinical information to distinguish between physiological and pathological somatostatin receptor expression, especially in the case of unclear anatomical correlation of the pancreas.

EP140

Evaluation of diagnostic value of TOF-^{18}F-FDG PET/CT in patients with suspected pancreatic cancer

S. Stanzel[1], F. Quehenberger[2], R. M. Aigner[1]; [1]Medical University of Graz, Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA, [2]Medical University of Graz, Institute for Medical Informatics, Statistics and Documentation, Graz, AUSTRIA.

Aim: Evaluation of the advantages of time-of-flight (TOF) in ^{18}F-FDG-PET/CT in the detection and characterization of pancreatic lesions in patients with suspected pancreatic cancer. Furthermore, the maximum standard uptake value (SUVmax) was assessed. TOF should improve image noise, local resolution and thus the demarcation of small lesions. **Materials and methods:** TOF-^{18}F-FDG PET/CT was prospectively performed in 30 patients with suspected pancreatic cancer. In all patients, a histopathologic confirmation was made. PET/CT images were performed 30 and 90 min. p.i. including a diagnostic CT of the upper abdomen with contrast medium and pancreas protocol. SUVmax of the lesions was measured and compared with and without TOF in the 30 and 90 min. p.i. images. Lesions with an increase of SUVmax on the delayed images were assessed as malignant, whereas lesions with a decrease of SUVmax were assessed as benign. The comparison of TOF-PET/CT with standard PET/CT images and the determination of cut-off values for malignant lesions were made using ROC-analysis. **Results:** Of 30 patients 17 patients had malignant and 13 patients a benign pancreatic lesion. In two patient IPMN was diagnosed correctly only with TOF. Based on the histopathologic findings sensitivity, specificity and diagnostic accuracy for TOF were 94% and 62% versus 82% and 92% without TOF. ROC analysis of SUVmax with TOF 30 and 90 min p.i. yielded a cut-off value of 4.3 and 4.4, respectively with a sensitivity and specificity of 67% and 82% and 82% and 92%, respectively. The area under the curve $(AUC)_{PET}$ and AUC_{TOF}-values showed no significant difference neither in the early nor the delayed images. **Conclusion:** Among patients with suspected pancreatic cancer, the use of TOF-PET/CT correlated due to a better anatomical localization and identification of pancreatic lesions with higher sensitivity. However, TOF-PET/CT is of no additional use in differentiating malignant and benign pancreatic lesions. To what extent patients can benefit from the higher statistical weighting of the sensitivity should be examined in a greater patient population.

EP141

^{18}F-FDG PET Findings of Lymphoepithelioma like Gastric Carcinoma

J. Yoon, S. Lee, Y. An, D. Lee, Y. Kim, H. Hur, S. Han, S. Lim, K. Lee; Ajou University School of Medicine, Suwon, KOREA, REPUBLIC OF.

Lymphoepithelioma-like carcinoma (LEGC) is a rare type of gastric cancer that constitutes about 4% of all gastric cancers. In this study, the diagnostic performance and the findings of ^{18}F-fluorodeoxyglucose (FDG) PET/CT in LEGC were evaluated. **Methods**: A total of 26 patients (20 men, 6 women, age = 54 years) who underwent preoperative ^{18}F-FDG PET/CT were enrolled retrospectively. Seven patients underwent follow-up ^{18}F-FDG PET/CT. Pathologic information was obtained through gastrectomy and the association with Epstein-Barr virus (EBV) was investigated in 24 patients. Maximum standardized uptake value (SUVmax) was measured from primary tumors. **Results**: Eighteen patients had advanced gastric cancers (AGC), while 8 patients had early gastric cancers (EGC). Tumors were located at upper in 11, mid in 13 and lower 3rd in 2 patients. Most of tumors (20/24, 83.3%) were EBV-associated. ^{18}F-FDG PET/CT detected 83.3% (15/18) of AGC and 12.5% (1/8) of EGC. The mean SUVmax of 16 primary tumors was 7.7±3.0 (5.1-16.8). Lymph node metastasis was detected by histology in 50.0% (13/26) of all patients. The sensitivity and specificity of ^{18}F-FDG PET/CT for lymph node metastasis is 30.7% (4/13) and 100.0% (13/13), respectively. ^{18}F-FDG PET/CT also detected sarcomatoid carcinoma of liver in one patient with EGC. ^{18}F-FDG PET/CT falsely diagnosed as metastasis for eosinophilic infiltration of liver in one case. Of 7 patients, follow-up ^{18}F-FDG PET/CT revealed a multiple liver metastasis in one patient, which was missed by conventional CT, and metachronous cholangiocarcinoma in one patient. In addition, ^{18}F-FDG PET/CT correctly excluded a recurrent disease in the rest of the patients. **Conclusion**: ^{18}F-FDG PET/CT has a high sensitivity for AGC and high specificity for lymph node metastasis in patients with LEGC. Moreover, ^{18}F-FDG PET/CT diagnosed a recurrent disease correctly. ^{18}F-FDG PET/CT might be a useful tool in evaluating patients with LEGC.

EP142

Whole body 18F-FDG PET/TC and CECT in comparison for the evaluation of patients with esophageal carcinoma

C. Altini, **A. Niccoli Asabella**, A. Di Palo, M. Fanelli, C. Ferrari, N. Merenda, G. Rubini; Nuclear Medicine Unit, D.I.M. – University of Bari "Aldo Moro", Bari, ITALY.

Aim: To evaluate the role of ^{18}F-FDG PET/CT and CT with contrast enhancement (CECT) in the management of patients (pts) with suspected primary or recurrent esophageal cancer. Furthermore to evaluate the role of the semiquantitative parameters such as SUVmax, SUVmean, Total Lesion Glycolysis (TLG) and Metabolic Tumor Volume (MTV) in relation to the tumor site (upper esophagus, middle esophagus, lower esophagus and surgical anastomosis) and histotypes. Materials and Methods: 55 ^{18}F-FDG PET/CT were performed in 55 pts (42 males and 13 females; median age 61 years old, range 36-83 years) for suspected esophageal carcinoma: 22/55 (40%) primitive, 33/55 (60%) recurrences. All total body CECT were performed within 30 days from the 18F-FDG PET/CT. The results of 18F-FDG PET/CT and CECT were compared with histology in 22 pts who underwent subsequent surgery, and clinical and instrumental follow-up of at least six months in the remaining 33 pts. Sensitivity (Se), specificity (Sp), Positive Predictive Value (PPV), Negative Predictive Value (NPV), and diagnostic accuracy (DA) of the two methods were calculated. The two techniques were compared with the McNemar test. The role of PET semi-quantitative parameters was evaluated by ANOVA and post-hoc. Results: The values of Se, Sp, PPV, NPV and DA of 18F-FDG PET/CT and CECT were, respectively, 79%, 92%, 85%, 92%, 80% and 72%, 84.6%, 78%, 84%, 73%; no statistical difference emerged between the two techniques ($p> 0.005$). Only SUVmax (mean value 7.76; range 1.9-19.5) and SUVmean (mean value 4.55; range 1.1-11.7) have an additional role in the identification of relapses in relation to the tumor site ($F=8.43$, $p=0.02$ and $F=7.35$, $p=0.03$). No differences between PET/CT semiquantitative parameters and histotype were observed. Conclusions: The lack of statistically significant difference between the two techniques suggests their combined use in the evaluation of suspected esophageal cancer. Furthermore PET semiquantitative parameters should be ever collected especially in case of suspected recurrences. It would be desirable to perform 18-FDG PET/CT with contrast enhancement, assessed jointly by a nuclear physician and a radiologist.

EP143

Prognostic Value of Psoas Muscle Area on Preoperative ^{18}F-FDG PET/CT in Patients with Surgically Treated Esophageal Cancer

S. Park, **J. Yoon**, S. Lee, Y. An, S. Haam, J. Jung; Ajou University School of Medicine, Suwon, KOREA, REPUBLIC OF.

Sarcopenia is a syndrome characterized by progressive and generalized loss of skeletal muscle mass and strength, which has been known as a poor prognostic factor in various cancers. ^{18}F-fluorodeoxyglucose (FDG) PET/CT has been widely used in the evaluation of esophageal cancer. In this study, the prognostic significance of psoas muscle area (PMA) and the mean standard uptake value (SUVmean) of psoas muscles measured on preoperative ^{18}F-fluorodeoxyglucose (FDG) PET/CT were evaluated. **Methods**: A total of 131 patients (125 men, 6 women, age = 63.4 years) who underwent preoperative ^{18}F-FDG PET/CT and esophagectomy with extensive lymphadenectomy were enrolled retrospectively. PMA was measured at third lumbar vertebra level on an axial section of a non-contrast CT part of PET/CT. SUVmean was calculated on a transaxial plane of FDG PET. Locoregional and distant recurrences were determined based on the results of follow-up PET/CT, chest CT or tissue biopsy. **Results**: Pathological stages were I for 38 (29.0%), II for 41 (31.3%) and III for 52 (39.7%) of patients. The median follow-up period was 32.5 months. The mean body mass index (BMI), the mean PMA and SUVmean of the psoas muscles were 59.5±10.1 kg/m^2, 14.4±4.3 cm^2 and 1.5±0.3 g/mL, respectively. Operative mortality developed in 7 (5.3%) patients. The BMI and the PMA were significantly lower in patients with operative mortality (19.2±1.8 kg/m^2 and 11.3±1.5 cm^2) than those without operative mortality (21.7±3.0 kg/m^2 and 14.6±4.4 cm^2). However, there's no significant difference in SUVmean between 2 groups. The 3-yr overall survival (OS) and disease free survival were 14.4% and 42.0%, respectively. A multivariate analysis revealed that PMA was a risk factor for OS (hazard ratio=0.930, p=0.004); 37.1% in low-PMA patients (<15.8) and 64.9% in high-PMA patients. Akaike's information criterion decreased in the multivariate model including PMA versus the model without PMA. **Conclusion**: PMA measured on the preoperative ^{18}F-FDG PET/CT was a significant prognostic factor for OS in patients with surgically treated esophageal cancer, however, SUVmean of psoas muscles was not.

EP144

Efficacy of Ga-68 DOTATE PET/CT for detecting suspected or unknown primary neuroendocrine tumors

U. Elboga, A. Sevinc, M. Ozkaya, Y. Celen; Gaziantep University, GAZIANTEP, TURKEY.

Objective: It has been reported that Ga-68 somatostatin analogue DOTATE PET/CT has higher diagnostic performance with higher affinity of somatostatin receptor 2 for detecting neuroendocrine tumors (NETs). The purpose of this study was to investigate the usefulness of Ga-68 somatostatin analogue DOTATE PET/CT in detecting clinically-suspected NET lesions. **Material anad Methods:** A total of 36 patients were retrospectively analyzed. Fifteen patients underwent a Ga-68 somatostatin analogue DOTATE PET/CT scan for detecting unknown primary tumors after histopathological confirmation of NET (group 1), 7 patients for detecting suspected recurrence by a rising hormone level after surgery for NET (group 2), and the remaining 14 patients for detecting unknown primary tumors due to high chromogranin A levels (group 3). The detection rate was evaluated according to their situation. **Results:** In group 1, primary tumors were suspected by Ga-68 somatostatin analogue DOTATE PET/CT in 9 of 15 patients (gastrointestinal NET in 9 patients), all gastrointestinal NET were confirmed by histopathology. In group 2, Ga-68 somatostatin analogue DOTATE PET/CT described suspected lesions in all 7 patients (liver metastasis in 3 patients and nodal metastasis in 4 patient). In group 3, Ga-68 somatostatin analogue DOTATE PET/CT did not show any abnormal uptake in this all patients with high chromogranin A levels. **Conclusion:** Ga-68 somatostatin analogue DOTATE PET/CT was useful for detecting NETs, especially when recurrence was suspected due to high hormone levels after surgery for NET or primary tumors were suspected after histopathological confirmation of NET. However, no relevant information was achieved in patients who had no history of NET clearly when chromogranin A levels were high.

EP145

Early phase of 18F-FDG dynamic image to detect liver tumour

L. Cai[1], C. Han[2], Y. Chen[1]; [1]Department of Nuclear Medicine of West-South University Hospital, Luzhou, CHINA, [2]Turku PET Centre and Turku University Hospital, Turku, FINLAND.

Introduction: Only parts (50-70%) of liver tumours exhibit glucose metabolism higher than that the liver parenchyma as uptake of 18F-FDG in clinical PET imaging. Early dynamic 18F-FDG has been shown to be useful for detecting different tumour, such as liver and prostate cancers. However, quantitative methods applied to early dynamic of FDG PET imaging data are confused. In the current study, we employed two simple quantitative methods, maximal upstroke and half time to peak, measured based on tissue-activity curves from to tumour, normal liver tissue and abdominal aorta to investigate liver tumours. **Materials and Methods**: Five patients (four: hepatocellular carcinoma and one: hemangioma) were enrolled in this study. All patients were involved surgical operation and pathological examination confirmed the diagnosis. Before surgical operation, all patients underwent liver early 18F-FDG PET imaging (250 MBq bolus injection). Four frames at 15 seconds intervals, followed by 3 frame at 60 seconds. Regions of interest(ROI) on liver lesions (tumour and hemangioma), normal liver tissue and abdominal aorta were drawn. Tissue-activity curves (TAC) were extracted for each ROI. Two parameters were used: half time to peak (T1/2) and maximal upstroke normalized by abdominal aorta ROI (MU). Furthermore, a global index(EDindex), combining T1/2 and MU, was defined as EDindex=(normal T1/2 / tumour tissue T1/2)*(tumour MU / normal MU). All analysis were performed using Carimas2 (developed in Turku PET Centre, Turku, Finland. http://www.turkupetcentre.fi/carimas). **Results**: In liver cancer patients, T1/2: 26.8s(+/-5.40) and 40.25s(+/-4.52), MU: 11.60(+/-4.52) and 6.59(+/-1.50), in tumour and normal tissue, respectively, with statistical significant (p<0.01). Meanwhile, in hemangioma patient, T1/2: 61.2s and 60.0s, MU: 2.74 and 4.09 in lesion and normal tissue, respectively, with statistical significant (p<0.01). In four tumour patients, EDindex is 3.57, 2.74, 2.97 and 1.21, respectively, meanwhile, in hemangioma patient, EDindex is 0.66. **Conclutions**: Early dynamic 18F-FDG PET imaging provides useful information for identifying liver lesion. Based on simple quantitative analysis methods, it seems that parameters of T1/2 and MU, especially global parameter, EDindex, could be used to detect tumour lesion from liver parenchyma.

EP146

FDG PET/CT versus multidetector computed tomography in the initial staging of pancreatic carcinoma

S. Sampath[1], B. Mittal[2], D. Bhasin[2], S. Rana[2], R. Gupta[2], A. Das[2], R. Nada[2]; [1]TamilNadu Government Multi Super Specialty Hospital, Chennai, INDIA, [2]Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim: To compare MDCT and FDG-PET/CT in the initial staging of pancreatic carcinoma. Materials and methods: Staging MDCT and PET/CT records of 54 patients diagnosed with pathologically proven pancreatic malignancy were reviewed. The sensitivity, specificity,

PPV, NPV and accuracy of MDCT and PET/CT for nodal and metastatic staging were calculated. The statistical difference was calculated by McNemar's test. Results: Of 54 patients, 29 had nodal metastasis and 14 had distal metastasis. The sensitivity, specificity, PPV, NPV and accuracy of MDCT vs PET/CT for nodal staging were 52% vs 93%, 84% vs 100%, 79% vs 92%, 60% vs 92%, and 67% vs 96% respectively, $p < 0.001$. The sensitivity, specificity, PPV, NPV and accuracy of MDCT for metastatic staging were 77%, 90%, 67%, 60%, 85% whereas the accuracy of PET/CT was 100%, $p = 0.01$. By correctly identifying distant metastates, PET/CT can change management in 15% of patients. Conclusion: PET/CT achieves excellent accuracy in the staging of pancreatic carcinoma and may be considered in the initial staging evaluation.

EP147

Incidental findings on low dose CTs performed as part of SPECT-CT following Yttrium-90 resin microsphere treatment for liver cancer and metastases

D. Ersahin[1], M. Chen[2]; [1]Yale New Haven Hospital, New Haven, CT, UNITED STATES, [2]Yale School of Medicine, New Haven, CT, UNITED STATES.

Introduction: Yttrium-90 (90-Y) resin microsphere treatment is often followed by a single-photon-emission computed tomography (SPECT) combined with low dose computed tomography (CT) to evaluate the distribution of the microspheres and potential immediate complications of the treatment. Despite low dose technique, unexpected or incidental CT findings are frequently encountered. The purpose of this study was to investigate the prevalence and significance of these unexpected findings. Methods: Reports from total 75 patients with post-treatment SPECT-CT scans performed between 1/1/2012 and 12/31/2015 at Yale New Haven Hospital were reviewed retrospectively. Abnormal CT findings other than known liver lesion(s) were recorded. For patients who had short interval repeat treatments, only one scan per patient was included in the study. Results: Forty-four scans of 75 patients (58.7%) demonstrated at least one incidental CT finding. The common encountered findings were lung atelectasis (28%), lung nodules (20%), splenomegaly (10.7 %), pleural effusion (9.3%), and ascites (9.3%). Patients also had other findings such as lymphadenopathy, skeletal metastases, renal cysts, gallstones, etc. Two patients (2.7%) had soft tissue hematomas related to the procedure and they were managed conservatively. Thirty one scans (41.3%) did not reveal any incidental CT findings per reports. Conclusion: Low dose CT scans performed as part of post-treatment SPECT-CTs frequently reveal unexpected findings. Therefore, nuclear medicine physicians and radiologists should be aware of these potential findings which can be critical requiring immediate attention from the referring physicians. Patient management can also be potentially impacted when previously unknown metastatic lesions are detected during post-treatment SPECT-CTs.

EP148

Use of 18F-FDG uptake (SUVmax) and CT attenuation (HUmean) for detection of hepatocellular carcinomas (HCCs) : preliminary study

H. Lee, S. Byun, S. Kim, K. Hwang; Gachon University Gill Hospital, Incheon, KOREA, REPUBLIC OF.

Purpose: Hepatocellular carcinomas (HCCs) have been known to have variable 18F-FDG uptake and this was suggested due to the degree of differentiation of HCC. The detection of HCC is sometimes difficult because of this variety of 18F-FDG uptake. Both SUVmax and Hounsfield Unit (HU) can be measured on PET-CT. We studies the detectability of HCCs when HU was considered as well as SUVmax. *Methods:* We retrospectively reviewed 18 patients who were newly diagnosed HCCs from January 2014 to December 2015. There were a total of 24 biopsy-proven HCCs. All PET, CT (no contrast), and fusion PET-CT images were analysed visually and both SUVmax and HUmean were measured for the areas of suspected abnormality on either PET-CT or CT. Locations of HCCs were confirmed by MRI or enhanced CT. *Results:* Average SUVmax of 14 HCCs were similar to those of normal liver (3.1 vs. 3.0, $P>0.05$). Other 10 lesions were definitely distinguished from normal liver (SUVmax 9.2 vs. 2.8, $P<0.05$). However, average HUmean was 42 for those 14 HCCs and was 41 for the rest 10 lesions, which showed no statistical difference ($P>0.05$). Total HCCs showed average HUmean of 42 regardless of 18F-FDG uptake. Normal liver showed average HUmean of 58 on the other hand ($P<0.05$). The ratio of HUmean to SUVmax were 13.7, 4.5, and 19.8 for non-FDG-avid, FDG-avid, and normal liver, respectively. Overall, the HUmean/SUVmax was 7.3 for all HCCs. *Conclusions:* In this preliminary study, HUmean of HCCs showed lower values compared with that of normal liver. As a result, the ratio of HUmean to SUVmax tended to be smaller for HCCs and this might have an influence on the detectability of lesions. Further study with greater number of samples is warranted for more such as cut-off. In addition, it is better to have a careful look of CT in PET-CT to detect abnormality especially when PET shows homogeneous 18F-FDG uptake in HCCs.

EP-09 – Sunday, October 16, 2016, during Exhibition hours, e-Poster Area
Clinical Oncology: Lung

EP149

Routinely including brain and use of contrast in whole body FDG PET-CT for staging NSCLC — its incremental value and comparison with MRI of brain for detection of asymptomatic brain metastases

S. RAY, J. DAS; TATA MEDICAL CENTER, KOLKATA, INDIA.

Aim: Brain MRI is the standard imaging to detect asymptomatic brain metastases (ABM) in non small cell lung cancers (NSCLC). In most centres, staging Fluorodeoxyglucose (FDG) PET-CT protocol for NSCLC doesn't include the brain. We investigated the incremental value of routinely including brain CT with contrast as a part of the PET-CT staging protocol in NSCLC and compared their asymptomatic brain metastases detection rates to MRI. Materials and methods:Data of the first 200 consecutive patients was retrospectively analysed.TNM staging information was tabulated. Comparison of brain image of the whole body PET-CT, non contrast plain CT and contrast enhanced CT images of the brain not fused with PET and dedicated brain PET images was performed in correlation with brain MRI as the standard. Results:T3/T4 primary lesions were found in 52% patients with 89.2% having N2/N3nodal disease on PET-CT scan. 18% had ABM on MRI, 61.1% of whom had adencarcinoma. Amongst adenocarcinoma 72.2% and 88.9% had T3, T4 lesions or N2, N3 disease respectively in the ABM group, compared to 45.1% and 64.6% in those without ABM. Similarly, in squamous cell carcinoma 100% versus 32.3% had either T3/T4 and/or N2/N3 disease respectively in the ABM versus non-ABM groups. Brain MRI detected ABM in 18% cases out of which 77.77% were also detected in both PET-CT and CECT, 50% were detected in non contrast CT and 83.33% ABM noticed in MRI were detected in dedicated brain PET-CT.28.5% of brain metastases detected in PET-CT had FDG avidity and in other 71.5% cases it was photopenic.Out of all ABM patients in 16.6% metastases were detected in MRI alone and in no other imaging modality. Conclusion:Routine inclusion of brain CECT as a part of FDG-PET-CT protocol could detect asymptomatic brain metastases in approximately 78% cases therefore negating the requirement of an additional staging brain MRI in NSCLC. This could enable resource optimised use

of MRI staging in more advanced T/N stages. There is no significant difference in sensitivity between CECT brain and fused PET-CT image of the brain. Non contrast plain CT has very poor sensitivity (50% only) for detection of brain metastasis. Addition of dedicated brain PET to contrast enhanced CT enhances the sensitivity for identification of brain metastasis to 83%. We recommend routine inclusion of brain in the whole body protocol for staging PET-CT in NSCLC along with use of iodinated contrast and preferably an additional dedicated brain PET acquisition.

EP150

Evaluation of 18F-FDG PET/CT and non-imaging factors in predicting patient survival in small cell lung cancer: A single tertiary centre experience

A. Agahi, C. Leung, E. Nowosinska, H. Jan; Barts Healthcare Trust, London, UNITED KINGDOM.

Aim Small-cell lung cancer (SCLC) is an aggressive malignancy that accounts for 15-25% of lung cancers. SCLC is classified as limited disease (LD), confined to hemithorax, mediastinum or ipsilateral supraclavicular lymph nodes, or extensive disease (ED) spreading beyond the hemithorax and supraclavicular nodes. There is mixed evidence in the literature regarding metabolic activity of primary tumour on Fluorine-18-Fluorodeoxyglucose Positive Emission Tomography/ Computer Tomography (18F-FDG PET/CT) and patient survival. We aim to determine whether staging 18F-FDG PET/CT in patients would be predictive of patient survival in LD and ED SCLC. **Materials and Methods** We retrospectively collected data of all patients with histologically proven SCLC who underwent 18F-FDG PET/CT staging over the period of 2010 to 2013 at our tertiary referral centre. These patients were followed up until the end of 2014. Data was collected using Electronic Patient Record (EPR) system and Patient Archiving and Communication System (PACS). Statistical analyses were performed to identify correlation between prognostic factors (primary tumour size, primary tumour SUV max, number of metastases and the age at diagnosis) and patient survival in both LD and ED categories. **Results** A total of 31 patients were identified. Four patients who remained alive at the end of the follow-up period were excluded. A total of 27 patients were included. There were 13 male and 14 female patients with a mean age of 68 years (ranges from 48 to 84 years). In patients with LD, there was statistically significant correlation between primary tumour size, primary tumour SUVmax, number of nodal metastases and patients' age, and patient survival ($p < 0.0001$). Similarly in patients with ED, there was statistically significant correlation between primary tumour size ($p = 0.0225$), primary tumour SUVmax ($p = 0.0097$), number of nodal and distal metastases ($p = 0.0097$) and patients' age ($p = 0.0252$), and patient survival. **Conclusion** SCLC is predominantly diagnosed in the elderly population. 18F-FDG PET semi-quantitative analysis, size of the primary tumour, number of metastasis at staging and patient's age all carry important prognostic value in both LD and ED patients. Further analysis of the above prognostic factors is currently being evaluated in a larger patient cohort.

EP151

Evaluation of anterior mediastinal tumors using a standard deviation as a heterogeneity index on FDG-PET/CT

K. TAMURA[1], I. Sakata[1], K. Yoshikawa[2], Y. Tajima[3], N. Shigematsu[4], M. Jinzaki[4], K. Murakami[4], H. Usui[5], K. Hayashi[6], Y. Ozeki[6], J. Ishida[1]; [1]Tokorozawa PET Diagnostic Imaging Clinic, Tokorozawa, JAPAN, [2]Tokyo Bay Advanced Medical Clinic, Chiba, JAPAN, [3]Tokyo Medical University Hospital, Tokyo, JAPAN, [4]Keio University Hospital, Tokyo, JAPAN, [5]Saiseikai Utsunomiya Hospital, Utsunomiya, JAPAN, [6]National Defense Medical College, Tokorozawa, JAPAN.

OBJECTIVE: Heterogeneity is one of the features in malignant tumors. The objective of this study is to investigate the intratumoral heterogeneity of 2-deoxy-2-[(18)F] fluoro-D: -glucose (18F-FDG) accumulation in patients with anterior mediastinal tumor.**METHODS:** Forty-six patients (18 females and 28 males, mean age 56.7±15.2) with anterior mediastinal tumor who had been referred to our clinic for PET/CT in Jul. 2006-Dec.2015, and besides had surgical removal or biopsy after PET/CT scan were evaluated. All PET/CT scans were performed both 60min and 120 min (delayed scan) after FDG injection. Standard Uptake Value (SUVmax) was calculated in all patients. Also, we placed circle ROIs (both 1cm and 2cm in diameter) in the tumor lesions, including the highest uptake area. We calculated standard deviations within the ROIs of 1cm (SD1) and 2cm (SD2) in diameter based on cumulative SUV-volume histograms as a heterogeneity index. **RESULTS:** Mean tumor size was 66.1±22.6mm (22 to 120 mm). Pathological findings (18 malignant and 28 benign) were thymoma in 25 patients, thymic carcinoma in 9, malignant lymphoma in 4, seminoma in 2, and the others in 6 (adenocarcinoma, germ cell tumor, malignant neuroendocrine tumor, mature teratoma, hyperplasis, and schwannoma). The mean SUVmax, d-SUVmax, SD1, and SD2 in the benign tumor group were 3.85±1.60, 4.44±2.19, 0.27±0.21, 0.39±0.18, while those in the malignant tumor group were 11.1±4.36, 13.9±6.30, 0.99±0.81, and 1.55±0.90. All parameters in malignant tumors were significantly higher than those in benign tumors ($p<0.0001$). In a diagnosis of malignant tumor, sensitivity, specificity, and accuracy were 88.9% (94.4%), 89.7% (82.8%), and 89.4% (87.2%) respectively using an SUVmax (d-SUVmax) cutoff of 6. Also, by using cut-off SD1 of 0.4 and SD2 of 0.6, sensitivity were 88.9 and 94.4%, specificity were 79.0 and 93.1%, and accuracy were 80.9 and 93.6% respectively. **CONCLUSIONS:** The standard deviation of SUV within 20mm ROI that is calculated easily is considered to be a valuable tool for a differential diagnosis between malignant and benign tumors in anterior mediastinal tumors.

EP152

Nodal Staging in Patients with Pulmonary Malignancies using 18FDG-PET and EBUS

S. Angelides, A. Markewycz; Westmead Hospital, Earlwood, AUSTRALIA.

Up to 40% of 18FDG-positive mediastinal nodes are not due to metastatic disease. EBUS is increasingly employed to evaluate mediastinal nodal status prior to definitive therapy. **Aim:** To retrospectively compare 18FDG-PET scans and EBUS findings in patients with documented pulmonary malignancies. **Methods:** 65 patients with documented pulmonary malignancies underwent 18FDG-PET scintigraphy followed by EBUS within the ensuing 3 weeks. One-two nodes were assessed in each patient, determined by 18FDG-PET findings and accessibility of the FDG-positive nodes. The mediastinal nodal status from each procedure was compared. **Results:** 53 of 110 18FDG-positive mediastinal nodes did not demonstrate any malignancy upon fine needle biopsy performed during EBUS. Mediastinal nodal status downgrading occurred in 28 (43%) patients. No upgrading was noted. Downgrading most likely occurred when there several non-enlarged lymph nodes of similar 18FDG-avidity distributed randomly and bilaterally in the mediastinum, often with bilateral hilar uptake (20 of 28 patients). Further, only 2 of 19 patients exhibiting such a pattern of mediastinal tracer distribution were found to have lymph node metastases (10%), and both had metastatic disease elsewhere on the PET scan. 23 of 25 patients with positive EBUS findings demonstrated discrete 18FDG-avid lymph nodes ipsilaterally, with minimal-to-no 18FDG-avid nodes contralaterally. EBUS findings in 14 (22%) patients were inconclusive, despite multiple sampling. Enlarged, rounded lymph nodes with avid FDG uptake (SUV>4) were also more likely to harbour metastatic disease. Conversely, a Hounsfield unit of >55 was associated with benign disease. **Conclusion:** The pattern of

mediastinal 18FDG uptake was highly predictive of metastatic disease, and may circumvent the need for EBUS evaluation. Prospective analysis of these parameters will be undertaken.

EP153

18F-FLT PET/CT in patients with advanced Non-Small Lung Cancer (NSCLC) treated with Nivolumab: preliminary results

G. Polverari[1], V. Ambrosini[1], F. Gelsomino[2], S. Diodato[1], F. Ceci[1], F. Sperandi[2], A. Ardizzoni[2], S. Fanti[1]; [1]Service of Nuclear Medicine, S.Orsola-Malpighi University Hospital, University of Bologna, Bologna, ITALY, [2]Division of Medical Oncology, S.Orsola-Malpighi University Hospital, University of Bologna, Bologna, ITALY.

Aim: to evaluate the role of 18F-FLT-PET/CT in Non-Small Lung Cancer (NSCLC) patients candidated to Nivolumab therapy. **Materials and Methods:** we prospectively enrolled patients with advanced NSCLC progressed after at least one prior platinum-based chemotherapy and candidated to Nivolumab within a compassionate use program (EAP). 9/11 patients did not perform surgery as primary treatment while 2/11 underwent lung surgery. 18F-FLT-PET/CT and contrast enhanced computed tomography (ce-CT) scan were performed before Nivolumab as baseline imaging procedures in all patients. To date only 6/11 patients have completed 4 cycles of treatment. In these six patients, 18F-FLT-PET/CT and ce-CT were performed 2 months after the fourth cycle of Nivolumab. Response to Nivolumab was assessed according to RECIST criteria v1.1. **Results:** Overall 11 patients were included. 18F-FLT-PET/CT was positive in all cases detecting the primary lung lesion in 9/11 with a mean SUVmax=7.2 (range 3.1-14.2). 9/11 patients showed lymph nodes metastases with a mean SUVmax=6.1 (range 3.3-13.3), 7/11 extranodal metastases with a mean SUVmax=6.9 (range 1.9-13.3). Sites of extranodal metastases included bone (1/11), spleen (1/11), adrenal gland (1/11), controlateral lung (4/11) and pleura (2/11). In the 6/11 patients who completed 4 cycles of therapy, response assessment showed progressive disease (PD) in 2/6, partial response (PR) in 2/6 and stable disease (SD) in 2/6 patients. 18F-FLT-PET/CT pretherapy SUVmax was higher than reference background uptake (mean SUVmean liver= 6.5; range= 4.8-9.6 and mean SUVmean L3= 7.6; range= 4.6-9.5) in patients who showed a partial response (mean SUVmax of lung primary=11.5; range= 8.8-14.2) while was lower in patients with SD/PD (mean SUVmax of lung primary=5.0; range 3.5-6.5). **Conclusions:** Nivolumab has become a standard of care in advanced pretreated NSCLC. To date, no predictive factors of clinical benefit have been identified. In our study, high 18F-FLT-PET/CT SUVmax value was associated with PR at 2 months, suggesting an attractive role as predictor of response. Further studies are needed to better assess the role of 18F-FLT-PET/CT imaging.

EP154

Can SUVmax or HU differentiated benign from malignant pleural effusion in FDG PET-CT scans?

H. Farghaly[1,2], S. Al Shaikh[2], A. Alqarni[2], H. Nasr[3,2]; [1]Assiut University, Assiut, EGYPT, [2]Radiology department, Prince Sultan Military Medical City, Riyadh, SAUDI ARABIA, [3]Nuclear Medicine Unit, Cairo University, Cairo, EGYPT.

Aim: To evaluate the ability of SUVmax or/and HU to differentiate benign from malignant pleural effusions. Material and Methods: Total of 4111 FDG PET/CT scans were reviewed for presence of pleural effusions. Any FDG PET/CT scan with pleural effusions and tapping with cytology of the effusions were included in this study. A region of interest was drown on the dependent region of pleural effusions in the trans axial plan without including the pleural edges and SUVmax and mean HU were recorded. The pleural effusion SUVmax to liver SUVmax ratio (P/L SUVmax) were calculated and recorded. The results of the pleural effusion cytology were recorded and compared with the SUVmax and HU values. The pleural effusions were divided based on cytology into two groups, one positive and the other negative for malignancy. Comparison made between mean SUVmax, mean P/L SUVmax ratio and mean HU for each group by T-test for independent samples. The amount of pleural effusion divided into two groups, group one with mild effusion and group two with moderate to large effusion based on visual assessment and comparison made between mean SUVmax in each group.. Results: Twenty two patients had pleural effusion tapping and cytology results revealed malignancy in 6 and no evidence of malignancy in the remaining 16 patients . The mean HU was significantly higher in patients with proved malignant effusion -2.17±6.52 vs. -16.13±12.64 in non-malignant effusion (p=0.02). Using ROC analysis there a cutoff point for mean HU value of >-12 was able to differentiate malignant from benign effusion with a 100% sensitivity and a 73.3% specificity (AUC 0.878; p=0.0001).There was no significant difference in the mean SUVmax, mean P/L SUVmax ratio between patients with malignant effusion and those with no evidence of malignancy. The mean SUVmax was 2.03±1.28 in malignant pleural effusion vs. 2.03±1.06 (p=0.99) while mean P/L SUVmax ratio was 0.59±0.19 vs. 0.61±0.17 (p=0.90). The mean SUVmax was significantly lower in patients with moderate to large effusion compared to those with mild effusion (0.96 ±0.33 vs. 1.68±0.60; p=0.009), suggesting a possible dilution effect. Conclusion: The mean HU value could be helpful to differentiation between malignant and benign pleural effusions. On the other hand no significant statistical relation was found between effusion SUVmax and pleural effusion cytology with tendency of lower SUVmax values in patients with large to moderate effusions.

EP155

Metabolic parameters in [18F] FDG PET/CT as an early predictor of Stereotactic Body Radiation Therapy response in primary lung tumor

D. Lopez[1,2], A. Domenech[1], V. Camacho[1], A. Fernandez[1], N. Farre[3], A. Flotats[1], J. Duch[1], M. Estorch[1], I. Carrió[1]; [1]Hospital de la Santa Creu i Sant Pau. Nuclear Medicine Department, Barcelona, SPAIN, [2]Universitat Autonoma de Barcelona, Barcelona, SPAIN, [3]Hospital de la Santa Creu i Sant Pau. Oncology Radiotherapy Deparment., Barcelona, SPAIN.

PURPOSE: Distinguishing morphological changes from recurrence after Stereotactic Body Radiation Therapy(SBRT) in primary lung tumor remains challenging. To compare metabolic tumor parameters (Maximum Standard Uptake Value[SUVmax], Metabolic Tumor Volume[MTV] and Total Lesion Glycolysis[TLG]) derived from [^{18}F]FDG PET/CT as predictors of clinical status at 1 year after SBRT in patients (p) with primary lung tumor. **MATERIALS AND METHODS:** Fifteen patients [14 male; mean age=82 y/o, range 67-86] with primary lung tumor (adenocarcinomas [7], squamous cell carcinoma [4], non-histology [3], non-small cell *lung cancer* [1]), who underwent baseline (before SBRT), early follow-up (1-3 months after SBRT) and late follow-up (6 months after SBRT)[^{18}F]FDG PET/CT were retrospectively reviewed. Images were visually assessed by 2 nuclear medicine physicians identifying morphometabolic response to SBRT (local recurrence [LR], disease progression [DP], stable disease [SD] and complete response [CR]). Morphological changes post-SBRT (mc-pSBRT) were also considered in CR. Quantitative measurements to track changes in tumor volume and metabolic activity between baseline and follow-up scans were performed using Philips Tumor Tracking Application. SUVmax, MTV and TLG were determined to compare their value in predicting response to SBRT. Clinical assessments at 1 year after baseline PET/CT were reviewed to evaluate patients evolution. **RESULTS:** In visual analysis of follow-up scans, 12 of the 15p were considered in CR, 2 in SD and 1 in DP. Ten of the 12p considered in CR presented mc-pSBRT in the follow-up scans while the remaining 2p did not present mc-pSBRT. In

quantitative analysis of the follow-up scans, all the patients visually considered in CR presented a decrease in SUVmax. Patients in CR with mc-pSBRT showed an increase in MTV and TLG values. Patients in CR without mc-pSBRT demonstrated a decrease of all metabolic parameters. The 2p visually considered in SD did not present significant changes in the metabolic parameters. The patient in DP showed local CR with distant metatases. Clinical evolution assessed one year after the last PET/CT demonstrated that 13p were in CR, 1p in SD and 1p exitus. Overall, SUVmax helped to predict clinical status at 1 year after the baseline PET/CT in 87% (13/15) of the patients with primary lung tumor treated with SBRT. **CONCLUSION:** SUVmax is the only PET/CT metabolic parameter at 3 and 6 months that may be useful to predict clinical status in patients with primary lung tumor treated with SBRT. Patients in CR with mc-pSBRT show increase of MTV and TLG values probably related with morphological changes.

EP156

Mediastinal staging in non-small-cell lung carcinoma: 18F-FDG PET/CT compared to postoperative pathological findings: our experience

S. Casagrande[1], I. Schiorlin[1], F. Tanzi[2], N. Rotolo[3], F. Berizzi[3], A. Imperatori[3]; [1]Nuclear Medicine, Circolo Hospital, VARESE, ITALY, [2]Health physics dept., Circolo Hospital, VARESE, ITALY, [3]Dept. of Surgical and morphological sciences center for thoracic surgery, Insubria University, VARESE, ITALY.

AIM: 18F-F PET/CT plays an important role in hilar and mediastinal lymph node staging of patients with non-small cell lung cancer (NSCLC), because it is more accurate than contrast-enhanced computed tomography (ceCT). According to the literature, PET/CT for lymph node staging has 80-90% sensitivity, 85-95% specificity, and in patients with peripheral NSCLC has greater NPV than ceCT. The purpose of this study was to assess the accuracy of PET/CT for hilar and mediastinal lymph node staging of NSCLC patient eligible for potentially radical surgery according to the T stage, and to identify risk factors correlated to lymph node involvement. **MATERIAL S AND METHODS:** We reviewed 67 patients (73% male) with NSCLC [adenocarcinoma (ADK), n=44; squamous cell carcinoma (SCC), n=16; miscellaneous, n=7] and node status assessed by surgical pathological findings. From September 2014 to January 2016 all patients underwent preoperative ceCT and PET/CT. The maximum standardized uptake value (SUVmax) and metabolic tumor volume (MTV) of the primary lung cancer were measured. Mediastinal lymph node positivity on PET/TC was defined as focally increased FDG uptake higher than mediastinal blood pool. Multivariate analysis was performed separately in patients with ADK and SCC, for the following factors associated with lymph node metastasis: age, gender, tumor location, grading, SUVmax, MTV. **RESULTS:** The primary tumor SUVmax was significantly higher in SCC patients (range : 2.7-51) compared with ADK (range:1.5-31). The sensitivity, specificity, accuracy, NPV, PPV of regional lymph node metastasis were respectively 47%, 82%, 74%, 82%, 47% , with PET/CT and 41%, 63%, 58%, 75%, 29%, with ceCT. Multivariate analysis showed that SUVmax (p= 0.0028) and MTV (p=0.0097) were significant predictors of lymph node metastasis only in ADK group. Moreover, in ADK the ROC curve showed an area under curve better for SUVmax, 0.859 (95%CI: 0.717-0.947) than for MTV. No significant differences were found in the SCC group, possibly because of small sample size. For PET/CT, the false-negative incidence (N1 or N2) was 13.4% (14.9% for ceCT). Interestingly, occult N2 metastases were found in 3 of 44 ADK patients (7%) and all these occurred in peripheral ADK. CeCT showed a trend to overstaging (false-positive rate was twice that of PET/CT). **CONCLUSION:** In patients with lung ADK the SUVmax and MTV predicts mediastinal nodal involvement. In patients with peripheral ADK with high SUVmax and MTV, and PET-negative mediastinal lymph nodes, our results suggest the need of pre-surgical mediastinal lymph node biopsy to rule out false-negative N2 status.

EP157

Texture analysis of FDG-PET/CT images to characterize lung cancer lesions and to predict outcome in patients undergoing primary surgery: preliminary results

M. Kirienko[1,2], F. Gallivanone[3], M. Sollini[4], G. Veronesi[2], E. Voulaz[2], L. Antunovic[2], G. Testanera[2], I. Castiglioni[3], A. Chiti[4]; [1]Università Milano-Bicocca, Milan, ITALY, [2]Humanitas Research Hospital, Milan, ITALY, [3]Laboratory of Innovation and Integration in Molecular Medicine of the Institute of Molecular Bioimaging and Physiology of the National Research Council, Milan, ITALY, [4]Humanitas University, Milan, ITALY.

Purpose: to assess the correlations between FDG-PET/CT image features, histological data and outcome in patients affected by non-small cell lung cancer (NSCLC) undergoing surgery. **Methods:** we retrospectively analyzed 31 stage I-III NSCLC patients (19 adenocarcinoma, 9 squamocell carcinoma, 3 other; differentiation grade was: G1=1/31, G2=13/31, G3=16/31, not available = 1/31) submitted to FDG-PET/CT for staging purpose and underwent surgery within 1 month. Mean follow-up was 28 ±9 months. At 2-years follow-up, 18 patients had no evidence of disease, 9 patients experienced relapse, 2 patients were dead and 2 lost at follow-up. Statistical analysis was used to correlate PET features (primary tumour Metabolic Tumor Volume (MTV), SUV_{max}, SUV_{mean} corrected for partial volume effect (PVC-SUV), Total Lesion Glycolysis (TLG), 14 textural features and 4 shape-and-size features extracted within the MTV), with histological data and with outcome (local relapse free survival (LRFS), distant metastasis free survival (DMFS) and disease free survival (DFS)). **Results:** We found significant correlations between PET features (Mean Absolute Deviation, PVC-SUV, Spherical disproportion, Sphericity, MTV, Surface, Surface-to-Volume ratio, SUV_{max}, TLG, Maximum, Mean, Minimum, Kurtosis, Standard Deviation, Variance, and Energy) and grading, T parameter, N status and pathological stage. Both features Energy and Kurtosis resulted predictive for DFS and DMFS. The features PVC-SUV and SUV_{max} were predictive for DMFS. These four features were able to separate the whole population into two groups with different outcome. **Conclusions:** Texture analysis of FDG-PET images is able to characterize lung cancer lesions, suggesting the possibility of an *in vivo* "imaging biopsy" by routine baseline FDG-PET/CT. Moreover, texture analysis parameters were predictive of DMFS and DFS in treatment naïve NSCLC patients undergoing primary surgical resection.

EP158

No significant association between EGFR gene mutation and FDG-PET maximum standardized uptake value in early-stage lung adenocarcinoma

N. Chiu, B. Lee; Cheng Kung University Hospital, Tainan, TAIWAN.

Purpose Correlation between EGFR gene mutation and 18F-FDG uptake in advanced lung adenocarcinoma has been reported. To investigate the association between EGFR gene mutation and FDG-PET maximum standardized uptake value (SUVmax) in early-stage lung adenocarcinoma we underwent this study. **Subjects and methods** We retrospectively collected all patients with early-stage lung adenocarcinoma who had EGFR mutation analysis and underwent FDG PET/CT before any therapy between December 2014 and October 2015. We analyzed the association between EGFR mutation status and SUVmax of the primary lung tumor. **Results** Forty patients with early-stage lung adenocarcinoma (12 men, 28 women; age, 61.6 ± 13.4 y) were included. Thirty (75%, 7 men, 23 women) had EGFR mutation. The mean SUVmax of EGFR-mutant adenocarcinoma was (4.14 ± 3.36) and that of the wild-type adenocarcinoma was (5.83 ± 2.77). The differences in SUVmax, age, disease stage between the two groups of patients were not statistically significant. **Discussion** There is no significant association between EGFR gene

mutation and SUVmax of the primary lung tumor in early-stage lung adenocarcinoma. FDG PET seems not suitable to predict EGFR mutation in early-stage lung adenocarcinoma.

EP159

A possible role of F-18 FDG PET/CT scan in differentiation of malignant and benign pulmonary lesions that tend to show lower FDG affinities

E. Tatci[1], F. Demirag[2], I. Uslu Biner[1], Y. Erdogan[3], U. Yılmaz[3], G. Findik[4], O. Ozmen[1], A. Ozturk[3], A. Gokcek[5]; [1]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, dept. of Nuclear Medicine, Ankara, TURKEY, [2]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, dept. of Pathology, Ankara, TURKEY, [3]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, dept. of Chest Diseases, Ankara, TURKEY, [4]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, dept. of Thoracic Surgery, Ankara, TURKEY, [5]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, dept. of Radiology, Ankara, TURKEY.

Purpose/Introduction: International Association for the Study of Lung Cancer/American Thoracic Society/European Respiratory Society (IASLC/ATS/ERS) has recently proposed a new lung adenocarcinoma classification. New terms as lepidic predominant adenocarcinoma and invasive mucinous adenocarcinoma were defined for the carsinomas of the lung formerly known as non-mucinous bronchioloalveolar carcinoma (BAC) pattern and mucinous BAC pattern respectively. The purpose of the present study was to assess the ability of 18F-fluorodeoxyglucose (FDG) Positron Emission Tomography (PET)/ Computed Tomography (CT) to discriminate hamartomas from lung tumors which tend to show low FDG uptakes such as pulmonary carcinoids, lepidic predominant adenocarcinoma and invasive mucinous adenocarcinoma. **Subject and Methods:** We retrospectively reviewed medical records of 79 patients with pathologically confirmed lepidic predominant adenocarcinoma, invasive mucinous adenocarcinoma, pulmonary carcinoid tumors and hamartomas between 2009 and 2015. All patients underwent preoperative 18F-FDG PET/CT. The maximum standardized uptake values (SUVmax) of the lesions were calculated for semiquantitative analyses. Kruskall- Wallis tests were used to compare differences in SUVmax values and the tumour size between lesions. This retrospective study was approved by Institutional Review Board Committee. **Results:** Of the 79 patients, 15 patients had low grade adenocarcinoma; 6 had lepidic predominant adenocarcinoma and 9 had invasive mucinous adenocarcinoma. Thirty-seven patients had pulmonary carcinoid tumors (12 atypical, 25 typical) and 27 patients had hamartomas. Tumor sizes were in a range from 0.7 to 13.5 (mean ± SD, 2.7±1.9). Adenocarcinomas were greater in dimension than typical carcinoids and hamartomas (P=0.007). There was no significant difference in the lesion size between adenocarcinomas and atypical carcinoids. SUVmax of all lesions ranged from 0.86 to 11.2 (mean ± SD, 3.6 ±2. 48). The mean SUVmax values of the hamartomas were significantly lower than typical carcinoids, atypical carcinoids and adenocarcinomas (p=0.0001). There were no statistically significant differences in SUVmax between adenocarcinomas and carcinoids. **Discussion/Conclusion:** 18F-FDG PET/CT has an important role in distinguishing between benign and malignant lung lesions. However, 18F-FDG uptake depends on the histologic type of the tumor. It has been reported that FDG uptake may be low in BAC and pulmonary carcinoids. Differentiation of these tumors from benign nodules may be difficult. Pulmonary hamartomas are one of the most common benign tumours of the lung. We found that 18F-FDG uptake of hamartomas were significantly lower than typical carcinoids, atypical carcinoids and adenocarcinomas. 18F-FDG PET/CT findings may be helpful in the differential diagnosis of hamartomas from pulmonary carcinoid tumors, lepidic predominant adenocarcinomas and invasive mucinous adenocarcinomas.

EP160

Usefulness of 18FDG-PET/CT in the evaluation of lung tumors treated with stereotactic body radiotherapy: preliminary results

J. L. Vercher-Conejero[1], C. Gámez-Cenzano[1], A. Navarro-Martin[2], M. Cortés-Romera[1], J. Mestres-Martí[1], J. Robles-Barba[1], A. Sabaté-Llobera[1], E. Llinares-Tello[1], L. Rodriguez-Bel[1], L. Gràcia-Sánchez[1], E. Andia-Navarro[2], M. Arnaiz-Fernandez[2], F. Guedea-Edo[2]; [1]Hospital U. de Bellvitge-IDIBELL, L´Hospitalet de Llobregat, SPAIN, [2]Hospital Duran i Reynals - ICO, L´Hospitalet de Llobregat, SPAIN.

Aim: Stereotactic body radiation therapy (SBRT) is a relatively new treatment modality whose main indications are inoperable non-small-cell lung cancer and oligometastases to liver and lung. The aim of our study was to evaluate the usefulness of FDG-PET/CT in monitoring treatment response and in the follow-up of patients with lung lesions treated with SBRT. **Materials and Methods**: We retrospectively reviewed 71 patients that received SBRT for stage I lung cancer or isolated pulmonary metastases of other tumors. Final analysis excluded 45/71 patients because of no baseline or follow-up PET was available or additional therapies were administered. We included 26 patients (76% male), mean age 73.3 y.o. (range 53-86) with lung lesions: 22/26 primary lung cancer and 4/26 colorectal metastases. SBRT dose ranged 34-60 Gy. FDG-PET/CT was performed at baseline (<1 month prior to SBRT) and post-SBRT to correlate metabolic to morphological response and clinical follow-up. The follow-up was performed in 3 timepoints after SBRT: early (<6 months), intermediate (6-18) and late (>18). SUVmax was recorded in every lesion. Clinical evaluation of response was classified as stable disease (SD) (including metabolic partial or complete response, independently of the lesion size) or progression disease (PD). **Results**: 92% had ≥ 1 FDG-PET/CT within first year and 32% had at least one FDG-PET/CT after 18 months post-SBRT. Primary lung tumors were adenocarcinomas (15) and squamous cell carcinoma (7), and adenocarcinomas (4) for colorectal cancer, presenting a baseline-SUVmax average of 6.9, 10.8 and 6.5 g/ml, respectively. At diagnosis, size of lesions ranged 7-42 mm with global SUVmax average of 7.9. 75% patients with SD already had a decrease of metabolic activity within early evaluation with no significant reduction of size. Diffuse low metabolic uptake was seen in most patients up to 18 months due to inflammatory changes. 25% had PD, both on PET and CT: 2 in early, 2 in intermediate and 1 in late evaluation. **Conclusion**: Although larger number of patients is required, these preliminary results show that metabolic response with FDG-PET/CT is more reliable than CT in monitoring lung tumoral lesions treated with SBRT, probably because SBRT-induced CT changes may have a consolidation/mass-like appearance and therefore, differentiation from tumor recurrence can be challenging. However, it's important to notice that moderate post-SBRT hypermetabolic activity may persist up to 18 months without definite evidence of recurrence. PET response correlated well with clinical response and appears to be a good early surrogate of outcomes following SBRT.

EP161

Role of late response evaluation in Non Small Cell Lung Cancer (NSCLC) treated with EGFR Tyrosine Kinase Inhibitor with PET quantitative parameters

A. BHOIL[1], B. Mittal[2], N. Singh[2], B. Singh[2]; [1]Regional Cancer Centre, Shimla, INDIA, [2]Postgraduate Institute of Medical Education and Research, Chandigarh, INDIA.

Objective: To evaluate significance of late imaging for response evaluation of 18F-FDG PET/CT compared to early response imaging following treatment by EGFR TKI in non-small cell lung cancer (NSCLC). **Method**: Prospective serial imaging with18F-FDG-PET /CT for response evaluation in 23 patients (14M, 9F; mean age 57.6) with Stage IIIB-IV advanced NSCLC was done before start of EGFR-TKI therapy, at 3week(early) & at 6week(late). The metabolic response was assessed

using modified PERCIST criteria for changes of SUV_{peak}, SUL_{peak} and TLG in hottest lesion. The statistical analysis using Kaplan-Meier analysis and the log-rank test were performed to analyze the association with the median overall survival (OS) and the progression free survival (PFS). **Results:** Disease was classified in patients at 6 weeks as disease control (DC=20) and no disease control (NDC=3) compared to that at 3 weeks (DC=22, NDC=1). The change in metabolic disease response in form of disease progression was seen in 2 patients at 6 weeks. The response evaluation with SUV_{peak} showed statistically significantly (p=0.049) median OS among DC-258 d was more compared to NDC-129d at 3 weeks and at 6 weeks (DC 271d vs NDC 172d;p=0.115). No statistically significant PFS was seen between the DC (172 vs 128 d; p: 0.183) and NDC at 3 weeks or at 6 weeks. (169 vs 172; p: 0.461) The response evaluation with TLG showed no change in disease classification in terms of DC=19 and NDC=4 in patients at 6 weeks compared to 3 weeks. The median OS time was similar at 3 weeks (p=0.496) and at 6 weeks with between DC-227d but was less compared to NDC-353d. No change in survival was seen at 6 weeks. No statistically significant PFS was seen between the DC (172 vs 165 d; p: 0.172) and NDC at 3 weeks or at 6 weeks (172 vs 165; p: 0.172) when evaluated with TLG. TLG analysis in progressive disease patients showed non-significant shorter time to progression (165 vs 172; p: 0.172) at 3 weeks and at 6 weeks **Conclusion**: Although the early imaging for response evaluation is highly recommended considering the cost effective results provided by early imaging. Our results suggest that late imaging may be of value in progressive prediction of treatment response especially in patients presenting with stable metabolic disease in early imaging. The semi-quantitative PET measures as TLG in early response assessment of NSCLC patients do not perform significantly better than the previously proposed SUV_{peak}.

EP162

Is there diagnostic and prognostic importance of serum anti-p53 antibody level in lung cancer?

Z. Hasbek[1], B. Turgut[1], O. T. Dogan[2], B. Yücel[3], S. Berk[2], I. Sarı[4], Y. Silig[4], M. M. Seker[5], S. A. Ertürk[1]; [1]Cumhuriyet University School of Medicine,Department of Nuclear Medicine, SIVAS, TURKEY, [2]Cumhuriyet University School of Medicine,Department of Chest Diseases, SIVAS, TURKEY, [3]Cumhuriyet University School of Medicine,Department of Radiation Oncology, SIVAS, TURKEY, [4]Cumhuriyet University School of Medicine,Department of Biochemistry, SIVAS, TURKEY, [5]Cumhuriyet University School of Medicine, Department of Medical Oncology, SIVAS, TURKEY.

Aim: Lung cancer is the leading cause of cancer-related deaths worldwide. Survival rate in lung cancer is low especially in advanced diseased inoperable patients in spite of new treatment options like immunotherapy. So there are studies which aimed at new treatment options and early diagnostic options. p53 is one of the most studied tumor supressor gene for this reason. Because p53 is mutated in 60-70% of cancer patients. Recent researches suggest that serum anti-p53 Ab level can be considered as biomarkers to detect many types of cancer, as ovarian cancer, esophageal cancer, breast cancer and lung cancer. In this study we aimed that are there any diagnostic and prognostic importance of serum anti-p53 Ab level in lung cancer patients. **Materials-Methods:** Patients were included who were referred to our department with the purpose of ^{18}F-FDG-PET/CT imaging for staging due to lung cancer diagnosis (LC) and patients who were performed ^{18}F-FDG-PET/CT for diagnosis in the cause of the suspected pulmonary nodule in thorax CT but not detected pathologic FDG accumulation (NAPN=pulmonary nodule with non-avid-FDG) and healthy volunteers. Serum anti-p53 Ab levels were measured with ELISA method in the all patients. **Results:** A total of 65 LC patients (age:37-80years;median age:63 years;58male/7female), 47 patients with NAPN (age:22-80years;median age:57years;20male/27female), and a total of 34 healthy volunteers (age:44-89years; median age:63years;26male/8female) were included in this study. Median serum anti-p53 Ab levels are 3.4 ng/mL in LC patients, 3.77 ng/mL in NAPN patients, 3.07 ng/mL in healthy volunteers. There is no statistically significant difference for serum anti-p53 Ab level in LC and NAPN patients (p=0.678). Moreover there is no statistically significant difference for serum anti-p53 Ab level in patients and healthy volunteers (p=0.377). Two-year median survival of patients was 14 month. It has been found that there is no effect of serum anti-p53 Ab level whether >3.4 or <3.4 on the patient survival rate (p=0.652). **Conclusion:** Even though serum anti-p53 Ab is very important in carcinogenesis, we think that serum anti-p53 Ab level by itself is not important in lung cancer diagnosis and survival rate. There are multiple factors in carcinogenesis and this may be the reason of this situation. But we think that this study must be done with further patient number.

EP163

Potential prognostic value of ^{18}F-FDG-PET/CT imaging in patients with non-small cell lung cancer using metabolic and anatomical parameters—exploratory analysis of retrospective data from 25 patients

T. S. Nakuz[1], F. Gröller[1], W. Wadsak[1], P. Anner[1], B. Fueger[2], A. Haug[1], M. Hacker[1], G. Karanikas[1]; [1]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Vienna, AUSTRIA, [2]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Radiology, Vienna, AUSTRIA.

Aim of the study: The objective of this study was to determine the prognostic value of relative changes in SUV_{max}, HU, and size of the primary lesion obtained by ^{18}F-FDG-PET/CT to predict overall survival in patients with non-small cell lung cancer (NSCLC). **Materials and Methods:** In this retrospective study, 25 patients (18 males and 7 females) 43 to 87 years of age (mean age, 64.2 years) were included. All patients underwent a pre-treatment ^{18}F-FDG-PET/CT-scan and a post-therapy scan. For statistical evaluation, the median decrease in SUV_{max}, HU, and size of the primary lesion in patients was dichotomized using the median observed value. Overall survivals were computed by the Kaplan-Meier method and then compared between the two groups. The significance of prognostic variables for outcome was calculated by the log-rank test. **Results:** The average timespan between the two scans was 225 days (66 to 485 days). Twelve patients received chemotherapy, nine received radiotherapy, and four received radio-chemotherapy. Eleven patients had an adenocarcinoma, ten had a squamous cell carcinoma, and results for the remaining four patients were not available. The median decrease of SUV_{max} was 36% (range, an increase of 58% to a decrease of 80%). The two-year overall survival was not significantly different for patients with a less than 36% decrease in SUV_{max}, at 61.5%, than for patients with a greater than 36% decrease, at 66.7% (p=.816). For HU, the median decrease was 7.8%; therefore, the two-year overall survival for patients under 7.8% decrease was 66.7% and for patients with a HU decrease higher than the median 58.3% (p=.215).The median decrease in the length of the primary tumor was 3%. The two-year survival of patients with a lower than median decrease was 66.7% and 58.3% with a higher than median decrease (p=.822). **Conclusion:** Based on the results in our patient cohort, the functional and anatomical parameters (SUV_{max}, HU, and size of tumor) using ^{18}F-FDG-PET/CT imaging do not appear to provide prognostic value. Further prospective studies should elucidate the usefulness of these parameters in the early/late stages of NSCLC.

EP164

Delayed 18F-FDG PET imaging can improve detection of lesions in patients with advanced non-small cell lung cancer

S. Krebs[1], M. Dunphy[1], J. Humm[1], J. Chaft[1], J. Fredrickson[2], W. A. Weber[1]; [1]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES, [2]Genentech, Inc., San Francisco, CA, UNITED STATES.

Objectives: For historic reasons, PET/CT imaging is usually started approximately 60 min after injection of 18F-FDG. However, there are only few data that have investigated if and to which extent lesion detection changes at later time points. The aim of this study was to investigate, whether delayed 18F-FDG-PET/CT improves image contrast and lesion detectability in patients with NSCLC based on changes in FDG uptake, tumor-to-normal tissue ratios, and signal-to-noise ratio (SNR). **Methods:** Retrospective review of 16 patients with advanced NSCLC who underwent FDG-PET/CT with a GE DSTE PET/CT. Each patient was scanned at 60 min and 180 min after injection of 12 mCi FDG (6-7 bed positions, 3 min each). Volumes of interest were placed over up to 5 FDG avid lesions (with typical CT features of metastases) on the 60 min images. The same lesions were identified on the 180 min images and maximum SUVs normalized to body weight (SUVmax) were determined. Image contrast was evaluated by dividing SUVmax of the lesions by the mean SUV of the liver. As a measure of the signal-to-noise ratio (SNR) we subtracted the average uptake in normal liver from the SUVmax of the lesion and divided by the standard deviation of FDG uptake in the liver. SUVmax, contrast and SNR were determined at early (E-SUVmax; E-C, E-SNR) and delayed (D-SUVmax, D-C, D-SNR) imaging and compared by a Wilcoxon signed-rank test. **Results:** A total of 71 lesions with an average E-SUVmax of 7.1 (1.1-18.2) were analyzed. At 180 min, SUVmax increased for 69 of the 71 lesions resulting in an average D-SUVmax of 9.3 (1.8-25.4, $p<0.0001$). Contrast and SNR improved for 71/71 and 56/71 lesions, respectively: E-C 4.4 (0.6-11.2) and D-C 7.1 (1.5-19.8); E-SNR 62.7 (-4.2-240, $p<0.0001$) and L-SNR 73.2 (3.8-221, $p<0.0001$). An additional 32 lesions were identified in 11 patients on the 180 min images with an average D-SUVmax of 3.5 (2.6-4.7). **Conclusions:** Imaging at 180 min increases image contrast and SNR of FDG PET/CT scans and identifies more lesions than standard imaging at 60 min. Modification of current PET imaging protocols may be justified.

EP165

Identification of factors contributing to misdiagnosis in assessment of lymph node metastases among patients with NSCLC imaged by 18F-FDG PET/CT

J. Teodorczyk[1], B. Brockhuis[1], G. Romanowicz[1], W. Cytawa[1], I. Wenzel-Duszynska[1], J. Kozlowska-Gladki[1], P. Lass[1,2]; [1]Department of Nuclear Medicine, Medical University of Gdansk, Gdansk, POLAND, [2]Division of Molecular Spectroscopy, Institute of Experimental Physics, University of Gdansk, Gdansk, POLAND.

Objective: Study aims to identify sources of errors in evaluation of lymphonodal metastases using 18F-FDG-PET/CT in NSCLC patients. Material and methods: Study included 89 patients and 436 nodal stations. Imaging results were compared to pathological status of operative material which served as the "gold standard". Results: The most relevant source of erroneous false negative assessment seems to be associated with limited spatial resolution and partial volume effect of PET - in most false negative interpretations lymph nodes were relatively small (subcentimeter). Another important factor increasing the probability of false negative result was location - the hilar nodes were most frequently omitted due to pulsation and breathing blurring, which were most pronounced in the hilum. Another factor complicating hilar nodes evaluation was relatively high vascular background activity reducing target-to-background ratio and chance for detection. Central, hilar location of the primary tumor increased the risk of false assessment of hilar nodes - both negative and positive. It seems to be due to Compton scattering of the primary tumor activity resulting in masking the nodal activity or misinterpretation of primary tumor broadly scattered activity as the nodal one. Frequent encasement of hilar nodes by the primary lesion makes imaging diagnosis of nodal involvement impossible, but can be reported by the pathologist being a source of false negative PET-CT result. Small group of false results seems to be related to inaccuracies in assignment to a particular nodal group by surgeon and nuclear medicine specialist. It especially affects nodes localized on the border of lymphonodal subgroups or in case of block resection (in one piece) of many lymphatic stations without detailed markings. Localization inaccuracies are aggravated by motion artifacts - both in low-dose-CT and PET. Interestingly some false positives with high uptake of radiotracer in lymph nodes were in cases with severe necrosis of the primary lesion probably due to intense inflammation reactive to tumor necrosis. Conclusions: Accuracy of 18F-FDG-PET/CT in nodal staging of NSCLC is negatively affected by many factors both technical and biological. Biological factors disturbing accurate nodal staging are better recognized. Numerous technical conditions can additionally impair accuracy of the nodal staging by PET-CT in NSCLC cases. Identification and constant awareness of all these factors can help reduce the risk of misdiagnosis.

EP166

Diffuse Increased Splenic FDG Uptake in Lung Cancer Patients: Accompanying Infection or Systemic Inflammation?

L. Ege Aktas, A. Sarikaya, S. Soyluoğlu Demir; Trakya University Medical Faculty Department of Nuclear Medicine, Edirne, TURKEY.

Objective: Chronic disease- inflammatory anemia is one of the common complications during cancer surveillance and it is multifactorial. Recently, a few studies suggested anemia, inflammations and infections were associated with increased splenic uptake on F-18 fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) during cancer surveillance. The purpose of this study was to investigate the association of diffuse splenic FDG uptake on PET/CT with tumor maximal standardized uptake values (SUVmax), presence of distant metastases, hematological and inflammatory parameters to clarify the clinical significance of this event in lung cancer patients. **Material and Methods:** We retrospectively analyzed the reports of FDG PET/CT scans and selected 15 lung cancer patients, with diffuse splenic FDG uptake on their initial scan, as the patient group (Group1). Also a total of 12 patients who underwent FDG PET/CT scans for histopathologically proven lung cancer recently were enrolled as a control group (Group2). All the 27 patients had hematological data including CRP within 5 days before or after PET/CT survey. ROIs were placed on the tumor, liver, spleen and iliac crest, to determine the SUVmax's. The possible associations between the spleen/liver (S/L) and bone marrow/liver ratios (BM/L) and tumor SUVmax, presence of metastasis, various hematological parameters were evaluated. **Results:** S/L ratio and hemoglobin (Hg) values were different between the two groups ($p=0{,}000$ and 0,05 respectively). The number of patients with anemia were significantly higher in Group1 ($P=0{,}02$). Although the mean Hg values were different between two groups, there was no correlation between Hg values and S/L ratios. There was not any significant difference between the numbers of patients which had an accompanying infection site in both groups. Twelve patients had not got any evidence of infection at the time of PET/CT survey. Eleven patients had accompanying pneumonia, 1 patient had meningitis, 1 patient had mastoiditis, 1 had lymphadenitis and another had osteomyelitis. Only CRP values were correlated with S/L ratios in Group1 among

various parameters (r=0,559, p=0,05). BM/L ratios were positively correlated with white blood cell (Wbc), neutrophil count (Neu) in all of the patients (r=0,421, p=0,02, r=0,426, p=0,02, respectively). **Conclusion:** Our results suggest that, increased splenic FDG uptake in lung cancer patients is related with the spleen's function in humoral immunity and hematopoiesis, during cancer surveillance. It is correlated with the inflammation degree and enhanced by anemia rather than an accompanying infection site.

Bone Marrow Involvement In Follicular Lymphoma; Correlation Between FDG-PET/CT And Bone Marrow Biopsy

M. CORTES-ROMERA[1], S. MERCADAL-VILCHEZ[2], E. LLINARES-TELLO[1], I. CARRO[2], A. SABATÉ-LLOBERA[1], J. VERCHER-CONEJERO[1], L. GRÀCIA-SÁNCHEZ[1], F. CLIMENT-ESTELLER[3], I. ROMERO-ZAYAS[1], E. GONZÁLEZ-BARCA[2], J. MESTRES-MARTIN[1], C. GÁMEZ-CENZANO[1]; [1]PET UNIT NUCLEAR MEDICINE. IDI. HOSPITAL U BELLVITGE-IDIBELL, L-HOSPITALET DE LLOBREGAT (BARCELONA)., SPAIN, [2]DEPARTMENT OF HEMATOLOGY. ICO. HOSPITAL DURAN I REYNALS-IDIBELL, L-HOSPITALET DE LLOBREGAT (BARCELONA)., SPAIN, [3]DEPARTMENT OF PATHOLOGY. HOSPITAL U BELLVITGE-IDIBELL, L-HOSPITALET DE LLOBREGAT (BARCELONA)., SPAIN.

Aim: Bone or bone marrow focal FDG uptake in PET/CT in Hodgkin lymphoma (HL) and diffuse large B-cell lymphoma (DLBCL) is highly sensitive for bone marrow involvement (BMI) and may obviate need for bone marrow biopsy (BMB). By contrast, BMB is required in staging and re-staging follicular lymphoma (FL) patients due to limited FDG-PET sensitivity. The aim of this study was to assess the utility of FDG-PET/CT for BMI detection in patients with FL compared to BMB. **Material and Methods:** Sixty-six patients with FL were studied with FDG-PET/CT for staging or re-staging. As the reference standard was BMB (in the left iliac crest), 14 patients were finally excluded due to absent or unsuccessful BMB (insufficient material). Regarding BMI, a positive PET scan was considered as diffuse bone marrow uptake (BMU) higher than liver uptake or focal/multifocal/heterogeneous BMU pattern. Negative PET scan was considered as diffuse BMU lower than liver uptake or normal distribution. Kappa agreement index was performed between both techniques. Sensitivity, specificity, negative and positive predictive values were calculated. **Results:** Fifty- two patients (30/22; F/M), with a mean age of 59 years (range 30-80) were analyzed. FL histological types were: grade 1-2 (58.5%), grade 3A (19.5%), grade 3B (9.7%) and composite FL/DLBCL (12.2%). The stages were I (4%), II (17%), III (27%) and IV (52%). BMI was detected in 23 patients (44%) by FDG-PET/CT and in 17 patients (33%) by BMB. Concordant results were obtained in 38 (73%); 13 with positive PET scans (5 uni-/multifocal, 6 heterogeneous and 2 diffuse patterns) and BMB and 25 with negative PET/CT and BMB. Discordant results were obtained in 14 (27%), 10 of them with positive PET scans (4 diffuse and 6 multifocal patterns) and negative BMB (not performed in active sites). The remaining 4 discordant cases had negative PET scans and positive BMB. Diffuse BMU higher than liver uptake had positive BMB in 2/6 patients (33%). Kappa index was 0.54. Sensitivity, specificity, negative and positive predictive values were 76%, 71%, 56% and 86%, respectively. **Conclusion:** FDG-PET/CT detects more BMI in follicular lymphoma compared with BMB. Concordant results between FDG-PET/CT and BMB were found in 73% of patients. Kappa index was moderate. Positive PET scan with a diffuse pattern was found in 6 patients; 2 of them with a positive BMB.

EP168

Diffusely increased bone marrow uptake of 18F-FDG is significantly correlated with total metabolic tumour volume in patients with newly diagnosed Hodgkin Lymphoma

M. A. Pedersen[1], L. C. Gormsen[1], P. H. Kamper[2], F. D'Amore[2]; [1]Department of Nuclear Medicine and PET-center, Aarhus University Hospital, Aarhus, DENMARK, [2]Department of Haematology, Aarhus University Hospital, Aarhus, DENMARK.

Background 18F-FDG PET/CT has become an established part of the initial staging process in patients with newly diagnosed Hodgkin Lymphoma (HL) and is recommended in international guidelines as the preferred imaging option. In a significant proportion of patients undergoing pre-therapeutic 18F-FDG PET/CT, diffusely increased 18F-FDG uptake is observed in the bone marrow (BMU). This is generally considered to be of benign aetiology but may also indicate para-neoplastic bone marrow activation. Recent studies have shown that pre-therapeutic metabolic tumour volume is a prognostic parameter in patients with newly diagnosed HL. However, evaluation of tumour burden is not done routinely since it is laborious and requires specialized tools for accurate quantification. Since BMU is easily evaluated on 18F-FDG PET/CT using widely available viewing tools, it was our aim to examine if there is a correlation between BMU and total tumour burden. **Material and methods** A total of 115 patients (median age 44, range 8-83) with newly diagnosed HL referred to 18F-FDG PET/CT for initial staging between 2008 and 2014 were retrospectively reviewed. 18F-FDG uptake was measured in the vertebral bone marrow (L3/L4) (SUVvertebra) and in the liver (SUVliver). BMU was calculated as SUVvertebra/SUVliver. In addition, the total metabolic tumour volume (TMTV) was measured using semiautomatic methods (Hermes Tumourfinder). A standardised uptake value (SUV)≥2.5 in pathological lymph nodes and extranodal lesions were considered to represent lymphoma (TMTV2.5). For each lesion with SUV≥2.5, a new tumour volume was calculated using a recommended 41% SUVmax threshold (TMTV41%). First, the correlation between BMU and TMTV2.5 as well as TMTV41% was analysed and second, a multivariate regression analysis was performed to identify independent predictors of BMU. **Results** Mean BMU was 0.98 (SD 0.26, range 0.56-2.13). Mean TMTV2.5 was 401 ml (SD 469, range 0 - 2510) and 102 ml (SD 169, range 0-1121) when 41% SUVmax was used. Both TMTV2.5 and TMTV41% were significantly and positively correlated with BMU, however, the correlation was better for TMTV2.5 (Pearson r=0.34, p<0.0001). In a multivariate regression model with BMU as dependent variable and age, lymphocytes, haemoglobin and TMTV2.5 as independent variables, TMTV2.5 and age were independent predictors of BMU (combined model r2 = 0.36, p<0.0001). **Conclusion** Diffusely increased 18F-FDG uptake in the bone marrow is significantly correlated with total tumour volume using both a SUV>2.5 and 41% of SUVmax threshold. Since BMU is easily measured, it could be a potential candidate parameter for evaluating prognosis at initial staging.

EP169

Bone Marrow FDG Uptake Predicts in Vitro CLL Cells Activation Through RANKL/RANK Loop

R. Piva[1], S. Bruno[2], F. Fiz[1,3], M. Sicignano[1], M. Pennone[1], S. Matis[4], G. Cutrona[5], A. Ibatici[6], A. Massone[7], C. Campi[8], M. Piana[8], E. Gugiatti[2], F. Fais[2], G. Sambuceti[1], C. Marini[9]; [1]Chair of Nuclear Medicine, Genoa University, IRCCS San Martino-IST, Genoa, ITALY, [2]Department Experimental Medicine, University of Genoa, Genoa, ITALY, [3]Nuclear Medicine Unit, Department of Radiology, Uni-Klinikum, Tubingen, GERMANY, [4]Molecular Pathology Unit, Genoa University, IRCCS San Martino-IST, Genoa, ITALY, [5]Molecular Pathology Unit, Genoa University, IRCCS San Martino-IST,, Genoa, ITALY, [6]Department of Haematology and Bone Marrow Transplants, IRCCS Martino-IST, Genoa, ITALY, [7]CNR SPIN (Superconductors, oxides and other innovative materials and devices), Genoa,

ITALY, [8]Department of Mathematics, University of Genoa, Genoa, ITALY, [9]CNR Institute of Molecular Bioimaging and Physiology, Milan, Section of Genoa, Genoa, ITALY.

Aim. B-cell Chronic Lymphocytic Leukemia (CLL) combines progressive insensitivity to apoptotic stimula with an accelerated proliferation of neoplastic lymphocytes. There is accumulating evidence that both features could be sustained by nuclear-factor kB and its ligand (RANK/RANKL) overexpression whose interaction can generate an autocrine loop, increasing interleukin secretion and providing a shield against apoptotic signals and cytotoxic treatments. In the present study we tested the correlation between RANK/RANKL activation, response to RANKL-specific antibody (Denosumab, DNS) and bone marrow metabolism, using a computational analysis application on FDG-PET/CT images. Materials and Methods. FDG-PET/CT images of 22 consecutive CLL patients (6 Binet A, 11 Binet B and 5 Binet C, mean age 69±13 years) were analyzed. The algorithm extracted the intraosseous volume (IBV) from whole-body PET/CT images. Mean IBV SUV, normalized by blood-pool (target-to-background ratio, TBR) was assessed from the co-registered PET images. CLL cells from each patient were cultured; vitality was defined as vital cells percentage after 96 hours of unstimulated culture. Proliferation (HDF) was defined by % of hyper diploid cells, i.e. cells in S+G2M cell cycle phases after five-days activation. Response to DNS was defined as % HDF reduction after DNS. Relative fluorescence intensity (RFI) was measured for both RANKL and RANK surface expression. Results. Viability of neoplastic clone did not correlate with bone marrow TBR (R=0,18, p=ns). By contrast, HDF directly correlated with TBR of the whole bone marrow (R=0,55, p<0,01) as well as TBR in axial (R=0,57, p<0,01) or appendicular segments (R=0,59, p<0,01). Patients with bone marrow TBR lower than the median value (1,21) showed a significantly lower neoplastic clone proliferating activity with respect to the remaining ones (11±6% vs. 18±7%, respectively, p<0.05). Moreover, HDF directly correlated with response to DNS (r=0,71, p<0,01). Finally, response to DNS correlated with RANK, but not with RANKL, expression (R=0,52, p<0,01). Conclusions. In CLL patients, analysis of FDG uptake in the bone marrow provides an index of leukemic clone proliferation. The relevance of this finding at least partially relies on the correlation between clone aggressiveness and RANK/RANKL loop activation, which might represent a potential therapeutic target.

EP170

Prognostic value of 18F-FDG PET-CT in patients with Lymphoma who underwent Allogeneic or Autologous Bone Marrow Transplantation. Preliminary results

L. G. Diaz[1], L. Lopez[2], B. Perez[1], C. Montes[3], R. Ruano[1], D. Caballero[2], P. Tamayo[1]; [1]Nuclear Medicine Department. Hospital Universitario de Salamanca, Salamanca, SPAIN, [2]Hematology Department. Hospital Universitario de Salamanca, Salamanca, SPAIN, [3]Radiological Protection Department. Hospital Universitario de Salamanca, Salamanca, SPAIN.

AIM: To study the role of 18F-FDG PET-CT in the evaluation of treatment response in those patients with Hodgkin and aggressive Non Hodgkin Lymphoma (HL and NHL, respectively) who underwent Bone Marrow Transplantation (BMT), making a difference between Allogeneic (AlloBMT) and Autologous (AutoBMT) transplantation. METHOD Prospective study of 22 patients (12 HL with 7 AutoBMT and 5 AlloBMT; 10 NHL, with 8 AutoBMT and 2 AlloBMT). In each patient, three 18F-FDG PET-CT were performed: immediately before BMT (PET0), to determinate patient status; and 100 days (PET1) and 1 year (PET2) after BMT, to evaluate early and late response to treatment, respectively. We considered as positive PET those ones with at least one hypermetabolic lesion with SUVmax bigger than Liver uptake. We evaluated HL from NHL patients separately. RESULTS - 15 AutoBMT patients (7 HL; 8 NHL). 5 of them were positive PET0 and remained so in PET1 and PET2 (Predictive Value for no metabolic response: 100%). The other 10 patients who were negative PET0 remained negative in PET1 and 50% of them showed positive PET2 (50% of HL and 50% of NHL). - 7 AlloBMT patients (5 HL, 2 NHL), all of them negative PET0 and PET1. 80% of HL and 100% of NHL remained negative in PET2. CONCLUSION According to our preliminary results, 18F-FDG PET-CT has an excellent positive predictive value in those HL and NHL patients with positive PET0 and AutoBMT, and it is also a good predictor of complete metabolic response in those HL and NHL AlloBMT patients with negative PET0.

EP171

The importance of uptake time in FDG imaging of patients with lymphoma

J. T. Dunn[1], N. G. Mikhaeel[2], T. Puri[1,3], P. K. Marsden[1], M. J. O'Doherty[1], S. F. Barrington[1]; [1]PET Imaging Centre, King's College London, London, UNITED KINGDOM, [2]Department of Clinical Oncology, Guy's & St Thomas' Hospital, London, UNITED KINGDOM, [3]Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.

Aim: EANM guidance recommends 60 minute uptake for FDG oncology scans, however uptake increases in several tumours beyond 60 minutes. The aim of this study was to determine the time course of FDG uptake in common lymphoma types after injection and how this might affect imaging assessment. Methods: Patients attending for routine staging FDG PET-CT scans with classical Hodgkin's lymphoma (cHL), diffuse large B cell lymphoma (DLBCL) or follicular lymphoma (FL) were recruited. The protocol involved dynamic imaging for 90 minutes after injection and subsequent 10 minute static scans at 120 and 180 minutes. Dynamic images were summed to create two static images representing uptake from 55-65 and 80-90 minutes. Four static images (55, 80, 120, 180 min) for each patient were visually assessed by an experienced nuclear medicine physician blinded to scan time. Images were viewed with Hermes Medical Hybrid Viewer and scored as good (4), satisfactory (3), suboptimal (2) or poor (1) and ranked in order of preference considering the number, uptake, extent and contrast of lymphomatous lesions. Tumours were segmented using in-house software using the standardised uptake value (SUV) = 2.5. SUVmax and SUVmean were calculated for each scan. Visual scores and ranks were analysed using the Skillings-Mack test. Quantitative parameters were analysed using a mixed model to assess effects of time and group. Results: Results are available for 36 patients with cHL (16), DLBCL(10) and FL (10). Means and ranges for SUVmax were 13.7, 4.4-27.5 (cHL) , 35.6, 6.6-97.9 (DLBCL), 8.7, 1.4-24.0 (FL). Visual scores showed no difference between time points (p=0.25) with an overall mean score of 3.6 (s.d. 0.6). Ranks showed a highly significant effect of time (p<0.0001) with the later time points ranking highest (mean ranks: 3.3, 2.7, 1.6 and 1.4 for 55, 80, 120 and 180 minute images respectively) and was present across lymphoma subtypes (p<0.002). SUVmean time activity curves were observed to increase during dynamic imaging for most patients and quantitative analysis revealed significant effects of time and group for SUVmean (p<0.0001), SUVmax (p<0.007). The average increases in SUVmean between 55-180 minutes were 22% for the cHL group, 41% for the DLBCL group and 58% for the FL group. Conclusion: Imaging was satisfactory or good at all time points but optimal at 120-180mins post injection. Imaging later than EANM guidance suggests may be beneficial in some lymphoma subtypes.

EP172

Splenic involvement in diffuse large B-cell lymphoma: Diagnostic criteria for FDG PET/CT determined by reproducibility of volumetric analysis in the normal spleen

M. Nogami[1], M. Nakabayashi[1], S. Hirabayashi[2], T. Hashimoto[1], D. Takenaka[1], S. Adachi[1]; [1]Hyogo Cancer Center, Akashi, Hyogo, JAPAN, [2]Institute of Biomedical Research and Innovation, Kobe, Hyogo, JAPAN.

PURPOSE: The purpose was to assess the reproducibility of FDG uptake and volume of the spleen in normal subjects and to determine the diagnostic criteria for splenic involvement in patients with diffuse large B-cell lymphoma (DLBCL). MATERIALS AND METHODS:Twenty normal subjects without hematological disorders and splenic impairments and 63 patients with DLBCL were retrospectively analyzed. For normal subjects FDG PET/CT was performed twice within 6 months, and the patients underwent PET/CT at initial staging and end of the therapy. SUVpeak, volume of the spleen on CT (CT volume) and spleen to liver- SUVpeak ratio (S/L ratio) were measured for both normal subjects and patients. To evaluate the reproducibility within same scan and limits of agreements between different scans, SUVpeak, CT volume and S/L ratio in normal subjects were statistically assessed by the Bland-Altman analysis in each normal subject. To determine the diagnostic criteria for splenic involvement, cut-off values for SUVpeak, CT volume and S/L ratio were defined from reproducibility coefficient for the normal spleen. The sensitivity and specificity by using each cut-off value and visual analysis according to the Lugano classification were then compared by the McNemar's test. The reference standard for splenic involvement was determined as the decrease in S/L ratio larger than reproducibility coefficient after therapy in each patient. RESULTS: The reproducibility of measurement of SUVpeak, CT volume and S/L ratio within same scan for normal subject was mean difference of 0.000, 0.38 [cm^3] and 0.00, respectively, and reproducibility coefficient of 0.000, 9.228 [cm^3] and 0.000, respectively. The limits of agreements of those values between different scans for normal subject was mean difference of 0.028, 10.96 [cm^3] and 0.024, respectively, and reproducibility coefficient of 0.506, 43.53 [cm^3] and 0.146, respectively. The sensitivity of S/L ratio (76.9%) was significantly higher than that of visual analysis (61.5%), CT volume (46.2%) and SUVpeak (53.8) (p=0.0313). CONCLUSIONS: The difference in CT volume between different scans for the same normal subject is relatively larger than that of SUVpeak and S/L ratio. Based on the cut-off values determined by reproducibility assessment of normal subjects, diagnostic performance of S/L ratio is significantly superior to the visual analysis, evaluation of CT volume and SUVpeak in patients with DLBCL.

EP173

Prognostic value of interim ^{18}F-FDG PET/CT in DLBCL according to molecular profiles

J. Kim, Y. Song, S. Kim; Seoul National University Bundang Hospital, Gyeonggi-Do, KOREA, REPUBLIC OF.

Purpose: Diffuse large B cell lymphoma is a pathologically heterogeneous disease with different prognosis according to its molecular profiles. Previous studies that have investigated the value of interim ^{18}F-fluoro-2-dexoy-D-glucose (FDG) positron emission tomography/computed tomography (PET/CT) in DLBCL have reported conflicting results. The purpose of this study was to evaluate the prognostic value of interim PET/CT in DLBCL according to germinal center B-cell-like (GCB) and non-GCB molecular profiling. Methods: We enrolled 118 newly diagnosed DLBCL patients treated with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP) retrospectively. Interim FDG-PET/CT scans performed after 2 or 3 cycles of R-CHOP treatment were evaluated based on the International Harmonization Project (IHP) criteria. Patients were grouped as GCB or non-GCB molecular subtypes according to immunohistochemistry (IHC) results of CD10, BCL6 and MUM1, based on Han's algorithm. Results: Results are as follows: 35% GCB, 65% non-GCB; interim PET/CT, 55% negative, 45% positive. Ann Arbor stage III or IV (HR = 5.12, 95% CI =1.26 -20.82, p=0.02) and positive interim PET/CT (HR = 2.20, 95% CI = 1.06 - 4.54, p= 0.03) were significant prognostic factors for progression free survival (PFS) in multivariate analysis. During the median follow-up period of 23 months, the positive interim PET/CT group showed significantly inferior PFS compared to the negative interim PET/CT group (p=0.03) in entire patients. A subgroup analysis according to molecular profiling demonstrated similar significant difference in PFS between the positive and negative interim PET groups in GCB subtype of DLBCL (p =0.02). However there was no significant difference of PFS between the positive and negative interim PET groups in non-GCB subtype of DLBCL. Conclusions: Interim PET/CT scanning had a significant predictive value for disease progression in the GCB subtype of DLBCL, but not in the non-GCB subtype. Therefore, molecular profiles of DLBCL should be considered for interim PET/CT utilization.

EP174

Semi-quantitative parameters could improve positive predictive value of interim FDG-PET/CT in Hodgkin Lymphoma

S. ANNUNZIATA[1], A. Cuccaro[2], S. Hohaus[2], A. Giordano[1], V. Rufini[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [2]Institute of Hematology, Università Cattolica del Sacro Cuore, Rome, ITALY.

Aim. Interim FDG-PET/CT after first cycles of chemotherapy (iPET) has recognized to be the best prognostic factor in patients with Hodgkin Lymphoma (HL). Nevertheless, recent studies indicated that iPET has still some limitations to optimally identify patients with different prognosis. In particular, positive predictive value in terms of relapse and progression (PPV) of visual analysis with five-point Deauville Score (DS) is still suboptimal. Semi-quantitative parameters could improve PPV of iPET and help clinicians to early identify patients with worse prognosis. Aim of this study is to compare PPV of visual and semi-quantitative analysis of iPET in patients with HL. Methods. Sixty-seven patients with HL who underwent iPET after two cycles of ABVD were retrospectively evaluated. For visual analysis, DS was used, considering DS>3 or DS>4 as positive findings. Semi-quantitative parameters considered were: ratio between target lesion and liver SUVmax (rPET); ratio between target lesion and mediastinal blood pool SUVmax (mPET); ratio between target lesion SUVpeak and liver SUVmean (qPET); target lesion metabolic tumour volume (MTV) and total lesion glycolysis (TLG). Two-years progression-free survival (PFS) and PPV were estimated, with relapse or progression recorded as adverse events. The receiver operating characteristic approach was applied to identify the optimal cut-point of semi-quantitative parameters with respect to events. Survival curves were estimated using the Kaplan-Meier product limit method. Log-rank tests were used to analyse for differences in PFS. A value of $p<0.05$ was considered statistically significant. Results. About visual analysis, DS was >3 in 25/67 patients, DS>4 in 14/67. PFS in patients with DS>3 and DS>4 was 53% and 27%, respectively. Nevertheless, patients with DS>3 and DS>4 had a low PPV (40% and 57%, respectively). About semi-quantitative parameters, SUVmax, rPET, mPET and qPET were prognostic factors in our population ($p<0.01$). Conversely, MTV and TLG were not prognostic factors ($p>0.05$). The most accurate cut-point in predicting adverse events for rPET, mPET and qPET were 1.14, 2 and 1.46, respectively. For values higher than the cut-point, PFS were 15%, 25% and 20%, respectively; PPV were 70%, 63% and 80%, respectively. Conclusion. iPET semi-quantitative parameters seem to have an incremental prognostic value over visual analysis in patients with HL. In particular, ratios between target lesion and background SUV (liver or mediastinal blood pool) could improve the predictive value in terms of relapse or progression. Further larger prospective studies are needed to evaluate the prognostic value of MTV and TLG.

EP175

Role of FDG-PET/CT in primary gastric diffuse large B-cell Lymphoma: a bicentric evaluation at staging and at the end of treatment

P. Ferro[1], M. Bertoli[2], D. Albano[2], M. Spallino[1], G. Bosio[2], F. Bertagna[2], F. Fallanca[3], R. T. Giubbini[2], L. Gianolli[3], M. Picchio[3]; [1]Università Milano Bicocca, Milano, ITALY, [2]Medicina Nucleare Spedali Civili di Brescia, Brescia, ITALY, [3]Ospedale San Raffaele, Milano, ITALY.

AIM: Primary gastrointestinal lymphoma represents the most common type of extranodal lymphomas. One of the more frequent subtypes is diffuse large B-cell lymphoma (DLBCL). The aim of this double institution study is to evaluate the role of flourine-18-fluorodeoxy glucose PET/CT (FDG-PET/CT) in staging DLBCL and its predictive value in the end of treatment (EOT) results. As far as we know this is the first study which deals with gastric DLBCL separately, and not as part of a haeterogenous group of gastric lymphomas or heterogeneous localizations of DLBCL. **MATHERIALS AND METHODS:** We retrospectively analyzed 60 patients (35 men and 25 women, mean age 60 years, age range 23-83) who underwent from 2006 to 2016 at San Raffaele Hospital in Milan and at Spedali Civili in Brescia both staging and EOT (chemotherapy) FDG-PET/CTscans for the evaluation of histologically confirmed DLBCL. A qualitative (FDG avidity) and semi-quantitative (maximum standardized uptake value body weighted (SUVmax), lesion-to-liver SUVmax ratio and lesion-to-mediastinum SUVmax ratio) analysis was performed on both PET/CT studies, considering gastric, nodal and extra-nodal localization of disease. Deauville score (DS) was calculated and compared to the qualitative evaluation of the scans. Treatment failure was defined by a DS >3. Statistical analysis was carried out with chi-squared test. P-Value of ≤0.01 was considered as statistically significant. **RESULTS:** Staging PET resulted postive in 95% of the patients, 35% with gastric involvement, 43% with gastric and nodal involvement and 22% with gastric, nodal and extranodal involvement (average SUVmax was 25,58; lesion-to-liver SUVmax ratio 10,51; lesion-to-mediastinum SUVmax ratio 12,59). EOT scans were positive in 33% patients, 47% with only gastric involvement and 53% with gastric and lymphnodal involvement (average SUVmax was 4,55; lesion-to-liver SUVmax ratio 1,61; lesion-to-mediastinum SUVmax ratio 1,91). DS indicated in 58% of the patients treatment failure and no statistically significant difference was found with the qualitative analysis of the scans. Neither SUV max of the lesion nor extragastric involvement in the staging scan showed statistically significant correlation to results of EOT scan considering both qualitative analysis and DS. **CONCLUSION:** FDG-PET is a usefull tool in staging gastric DLBC lymphoma, detecting succefully either gastric, nodal and extranodal localizations of disease. In our experience SUVmax , lesion-to-liver/blood pool SUVmax ratio, extranodal involvement in the staging scan are not capable of predicting EOT results. No statistically significant difference was found in the interpretation of EOT FDG-PET/CT between a qualitative analysis of the scans and the DS.

EP176

Utility of FDG-PET in initial assessment of primary central nervous system lymphoma

M. Bertaux[1], A. Kas[1], C. Soussain[2], E. Veronique[3]; [1]Hospital Pitié-Salpétrière, Paris, FRANCE, [2]Hospital René-Hughenin, Curie, Saint-Cloud, FRANCE, [3]Hôpital René-Huguenin, Saint-Cloud, FRANCE.

Introduction: Primary central nervous system lymphoma (PCNSL) is a rare form of non-Hodgkin lymphoma (diffuse large B-cell lymphoma (DLCBL) in more than 90% of cases) limited to the brain, eye and spinal chord. Initial systemic work-up is needed to exclude systemic localisations of DLCBL and is usually done with computed tomography (CT) and bone marrow biopsy (BMB). Aim: The aim of this study was to evaluate the utility of 18-fluoro-deoxy-glucose positron emission tomography (FDG-PET) in the initial assessment of PCNSL. Materials and methods: In this bi-centric study, 70 patients who had an FDG-PET before chemotherapy for a PCNSL were included and had their imaging, pathological, clinical and biological data reviewed. Results: For 6 patients (8,5 %), the eyes were the only CNS structures involved and vitreous analysis showed large B-cells in all cases. In total, pathological analysis showed DLCBL in 64 patients/69 (92,7 %), immunoblastic B-lymphoma in 2 patients (2,8%), Lymphomatosis cerebri in two patients (2,8%) and T lymphoma none otherwise specified in one patient. In FDG-PET, systemic significant uptakes were seen in 12 patients and were considered as malignant lymphoma systemic involvement in 6 patients (8,5%): two patients with bone marrow involvement for which BMB were negative, one patient with bowel involvement, one with hepatic involvement, one patient with adrenal involvement and one patient with nodal, adrenal and splenic involvement. In initial brain MRIs there was enhancing lesions in 56 of the 64 patients with cerebral involvement (87,5%) and only FLAIR hypersignals in 8 patients (12,5%). Mean size of greatest enhanced lesion was 32 mm. There was one lesion in 29 patients (45%) and multiple lesions in 35 patients (55%). For patient with brain involvement, FDG-PET showed at least one abnormal uptake in 53 patients (83%) and none in 11 patients (17%). Visibility of lesions in FDG-PET was strongly correlated with their size in MRI ($p< 0,001$). Visibility of at least one cerebral pathological uptake was correlated with event-free-survival ($p<0,05$) but intensity of tumoral hypermetabolism of visible lesions expressed as SUVmax or its ratio to contralateral, cerebellar or hepatic uptake was not. Corticosteroids therapy before FDG-PET was associated with the absence of visible uptake of brain lesions and lower tumoral SUVmax. Conclusion: FDG-PET is a useful imaging modality for initial staging of suspected PCNSL, especially in bone marrow. High initial tumoral hypermetabolism is not an independent pejorative prognosis factor in treated patients.

EP177

Can SUVmax-based Criteria accurately interpreting interim and end-of-treatment 18F-FDG PET/CT for the prognosis of patients with diffuse large B cell lymphoma?

Y. Zhang[1], Y. Fan[2], Z. Yang[2], X. Wang[2]; [1]Peking university cancer hospital & Institute, Beijing, CHINA, [2]Peking university cancer hospital, Beijing, CHINA.

Objective Our aim was to further investigate whether SUV_{max}-based criteria could be superior to the other two methods in analyzing interim and end-of-treatment PET.**Method** One hundred twenty six patients with DLBCL were recruited in the research and underwent baseline PET/CT scans. Eight-eight patients carried out PET/CT after 4 cycles of chemotherapy (PET-4), 91 ones performed end-of-treatment PET/CT (PET-end), and 53 ones were with both interim and posttherapy PET/CT scan. SUV_{max}-based criteria were adopted to analyze the interim and end-of-treatment PET/CT scans, comparing to five-point criteria and $\%\Delta SUV_{max}$ criteria. The optimal threshold of SUV_{max}-based criteria was decided via interobserver agreements and prognostic accuracies. Residue SUV_{max} higher than the optimal threshold or new ^{18}F-FDG avid lesions indicated the positive lesion in interim and end-of-treatment PET. Prognostic values of PET/CT interpreting with three criteria were compared via accuracy of survival analysis. Survival curves were obtained using Kaplan-Meier estimates compared using the log-rank test. Uni- and multivariate analysis of outcomes were performed using clinical variables and PET-4 and PET-end.**Results** The median follow-up was 19 months for 88 patients with PET-4 and 24 months for 91 patients with PET-end. Interobserver agreements were almost perfect (*k*value: from 0.824 to 1) when the threshold was set above 1.4 times of $SUV_{max\text{-}liver}$. In both PET-4 and PET-end, the better specificity, positive predictive value (PPV) and good negative predictive value (NPV) were achieved for progress free survival (PFS) and overall survival (OS)

using SUV_{max}-based criteria, comparing to 5-PS or $\%\Delta SUV_{max}$ interpretation. The 3-year PFS and OS were 6.7% and 28.6% for PET-4 with positive lesion and 77.1% and 78.1% for negative PET-4, respectively. Also, all of patients with positive lesion in PET-end suffered the progression of disease, while 3-year PFS of negative PET-end was 79.3%. Three-year OS was 44.4% for positive PET-end while 90.6% for the negative. Univariate analysis suggested stage, level of LDH, IPI, and performance status were adverse factors for PFS and OS. Cox regression multivariate analysis showed positive residue interpreting with SUV_{max}-based criteria in PET-4 and PET-end was an independent prognostic factor for PFS and OS.**Conclusion** This retrospective research demonstrated SUV_{max}-based criteria were better than five-point criteria and $\%\Delta SUV_{max}$ criteria in analyzing the interim and end-of-treatment PET imaging for the prognosis of DLBCL patients. Further test of SUV_{max}-based criteria will be investigated in HL and other NHL.

EP178

Utility Of Initial Staging ^{18}F-FDG PET-CT Scan To Detect Bone Marrow Infiltration In Patients Diagnosed Of Lymphoma: Can We Avoid Bone Marrow Biopsy?

M. Pedrera-Canal, M. Martínez de Bourio, R. M. Couto Caro, L. F. León-Ramírez, C. Riola-Parada, A. Serrano-Palacio, O. Salsidua-Arroyo, E. Cala-Zuluaga, J. L. Carreras-Delgado; HOSPITAL CLINICO SAN CARLOS, MADRID, SPAIN.

Objective: To evaluate the ability of 2-fluorine-18-luoro-2deoxy-D-Glucose (^{18}F-FDG) positron emission tomography/computed tomography (PET/CT) performed for initial staging in patients with newly diagnosed lymphoma compared to bone marrow biopsy (BMB), to detect bone marrow infiltration. Material and methods: Retrospective study from December/2014 until February/2016 including 40 patients (21 male and 19 female), with a mean age of 57.2 years old. They all had been recently diagnosed of lymphoma, classifying them as Hodgkin´s Lymphoma (HL) 22.5%, diffuse large B-cell lymphoma (DLBCL) 30%, mantle cell lymphoma 5%, follicular lymphoma 30%, T-cell lymphoma 7,5% and others 5%. ^{18}F-FDG PET-CT scan for initial staging was performed in all of them, as well as a BMB, with a mean of 20 days between both. We compared right iliac crest Standardized Uptake Value (SUVmax) measured in PET/CT scan and the histology of the sample obtained from the BMB. PET/CT was considered positive in those cases with a right iliac crest SUVmax $\geq$ 2.3. Results: PET/CT was negative for bone marrow infiltration in 72.5 % (29/40) and positive for it in 27.5% (11/40). However, BMB was negative for malignancy in 80% (32/40), positive in 17.5% (7/40), and doubtful in one case. In 85.7% (6/7) of the patients with a positive BMB, PET/CT scans as well as BMB were positive for bone marrow infiltration. In just 2.6% (1/29) of the patients with a negative PET/CT scan, BMB was positive and PET-CT was negative for malignancy, obtaining a good Kappa Index (0,685) between both techniques. Furthermore, we made the comparison between the different histological subtypes, dividing them into HL, aggressive B-NHL (DLBCL and mantle cell lymphoma), indolent B-NHL and T-cell NHL. In HL, both BMB and PET/CT were negative for malignancy in 75%, whereas in 25%, PET/CT was positive with a negative BMB. In aggressive B-NHL, PET/CT results corresponded to BMB results in 85.8%, whereas in 14.2 % did not. In indolent B-NHL and T-cell NLH, we obtained the same results in both techniques in 100% cases. Conclusion: In our study, PET/CT performed for initial staging in patients with lymphoma, was well correlated to BMB to detect bone marrow infiltration. From all the subtypes, indolent B-NHL and T- cell NHL had the best correlation between both tests. These results suggest that in those subtypes, we could avoid BMB using initial PET/CT scan as reference. However, we should make more studies with more patients.

EP179

PET/CT And Beta-2-Microglobulin In Lymphoma Patients After Standard Chemotherapy

D. Vassileva[1], **B. Spassov**[1], K. Mladenov[2], V. Hadzhiyska[2], M. Guenova[1], G. Mihaylov[1]; [1]Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, BULGARIA, [2]Clinic of Nuclear Medicine, University Hospital "Alexandrovska", Sofia, BULGARIA.

Background: The detection of residual disease after standard chemotherapy using imaging methods and tumor markers in lymphoma patients (pts) is essential to determine which pts would benefit from additional treatment. Positron emission tomography/computed tomography (PET/CT) imaging has become a very sensitive technique for monitoring therapy response in lymphoma pts. Beta-2-microglobulin (β_2M) is low molecular protein used as a major tumor marker in lymphoproliferative diseases. However the data regarding the detection of residual disease by PET/CT and serum β_2M levels after standard chemotherapy in lymphoma pts are limited. **Aim**: The aim of the study was to assess the role of PET/CT and β_2M in lymphoma pts after standard chemotherapy for determination of the further management. **Materials and methods**: A total 128 pts, aged 19-71 years, were analyzed - 45 and 83 pts with Hodgkin's disease (HD) and non-Hodgkin's lymphoma (NHL), respectively. These pts were examined 4-6 weeks after the end of the standard chemotherapy by 18F FDG PET/CT according to the accepted protocol. Serum β_2M levels were also measured radioimmunologically for disease activity assessment. **Results**: By applying PET/CT results two pts' groups were formed: [1] pts with complete metabolic response (PET/CT negative results) and [2] pts with partial metabolic response or progressive disease (PET/CT positive results). Using Deauville criteria complete response was observed in 26 (58 %) HD and 39 (46%) NHL pts (Deauville score 1-3). Sixty three pts (49%) had partial response, stable or progressive disease (Deauville score 4-5): 16 of them had one hypermetabolic lesions and 47 - disseminated nodal or extranodal involvement located in the lungs, thyroid gland or bones. PET/CT revealed 3 previously unknown additional lesions in two pts undetected by conventional visualization methods. The pts with one hypermetabolic lesions were considered for radiotherapy, while pts with more than one nodal and extranodal lesions after completion of standard chemotherapy were considered for high dose chemotherapy ± autologous stem cell transplantation (ASCT). The median serum β_2M levels were significantly higher in HD and NHL pts with PET/CT positive results compared to those pts with PET/CT negative results (HD pts - 3.3 vs 1.6 mg/L and NHL pts 4.4 vs 1.8 mg/L) respectively. **Conclusion**: The combination of PET/CT and serum β2M levels was useful in lymphoma pts after standard chemotherapy for determination of those who need additional therapy: radiotherapy, chemotherapy or ASCT. These results should be confirmed in prospective clinical trials.

EP180

The role of 18 F-FDG PET/CT in identifying bone marrow infiltration in patients with non-Hodgkin's Lymphoma

T. Mannarino, C. Mainolfi, N. Frega, G. Rossi, S. Pellegrino, L. Marano, F. Trastulli, L. Simeone, O. Vitagliano, V. Russo, S. Del Vecchio, A. De Renzo, M. Petretta, A. Cuocolo; Federico II University, Naples, ITALY.

Aim: Bone marrow infiltration (BMI) evaluation plays a key role in lymphoma staging, treatment and prognosis. The role of PET/CT in the assessment of BMI is still controversial, especially in non-Hodgkin's lymphoma (NHL). We compared 18F-FDG PET/TC visual and

quantitative analyses with bone marrow biopsy in NHL patients. Material and Methods: Fifty patients with newly diagnosed NHL from February 2011 to February 2016 were retrospectively analyzed. Of these, 26 (group A) patients had aggressive NHL and 24 (group B) indolent NHL. To detect BMI on the posterior iliac crest 3 different PET/CT evaluation methods were used: 1) visual analysis, 2) maximal standardized uptake values (SUVmax, cut-off >2.5), and 3) Deauville score (categorical). Each method was applied in the whole patients cohort, in group A and in group B. Images were blindly reviewed separately by 3 nuclear medicine physicians. PET/CT results were compared with the bone marrow biopsy performed after imaging in all patients. Decision-curve analysis was used to evaluate the increment in net benefit (NB) obtained considering the Deauville score over a biopsy-all strategy. Results: The prevalence of a positive biopsy was 38% in whole cohort, 19% in group A and 58% in group B. In the whole cohort, sensitivity, specificity and accuracy were 21%, 84% and 60% for visual analysis; 58%, 55% and 50% for SUVmax; and 47%, 81% and 68% for Deauville score. In group A, sensitivity, specificity and accuracy were 0%, 76% and 62%, for visual analysis; 40%, 52% and 50% for SUVmax; and 20%, 71% and 62% for Deauville score. In group B, sensitivity, specificity and accuracy were 29%, 100% and 58% for visual analysis; 64%, 60% and 62% for SUVmax; and 57%, 100% and 75% for Deauville score. At probability threshold equal to the prevalence of a positive biopsy, the increase in NB by Deauville score was 0.11 in the whole cohort, 0.02 in group A and 0.33 in group B. In this latter group, biopsying patients on the basis of the Deauville score is a strategy that reduced the biopsy rate by 24%, without missing any BMI. Conclusions: FDG-PET/TC visual analysis has a limited value for detecting BMI in patients with NHL, while quantitative analysis by Deauville score provides a higher diagnostic performance. Noteworthy, the high positive predictive value in patients with indolent NHL suggests a potential role of FDG-PET/TC in avoiding bone marrow biopsy in this subtype of lymphoma.

EP181

Analysis of early interim PET/CT results for treatment individualization in patients with lymphoma: comparison between Deauville criteria and ΔSUV_{max}

M. Khodjibekova, L. Tyutin, N. Kostenikov, N. Il'in; Russian research center of radiology and surgical technologies, Saint-Petersburg, RUSSIAN FEDERATION.

Aim: Treatment of lymphoma requires an early and accurate assessment of prognosis. This study aimed to assess the value and reproducibility of early PET/CT with ^{18}F-FDG after two-four cycles of chemotherapy using Deauville five-point scale and ΔSUV_{max}.Methods: Sixty four patients with newly diagnosed Hodgkin and non-Hodgkin lymphoma were evaluated. All patients underwent PET/CT scan at baseline, after two-four cycles of chemotherapy and after completion of chemotherapy. Scans were interpreted using Deauville five-point scale, between baseline and interim PET/CT scans ΔSUV_{max} was calculated. Results: According to Deauville five-point scale 27 (42,2%) patients were scored as negative and 37 (57,8%) patients as positive. In all patients with interim PET-negative scan ΔSUV_{max} between baseline and interim examination was more than 71%. SUV_{max} in all patients with score 5 of PET-positive group was stable or didn't decrease significantly between studies. However the ΔSUV_{max} in most of the patients (58,8%) with score 4 of PET-positive group was more than 71% indicating a favorable prognosis of the disease. The prognostic value of PET/CT using Deauville score ≥ 4 was moderately inferior (p=0,004) than cut-off of $\Delta SUV_{max} \geq 71\%$ (p=0,0002). Conclusion: Combined application of visual and quantitative analysis in the evaluation of the early PET/CT results increases the accuracy of the method. Calculation of ΔSUV_{max} in patients with Deauville high score (≥ 4) leads to better outcome prediction.

EP182

18F-FDG PET/CT In The Initial Evaluation And Response Assessment In Primary Central Nervous System Lymphoma

R. FERNÁNDEZ LÓPEZ[1], Á. De Bonilla Damiá[1], J. Lojo Ramírez[1], I. Acevedo Bañez[1], L. Caballero Gullón[1], V. Pachón Garrudo[1], F. Capote Huelva[2], I. Borrego Dorado[1]; [1]H.U. VIRGEN DEL ROCÍO, SEVILLE, SPAIN, [2]H.U. PUERTA DEL MAR, CÁDIZ, SPAIN.

Objective: To evaluate the role of positron emission tomography combined with computed tomography with 18F-FDG (18F-FDG PET/CT) in the initial evaluation and response assessment in primary central nervous system lymphoma (PCNSL). **Material and methods:** A total of 16 patients (7 males and 9 females) with a median age of 56 years diagnosed of PCNSL between October 2011 and January 2015 were retrospectively analyzed from our institution. All patients presented a histological subtype of diffuse large B-cell lymphoma. A brain and whole body 18F-FDG PET/CT were performed in the initial evaluation. In 7 patients a PET/CT after treatment was performed in order to evaluate response and follow-up after treatment. Images data were collected, analyzed and correlated with outcome with an average of follow-up of 10,59 months. **Results:** 18F-FDG PET/CT showed at diagnosis a hypermetabolic focal lesion in 9 patients, multiple lesions in 6 patients and one patient did not evidence significant uptake. No patient showed hypermetabolic lesions outside central nervous system. The mean of maximum SUV (SUVmax) of the primary tumours was 17.86 (range: 9.2 - 29.5). The average follow-up was 10.59 months (0.5-43) with an overall mortality of 62.5% (10/16 patients). From the seven patients with PET/CT scan images after treatment**:** 3 developed complete metabolic response (CMR), 1 reached nearly complete metabolic response (NCMR) and 3 had progressive metabolic disease (PMD). The overall mortality in this subset of patients was of 57.1% (4/7 patients). Two out of the three patients with CMR died because of disease relapse with an overall survival (OS) of 25 and 22 months, respectively. Two out of the three patients with PMD died with an OS of 7 and 8 months, respectively. The remaining 3 patients (1 NCMR, 1 CMR and 1 PMD) are alive without evidence of disease with an OS of 19, 26 and 43 months, respectively. It seems to be unrelated between the type of metabolic response and survival although the data are limited. **Conclusions:** 18F-FDG PET/CT can be useful in the initial evaluation and may contribute as valuable information for the management of PCNSL, particulary in the assessment of the treatment response. Prospective studies are needed to confirm their possible prognostic value.

EP183

The clinical value of ^{18}F FDG Positron Emission Tomography in high risk Mycosis Fungoides

S. Usmani, F. Marafi, A. Esmail, F. al Kandari; Kuwait Cancer Control Center, kuwait, KUWAIT.

The aim of the present study is to evaluate the possible role of 18F-FDG PET-CT in the management of high risk mycosis fungoides. **Materials and Method**: Twenty three patients (mean age, 41.5yrs; median age 42yrs; 18 males and 5 females) with risk of secondary lymph node involvement (those with large cell transformation, tumors, erythroderma, or enlarged LNs on physical examination) were included in the study. FDG PET-CT was performed at the time of initial diagnosis or suspected relapse. We excluded patients who had done scans at mid-treatment. All patients underwent PET-CT scan by injecting 0.06mCi/kg of F18 FDG. The maximum standard uptake value (SUV max) was recorded for each patient. **Results**: The 18F-FDG PET-CT was positive in 19 patients. PET-CT detected local cutaneous disease in 17 cases. The range of SUV max is 2.8-14.1. Out of 23 patients hypermetabolic adenopathy are in found in 12 patients and visceral involvement in one. **Conclusions**: Although the study population is small our findings suggests that 18F-FDG PET-CT

can detect cutaneous and extra-cutaneous lesions in mycosis fungoides and may guide biopsies especially in patients with risk of secondary lymph node involvement.

EP184

Clinical significance of FDG-PET negative residual masses in DLBCL patients treated with R-CHOP

Y. Ramirez Escalante[1], M. Coronado Poggio[1], P. Gómez[2], S. Rizkallal Monzón[1], S. Rodado Marina[1], C. Escabias del Pozo[1], G. Villoria Almeida[1], I. Santos Gómez[1], J. Guzmán Cruz[1], M. Orduña Diez[1], L. Dominguez Gadea[1]; [1]Medicina Nuclear, Hospital Universitario La Paz, Madrid, SPAIN, [2]Hematologia, Hospital Universitario La Paz, Madrid, SPAIN.

INTRODUCTION FDG-PET/CT is the standard method for assessment of response at the completion of treatment in Diffuse Large B Cell Lymphoma (DLBCL) patients. Recent data suggest that patients with a complete metabolic response but a residual mass on CT (CMRr) may have different outcome to patients with CMR and no radiological residual lesions (CMR). OBJETIVE The aim of this study was to investigate the significance of PET negative residual masses in DLBCL patients treated with standard regimen. MATERIAL AND METHODS Fifty-two patients diagnosed of DLBCL between 2010 and 2014 who underwent PET before treatment (PET0) and final PET after 6 cycles of R-CHOP (PET6) were retrospectively reviewed. Age at diagnosis: 20-86 years old. Ann Arbor stage and IPI at diagnosis were recorded. PET6 result was defined as positive or negative, and negative PET patients were classified as CMR or CMRr following Lugano recommendations (*J Clin Oncol 32:3048-3058*). Follow up was made for 6 to 101 months (median: 41 months). Survival of CMR and CMRr groups was calculated. RESULTS From the total population, 39/52 patients (75%) were PET6 negative and 13/52(25%) patients were PET6 positive. 26 out of 39 negative PET6 patients were classified as CMR and 13/39 negative PET6 patients were classified as CMRr. Two patients relapsed from the CMRr group versus one patient from the CMR group. Mean free time survival was higher in the CMR group than in the CMRr one (p=0.064). One patient from CMRr died and no patients from CMR group were dead in the follow up time. Overall survival of CMR and CMRr groups could not be calculated due to the small number of patients. CONCLUSIONS DLBCL patients with negative PET after 6 cycles of R-CHOP seem to have a higher risk of relapse when there is residual lesion in CT. Larger series are needed to stablish the prognostic value of PET negative residual masses in this population.

EP185

FDG-PET/TC in mantle cell non Hodgkin lymphoma: experience in our institution.

A. Perissinotti[1], A. Allende-Riera[1], J. Uña-Gorospe[1], M. J. Rodriguez-Salazar[2], J. M. Raya-Sanchez[2], D. Cabello[1], M. De Sequera-Rahola[1], E. Martinez-Gimeno[1], C. Cardenas-Negro[1], O. Vilahomat[1]; [1]Hospital Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, SPAIN, [2]Hospital Universitario de Canarias, Santa Cruz de Tenerife, SPAIN.

Aim: Our aim is to report our experience in the assessment of patients with mantle cell non Hodgkin lymphoma (MCL) with ^{18}F-Fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/TC). **Materials and methods:** We retrospectively reviewed 27 patients (mean age 63, range 38-82. 19 male/9 female) with histologically proven MCL disease studied with 138 FDG-PET/TC scans (mean dose 2.76 MBq/Kg) during their initial staging, interim, end-of-therapy, surveillance or relapse phase of the disease. All patients were classified as WHO grade III or IV. A mean number of 5 (ranging from 1 to 13) FDG-PET/TC studies per patient were performed. **Results:** 70% (19/27) of patients showed at least one pathological FDG-PET/TC study showing hypermetabolic lesions during the course of the disease: FDG uptake in the most active lesion of all FDG-PET/TC studies had a mean SUVmax of 10.4 (ranging from 2.8 to 27). 8 out of 27 patients were studied with FDG-PET/TC as part of their initial staging and also were subsequently studied with FDG-PET/TC: all of them showed positive pathological scans with a mean SUVmax of 8.5 (ranging from 17.64 to 3.35) in the most active lesion. One of them showed unsuspected splenic involvement and two of them splenic and bone marrow compromise. Four out of this eight patients reached complete metabolic response after chemotherapy treatment. **Conclusion:** Despite the fact that FDG-PET/TC is not currently included in all mantle cell non Hodgkin lymphoma assessment guidelines, our experience suggests that FDG-PET/TC can be a valuable diagnostic tool because of its ability to detect hypermetabolic lesions at all stages of the disease and treatment monitoring evaluation; specially for the initial staging as all of our FDG-PET/TC staging studies showed positive pathological scans.

EP186

18F-FDG-PET/CT in the Staging and Prognostic Evaluation of Patients with Indolent Lymphoma

R. Fonti[1], S. Pellegrino[2], B. Salvatore[1], O. Vitagliano[3], L. Simeone[3], F. Cacace[3], M. Memoli[3], S. Leone[3], A. De Renzo[3], S. Del Vecchio[2]; [1]IBB-CNR, NAPLES, ITALY, [2]Department of Advanced Biomedical Sciences, University "Federico II", NAPLES, ITALY, [3]Haematology Division, University "Federico II", NAPLES, ITALY.

Indolent lymphomas are a group of low-grade non-Hodgkin lymphomas characterized by slow growth and chronic clinical course. Recent studies have reported that indolent lymphomas almost always show variable FDG avidity regardless of tumor grade thus providing a rationale for using 18F-FDG-PET/CT in the management of these patients. **Aim.** The aim of our study was to evaluate lymph node involvement in patients with indolent lymphomas by 18F-FDG-PET/CT and to correlate the derived imaging parameters with clinical, biochemical and haematological variables routinely used in the staging and prognosis of low-grade lymphomas. **Methods.** We evaluated retrospectively 43 patients (16 males, 27 females; mean age±SD, 60±10.2 years) with indolent lymphoma (27 with follicular lymphoma, 11 with marginal zone lymphoma and 5 with small lymphocitic lymphoma) who had undergone whole-body 18F-FDG-PET/CT and contrast-enhanced CT alone or as part of 18F-FDG-PET/CT examination at the time of diagnosis. All patients were staged according to standard criteria and were stratified in risk groups based on Follicular Lymphoma International Prognostic Index (FLIPI) 1 that include parameters such as age, stage, lactate dehydrogenase levels, haemoglobin levels and number of pathological nodal sites. **Results.** In the 43 patients studied, the number of positive lymph node basins at 18F-FDG-PET/CT ranged between 1 and 33 and the SUVmax of the lymph node with the highest tracer uptake varied from 2 to 19.9. While the number of positive lymph node basins at contrast-enhanced CT ranged between 1 and 28 and the maximum diameter of the largest lymph node varied from 11 to 80 mm. The number of pathological lymph nodes at both 18F-FDG-PET/CT and contrast-enhanced CT were significantly correlated with stage (Spearman rank correlation coefficient r=0.42, P=0.0065 and r=0.37, P=0.0149, respectively). In addition, also the size of the largest lymph node showed a significant correlation with stage (Spearman rank correlation coefficient r=0.40, P=0.0153). Moreover, the number of pathological lymph nodes at both 18F-FDG-PET/CT and contrast-enhanced CT was significantly correlated with FLIPI 1 score (Spearman rank correlation coefficient r=0.48, P=0.0009 and r=0.54, P=0.0002, respectively). **Conclusion.** 18F-FDG-PET/CT may contribute to the evaluation of lymph node involvement and thus may help in the staging and prognostic assessment of patients with indolent lymphoma.

EP187

Clinical importance of bone marrow 18F - FDG uptake after treatment in lymphoma patients

V. Hadzhiyska[1], M. Garcheva[2], P. Nikolova[1]; [1]University Hospital Alexandrovska, Sofia, BULGARIA, [2]City Clinic, Sofia, BULGARIA.

A lot of examinations confirm the importance of 18F-FDG PET/CT for initial evaluation of bone marrow involvement in lymphoma. **The aim** of this study was to evaluate the clinical significance of the patterns of bone marrow uptake in different periods after the end of the chemotherapy.**Material and methods.**Sixty six patients, examined by the standard protocol of -FDG PET/CT were retrospectively evaluated: 36 with Hodgkin disease (HD), 17 with diffuse large B-cell lymphoma (DLBCL), 7- with follicular lymphoma (FL) and 6 - with other lymphoma types. The exclusion criteria were patients with initially proved bone marrow involvement. Twenty patients (gr.1) were examined in one month, 26 (gr.2) - in the period between the 2nd and the 6th month and 20 pts (gr.3) - in one year period after chemotherapy. **Results.** In gr. 1 diffuse uptake was detected in 7 pts (35%), and in the rest 13 pts (65%) - negative bone marrow uptake. In gr. 2 diffuse uptake was found in 2 pts, (8%) and focal uptake abnormalities was detected in 1 pt (4%), twenty three, 88% of patients were with negative bone marrow uptake. In gr. 3 four of the pts (20%) were with diffuse uptake and other three (15%) with focal uptake abnormalities, 65% remained with negative bone marrow. The consequent biopsy proved in 2 out of 4 patients with diffuse uptake bone marrow involvement. **Conclusion**. While the diffuse bone marrow uptake early after the end of the chemotherapy can be attributed to post therapeutic activation, its presence in one year period after the end of the therapy parallels the increase of the rate of the focal uptake abnormalities and is highly suspicious for bone marrow involvement. We consider that these patients should be reevaluated by magnetic resonance imaging, or bone marrow biopsy.

EP188

Role of 18F FDG PETCT in Marginal Zone Lymphomas

E. ABAMOR[1], A. Kucukoz Uzun[2], T. Cakır[1], A. Cakır[3], A. N. Karadayı[4], T. Atasever[1]; [1]Medipol University, Faculty of Medicine, Department of Nuclear Medicine, ISTANBUL, TURKEY, [2]Dr.Lutfi Kırdar Kartal Education ve Research Hospital, Department of Nuclear Medicine, ISTANBUL, TURKEY, [3]Medipol University, Faculty of Medicine, Department of Pathology, ISTANBUL, TURKEY, [4]Dr. Lutfi Kırdar Kartal Education and Research Hospital, Department of Pathology, ISTANBUL, TURKEY.

Aim: Role of FDG PETCT remains controversial in marginal zone lymphomas (MZL), due to variable F18-FDG avidity. We evaluated the value of FDG PETCT in a limited group of patients with diagnosis of marginal zone lymphoma (MALT, splenic and nodal subtypes). **Material and methods:** We reevaluated FDG PETCT findings in 15 patients with MZL. All patients were histopathologicaly diagnosed by biopsy of bone marrow or lymph node or primary solid lesion. Six women and 9 men, aged between 61 - 77 (mean age: 62,53) were reviewed. Six patients (% 40) had MALT, 6 patients had splenic involvement (% 33) and 11 patients had nodal involvement (% 73). All patients had FDG PETCT at baseline staging. **Results:** Six MALT lymphoma patients had primary lesions in orbita, eyelid, paraphyrangeal region, larynx, colon and cervix with significant FDG uptake, SUV between 5,1 - 15,3 (mean: 10,25). One MALT patient had also spleen involvement by diffuse increased FDG uptake (SUV 4,5). Another MALT patient had hepatomegaly with diffuse increased FDG uptake (SUV 4,4). One patient with MALT had brain metastasis (SUV: 13,6) and 2 other MALT patients had lung metastasis (SUV: 4,2 - 6,2). Eleven patients had lymph nodes involvement, with SUV between 2,6 - 10 (mean: 6,51). Spleen involvement was observed in 6 patients with SUV between 3,3 - 10,2 (mean: 5,96). Only 5 patients represented increased FDG uptake in bone marrow and at metastatic bone, SUV between 2,8 - 8,2 (mean: 5,26). Six patients had metastatic FDG uptake at liver, brain, lung or muscle tissue, in which SUV was between 3,1 - 13,6 (mean: 6,28). The overall mean SUV was 6,80 for all lesions. Primary and metastatic sites of MALT lymphoma had highest metabolic activity rates (the overall mean SUV: 8,89). FDG nonavidity was not detected in patients. Weak FDG affinity (SUV: 2,6 - 3,3) was observed in only 1 patient. The stage of disease was increased with splenic involvement, organ and bone metastasis by PET/CT. **Conclusion:** Although in limited number of patients, our data shows significant metabolic activity in marginal zone lymphoma lesions. MALT lymphoma lesions of primary and metastatic sites show higher FDG uptake than splenic and nodal MZL. But splenic and nodal MLZ also tend to have significant FDG uptake. Though it needs a larger population with followup study, our data suggests a valuable role for PET/CT in all subtypes of MZL at baseline diagnostic and staging study.

EP189

18F-FDG PET-CT imaging in patients with cutaneous lymphoma: single institutional experience

K. K. AGARWAL, A. MUKHERJEE, P. SHARMA, H. SINGH, R. KUMAR, C. BAL; ALL INDIA INSTITUTE OF MEDICAL SCIENCES, NEW DELHI, INDIA.

Purpose: To evaluate the role of 18F-FDG PET/CT in patients with cutaneous lymphoma. **Methods:** The data of 40 patients (Age: 52 ± 20.5 years; Male: 22) with cutaneous lymphoma who underwent total 60 18F-FDG PET/CT studies for staging (n=17) or restaging (n=43) were retrospectively evaluated. The primary histopathology was T cell lymphoma in 19, mycosis fungoides in 13, DLBCL in 3, ALCL in 2 and marginal zone B cell lymphoma in 3 patients. PET/CT studies were evaluated qualitatively and semiquantitatively (SUVmax) and interpreted as positive or negative for disease. The site of the lesions was also noted. Histopathology/cytology (when available) and clinical/imaging follow up of minimum 6 months was taken as reference standard. **Results:** 37 PET/CT studies were positive for active disease. Per study wise sensitivity, specificity, PPV, NPV and accuracy of PET/CT were 93.5%, 89%, 93.5%, 89% and 92%, respectively. The accuracy of PET/CT in staging group and restaging group was same, 92% (p=0.541). 32 Cutaneous lesions (unifocal-14, multifocal-18), 22 nodal lesions (single group-8, multiple groups-14), 5 splenic lesions and 2 liver lesions were noted. The sensitivity, specificity and accuracy of PET/CT for cutaneous lesions was 90%, 100% and 94%, and for nodal lesions was 100%, 94%, and 96%, respectively (p=1.00). The mean SUVmax of cutaneous lesions was 5.1±2.8, nodal lesions was 4.4±2.7 and splenic lesion was 5.4±2.8. **Conclusions:** 18F-FDG PET/CT has high diagnostic accuracy for staging and restaging patients with cutaneous lymphomas. It can detect both cutaneous and non cutaneous lesions with high sensitivity and specificity.

EP190

Prognostic Importance of Bone Marrow Uptake on Baseline 18F-FDG Positron Emission Tomography/Computed Tomography in Diffuse Large B-Cell Lymphoma

C. Soydal[1], E. Koksoy[2], A. Yasar[2], E. Turgal[3], B. Doganay Erdogan[4], H. Akbulut[2], N. O. Kucuk[1]; [1]Ankara University Medical Faculty Nuclear Medicine Department, Ankara, TURKEY, [2]Ankara University Medical Faculty Medical Oncology Department, Ankara, TURKEY, [3]Hitit University Medical Faculty Biostatistics Department, Corum, TURKEY, [4]Ankara University Medical Faculty Biostatistics Department, Ankara, TURKEY.

Aim: To define prognostic importance of bone marrow uptake on pretreatment ^{18}F-Flourodeoxyglocose (FDG) Positron Emission Tomography (PET)/Computed Tomograpy (CT) in Diffuse Large B-Cell Lymphoma (DLBCL) Patients. Material and Methods: Fifty-four (mean age: 55.5±18.3, 20F and 34M) DLBCL patients who underwent pretreatment ^{18}F-FDG PET/CT were included to the study. Prognostic effect of age, gender and serum LDH levels of patients, disease stage, presence of extranodal and bone marrow involvement, Deauville Score, SUVs to progression free survival (PFS) were analyzed by using Cox-Regression Analysis. Results: Mean PFS was calculated as 19.5 (min-max: 1-64) months. While extranodal FDG uptake was seen 36 (67%) (stomach in 6, lung in 6, spleen in 6, skin-soft tissue in 6, liver in 4, bowel in 4, tonsil in 4, nasopharyngeal region in 3, pancreas in 3, thyroid in 2, peritoneum in 1 patients), bone marrow uptake was observed in 8 (15%) patients. Female gender (p=0.025), presence of bone marrow uptake (p=0.013) and serum LDH levels (p=0.001) were found as significant factors to predict PFS. Additionally Negatif Predictive Value (NPV) for bone marrow uptake was calculated as 100%. Conclusion: Bone marrow uptake in pretreatment ^{18}F-FDG PET/CT is an important prognostic factor in DLBCL patients. Moreover in consideration of high NPV, ^{18}F-FDG PET/CT could eliminate unnecessary bone marrow biopsy in FDG negative patients.. Although pretreatment PET/CT could give useful information in staging of disease, in this analysis other parameters in PET/CT did not reach to prognostic significant level.

EP191

Optimization criteria for metabolic prognostic assessment in patients with lymphoma

M. Cozar Santiago[1], J. Garcia Garzon[2], M. Soler Peter[2], R. Sanchez Jurado[1], J. Aguilar Barrios[1], R. Sanz LLorens[1], R. Brisa Vazquez[1], J. Ferrer Rebolleda[1]; [1]ERESA-GENERAL UNIVERSITARY HOSPITAL, VALENCIA, SPAIN, [2]CETIR-ESPLUGUES PET UNIT, BARCELONA, SPAIN.

AIM: to identify metabolic response evaluation criteria that optimizes a prognostic assessment of disease **MATERIALS AND METHODS:** there were included 138 patients affected by lymphoma (43 Follicular Lymphoma, 43 Hodgkin Lymphoma, 43 Diffuse large B-Cell Lymphoma) on whom three 18F-FDG PET/CT studies were performed: the first one for staging the disease or "basal PET" (bPET), the second one after three/four cycles of treatment or "interim PET" (ipet), and the last one at the end of the chemotherapy and/or radiotherapy, or "end PET" (ePET). Images were analyzed using 2 interpretation criteria: visual method using the Deauville scale and semiquantitative method or "percentage reduction SUVmax" (ΔSUVmax). Chi square (X^2) was calculated to determine whether there were significant differences between DS and %ΔSUVmax and the Kappa (K) concordance degree. iPET prognostic utility with both methods was assessed depending on the clinical status after at least 13 months of follow-up and if they are able to identify treatment failure patients who would be able to benefit from a second-line treatment. Survival curves (Kaplan Meier product test and long Rank test) were calculated. **RESULTS:** we saw a good correlation between the two methods of evaluation, for the three types of lymphomas; for ePET as well as for the iPET with a significant X^2 (X^2: 52.12 p <0.05) and good agreement between them (K: 0.60). Both methods proved to be useful for the prognostic assessment of iPET. Regarding to survival, both methods were useful for identifying potential relapse after the proposed PFS (long Rank test 23, 15, p = 0.00). **CONCLUSION:** metabolic criteria allow a correct assessment of patients with lymphoma obtaining similar values of agreement. Taking into account the potential utility of them in iPET, both methods have a similar reliability.

EP192

Variability in 18F-FDG avidity in extranodal marginal zone B-cell lymphomas

A. Sadija, N. Beslic, R. Milardovic, S. Ceric; University Clinical Center, Sarajevo, BOSNIA AND HERZEGOVINA.

Introduction: Most lymphomas are proven to be highly avid to 18F-FDG, but there are some lymphoma subtypes with lower avidity such as small lymphocytic lymphoma, peripheral T-cell lymphoma and extranodal marginal zone B-cell lymphoma. Current guidelines advise the use of 18F-FDG imaging for staging of lymphomas with already known high 18F-FDG avidity, but there are small amount of information on rare lymphomas. It is also advised that for other lymphoma subtypes considered as variably tracer-avid, 18F-FDG imaging is recommended only if patients are included in clinical trials with endpoint which mainly considers response rate. The aim of this pilot study is to investigate 18F-FDG avidity in different extranodal sites of marginal zone lymphomas by reviewing the reports of all 18F-FDG PET-CT studies. **Patients and methods:** PET-CT studies were performed in all 12 extranodal marginal zone lymphoma patients referred to University Clinical Center Sarajevo for initial staging. All information were analyzed retrospectively reviewing medical records and PET-CT scans performed in period from 8/2014 to 3/2016. All PET-CT scanns were analyzed for the presence of 18F-FDG avidity measuring SUVmax values in all extranodal sites of lymphoma involvement, and all data recorded. 18F-FDG avidity was defined as the presence of at least 1 focus of 18F-FDG uptake in involved site. Non-18FFDG-avidity was defined as disease proven by clinical examination and histopathology but with no 18F-FDG uptake in any of the involved sites. **Results:** There were 11 patients with extranodal marginal MALT lymphoma and one patient with splenic marginal zone lymphoma. Sites of MALT lymphoma involvement were stomach, lung, parotid gland, epipharynx, submandibular gland, maxilla, orbit and thyroid gland. Only two patients with biopsy proven MALT lymphoma were non-avid to 18F-FDG in initial staging, with stomach and lung as lymphoma involved sites. SUVmax values were in the range of 2.6 - 12.2 with lowest SUVmax values measured in lung and stomach MALT lymphoma and highest in submandibular gland, maxilla, orbit and epipharynx. **Conclusion:** This study suggests that imaging with 18F-FDG PET-CT is useful for both initial staging and also follow-up of patients with extranodal marginal zone B-cell lymphoma. We found out that certain sites of lymphoma involvement as lungs and stomach have lower FDG avidity comparing to sites of involvement localized in head region, and we are suggesting larger studies to investigate the heterogenity of 18F-FDG avidity in different sites of involvement. **Key word:** extranodal**,** lymphoma, avidity, 18F-FDG PET-CT

EP193

Role of 18F-FDG PET-CT and MRI in diagnosis of smoldering multiple myeloma and plasmocytoma

A. Mestre Fusco[1], A. Senín[2], E. Abella[2], F. García-Pallarols[2], J. Ares[3], A. Solano[3], M. Suárez-Piñera[1]; [1]Nuclear Medicine. Hospital del Mar., Barcelona, SPAIN, [2]Hematology. Hospital del Mar., Barcelona, SPAIN, [3]Radiology. Hospital del Mar., Barcelona, SPAIN.

Background: Smoldering Multiple Myeloma (SMM) is defined by more than 10% of clonal bone marrow plasma cells and serum monoclonal protein without end-organ damage (CRAB criteria). Solitary Plasmocytoma (SP) is characterized by presence of clonal plasma cells outside the bone marrow. The Revised International Staging System (R-ISS) stratifies patients in three prognostic groups. Magnetic Resonance Imaging (MRI) is used in SMM and SP as gold standard imaging modality in order to guide decision making. In addition, 18F-FDG PET-CT (FDG-PET) may upgrade SMM and SP to Multiple Myeloma (MM). Aim: 1.-To compare FDG-PET and MRI in SMM and SP and evaluate the

concordance between both imaging modalities. 2.-To study the sensitivity of FDG-PET compared to MRI. 3.-To evaluate an association between metabolic activity on FDG-PET (SUVmax) and R-ISS score. Methods: FDG-PET and MRI were performed in 27 patients diagnosed of SMM or SP who were prospectively included (11 males, mean:61.5 years, range:38-85). FDG-PET whole body studies were performed in a PET-CT (Siemens Biograph6). A positive PET-CT was defined of abnormal increased uptake of FDG and/or evidence of lytic bone destruction on CT. SUVmax was calculated of each lesion. MRI whole body studies were acquired in a 1.5 Tesla (Signa GE Healthcare) with T1-weighted and STIR-weighted sequences. In all patients MRI was performed within 45 days of PET-CT. Concordance kappa was calculated. FDG-PET sensitivity was estimated. Correlation between R-ISS and SUVmax was estimated (ANOVA). Results: Of the 16 patients who were diagnosed initially as SMM, eight of them (50%) were upstaged to MM based on FDG-PET and MRI. Of the 7 diagnosed initially as SP, three of them (43%) were upstaged to Multiple Plasmocytoma or MM. FDG-PET and MRI were both negative in seven patients. Three patients showed extra-osseous involvement only detected by FDG-PET. However, FDG-PET fails to detecte bone disease in three patients with blastic pattern on MRI. Estimated FDG-PET sensitivity was 88%. A correlation between FDG-PET and MRI was found ($k=0.667$, $p<0.05$). In 12 out of 16 (75%) there was a discrepancy in the number of lesions detected by both techniques. No correlation between SUVmax and R-ISS was found. Conclusion: FDG-PET and MRI offer complementary information in diagnostic evaluation on SMM and SP. In addition, FDG-PET provides additional information of disease in areas not covered by MRI. On the other hand, MRI seems to be more sensitive than PET in case of focal or smaller osteoblastic lesions.

EP194

The Comparison Of F-18 FDG PET/BT VE Tc-99m MIBI SPECT/BT In Multiple Myeloma

S. Razavi Khosroshahi[1], H. Sayman[1], S. Berk[2], O. Balkanay[3], J. Nematyazar[1], B. Vatankulu[1], S. Sager[1], M. Halac[1], M. Demir[1], L. Kabasakal[1], I. Uslu[1], K. Sonmezoglu[1]; [1]istanbul university, cerrahpaşa medical faculty, nuclear medicine department, istanbul, TURKEY, [2]istanbul university, cerrahpaşa medical faculty, hematology department, istanbul, TURKEY, [3]istanbul university, cerrahpaşa medical faculty, cardiovascular surgery department, istanbul, TURKEY.

Multiple myeloma (MM) is a malignant disease of plasma cells derived from B cells in the bone marrow. Different imaging methods for staging, evaluation of relapse, response to therapy and prognosis are used. Despite the role of Tc-99m MIBI planar whole body scintigraphy is demonstrated, it is replaced by F-18 FDG PET/CT. Considering that the sensitivity and specificity will increase after the introduction of the newly developed SPECT/CT technology and its cost-effectiveness let us to compare these two methods prospectively. With this purpose, in 40 patients diagnosed as MM and referred for F-18 FDG PET/CT for further examination, additional Tc-99m MIBI planar and SPECT/CT imagings were performed. The obtained data were statistically evaluated by using Chi-square test. When the lesions were evaluated on regional basis SPECT/CT had a dual positive rate of 80.6% and a dual negative rate of 90.5%. On the other hand, when the evaluation was done on patient base, these ratios were calculated as 93.1% and 72.7%, respectively. Similar results were obtained when both methods were evaluated in subgroups. When bone marrow biopsy was accepted as a gold standard method, PET/CT sensitivity, specificity, PPV and NPV were calculated as 86.7%, 87.5%, 92.9% and 77.8% respectively, whereas for SPECT/CT were 93.3%, 87.5%, 93.3 and 87.5% respectively. When Tc-99m MIBI scintigraphy planar whole body and SPECT/CT images were compared, of 18 patients without any lesion on whole body imaging, 8 had lesions on SPECT/CT. According to the study results, in all clinical evaluation steps of patients with MM, having less cost as well as same diagnostic value, Tc-99m MIBI SPECT/CT can be a replacement for F-18 FDG PET/CT.

EP195

Could 18F-Choline PET/CT scan be a new diagnostic tool in assessing bone involvement in patients with multiple myeloma?

Z. Meckova[1], L. Lambert[2], J. Kubinyi[1], I. Spicka[3]; [1]Institute of Nuclear Medicine, GUH Prague, Prague, CZECH REPUBLIC, [2]Clinic of Radiodiagnostic, GUH Prague, Prague, CZECH REPUBLIC, [3]First Internal Clinic, GUH Prague, Prague, CZECH REPUBLIC.

Background: Multiple myeloma is a clonal plasma cell disorder resulting in infiltration of bone marrow and osteolytic lesions of the skeleton. The diagnosis and staging of multiple myeloma are based on blood and urine tests, bone marrow biopsy and imaging (radiography, CT, MRI and 18 F-FDG PET-CT). The presence and extent of bone marrow involvement is an important factor influencing prognosis and clinical management. Therefore, the imaging is vital for making the decision on the treatment initiation. **Aim:** Due to the fact that bone and bone marrow infiltration is difficult to detect by standard imaging methods, the aim of this study was to find out whether imaging by ^{18}F-Choline could be of any additional value to that of 18F-FDG PET/CT in a patient affected with multiple myeloma. **Methods:** Series of ten patients untreated with extra medullary extensive disease will undergo a standard ^{18}F-Choline PET/CT and ^{18}F-FDG PET/CT within ten days. The results of the two scans will be compared in terms of number, sites and SUV_{max} of lesions. **Results:** At this stage two patients had a positive ^{18}F-Choline and ^{18}F-FDG PET/CT scans and the scans identified different number of lesions. Choline showed a mean SUV_{max} of 13.94 while FDG showed a mean SUV_{max} of 9.9 ($p = 0.0004$). Overall, ^{18}F-Choline PET/CT scans detected eight more bone lesions than ^{18}F-FDG PET/CT scans but the difference was not statistically significant ($P = 0.29$). **Conclusion:** The preliminary data show that ^{18}F-Choline PET/CT could be more sensitive than ^{18}F-FDG PET/CT for the detection of bone myelomatous lesions. It is necessary to extend our study and if the data are confirmed then ^{18}F-Choline PET/CT can be considered as more appropriate functional imaging method in association with MRI for MM bone staging.

EP196

Diagnostic accuracy of 18F-FDG PET/CT in detection of bone lesions in patients with Multiple Myeloma

B. Chaushev, I. Micheva, P. Bochev, J. Dancheva, C. Yordanova, A. Klisarova, I. Krasnaliev; MBAL``ST.MARINA``, VARNA, BULGARIA.

Multiple myeloma (MM) is the most common cause of primary malignancy in bones. Diagnostic imaging plays a pivotal role in staging and prognostic assessment as well as in planning and monitoring treatment. The aim of our study was to estimate the diagnostic accuracy of 18F-FDG PET/CT in 18 patents with MM in the evaluation of the extent of bone disease at the time of initial diagnosis. Materials and methods: 18 patients (9 males and 9 females; age range 42- 68 years) with newly diagnosed IgG MM were included in the study. PET/CT was used as staging procedure for the detection of the bone lesions and the stage was determined according Durie - Salmon PLUS Staging Systems. Correlative imaging data was available in most of the cases and included skeletal radiographic survey in 11, CT in 7 and MRI in 2. Results: In 13 patients 18F-FDG PET/CT detected higher number of bone lesions in comparison to the other imaging methods. In 5 patients there was no difference in the number of bone lesions, including the two cases where MRI was performed. According to Durie - Salmon PLUS Staging Systems 18F-FDG PET/CT detected 13 patients in stage I, 4 in stage II and 1 patient in stage III. Conclusion: 18F-FDG PET/CT has shown to have high sensitivity specificity and key prognostic value in patients with MM. It is a superior imaging modality for diagnosis of bone lesions in myeloma compared to conventional radiography.

Cutaneus Melanoma: clinical and prognistic value of FDG PET/CT after surgery

D. Familiari[1], M. C. Fornito[1], R. Gentile[2], S. Russo[1], A. Ruggeri[1], M. Midiri[3], P. Alongi[2]; [1]Nuclear Medicine Department - A.R.N.A.S. Garibaldi, Catania, ITALY, [2]Nuclear Medicine Unit - San Raffaele G. Giglio Institute, Cefalù (Pa), ITALY, [3]University of Palermo, Palermo, ITALY.

Aim: The aim of this retrospective study, through a collaboration between San Raffaele G.Giglio Institute (Cefalù, Italy) and ARNAS Garibaldi (Catania, Italy), was to evaluate the clinical and prognostic impact of FDG PET in the restaging process of melanoma after surgery.**Materials and Methods:** data from 74 pts surgically treated for cutaneus melanoma, who underwent FDG-PET for suspicious of recurrent disease were collected. The diagnostic accuracy of visually interpreted FDG-PET was obtained by considering histology (n=21pts), other diagnostic imaging modalities (ceCT in 52/74 pts and MRI in 18/74 pts) and clinical follow-up (n=74pts). Progression-free survival (PFS) and overall survival (OS) were assessed by using Kaplan-Meier method. The risk of progression (Hazard Ratio-HR) was computed by Cox regression analysis. **Results:** suspicious of recurrent melanoma was confirmed in 24/27 pts with a positive FDG-PET scan. Overall, the sensitivity, specificity, positive predictive value, negative predictive value and accuracy of FDG-PET were 82%, 93%, 88%, 89%, 89%. AUC was 0.87 (95%IC 0.78-0.97; p<0.05). FDG-PET findings influenced significantly the therapeutic management in 18 patients (modifying therapy in 10 pts; guiding surgery in 8 pts). After 2 years of follow-up, PFS was significantly longer in pts with a negative vs. a positive FDG-PET scan (90% vs 46%, p<0.05). Moreover, a negative study was associated with a significantly longer OS than a positive one (76% vs 39% after 2 years, p<0.05). In addition, a positive PET scan was associated with an increased risk of disease progression (HR=8.2; p<0,05).**Conclusion:** FDG-PET/CT showed a valuable diagnostic performance in pts with suspicious of recurrent melanoma. This method has an important prognostic value in predicting the survival outcomes and assessing the risk of disease progression.

EP198

Leakage monitoring method in Isolated Limb Perfusion. Our experience

C. Calvo Morón, A. Agudo Martinez, F. García Gómez, P. De la Riva Pérez, T. Cambil Molina, J. Castro Montaño; Hospital Virgen Macarena, Sevilla, SPAIN.

Aim: *Isolated* limb *perfusion* (ILP) by the use of extracorporal circulation allows the infusion of high-doses of chemotherapeutic agents to avoid amputation of irresectable tumors of the extremities. Regional-to-systemic leakage is continuously monitored during the infusion procedure (60-minutes) since flow of the cytotoxic drug to the systemic circulation could result in a life-threatening situation. ILP have to be discontinued if leakage rates of 10-12% are detected. We report our experience in the leakage monitoring method through the continuous measuring of systemic 99mTc-human serum albumin (99mTc-HSA) with a portable gamma-camera. **Methods:** 15 patients underwent ILP: 14 patients were diagnosed of locally advanced malignant melanoma being trated with melphalan while 1 patient was diagnosed of undifferentiated pleomorphic sarcoma grade 3 being trated with melphalan and TNF-alpha. Two doses of 99mTc-HSA (20μCi for systemic and 200μCi for limb circulation measurements, respectively) are used. Systemic dose is injected once the limb is isolated. When basal plateau of precordial counts is reached, limb dose can be injected. Gamma-camera detector is placed on the precordial for leakage monitoring during procedure. Counts measures are performed throughout the drug infusion, determining the percentage of leakage by calculating the increase of precordial activity from the basal plateau and adjusted to decay of the radiotracer. Local toxicity of ILP is classified by Wieberdink scale while systemic toxicity is directly related to percent of leakage. **Results:** Procedure was suspended in 1 patient because a significant leakage (25%) was detected before starting the infusion of chemotherapy agent. Subsequently, procedure was repeated with undetectable leak (0%). Leakage >15% was observed in 1 patient, 15-minutes after starting melphalan infusion, with no postoperative complications. Leakage >10% was detected in 2 patients, with no systemic or local complications after completing the procedure. Leakage <10% was demonstrated in the remaining patients. 1 patient suffered systemic complications -nausea, vomiting and sepsis- and local complications (Wieberdink IV), as well as only local comlpications was related in 4 patient (2 patients Wieberdink II-II, 1 patient Wieberdink IV). In the patient treated with TNF-alpha, 2% leakage was detected and evolving favorably with only local complications (Wieberdink I-II). **Conclusions:** ILP is an alternative procedure that can effectively be used as a palliative treatment which requires strict leakage monitoring to reduce systemic complications, possible thanks to advances in technology and the development of appropriate software. In our experience, control method allowed the treatment even in the leakage limits with satisfactory results.

EP199

Staging 18F-FDG PET/CT as a further determinant of prognosis in patients with cutaneous melanoma associated to Breslow thickness

S. Diodato[1], E. Dika[2], M. A. Chessa[2], G. Veronesi[2], S. De Vivo[3], G. Polverari[1], S. Sanfilippo[1], I. Sandler[1], C. Nanni[1], P. A. Fanti[2], S. Vaccari[2], A. Patrizi[2], S. Fanti[1]; [1]Service of Nuclear Medicine, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [2]Unit of Dermatology, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [3]Service of Nuclear Medicine, Bufalini Hospital, Cesena, Cesena, ITALY.

Aim: Breslow thickness (BT) is an important determinant of prognosis in cutaneous malignant melanoma (CMM). The aim of our study was to determine whether staging 18F-FDG PET/CT associated to BT could further stratify patients with CMM. **Materials and methods**: we retrospectively included 54 patients (mean age 62.8 years, range 28-88) with histologically proven CMM and BT available, who underwent staging FDG-PET/CT between November 2004 and November 2011 and had at least 6 months of clinical/imaging follow-up. We divided PET/CT results in positive and negative. Furthermore, two patient groups were defined according to BT: low-BT group (thickness < or = 2.0 mm, 22 patients) and high-BT group (thickness > or = 2.01 mm, 32 patients). A Kaplan-Meier survival analysis of melanoma-specific-survival (MSS) and disease-free-survival (DFS) with positive/negative PET/CT result and BT was performed. **Results:** the mean follow-up was 51 months (range 6-122 months). 46/54 PET/CT were negative and 8/54 were positive. A significant correlation between positive/negative PET/CT results and MSS was found (p=0.0007). On the contrary, no significant correlation between PET/CT results and DFS was reported (p=0.1520). An analysis per BT-group associated to PET/CT positive/negative was performed and a significant correlation was found for MSS and DFS (p=0.0001 and p=0.0129, respectively). Median SUVmax of true-positive lesions was 12.1 (range 6.4-19.6). No statistical analysis was performed for SUVmax due to the small number of positive findings. However, patient with the highest SUVmax had the shortest survival (2 months) and patient with the lowest had late recurrence (87 months). **Conclusions:** staging 18F-FDG PET/CT is significantly related to MSS. PET/CT positive/negative result can be used to further stratify patients risk within the standard BT groups. SUVmax could be associated with increased recurrence and death but further studies are needed to better assess its prognostic role in CMM and its correlation with BT.

EP200

Effectiveness of 18F-FDG-PET/CT in the staging and follow-up of patients with high-risk cutaneous melanoma

J. Lojo Ramírez[1], R. Fernández-López[1], I. Acevedo-Báñez[1], V. Pachón-Garrudo[1], L. Caballero-Gullón[1], B. Russo[1,2], M. Sancho-Márquez[1], J. Domínguez-Cruz[1], T. Zulueta-Dorado[1], I. Borrego-Dorado[1]; [1]Hospital Universitario Virgen del Rocío, Sevilla, SPAIN, [2]Universitá Federico II di Napoli, Napoli, ITALY.

Objetive: The aim of this study was to evaluate the effectiveness of fluorine-18 fluorodeoxyglucose (^{18}F-FDG) positron emission tomography combined with computed tomography (PET/CT) in the staging and follow-up of the high-risk malignant cutaneous melanoma.Material and methods: A prospective cross-sectional cohort study was performed including 26 consecutive patients (17 males and 8 females with a medium age of 59 years-old at the moment of the initial scan), with the inclusion criteria of being diagnosed with high-risk cutaneous malignant melanoma (stage IIB, IIC or III) and have underwent at least one FDG-PET/CT study between October 2012 and October 2015 (performing a total of 63 FDG-PET/CT). This criteria was established by the Melanoma Board at our hospital. FDG-PET/CT results (positive/negative) and location of disease (lymphatic-regional, local or distant metastasis) after qualitative and semiquantitative evaluation were correlated with histopathological confirmation or confirmation by clinical-radiological follow-up of at least 6 months.Results: Initial staging: In 23% patients (6/26) was demonstrated the existence of tumor disease at the time of initial staging. Regarding to the initial FDG-PET/CT, it was achieved 6/26 TP, 1/26 FP and 19/26 TN, with a sensitivity, specificity, PPV, NPV and accuracy of 100% (95%IC: 61-100%), 95% (95%IC: 76.4-99.1%), 85.7% (95%IC: 48.7-97.4%), 100% (95%IC: 83.2-100%) and 96.2% (95%IC: 81-99%), respectively. Follow-up: During follow-up it was demonstrated recurrence of tumor disease in 15% (3/20) patients in whom it had not been demonstrated its existence in the initial staging. It was achieved 3/20 TP, 1/20 FN and 16/20 TN, with a sensitivity, specificity, PPV, NPV and accuracy of 75% (95%IC: 30-95.4%), 100% (95%IC: 80.6-100%), 100% (95%IC: 43.8-100%), 94,1% (95%IC: 73-99%) and 95,0% (95%IC: 76.4-99%), respectively.Overall, it was obtained a global detection rate of disease of 34,6% (9/26), with a sensitivity, specificity, PPV, NPV and accuracy of 90% (95%IC: 59.6-98.2%), 93.8% (95%IC: 71.7-98.9%), 90% (95%IC: 59.6-98.2%), 93.8% (95%IC: 71.7-98.9%) and 92.3% (95%IC: 75.9-97.9%), respectively.Conclusions:18F-FDG PET/CT in the initial staging and follow-up every six months is an effective and usefull tool in the control and management of patients with high risk cutaneous melanoma.

EP201

FDG-PET/CT in Preoperative Staging of Sentinel Node Biopsy Positive Melanoma Patients: A One-Year Evaluation of a Novel Diagnostic Strategy

E. Frary, D. Gad, L. Bastholt, P. Høilund-Carlsen, S. Hess; Odense University Hospital, Odense, DENMARK.

Aim: On April 1st 2015 the Region of Southern Denmark began a new diagnostic strategy wherein all malignant melanoma (MM) patients with positive sentinel lymph node biopsies (SLNB) undergo FDG-PET/CT prior to lymph node dissection treatment to reveal and localize remote metastases preoperatively. The aim of this study was to evaluate this new strategy by analyzing preoperative FDG-PET/CT findings and examine to what degree they altered treatment or triggered additional diagnostic tests. **Methods:** The patient population included an unselected retrospective cohort of all MM patients from the Region of Southern Denmark with positive SLNB, who from April 1st 2015 to March 31st 2016 underwent routine FDG-PET/CT, i.e., with scans from vertex of the skull to the proximal femurs or the entire body if the primary lesion was in the lower extremities. CT was low-dose and non-contrast-enhanced. Clinical data were collected from the Danish Melanoma Database and cross-referenced with patient reports for basic information (e.g. about age and sex), primary tumor characteristics, and SLNB findings. FDG-PET/CT results were obtained as routine scan interpretations made by a nuclear medicine specialist. **Results:** A total of 47 patients, 27 male and 20 female with a median age of 61 years [range 26-82], were included. Median follow-up was five months [range 1-11]. Increased FDG-uptake suggestive of remote metastases was found in 7/47 patients (15%). One case was determined to be progression of preexisting concomitant carcinoma of the lungs and not a MM metastasis. In the remaining six patients, focal FDG-uptake was localized in the colon (n=3), thyroid gland (n=1), lungs (n=1), and hilar lymph nodes (n=1). These findings led to additional testing in the form of colonoscopy (n=3), ultrasound-guided biopsy (n=1), pulmonologist referral (n=1), and endobronchial ultrasound biopsy (n=1). Ultimately, no remote MM metastasis or anything else of relevance was found. **Conclusion:** Surprisingly and contrary to findings in the literature, this new diagnostic strategy revealed no remote MM metastases during its first year. FDG-PET/CT triggered a number of additional diagnostic procedures, none of which did lead to a change in treatment. Although results are preliminary and our population is limited, these findings seem to indicate a need for re-evaluation of the strategy including considerations about optimal scan protocol, i.e., scanning of the entire body in all patients, and CT procedure, i.e., low-dose versus diagnostic CT with contrast enhancement.

EP202

Diagnostic yield of selective sentinel lymph node dissection in melanoma, our experience between 2013-2015 La Paz Hospital, Madrid, Spain

G. VILLORIA, C. Escabias del Pozo, I. Santos Gomez, Y. Ramirez Escalante, S. Rizkallal, Y. Guzman Cruz, M. Orduña Diez, L. Dominguez Gadea; LA PAZ UNIVERSITY HOSPITAL, MADRID, SPAIN.

OBJECTIVE: Assess the diagnostic performance of selective sentinel lymph node dissection to reduce the number of unnecessary lymphadenectomy in patients with malignant melanoma without clinical evidence of regional lymph nodes or distant metastases. Assess the value of monitoring and characterizing the tumors in our environment. MATERIALS AND METHODS: A retrospective, analytical study of 43 patients from September 2013 to July 2015 diagnosed with melanoma referred to our service for selective sentinel node biopsy (SLNB), with an average age of 57 years (14-92), 22 were men. Breslow index was 2.03 +/- 2.2 studied (0-9) and the Clark level was III (I-V), 14 (32.6%) had ulceration. The location of melanomas was: 6 (14%) head and neck, 22 (51.2%) trunk, 3 (7%) upper limbs, 9 (20.9%) lower limbs. and 3 (7%) in other locations. The time from diagnosis to performing SLNB time was 0.9 +/- 0.7 months. All patients underwent lymphoscintigraphy prior to surgery day, resulting in dynamic and static images according to location of drainage and SPECT-CT in all cases. The average follow-up time was 11.6 months (4-24).RESULTS: Most melanoma were histological type of Superficial spreading melanoma, in 76.7%. 1.6 +/- 0.7 GC were detected in lymphoscintigraphy, surgically analyzed GC 3.09 +/- 4, 8 (18.3%) were positive and 7 underwent lymphadenectomy. During lymphadenectomy 7 positive nodes extracted of a total of 156 nodes (4%) were obtained. The locations with the highest number of GC were Axillary 48% and inguinal in 32% of cases. 3 (7%) patients had locoregional and/or distant recurrence. CONCLUSION: Undoubtedly selective sentinel node biopsy in melanoma decreases the number of lymphadenectomy in our patients. Recurrence is low and monitoring is appropriate in our environment. It is confirmed that the sentinel node is a simple technique, low morbidity, with an important role in staging for the treatment of malignant melanoma.

EP203

The value of a non-dedicated brain PET/CT whole body protocol for evaluation of brain metatastes of metastasized malignant melanoma under immune therapy

H. Einhellig[1], A. Krackhardt[2], J. Kohlmeyer[3], R. Hein[3], M. Schwaiger[1], **M. Mustafa**[1]; [1]Klinikum rechts der Isar, Dept. of Nuclear Medicine, Munich, GERMANY, [2]Klinikum rechts der Isar, Dept. of Hematooncology, Munich, GERMANY, [3]Klinikum rechts der Isar, Dept. of Dermatology, Munich, GERMANY.

Aim: FDG PET proves to be a growingly important tool in staging and restaging patients with metastasized melanoma - even more so in the age of immune therapy with novel checkpoint inhibitors. The ideal PET/CT protocol is including brain and lower extremities, although the usefulness of this total body approach has been questioned lately. The aim of this retrospective study is to investigate specificity and sensitivity of FDG-PET in diagnosing brain metastasis in comparison to serial ceMRI as a gold standard. Methods: We retrospectively evaluated 124 patients (pts) with metastasized malignant melanoma under immune therapy who were treated at the interdisciplinary melanoma group of our institution 05/2011 - 01/2016. They received contrast enhanced brain MRI within 8 weeks after every routine total body FDG- PET/CT-scan. Brain glucose metabolism of this non-dedicated FDG-PET was evaluated blinded to the outcome of consecutive MRI with regards to focal FDG-uptake or reduced regional FDG-metabolism. Results: Of 122 pts 20 pts developed cerebral metastases during follow-up (11%). FDG PET was able to identify 8 patients with suspicious glucose metabolism, of which 6 pts showed increased and 2 pts showed decreased FDG-uptake. Two pts who showed a regional decrease of FDG-uptake proved to have regional ischemic lesions in the consecutive cMRI without underlying metastastic disease. This results in a low sensitivity of 40% but an exeptionally high specificity of 98% for FDG-PET in detecting undiagnosed brain metastases (PPV 80%, NPV 89,5%). Conclusion: FDG-PET even in non-dedicated brain protocols is in spite of the physiological cortical brain metabolism a highly specific tool diagnosing cerebral metastases in a metastasized melanoma cohort. In conclusion, standard FDG-PET/ CT protocols should always include the brain, although the low sensitivity does not render it suitable for stand-alone restaging of high-risk melanoma patients. In this context FEG-PET/MR might prove more suitable for restaging and therapy monitoring.

Matched Pair Validation of Ultra-low-dose CT Compared to Low-dose CT for Oncologic ^{18}F-FDG PET/CT

N. C. Hall[1], C. L. Wright[2], N. Gortanla[2], V. Nagar[2], J. Zhang[2], M. V. Knopp[2]; [1]Philadelphia VA Medical Center, Philadelphia, PA, UNITED STATES, [2]The Ohio State University, Columbus, OH, UNITED STATES.

Aim: To validate by matched pair assessment the equivalency of ultra-low-dose adaptive-current iterative reconstructed CT compared to low-dose CT in clinical oncologic ^{18}F-FDG PET/CT. **Materials and Methods:** 65 consecutive patients receiving follow-up PET/CTs were retrospectively evaluated after a system upgrade (VA40A) enabling modulated ultra-low dose CT on a Siemens mCT 64 PET/CT. Three experienced reviewers evaluated the de-identified and blinded paired CT data sets (standard low-dose CT without VA40A [150 mAs] versus ultra-low-dose CT with VA40A [adaptive mAs with 100mAs as reference]) using a 4-point scoring system for clinical image quality. Assessment scores and CT radiation doses for each data set were independently recorded. CTDIvol, DLP as well as EDE were calculated and analyzed for each data set. **Results:** 65 matched pair data sets were evaluable and were independently reviewed by the 3 readers. Equivalent diagnostic CT image quality was determined by every reader individually and collectively with no case identified in which the ultra-low-dose CT did not render diagnostic quality images. The CT radiation dose reduction was found to be: CTDIvol (mGy) from 13 ± 3 to 5 ± 2; DLP (mGy*cm) from 1367 ± 382 to 515 ± 231; EDE (mSv) from 21 ± 6 to 8 ± 4 (all $P < 0.01$). Minor notable observable differences included a more pixelated skin-subcutaneous fat interface. No significant differences ($P < 0.01$) in Houndsfield Units for tissues relevant for attenuation correction were noted. **Conclusion:** Significant radiation dose reduction ($P < 0.01$) was achieved with ultra-low-dose iterative reconstructive CT without compromising image quality in patients undergoing routine oncologic PET/CT. Given the increasing clinical need for repeated PET/CT imaging assessment in such oncologic patients, the findings support the implementation of ultra-low-dose CT for routine oncologic ^{18}F-FDG PET/CT in order to promote and achieve ALARA.

EP205

PET/CT for primary staging of rectal cancer patients with and without extramural vascular invasion detected by MR (EMVI-MR)

M. Queiroz, C. Ortega, T. Morita, P. Viana, M. Zagatti, R. Blasbalg, M. Menezes, C. Buchpiguel; Unviersity of Sao Paulo, Sao Paulo, BRAZIL.

PURPOSE To evaluate the use of PET/CT for primary staging of rectal cancer according to EMVI-MR status. **METHOD AND MATERIALS** Twenty-two patients with rectal cancer before neoadjuvant radio and chemotherapy were enrolled in this prospective study. All patients underwent contrast-enhanced CT of thorax and abdomen, pelvic MR, whole-body PET/CT and liver MR with DWI and Primovist®. Imaging analysis consisted on evaluation of the primary tumor on MR concerning T- and N-staging, mesorectal involvement and EMVI status. PET/CT, ceCT and liver MR were analyzed for the presence of distant metastases. Biopsy of rectal tumor was obtained in all patients before treatment. The patients were divided based on the presence of EMVI-MR and the detection rate of metastatic disease was compared between ceCT, PET/CT and liver MR. Additionally, quantitative analysis of the primary tumor was done using DWI (ADC) and PET parameters (SUV, TLG, MTV) and compared to histology. **RESULTS** Metastatic disease was found in 4/22 patients (18%) accounting for 28 lesions. There were 13/22 (59%) patients without EMVI-RM and 9/22 (41%) patients with EMVI-RM, which 4/9 (44%) presented distant metastases. PET/CT detected two more lesions than ceCT, which had high clinical impact, changing the patient management from curative to palliative intention. Liver MR did not identify any additional lesion to PET/CT or ceCT. Quantitative analysis showed an inverse correlation of TLG and grade of histological differentiation of the primary rectal tumor. **CONCLUSION** Positive EMVI-MR can be used to select patients that would benefit from whole-body staging with PET/CT. Quantitative data of PET/CT aid on the characterization of tumor aggressiveness. **CLINICAL RELEVANCE/APPLICATION** PET/CT might be preferred to stage rectal cancer with EMVI-MR due to higher detection rate of distant metastases and potential clinical impact on patient management.

EP206

Bone metastasis in neuroendocrine tumors. 68Ga DOTA-TOC PET-CT vs CT alone: retrospective analysis

A. Sartorello[1], R. Butini[2], E. Milan[1], S. Bissoli[1], V. Fiore[1], S. Medea[1], M. Gregianin[1]; [1]UOC Medicina Nucleare Osp. S. Giacomo, Castelfranco Veneto TV, ITALY, [2]UOC Radiologia Osp. S. Giacomo, Castelfranco Veneto TV, ITALY.

AIM: aim of the study was to evaluate retrospectively the role of 68Ga-DOTA-TOC PET-CT vs CT alone in the detection of bone metastasis in patients with neuroendocrine tumors. Materials and Methods: from January 2013 to July 2015 792 PET-CT with 68Ga-DOTA-TOC were performed. 51 Pts (24 M, mean age 63.92 y) showed bone lesions at first PET/CT evaluation. The primary site of the tumor was gastrointestinal (20), pancreas (11), lung (11), unknown (5), thyroid (3) and ovary (1). PET/CT scan was performed for evaluation after surgery or chemotherapy (12), during therapy (12), staging (7), marker increase (6), suspect of recurrence (12), detection of primary unknown tumor (2). PET/CT scan were performed 60 minutes after the i.v. injection of 3MBq/bw of radiopharmaceutical acquiring images from the base of the skull to the upper third of the thighs. PET/CT and CT alone images were independently evaluated by a Nuclear Physician and a Radiologist unaware of the results of the other modality and of patient history. Bone lesions were calculated in each patient for both PET-CT and CT alone and assigned to 8 regions: base of the skull, column, ribs, scapula, clavicle, sternum, pelvis, long bones. Moreover, Radiologist described the bone lesions as lytic, sclerotic or mixed. Results: PET-CT showed 610 bone lesions whereas CT only 147 (PET-CT vs CT): base of the skull 6 vs 2, column 168 vs 76, ribs 98 vs 24, scapula 24 vs 1, sternum 33 vs 6, clavicle 16 vs 1, pelvis 211 vs 34, long bones 54 vs 3. At CT 31 lesions were lytic, 115 sclerotic and 1 mixed; this technique showed 27 lesions PET-CT negative: 20 sclerotic and 7 lytic. Interestingly two positive PET-CT lesions were vertebral haemangioma at CT. Twenty-five patients were PET-CT positive and CT negative. Conclusions: In our retrospective study 68Ga-DOTA-TOC PET-CT enabled early evaluation of suspected metastatic site in the cortical bone, but also in bone marrow before cortical destruction has occurred. 68Ga-DOTATOC PET-CT results to be a reliable technique for early detection of bone metastasis regardless the characteristics of the lesions. PET scan confirmed its crucial role in the evaluation of NET patients and can led to a change in their management and prognosis.

EP207

Esthesioneuroblastoma- evaluation of ^{68}Ga-DOTATATE PET/CT imaging efficacy in diagnosing and treatment monitoring-initial experience

G. Lapinska, A. Jarząbski, M. Dedecjus; Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, WARSAW, POLAND.

Introduction: Esthesioneuroblastoma (olfactory neuroblastoma) is a rare primary sinonasal tumour with neuroendocrine differentiation originating from olfactory epithelium. It is often highly aggressive and leads to local recurrence and distant metastases. The aim of the study was to present our experience concerning the efficacy of 68Ga-DOTATATE in staging, restaging, treatment monitoring as well as its usefulness in radiotherapy planning. Materials and methods: From 2011 to 2016, PET/CT examination was performed on nine patients diagnosed with histological esthesioneuroblastoma (3 women, 6 men, aged 26-66, median 36 years). All of the patients underwent their first PET/CT after surgical resection of primary tumour. 2 patients were after, 1 during and 1 before chemotherapy (chth). 4 out of 9 were before radiotherapy (rth). So far, 3 of the patients had only one PET/CT scan, 5 underwent the examination 3 to 4 times in order to monitor the efficacy of the treatment or as a follow-up. The remaining one patient was examined 8 times with PET/CT. PET/CT was performed on Phillips Gemini 16TF PET/CT scanner. Images were obtained 60 minutes (+10 min) after i.v. administration of 111-185 MBq 68Ga-DOTATATE (depending on patient's weight). Results: First PET/CT scans were negative in 2 patients, in 4 patients before, during or after chth the primary tumour resection scans revealed metastases. In the remaining 3 patients moderate uptake of tracer was present in the postoperative localization. 2 patients (26 and 30 years old) that underwent rth and chth died within a year of diagnosis due to the progression of disease visible on PET/CT scans (bone and liver metastases). The remaining patients are still undergoing treatment monitoring or follow-up using gallium PET/CT. PET/CT scan was used for radiotherapy planning for 3 patient. For the first time it was used for a patient with primary lesion located in nasal cavity, close to the optic nerve. The scan proved to be helpful in determining target volumes for radiotherapy which prevented the patient from losing his sight after therapy. Additionally, in 1 patient PET/CT scan revealed in the right breast small lesion with moderate increased uptake of the tracer, which was identified as a breast cancer. The patient is after tumorectomy and rth. Conclusion: 68Ga-DOTATATE PET/CT scan seems to be an effective tool in staging, restaging and therapy monitoring in esthesioneuroblastoma, however this it still requires further investigation.

EP208

Neurocrine Tumour Evaluation: ^{18}F-FDG-PET/CT Versus Somatostatin Receptor Scintigraphy (SRS)

I. Cillero[1], A. Mendiola[1], A. Gomez[1], A. Lacasta[2], P. Santesteban[1], G. Rios[1], F. Rodriguez[1]; [1]Fundación Onkologikoa, San sebastian, SPAIN, [2]Hospital Universitario Donostia, San sebastian, SPAIN.

OBJECTIVE The aim of this study is to identify which imaging modality is the most appropriate in the evaluation of neuroendocrine tumours (NET) based on clinic, histologic and analytic parameters **MATERIAL AND MHETODS** Between June 2013 and April 2016, 72 consecutive patients with neuroendocrine tumours were enrolled in the study. These patients had a somatostatin receptor scintigraphy (SRS) and ^{18}F-FDG PET/CT. The scan result (positive or negative) was correlated with different variables: localization, tumour grade, Ki67, chromogranin A (Cg A) and serotonin. **RESULTS** All of 72 patients had a SRS and out of them 44, have performed both scans (^{18}F-FDG PET/CT and SRS). The overall sensitivities (S) of SRS and ^{18}F-FDG PET for detection of either primary tumour or metastases were 55,5% and 84,1%, respectively. Based on tumour grade (no available in 52%), the sensitivity for ^{18}F-FDG PET/CT and SRS, was for grade 1, 63,6% vs 75%; for grade 2, 100%(n=2) vs 60%(n=5) and for grade 3, 100%(n=5) vs 55,67%(n=9) (p=0,19 and p=0,5 for PET/CT and SRS respectively). Taking into account the proliferation index, S of PET/CT and SRS respectively was: Ki67 &lt 2%: 42,9% vs 57,1%; Ki67 2-20%: 90% vs 71,4% and Ki67&gt 20%: 100% vs 46,7% (p=0,006 and p=0,31). Cg A and serotonin values do not seem to influence in PET/CT sensitivity. For SRS, the sensitive is 76,9% when Cg A&gt 109ng/ml and 46,7% if Cg A &lt 108ng/ml (p=0,029). When serotonin&gt 401ng/ml sensitivity is 90,9% and if serotonin &lt 400 is 59,4% (p=0,071). The sensitivity for localization is the same for both SRS and PET/CT scans. **CONCLUSION** For choosing the best the imaging modality to assess TNE, the sensitivity of PET/CT is higher in grade 3/poorly differentiated and Ki67 values&gt 20%. SRS has greater sensitivity in grade 1/well differentiated and Ki67 values &lt 20%. Cg A and serotonin do not seem to influence the sensitivity of PET/CT. The sensitivity of SRS increases at higher values of serotonin and Cg A. The location of TNE does not influence the sensitivity in both tests.

EP209

Comparison of sensitivity and specificity of Tc-99m octreotide and I-131 MIBG scintigraphies in diagnosis and localization of pheochromocytoma and neuroblastoma

A. Fard-Esfahani, A. Emami-Ardekani, A. Mirzabeigi, B. Fallahi, A. Hassanzadeh-Rad, D. Beiki, P. Geramifar, M. Eftekhari; Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: Tc-99m octreotide scan and I-131 metaiodobenzylguanidine (MIBG), are both valuable agents in diagnosis and localization of neuroendocrine tumors. This study was performed to compare the sensitivity and specificity of these agents in detection of pheochromocytoma and neuroblastoma. Materials and methods: 40 patients with pathologically proven pheochromocytoma/neuroblastoma were enrolled and octreotide and MIBG scans were performed for every patient. A composite reference standard consisting of cytopathology , biomarkers, anatomical imaging and six-month follow-up data was used as a reference for final diagnosis to evaluate the scintigraphic imaging results. Lesion-based and patient-based analysis were performed. Findings: On the basis of lesion-based analysis, overall sensitivity of MIBG was better than octreotide study (94.44% vs 80.56%). Cosidering each disease separately, sensitivity of both scans for pheochromocytoma was 100%, but MIBG study showed a higher specificity (%100) than octreotide (87.5%). In neuroblastoma, MIBG sensitivity (100%) was better than octreotide (81.25%); however specificity was higher with octreotide study (100% for octreotide versus 92.85% for MIBG). On the basis of patient-based analysis, MIBG had equal sensitivity and specificity of 100% for both diseases. Although octreotide also had 100% sensitivity for pheochromocytoma, its specificity was 87.50%. For neuroblastoma, octreotide study had 81.25% sensitivity and 100% specificity. Conclusion: Both MIBG and octreotide scans show high sensitivity and specificity in detection of neuroendocrine tumors of pheochromocytoma and neuroblastoma. However, MIBG scan with its better sensitivity may be considered the first line functional imaging modality; octreotide can be used to provide complementary information. It is advisable that if any of these two scans becomes negative in a patient with high clinical suspicion, the other one is performed, so that no useful data is missed in patient's management.

EP210

Clinical Value of Serum Chromogranin A, Neuron Specific Enolase, CEA, and Calcitonin in Neuroendocrine tumors : Comparison by The 68Ga-DOTA-PEPTIDE PET-CT imaging SUVmax value

F. AYDIN[1], E. SURER BUDAK[1], S. BOZKURT[1], A. ONER[2], A. BOZ[1]; [1]AKDENIZ UNIVERSITY, Antalya, TURKEY, [2]AFYON KOCATEPE UNIVERSITY, AFYON, TURKEY.

Aim: Neuroendocrine tumors (NET) are malignant solid tumors originating from neuroendocrine cells dispersed throughout the body. Differentiated NET overexpress somatostatin receptors (SSTRs), which enable the diagnosis using radiolabeled somatostatin analogues. Most NET produce and secrete a multitude of peptide hormones and amines. In this study, our aim was to determine if there was a relationship between the SSTRs activity obtained from 68Ga PET imaging (SUVmax) and serum tumor markers (chromogranin A, neuron specific enolase: NSE, CEA, and calcitonin). **Materials and Methods:** Sixtyseven patients with histologically confirmed NET who had undergone 68Ga-DOTA-PEPTIDE PET/CT images were included in the study. Serum chromogranin A levels (n:36), NSE (n:17), CEA (n:15), and calcitonin (n:9) were measured. 68Ga-DOTA-PEPTIDE PET/CT images SUVmax values were compared with serum tumor markers, retrospectively. **Results:** The values of lesions SUVmax of the cases were seen that ranged between 4.3 to 181 (median: 24). Serum chromogranin A, NSE, CEA, and calcitonin levels were in the range of 7-817 (median:82), 5.3-278.3 (median:21.2), 0.9-2190 (median:4.5), and 4-13010 (median:800), respectively. There were statistically significant correlation between the SUVmax and serum chromogranin A level. The correlation coefficient value was calculated as r=0.34, ($p<0.046$). Any statistically significant correlation between SUVmax value and other serum tumor markers ($p>0.05$) could not be found. **Conclusion:** 68Ga-DOTA PEPTIDE is suited equally well for staging and patient selection for PRRT with 177Lu-DOTA PEPTIDE. Chromogranin A is considered the best general neuroendocrine serum marker available both for diagnosis and therapeutic evaluation and is increased in 50-100% of patients with various NET. In litherature is not found clinical value of serum tumor marker and 68Ga DOTA PEPTIDE. Our study is the first. Serum chromogranin A level together with 68Ga DOTA PEPTIDE PET/CT could be important in diagnosis, and management in NET. They may be an independent markers of prognosis in patients with NET.

EP211

Comparison of lesions detected on F-18 FDG PET-CT and Ga-68 DOTANOC PET-CT and their correlation with Ki-67 index in neuroendocrine tumour patients

A. Passah, M. P. Yadav, G. Kumar, R. Kumar; All India Institute Of Medical Sciences, New Delhi, INDIA.

Aim: To study the correlation between F-18 FDG PET-CT and Ga-68 DOTANOC PET-CT with Ki-67 index in patients with neuroendocrine tumours (NET). Materials and Methods: This is a retrospective study in which records of 21 patients diagnosed with NET were analysed. The study included patients sent for staging and response assessment after therapy. All patients had both F-18 FDG PET-CT and Ga-68 DOTANOC PET-CT done in any order. The scans were analysed qualitatively based on the sites of lesions detected or maximum standardised uptake value (SUVmax) of primary lesion or metastatic site, if primary has been resected, detected on one or both scans and correlated with Ki-67 index of each patient. The nuclear medicine physician was blinded to the results of either scan and Ki-67 index and each scan was assessed independently. Results: There were 4 patients in which both F-18 FDG PET-CT and Ga-68 DOTANOC PET-CT detected same sites of lesions. These patients had a median Ki-67 index of 7.5 (range 1.9 to 15). In 8 patients, more lesions were detected on F-18 FDG PET-CT compared to Ga-68 DOTANOC PET-CT. These patients had a median Ki-67 index of 21.5 (range 4.5 to 81). In 9 patients, more lesions were detected on Ga-68 DOTANOC PET-CT as compared to F-18 FDG PET-CT. These patients had a median Ki-67 index of 2 (range 0.9 to 35). However one patient had an unusually high Ki-67 index in this group. If this patient is excluded, then 8 patients in this group had a median Ki-67 index of 1.95 (range 0.9 to 7). Conclusion: This study shows a good correlation between molecular imaging using dual isotopes and a marker of cellular proliferation. Poorly differentiated cells with high index of proliferation show high uptake of F-18 FDG whereas well differentiated cells show high uptake of Ga-68 DOTANOC. This behaviour of cells can guide us in patient directed selection of isotopes and also plan for therapy.

EP212

Semiquantitative Analysis Of Physiological Biodistribution of ^{68}GA-DOTATATE and ^{68}GA-DOTANOC

E. S. Budak[1], A. Oner[2], S. Demirelli[3], M. Erkılıç[4], A. Boz[4], B. Karayalçın[4]; [1]Antalya Training and Research Hospital, Department of Nuclear Medicine, Antalya, TURKEY, [2]Afyon Kocatepe University Faculty of Medicine, Department of Nuclear Medicine, Afyon, TURKEY, [3]Denizli State Hospital, Department of Nuclear Medicine, Denizli, TURKEY, [4]Akdeniz University Faculty of Medicine, Department of Nuclear Medicine, Antalya, TURKEY.

Objectives: In this study, in patients who underwent 68Ga-DOTATATE and 68Ga-DOTANOC PET/CT imaging modalities with the diagnosis of NET, it was aimed 1) to determine the areas of physiologic uptake and means (± SD) and value ranges (min. and max.) of these areas, using semiquantitative parameters as SUVmax and SUVmean(±SD) 2) to compare the data obtained with those of the literature so as to define helpful reference ranges for intermediate cases with the intention to discriminate between physiologic and pathologic uptakes. **Materials and methods:** Radiological images of 40 patients (female, n=23 and male, n=17; mean age**,** 52.50±15.82 years) who had undergone ^{68}Ga-DOTA labeled (TATE

and NOC) PET/CT imaging modalities with the diagnosis of GEP-NET, non-GEP-NET and thyroid cancer were retrospectively evaluated. Measurements were performed from areas of physiologic uptake including pituitary gland, parotid gland and submandibular gland, palatine tonsils, thyroid, lungs, blood pool (left ventricular cavity), thymus, lymph nodes, liver, pancreas (from head, body and tail parts), spleen, stomach (fundus and other parts), both adrenal gland, kidney (from cortex), small bowel and colon, bone marrow, prostate, glandular breast tissue and muscle tissue. **Results:** In spleen, adrenal glands, head of the pancreas, palatine tonsils and breast, a statistically significant intergroup difference was not detected as for SUVmax and SUV mean values. As for the lymph node measurements, SUVmax values were statistically significantly higher in the TATE group, while SUVmean value did not differ between groups. Due to scarce number of cases, statistical analysis between both groups could not be performed for prostate and thymus. In the TATE group, significantly higher uptake in the body and tail of the pancreas compared to the head, and significantly higher uptake in the gastric fundus was observed. For both TATE and NOC, a statistically significant difference was not found between SUVmax and SUVmean values of the right and left adrenal glands, and of small bowel and colon. A statistically significantly higher SUVmax and SUV mean values were detected in the TATE group relative to the NOC group in all other organs in the study. **Conclusion:** This study used SUVmax and SUVmean values to demonstrate semiquantitatively distribution pattern of ^{68}Ga-DOTATATE and ^{68}Ga-DOTANOC in normal organs. We think that determination of uptake patterns and related range of values we defined for both agents in many organs will aid in discrimination between physiologic and pathologic uptake during interpretation of images.

EP213

Comparison Of 18F-FDG PET/CT With 111In Penteotride Scan For Detection Metastatic Neuroendocrine Tumors

F. Iuele, **A. Niccoli Asabella**, C. Altini, C. Ferrari, A. Di Palo, F. Duni, G. Rubini; Nuclear Medicine Unit, D.I.M. – University of Bari "Aldo Moro", Bari, ITALY.

AIM. To compare the 18F-FDG PET/CT and 111In penteotride imaging (OCT) to characterize the metastatic neuroendocrine tumors (NETs) MATERIALS AND METHODS: we retrospectly analyzed 27 patients (pts) (13 female, 14 male, mean age: 65, range 39 - 81 years) with previously diagnosed NETs who underwent between January 2014 and March 2016 both 18F-FDG PET/CT and OCT imaging within 3 month interval. 7/27 pts had SCLC, 12/27 GEP, 4/27 NETs of unknown origin, one Merkel cell carcinoma, one NETs of adenohypophysis, one of thyroid, one of bladder. PET/CT and OCT abnormal uptake was evaluated, according the following anatomic district: lung, liver, bone, thoracic or abdominal lymph nodes and other sites. The comparison between the PET/CT and OCT results and abnormal uptake was performed by K of Cohen. RESULTS: The comparison between OCT and 18F-FDG PET/CT, regarding the overall district, showed that the two methods were concordant in 23/27 pts. The correlation was good (K: 0.684, 95% C.I.: 0.403-0.965). The comparison of lung lesions showed that the two methods were concordant in 26/27 pts and the correlation was very good (K: 0.899, 95% C.I.: 0.705-1). The comparison of hepatic lesions showed that the two methods were concordant in 23/27 pts and the correlation was good (K: 0.617, 95% C.I.: 0.289-0.952). The comparison of bone metastatic lesions showed that the two methods were concordant in 25/27 pts and the correlation was good (K: 0.710, 95% C.I.: 0.339-1). The comparison of mediastinal lymph node involvement showed that the two methods were concordant in 22/27 pts and the correlation was fair (K: 0.348, 95% C.I.: -0.085-0.780). The comparison of abdominal lymph node metastasis, showed that the two methods were concordant in 23/27 pts and the correlation was good (K: 0.614, 95% C.I.: 0.273-0.956). As regard the other sites of metastasis, the comparison showed that the two methods were concordant in 21/27 pts and the correlation was moderate (K: 0.540, 95% C.I.: 0.217-0.863). PET/CT overall evaluation detected a greater number of lesions than OCT (44 versus 37) especially in bone and mediastinal lymph nodes. CONCLUSIONS: 18F-FDG PET/CT reflects the grade of malignancy and recognizes rapidly progressive tumors, while OCT reflects the grade of differentiation and somatostatin receptor. Although PET/CT detected a greater number of lesions, the concordance between the two methods was good, so we advice a combined use to improve the diagnostic accuracy.

EP214

SPECT-CT Somatostatin-Receptor Scintigraphy with ^{99m}Tc-Tektrotyd in Pulmonary and Thymic Neuroendocrine Tumors (NETs)

S. Sergieva[1], M. Dimcheva[1], A. Jovanovska[1], A. Fakirova[2], B. Robev[1]; [1]Sofia Cancer Center, Sofia, BULGARIA, [2]Military Medical Academy, Sofia, BULGARIA.

Pulmonary NETs and mediastinal NETs, developing from the thymus are unusual tumors that account for less than 5-6% of all lung/thymic neoplasms. Neuroendocrine tumors are classified according to the grade of biological aggressiveness (G1-G3) and the extent of differentiation (well-differentiated, poorly-differentiated). The well-differentiated neoplasms comprise typical (G1) and atypical (G2) carcinoids. Large cell neuroendocrine carcinomas as well as small cell carcinomas (G3) are poorly differentiated. The purpose of this study was to determine clinical role of SPECT-CT studies with ^{99m}Tc-Tektrotyd in patients with pulmonary and mediastinal NETs. Patients & Methods: 35 pts (31 with pulmonary/4 with mediastinal tumors) with neuroendocrine differentiation: 50%-100% positive-staining tumor cells, were studied: Ø 8 were with Large cell NE carcinomas Ø 7 were with SCLC Ø 8 were with lung carcinoids (typical and atypical) Ø 4 were with thymic NETs Ø 4 were with metastatic lesions from tumor with unknown primary origin (UPO), expressed NE markers, suspective for lung NE origin. • SPECT-CT gamma camera Symbia T2, Siemens with Low Dose CT was used. 58 examinations including SPECT-CT studies of the chest and/or abdomen were performed 2-6 hrs post i.v.inj. of 740 MBq ^{99m}Tc-HYNIC-TOC (Tektrotyd, Polatom). • Results: Primary lung NE tumors were visualised in 4 pts with UPO, proven histologically. Locoregional mediastinal and hilar lymphadenopathy were imaged in 17 pts. Distant liver, pulmonary, bone and/or suprarenal positive metastatic lesions were visualized in 15 pts, correlated with increased level of secret serum marker - CgA. There was not a tracer uptake in 3 pts with liver multiple secondary lesions due to metastatic dedifferentiation. Some of these patients were followed-up after the complex treatment. It can be summarized that main indications for SPECT-CT studies are as follows: • For diagnosis these studies have limited role only to depict the most appropriate tumor lesion for correct biopsy and to image primary tumor in cases with UPO. • To assess SSTR expression and thus could effectively influence the management of individuals with NETs. • For correct pre-treatment N-/M-staging of pulmonary and thymic NETs and to determinate treatment response. • To differentiate pathological lesions from benign and physiological uptake. • For early determination of recurrence in cases with negative anatomical imaging (CT,MRT) but with clinical and biochemical indices for NET. In conclusion SPECT-CT somatostatin - receptor scintigraphy imaging is a potential new technique for staging and follow-up of patients with pulmonary and thymic NETs in coming years.

EP215

Predictive value of Chromogranin A in the assessment of neuroendocrine tumors uptaking octreotide-^{99m}Tc

S. E. Bouyoucef, M. Habbeche, C. Mahmoudi, s. Rahabi, A. Talbi, M. Tiar; CHU Bab El Oued, Algiers, ALGERIA.

Introduction : Chromogranin A (CGA) is an hydrophyle and acid protein of 439 amino acids (49KD) which is present in chromaffine cells of neuroendocrine tumors (NETS). High blood levels of CGA may reflect the well differentiation and the aggressiveness of NETS. However, the value of normal CGA blood level is still not well established and controversial. Objective: To compare and study the sensitivity of serum CGA in patients with positive octretide-^{99m}Tc Patients and method: 58 patients have had a simultaneously an octretide-^{99m}Tc scan and test of serum CGA. The serum of CGA was determined by radio immunoassay techniques using sandwich method (Cis Bio, normal range: 20 to 115ng/ml). Whole body octretide-^{99m}Tc followed by two tomographic acquisition in mode SPECT/CT were performed 4hours after injection of 560MBq of octretide-^{99m}Tc with a SPECT/CT gamma camera Symbia T6 (Siemens). For the comparison, all selected patients have had a positive octretide-^{99m}Tc scan. Results Among the 58 patients with positive octroetide scan, 19 patients have had a normal CGA level. Among those 19 patients, 10 which represents more than 52%, have had a unique lesion seen in octreotide scan and the other 7 patients have had a multiple lesions uptaking octretide-^{99m}Tc (47%). The level of serum CGA was elevated in 39 patients. This level was ten times the normal values elevated in 17 patients and 15 of them presented metastatic disease of NETS meanwhile the two others presented an unique uptake on the primary tumor. The serum level of CGA raised to three time the normal level in 13 patients from whom 9 have had a metastatic disease of NETS and 4 only a primary. It was to note that when the level of CGA was higher than three times but less than ten times the normal value in 9 patients who presented all a metastatic disease of NETS. Conclusion Serum level of CGA has a good predictive value of NETS when the level is significantly high above three times the normal values and in those cases CGA level is well correlated with metastatic diseases of NETS. Unique uptake by the primary tumor of NET may also express high level of CGA. However, when the CGA level is normal it could not exclude a metastatic or a primary NET.

EP216

Role of somatostatin receptor scintigraphy in neuroendocrine G3 tumor imaging

M. Catalano, G. Annunziata, D. Scala, V. Ippolito, I. valenti, I. Sepe; AORN, Naples, ITALY.

Aim : Neuroendocrine tumors (NET) present pathological characteristics that can be investigated by different functional imaging modalities as somatostatin receptor scintigraphy (SRS) and PET-CT. Imaging technique choice depends on pathological tumor characteristics: well differentiated tumors can be investigated by SRS or 68 GaPET-CT , poorly differentiated tumors by 18F-FDG-PET-CT and mildly differentiated tumor by both techniques. Aim of the study is to evaluate SRS **diagnostic role in** patients (pts) with histologically verified poorly differentiated NET and targeted specific treatment derived from SRS data. Materials and **Methods:** Between October 2013 and March 2016, 160 pts affected with NET underwent to SRS. Mean age was 59.6 ± 17. 16/160 pts (10%) were G3 NET, with Ki67 > 25% (ranging from 25% to 90%). Pathological diagnosis identified 6 NET of lung , 3 pancreas , 2 bladder , 2 stomach, 1 colon, 1 rectum , 1 Merkel . 166-269 MBq of ^{111}In pentetreotide (OctreoScan; Mallinckrodt) was intravenously injected. Whole-body scans at a speed of 5 cm/min and a matrix size of 256 × 1,024 using a dual-head γ-camera equipped with a medium-energy general-purpose parallel-hole collimator and static images over 15 min, with a matrix size of 256 × 25 6 were acquired after 4 h and 24 h from injection. SPECT was performed using 3° steps, 40 s/step, a 180° orbit, and a matrix size of 128 × 128 after 4h e 24 h too. **Results:** 5/16 pts (68%) were SRS negative, 11/16 pts had SRS positive lesions, with low uptake score in all lung NET and in one pt with stomach tumor; score 3 in 3 pts with liver metastasis from pancreas and colon; score 4 in one pt with rectum tumor with diffuse metastatic involvement of liver, bone, lymphonodes and rectum. **Conclusion** Although SRS has never been used on a routine basis for imaging of G3 NET and its diagnostic performance in these tumors is unsettled , it could be added in diagnostic protocol of this group of NET. Its complementary diagnostic information could influence therapy and follow-up of these tumors charachterized by overexpression of somatostatin receptors and high proliferation index. We noted low uptake score in lung NET but higher indium pentetreotide uptake in metastatic more aggressive disease. The meaning of this data is still uncertain and the small sample size of the study requires further investigation about the real contribute of SRS in G3 NET diagnosis and therapy.

EP217

Intraindividual comparison of SUVmax, SUVmean and tumor volume results with ^{177}Lu-DOTA-TATE SPECT/CT and ^{68}Ga-DOTA-TOC PET/CT in neuroendocrine tumor patients

M. Rodrigues, E. Thorstensen, C. Uprimny, D. Kendler, I. Virgolini, B. Warwitz; Department of Nuclear Medicine, Innsbruck Medical University, Innsbruck, AUSTRIA.

Aim: to evaluate whether results obtained with ^{68}Ga-DOTA-TOC PET/CT - the current procedure for diagnostic, staging and restaging of neuroendocrine tumors (NET) - correlate with those gained with post therapeutic ^{177}Lu-DOTA-TATE SPECT/CT. **Patients and Methods:** 18 patients (9 males, 9 females; age: 42-85, mean 61.6 years) with histologically proven NET grade 1 (n=1), grade 2 (n=11) and grade 3 (n=6) were investigated with ^{68}Ga-DOTA-TOC PET/CT (79.5-154 MBq, mean 103 MBq ^{68}Ga; GE Discovery 690 time of flight PET/CT) and thereafter with ^{177}Lu-DOTA-TATE SPECT/CT (3.49-7.85 GBq, mean 5.67 GBq ^{177}Lu; Philips Brightview XCT). Both imaging modalities were performed within 21-33 (mean 29.1) days apart from each other. The SUVmax, SUVmean and tumor volumes obtained with these imaging modalities were compared in a total of 45 tumor lesions (3 primaries, 42 metastases). Furthermore, SUVmax and SUVmean in a liver region without metastases were calculated and used as reference in each patient. **Results:** SUVmax ranged 4.63-78.08 (mean 31.01) and 1.62-61.00 (mean 23.98), and SUVmean ranged 3.08-45.81 (mean 20.12) and 0.95-38.14 (mean 15.11) with ^{68}Ga-DOTA-TOC PET and ^{177}Lu-DOTA-TATE SPECT, respectively. Using tumor/liver ratio, SUVmax and SUVmean were significantly higher with ^{177}Lu-DOTA-TATE SPECT (1.22-44.2, mean 10.21, and 1.08-40.36, mean 11.25, respectively) than with ^{68}Ga-DOTA-TOC PET (0.52-7.88, mean 3.43, and 0.52-9.01, mean 4.68, respectively). Tumor volumes measured with ^{68}Ga-DOTA-TOC PET and ^{177}Lu-DOTA-TATE SPECT ranged 0.39-256.68 (mean 18.3) ml and 1.12-172.33 (mean 6.5) ml, respectively. No correlation was found between the SUV-values obtained with ^{68}Ga-DOTA-TOC PET and ^{177}Lu-DOTA-TATE SPECT while the measured tumor volumes correlated strongly. **Conclusions:** The SUV-values in tumor lesions are significantly higher and in tumor/liver lower with ^{68}Ga-DOTA-TOC PET than with ^{177}Lu-DOTA-TATE SPECT while tumor volumes correlate strongly between the two imaging modalities. Therefore SUV-results obtained with ^{68}Ga-DOTA-TOC PET should be used with precaution when planning further therapy with ^{177}Lu-DOTA-TATE.

EP218

The usefulness of ^{111}In-pentetreotide SPECT/CT in the diagnosis of non-functioning neuroendocrine gastroenteropancreatic (GEP) tumors and their metastases: a comparison with conventional imaging procedures (CIP)

A. Spanu[1], O. Schillaci[2], B. Piras[1], A. Falchi[1], R. Danieli[2], P. Ferro[3], S. Nuvoli[1], F. Dore[3], G. Madeddu[1]; [1]University of Sassari, SASSARI, ITALY, [2]University of Rome Tor Vergata, Rome, ITALY, [3]Hospital of Trieste, Trieste, ITALY.

Introduction: Some GEP tumors can be non-functioning with absence of clinical symptoms due to polypeptide hormone or other substance over-production in respect of functioning tumors, also occurring later, with more elevated size and, in some cases, with exocrine carcinoma similar characteristics. We evaluated ^{111}In-Pentetreotide SPECT/CT usefulness in diagnosing non-functioning primary GEP tumors and their metastases compared with CIP, such as US, CT, MRI. **Methods:** We studied retrospectively 104 non-functioning GEP tumor patients, 30 in initial diagnosis phase and staging (DS), 74 in follow up (F) with previous ascertained primary tumors; 35 patients (18 DS,17 F) were classified as inoperable for disseminated metastases and treated with octreotide or chemotherapy. Definitive diagnosis was performed by histology and, when not possible in recurrences and metastases, by CIP or radioisotopic procedures with follow up period of 6-36 months. According WHO 2010 digestive system tumor classification, the patients were classified as neuroendocrine tumor grade 1 (G1; 65 cases) and 2 (G2; 22 cases), neuroendocrine carcinomas (NEC; 12 cases) and mixed-adeno-neuroendocrine carcinomas (MANEC; 5 cases). In all cases, SPECT/CT images were obtained using a hybrid variable-angle dual-head gamma camera, including low dose x-ray tube, 4th, 24th,48th hours following i.v. injection of 148-222 MBq of 111In-pentetreotide. SPECT was first acquired followed by CT and the images, reconstructed by iterative method, were fused with those of CT using a dedicated software package. **Results:** Both sensitivity and accuracy of SPECT/CT were higher than CIP in G1 patients (92.3 vs 74.4% and 95.4 vs 85.6%, respectively), G2 (88.2 vs 70.6 % and 90.9 vs 77.3%. respectively), NEC (88.9 vs 60% and 83.4 vs 66.7%, respectively) and MANEC (100vs 75% and 100 vs 80%, respectively), but significantly (p= 0.0009) only for G1. In all single patient groups SPECT/CT evidenced more lesions, primary and metastatic, than CIP, but significantly (p=000006) only for G1 group. Globally, SPECT/CT incremental value was 35.6%, correctly changing CIP classification and patient management in 27.9% of cases, while it down-staged the disease in 9.6% of cases than CIP. **Conclusion:** Our data show that ^{111}In-Pentetreotide SPECT/CT is useful in detecting non-functioning GEP tumors and revealing their neuroendocrine origin in patients without either clinical signs of hormone over-expression or characteristic secretion pattern in blood. In particular, SPECT/CT was significantly more sensitive and accurate than CIP, but their combined use achieved the highest accuracy values and gave the most accurate staging, thus suggesting their use together.

EP219

Impact of 68Ga-DOTATOC PET Imaging to Assess SSTRs Expressing Lesions in a Tertiary Care Center

M. Scarlattei[1], G. Baldari[1], C. Cidda[1], M. Silvia[1], A. Sammartano[1], R. Dalla Valle[2], G. Missale[3], **L. Ruffini**[1]; [1]Nuclear Medicine Dept, University Hospital of Parma, Parma, ITALY, [2]Surgery and Transplant Unit, University Hospital of Parma, Parma, ITALY, [3]Haepatology Unit, University Hospital of Parma, Parma, ITALY.

Functional imaging with PET tracers is an evolving field for neuroendocrine tumors (NETs). Recently, somatostatin receptor (SSTR)-based imaging with gallium-68-based radiopharmaceuticals showed promising results in looking for primaries and determining the extent of metastatic disease. Aim of this work was to assess clinical impact of PET imaging with 68Ga-DOTA-TOC in the decision making process of patients with known or suspected NETs. METHODS We prospectively enrolled all the PET studies performed with 68 Ga-DOTATOC since Dec 2014. PET studies were acquired using an integrated system (GE IQ) 60 min after i.v. tracer injection. 68Ga-DOTATOC is produced on-site and on demand by an automated module (Scinthomics GRP®). All reagents used in the preparation of 68Ga-DOTATOC are of pharmaceutical quality. Before administration, the quality of the final solution was analysed according to the European Pharmacopoeia. Patients receiving therapy with somatostatin analogues (SSAs), interrupted their analogues 24 h before PET/CT for short-acting SSAs, or 4-6 weeks before PET/CT for long-acting SSAs. Whole-body (WB) 68Ga-DOTATOC PET/CT images from the head to mid-femur were acquired. All the PET studies were evaluated independently by two expert Nuclear physicians. RESULTS PET imaging with 68Ga-DOTATOC was performed in 81 patients. Mean administerd activity was 143+/-29 MBq). Mean yield of labelling reaction was 63.78%, mean RCP 98.54% and the minimum specific activity 15.93 GBq/μmol. PET issue was characterization of lesions detected by CT or MRI in 31 pts (of them, 7 were studied for pancreatic NETs and 4 for suspected insulinoma), staging in 22, restaging in 17, detection of primary tumor in 11 pts (of them, 2 for suspected insulinoma). PET showed SSTRs expressing lesions in 49/81 pts. Characterization PET detected SSTRs expressing tissue in 14/31 pts. Insulinoma was confirmed in 4/6 pts by imaging and surgery. All PET scans performed to identify hormone producing tumour resulted as negative (n=6). In 1 patient with SDHB mutation PET identified malignant metastatic paraganglioma. PET informations have driven patient management in 86% pts and changed treatment options or sequence in 30& of the cases (10% from surgery to medical drug, chemo-radiotherapy before surgery in 5%, debulking before raionuclide therapy in 15%). CONCLUSIONS Results demonstrate that a reliable and well suited ^{68}Ga-agents output for use in a hospital-based radiopharmacy allows high accuracy in NET's imaging and diagnosis with correct allocation and appropriateness use of resources in patient management changing or well driving treatment option in most of them.

EP220

Physiological uptake in the pancreatic head on SRS using 111In-DTPA-octreotide; Incidence and Mechanism

T. Brabander, J. J. M. Teunissen, D. J. Kwekkeboom; Erasmus MC, Rotterdam, NETHERLANDS.

Purpose Physiological uptake in the uncinate process or pancreatic head has been described with Gallium-68 labelled PET tracers for somatostatin receptor imaging. ^{111}In-DTPA-octreotide is the only registered radiopharmaceutical for the imaging of neuroendocrine tumours. We studied the uptake in this region of the pancreatic head on somatostatin receptor scintigraphy (SRS) using ^{111}In-DTPA-octreotide in a large group of patients. Methods 407 patients underwent SRS using ^{111}In-DTPA-octreotide in our department in 2014. After excluding patients with a known malignancy in or close to the pancreas, as well as all scans without SPECT/CT of the upper abdomen, we reviewed 178 scans in total. The uptake was graded on a 4-point scale that correlates the uptake in the pancreatic head to physiological uptake in the liver. Results Uptake in the region of the pancreatic head, including the uncinate process, was seen in 46/178 patients (26%) on SPECT-CT and in 12 patients (7%) on planar imaging. On SPECT/CT uptake was lower than the liver in 26 patients (15%), equal to the liver in 17 patients (10%) and higher than the liver in three patients (2%). In patients with diabetes mellitus the incidence of uptake in the pancreatic head was 50% on SPECT/CT. Conclusion Physiological uptake in the pancreatic head is seen on SPECT/CT with ^{111}In-DTPA-octreotide in 26% of patients and the incidence is doubled in patients with diabetes mellitus. Previous case reports showed uptake in the pancreatic head due to histologically proven pancreatic polypeptide cell hyperplasia. Also, patients with DM have elevated serum PP concentrations, which is likely due to PP-cell hyperplasia. Since 90% of PP-cells are present in the pancreatic head, PP-cell hyperplasia is the most likely explanation for visualization of the pancreatic head on SRS in a substantial number of patients.

EP-13 – Sunday, October 16, 2016, during Exhibition hours, e-Poster Area
Clinical Oncology: Prostate 1

EP221

^{18}F-FCH PET/CT disease detection rate in recurrent prostate cancer in relation to PSA level and PSA kinetic indexes

C. Ferrari, A. Niccoli Asabella, V. Lavelli, A. Di Palo, M. Fanelli, N. Merenda, G. Rubini; Nuclear Medicine Unit, D.I.M. – University of Bari "Aldo Moro", Bari, ITALY.

Aim: To investigate the ^{18}F-fluorocholine (^{18}F-FCH) PET/CT reliability for the detection of recurrent prostate cancer in relation to the prostate-specific antigen (PSA) level and to evaluate if PSA doubling time (PSAdt) and PSA velocity (PSAvel) can improve the patient selection and the ^{18}F-FCH-PET/CT performance. **Methods**: ^{18}F-FCH-PET/CT was performed in 159 prostate cancer patients (mean age 75±7 years, range 49-88 years), who underwent to radical treatment and with rising PSA level at time of imaging. The last PSA dosage (PSAlast) was available in all patients while PSAdt and PSAvel were available in 103/159. ROC analysis was used to assess diagnostic capability and optimal cutoff points for PSAlast, PSAdt and PSAvel to predict ^{18}F-FCH-PET/CT positive findings. Non-parametric Mann-Whitney-Wilcoxon test was used to assess differences between the median values of each PSA index. Spearman's coefficient correlation was then used to evaluate the relation among PSA indexes. Contingency tables were performed to test the association between ^{18}F-FCH-PET/CT results and classes of age (≤50, 51-60, 61-70, >70), Gleason score (≤6, 7, ≥8) and PSAlast (<1, 1-2, >2), by using Chi-square test. p-value <0.05 was considered statistically significant. **Results**: In 159 patients, PSAlast median level was 3,49 ng/ml (range 0,20-1129,93); ^{18}F-FCH-PET/CT was positive in 82/159 (51,6%) patients. In 103/159 patients PSAdt median level was 5,13 months (range 0,70-89,95) and PSAvel median level was 0,29 ng/ml/months (range 0,01-848,9); ^{18}F-FCH-PET/CT was positive in 58/103 (56,3%) patients. Among PSA indexes, PSAlast (0.826; cut-off>4, sensitivity 68,3%, specificity 84,4%) and PSAvel (0.810; cut-off>0,4, sensitivity 67,2%, specificity 82,2%) demonstrated the best diagnostic capability with no statistically significant difference (p=0,557). For PSAlast >4 ng/ml the ^{18}F-FCH-PET/CT detection rate was 65,8% and for PSAvel >0,4 ng/ml/months was 67,2%. Differences between the median values of each PSA index in ^{18}F-FCH-PET/CT-positive and ^{18}F-FCH-PET/CT-negative patients were statistically significant (PSAlast p=0; PSAdt p=0,008; PSAvel p=0). A statistically significant correlation was found between PSAdt and PSAvel (rs=-0,63; p=0), PSAdt and PSAlast (rs=-0,29; p=0,003), PSAvel and PSAlast (rs=0,89; p=0). A positive association was observed between ^{18}F-FCH-PET/CT results and classes of age (χ^2=17,061, p= 0,001), Gleason score (χ^2=7,256, p=0,027) and PSAlast (χ^2=29,616, p=0). **Conclusion**: Our results suggest that ^{18}F-FCH PET/CT is a reliable method for the evaluation of patients with biochemical recurrence of prostate cancer. The employment of PSAlast and PSAvel in clinical practice could improve patients' selection and correlate with ^{18}F-FCH-PET/CT results. Moreover, higher age and Gleason score also represent positive predictive factors for recurrent disease.

EP222

Role of 18F Choline PET/CT in guiding biopsy in patients with risen PSA levels and previous negative biopsy for prostate cáncer

G. A. Jimenez Londoño, Sr.[1], A. M. García Vicente[1], M. Amo Salas[2], M. A. Lopez Guerrero[3], V. M. Poblete Garcia[1], F. Funes Mayorga[4], P. Gutierrez Martin[5], M. J. Tello Galán[1], A. M. Soriano Castrejon[1]; [1]Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN, [2]Castilla La Mancha University, Ciudad Real, SPAIN, [3]Hospital Virgen de la Salud, Toledo, SPAIN, [4]Hospital Virgen de Altagracia, Manzanares, SPAIN, [5]Hospital General Nuestra señora de la Reina, Talavera de la Reina, SPAIN.

Objective: To study 18F-Choline PET/CT in the diagnosis and biopsy guide of prostate cancer (pCa) in patients with persistent high prostate-specific antigen(PSA) level and previous negative prostate biopsy. To compare the clinical risk factors and metabolic variables as predictors of malignancy. **Methods:** Patients with persistently elevated level of PSA in serum (total PSA >4 ng/mL) and at least a previous negative or inconclusive biopsy were consecutively referred for a whole body 18F-choline PET/CT. Patient age, PSA level, PSA doubling time (PSAdt) and PSA velocity (PSAvel) were obtained. PET images were visually (positive or negative) and semiquantitatively (SUVmax) reviewed. 18F-choline uptake prostate patterns were defined as focal, multifocal, homogeneous or heterogeneous. Histology on biopsy using TRUS-guided approach was the gold standard and additional intraprostatic tissue samples were obtained by using PET findings as guidance. Sensitivity (Se), specificity (Sp) and accuracy (Ac) of PET/CT for diagnosis of pCa were evaluated using per-patient and per-prostate lobe analysis. Receiver-operating-characteristic (ROC) curve analysis was used to assess the value of SUVmax to diagnose pCa. Correlation between PET/CT and biopsy results per-prostate lobe was assessed using the Cohen's kappa statistic. Univariate and multivariate logistic regression analysis was applied to compare clinical risk factors and metabolic variables as predictors of malignancy. **Results:** Thirty six out of 43 patients with histologic confirmation were included. In 11 (30.5%) patients, pCa was diagnosed (Gleason score from 4 to 9). The mean values of patient age, PSA level, PSAdt and PSAvel were: 65.5 years, 15.6 ng/ml, 28.1 months and 8.5 ng/mL per year, respectively. Thirty three patients had a positive PET/CT; 18 had a focal pattern, 7 multifocal, 4 homogeneous and 4 heterogeneous. The Se, Sp and Ac of PET/CT were of 100%, 12% and 38% in the patient analysis, and 87%, 29% and 14% in the prostate lobe analysis, respectively. The ROC curve analysis of SUVmax showed an AUC of 0.568 (p=0.52). On a lobe analysis, poor agreement was observed between PET/CT findings and biopsy results (k=0.097). In the univariate/multivariate analysis, none of clinical and metabolic variables was statistically significant as predictor of pCa. **Conclusion:** 18-F Choline PET/CT could be offered as a screening option in the selection of patients in which the repetition of prostate biopsy should be considered. However, a high rate of false positive results should be expected.

EP223

11C-choline PET/CT for restaging prostate cancer. Results in 4426 scans of a single-centre patient series

T. Graziani[1], F. Ceci[1], P. Castellucci[1], G. Polverari[1], G. M. Lima[1], J. J. Morigi[1], P. Ghedini[1], A. G. Morganti[2], R. Schiavina[3], S. Fanti[1]; [1]Service of Nuclear Medicine, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [2]Department of Radiotherapy, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [3]Department of Urology, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim: to evaluate the importance of ^{11}C-choline-PET/CT as a diagnostic tool for restaging prostate cancer (PCa), in a large, homogenous and clinically relevant population of recurrent PCa patients with biochemical relapse (BCR), after primary therapies. Secondary aim was to assess the best timing for performing ^{11}C-choline-PET/CT during BCR. **Material & methods**: we retrospectively analysed 9632 ^{11}C-choline-PET/CT performed in our institution for restaging PCa from January 2007 to June 2015. Inclusion criteria were: 1) proven PCa radically treated with RP or with primary EBRT; 2) PSA serum values available; 3) proven BCR: PSA>0.2 ng/mL after radical prostatectomy (RP) or PSA>2 ng/mL above the nadir after primary radiotherapy (EBRT), with rising PSA levels. 3203 recurrent PCa (rPCa) patients matching all the inclusion criteria were retrospectively enrolled and 4426 scans were analysed. **Results**: Overall, 52.8% of ^{11}C-choline-PET/CT scans (2337/4426) and 54.8% of patients (1755/3203) resulted positive. In 29.4 % of scans, at least one distant finding was observed. The mean and median PSA values were respectively 4.9 and 2.1 ng/mL at the moment of the scan (range 0.2-50 ng/mL). In our

series, 995 scans were performed with PSA levels between 1-2 ng/mL: in this subpopulation the positivity rate was 44.7%, with an incidence of distant findings of 19.2% and an incidence of oligometastatic disease (1-3 lesions) of 37.7%. PSA absolute value at the time of the scan and ongoing ADT were associated with an increased probability of a positive ^{11}C-choline-PET/CT ($p<0.0001$). At ROC analysis, PSA=1.16 ng/mL resulted the optimal cut-off value. In patients with PSA<1.16 ng/mL (1426 scans), ^{11}C-choline-PET/CT was positive in 26.8% of cases, with an incidence of oligometastatic disease in 84.7% of positive scans. **Conclusion**: ^{11}C-choline-PET/CT confirmed, in a large cohort of patients, its feasibility to detect the sites of metastatic disease in PCa patients with BCR. PSA resulted the main predictor of a positive scan with an optimal cut-off value of 1.16 ng/mL. In the majority of positive scans an oligometastatic disease, potentially treatable with salvage therapies, was observed.

EP224

11C- Choline uptake at initial diagnosis predicts patient outcome

M. Rodríguez-Fraile, L. Sancho, F. Guillén, B. García-García, G. Quincoces, M. Collantes, J. Richter; Clinica Universidad de Navarra, PAMPLONA, SPAIN.

Objective To investigate the potential utility of 11C-Choline PET/CT semiquantitative parameters in the prediction of recurrence in patients with prostate carcinoma (PC) at initial diagnosis. **Materials and Methods**: 45 patients with biopsy-confirmed PC were prospectively followed after being studied by 11C-Choline PET/CT before radical prostatectomy (RP). Choline uptake in the whole gland were measured by SUVmax, SUVmin and SUVmean. Two indexes were calculated: SUVmax-SUVmin and SUVmax/SUVmin. All this parameters were correlated with the biochemical relapse (BR) (PSA >0.2 ng/ml after RP). Patients with less than 4 years of follow-up were excluded from the analysis. **Results**: 31 patients were finally included in the analysis. The mean follow-up time were 8 years (98.6 months ±39). During this period, 8 patients suffered BR. Only SUVmax, SUVmax/SUVmin and SUVmax-SUVmin at diagnosis showed correlation with BR ($p=0.003$, $p=0.005$ and $p=0.002$, respectively). SUVmax (AUC-ROC: 0.85) and SUVmax-SUVmin (AUC-ROC: 0.88) discriminated better those patients who suffered BR. A value of 4.76 for SUVmax and of 4 for SUVmax-SUVmin resulted in both cases in a sensitivity of 87.5% and a specificity of 83%. **Conclusion**: 11C-Choline SUVmax and SUVmax-SUVmin at diagnosis, predicts the recurrence of prostate carcinoma with good diagnostic accuracy.

EP225

The value of ^{18}F-FDG PET-CT as a prognostic factor in penile cancer patients

A. L. Salazar[1], S. Lage[2], L. Salomão[2], M. Drummond[2], M. F. Cunha[2], E. P. Junior[2], P. G. Salles[1], E. A. Reis[2], M. Mamede[2]; [1]Mário Penna Hospital, BELO HORIZONTE - MG, BRAZIL, [2]Federal University of Minas Gerais, BELO HORIZONTE - MG, BRAZIL.

Introduction: The penile cancer (PC) is a rare neoplasm in the world. This rarity is most evident in more developed countries, however, in developing regions, its incidence can be high. In Brazil, according to the Brazilian National Cancer Institute (INCA), PC represents up to 2% of cancers in men, reaching 17% in the North and Northeast regions. The dilemma in the treatment of penile cancer is the correct assessment and approach to regional inguinal nodes. This assessment is of utmost importance as directly impacts the prognosis. Clinical staging of the inguinal region is flawed mainly due to enlarged lymph nodes secondary to inflammatory reaction. Morphological imaging techniques have also conflicting results, while the use of ^{18}F-FDG PET/CT has shown promising results. Objective: The objective of this study was to investigate the role of ^{18}F-FDG PET/CT as a prognostic factor in PC patients. Methods: Fifty-five patients with histological diagnosis of PC underwent ^{18}F-FDG PET/CT scans before surgery. SUVmax of PC (SUVmax-P) and of inguinal lymph node (SUVmax-L) were correlated with pathologic findings and clinical outcome for prognostic evaluation. Results: Two patients were excluded due to high blood glucose level. Thirty patients (60.0%) underwent inguinal lymphadenectomy and 13 (24.5%) died due to primary lesion. ROC analyses showed SUVmax-P higher than 11.5, 14.0, 14.0, 14.9 and 16.5 as significant cut-off values to differentiate patients pT1b ($p<0.005$), cN ($p<0.01$), perineural invasion ($p<0.05$), death ($p<0.0001$), and pN ($p<0.05$), respectively. SUVmax-L higher than 5.1, 5.5, 6.2 and 6.5 as significant cut-off values to differentiate patients pT1b ($p<0.05$), death ($p<0.05$), pN ($p<0.01$) and cN ($p<0.05$), respectively. The best significant survival predictor value for SUVmax-P and SUVmax-L were 14.9 and 6.2, respectively ($p<0.05$ for all). Multivariate logistic regression analyzes showed pathologic lymph node positive and SUVmax-P as significant variables to predict death with OR (95%CI) of 16.5 (2.4 to 114.1) ($p<0.001$) and 1.2 (1.0 to 1.4) ($p<0.05$), respectively. Conclusions: This study demonstrated that PET/CT with ^{18}F-FDG can be used as predictor value in PC patients. Financial Support: Fapemig, CNPq

EP226

Fluorescence camera navigation during sentinel node biopsy for penile cancer: A clinical pilot study

G. H. KleinJan[1], **N. S. van den Berg**[1], M. N. van Oosterom[1], T. Wendler[2], M. Miwa[3], K. Hendricksen[4], A. Bex[4], S. Horenblas[4], F. W. B. van Leeuwen[1]; [1]LUMC, Leiden, NETHERLANDS, [2]TUM, Munich, GERMANY, [3]Hamamatsu Photonics, Hamamatsu, JAPAN, [4]NKI-AVL, Amsterdam, NETHERLANDS.

Introduction The clinical introduction of indocyanine green (ICG)-^{99m}Tc-nanocolloid, a hybrid tracer for sentinel node biopsy has resulted in the ability to directly translate preoperative imaging findings into the operation room. Here, the addition of the fluorescence signature allows the surgeon to perform fluorescence image-guided resection of the lesions of interest as seen on preoperative imaging. Lacking herein is the physical link between the fluorescence camera and the preoperative imaging. In the current pilot study we evaluated a SPECT/CT-based navigation concept that allows navigation of a fluorescence camera in preoperative SPECT/CT images to ICG-^{99m}Tc-nanocolloid containing sentinel nodes in patients with penile cancer. **Methods** Five penile cancer patients scheduled for SN biopsy were injected with ICG-^{99m}Tc-nanocolloid on the morning of surgery followed by lymphoscintigraphy (15 min and 2 h post-injection). SPECT/CT imaging was performed with a reference tracker fixed on the patient (2.5 h post-injection). In the operation room a sterile reference tracker was placed on the patient, and a second tracker on the fluorescence camera. Subsequently SPECT/CT images were uploaded into the navigation device. The fluorescence camera video feed was also uploaded into the navigation device which resulted in a real-time overlay of the preoperative SPECT/CT findings and the video output of the fluorescence camera on the patient. The error between SPECT/CT-based SN localization and the location of the SN as determined via fluorescence imaging was determined on a per SN base. **Results** Preoperatively 13 SNs were identified in 9 groins. Intraoperatively, fluorescence camera navigation in preoperative SPECT/CT images was successful for the identification of 12 SNs with a median error of 7.5 mm (range: 0-20 mm). Reference tracker placement, and the interference of the optical signal from the tracking-device of the navigation system with that of ICG-^{99m}Tc-nanocolloid were of influence on the navigation accuracy. **Conclusion** Fluorescence camera navigation in preoperative SPECT/CT images is feasible with reasonable accuracy. Upon accuracy improvements the combined technique has the potential to further refine fluorescence imaging-guided surgery.

EP227

Automatic 3D-segmentation of the prostate gland

E. Polymeri[1], M. Sadik[1], N. Hasani[1], F. Fejne[2], F. Kahl[2], C. Geronymakis[3], L. Edenbrandt[4]; [1]Department of Clinical Physiology, Göteborg, SWEDEN, [2]Dept of Signals and Systems Chalmers University of Technology, Göteborg, SWEDEN, [3]Department of Radiology, Göteborg, SWEDEN, [4]Department of Clinical Physiology, Göteborg and Malmö, SWEDEN.

Aim: PET/CT have been proposed as an imaging modality to increase accuracy in the management of prostate cancer patients. Uptake of different PET tracers can be used to assess the underlying altered biology in cancer in the prostate gland and for the detection of metastases. Our long-term aim is to develop imaging biomarkers for the analysis of PET/CT as indicators of prognosis. The aim of the present study is to develop an algorithm for automated segmentation of the prostate gland in CT images. **Materials and Methods:** CT images from 20 patients who had undergone FDG-PET/CT scans were selected as training group. Manual prostate gland segmentations performed separately by two physicians were used as training data. CT images from additional 50 consecutive patients who had undergone FDG-PET/CT scans were included as test group. All PET-CT images were obtained with a biograph 64 True V PET/CT scanner (Siemens 2008) using a low dose radiation CT (Helical scan, pitch 0.8, 120 kV, tube load 30 mAs). A multi-atlas registration based method was applied for automated segmentation of the prostate gland. A test image was registered separately to all the images in the training set and the result was used on the manual delineations to obtain 20 rough segmentations of the image. These segmentations were fused together using a random forest classifier and the final segmentation was obtained with graph cuts. The Dice index was used to quantitatively evaluate the similarity between the automated and the manual prostate segmentations. The automated segmentations in the training and test groups were also evaluated independently by two experienced radiologists who categorized each prostate segmentation as "optimal", "acceptable" or "inadequate". **Results:** In the training group the mean Dice index comparing the automated to manual segmentations was 0.73 (SD 0.09). The automated segmentations for the training and test groups were considered as optimal or acceptable by at least one of the two radiologists, (20/20) and (35/50) respectively. The two radiologists presented substantial visual agreement, percentage agreement (PA) 83% and Kappa (*K*) 0.72 for the whole group (70 patients). **Conclusion:** A completely automatic algorithm for 3D-segmentation of the prostate gland in CT images is proposed. This is the first step in the development of an objectively measured PET/CT imaging biomarker. The CT segmentations will for example be used for automated quantification of choline uptake in the prostate gland.

EP228

Contribution of Ga-68 PSMA PET/CT in primary staging of prostate cancer

N. Ergül[1], T. F. Çermik[2]; [1]Istanbul Training and Research Hospital, Istanbul, TURKEY, [2]Sakarya University Medical Faculty, Department of Nuclear Medicine, Sakarya, TURKEY.

Introduction: PSMA (prostate specific membrane antigen) is a surface antigen located on the prostate cell membranes. It is highly expressed on the prostatic adenocarcinoma cells and can be used to image the primary tumor, metastasis and the recurrence as well. We evaluated the role of Ga-68 PSMA-HBED-CC (Ga-68 PSMA) positron emission tomography/computed tomography (PET/CT) for primary staging in patients with prostate cancer (PCa). Materials and Methods: Thirty-one patients with histologically proven PCa were enrolled. Two patients were at low risk (Gleason score 6 and PSA<10), 15 patients were at intermediate risk (Gleason score 7 or PSA between 10-20 ng/ mL) and 14 patients were at high risk (Gleason score ≥8 or PSA ≥20). All patients underwent Ga-68 PSMA PET/CT imaging before operation and treatment. PET/CT finfings were compared with other imaging and clinical findings. Results: In the intermediate risk group, pelvic lymph node metastases were detected in 5 patients, distant lymph node metastases in 2 patients, bone metastases in 6 patients and liver metastase in 1 patient. In the high risk group, in 7 patients pelvic lymph node metastases, in 3 patients distant lymph node metastases and in 6 patients bone metastases were detected. In 2 patients with low risk no metastases was detected. In 18 of 31 patients (58%) Ga-68 PSMA PET/CT detected M1 disease and changed the therapy management. In 27 patients the Ga-68 PSMA PET/CT findings were compared with bone scintigraphy findings. In 17 patients the findings of both imagings were congruent. However in 10 patients (37%), findings were discordant. In 6 patients the metastatic foci in bones detected by PET/CT were not detected by bone scan, and in 4 patients the suspected metastases in bone scan were nor mal in Ga-68 PSMA PET/CT. Conclusion: 68Ga-PSMA PET/CT has a big potential to change the therapy management in patients with prostate cancer, especially with intermediate or high risk disease showing the distant metastatic foci. For detection of bone metastases it is more accurate than bone scintigtaphy demonstrating both lytic and sclerotic metastases specifically.

EP229

Clinical application of ^{18}F FDG PET/CT in evaluation of radiological suspected cases of renal cell carcinoma and comparison with conventional imaging: experience at a tertiary care center

A. Sood, A. Jois, R. Kumar, T. K. Jain, B. R. Mittal, A. Bhattacharya; PGIMER, Chandigarh, INDIA.

Objective: The aim of this retrospective study was to analyze the diagnostic performance of ^{18}F-FDG PET/CT for evaluation of renal masses with radiological suspicion of renal cell carcinoma and its comparison with conventional imaging. **Material and methods:**In this retrospective study, we evaluated 68 patients (median age = 53.9 years; range = 14-74 years; male = 44, female = 24) with radiological imaging (USG/ CT/MR) suspicion of renal cell carcinoma. All the patients underwent whole-body ^{18}F-FDG PET/CT for characterization of the lesions. ^{18}F FDG PET/CT findings was evaluated by two experienced nuclear medicine physicians and any abnormal FDG uptake on PET images was correlated with lesion on CECT and taken as positive. SUVmax values of the primary renal lesion and existing metastatic foci were also evaluated. For the validation of PET/CT results, histopathological examinations, clinical or imaging follow up were taken as reference standard. Conventional anatomical images (USG / CT or MR scans) were also evaluated for comparison with FDG PET/CT. **RESULTS:**Out of total 68 patients with suspicion of renal cell carcinoma on conventional imaging (CI), the final diagnosis of renal cell carcinoma was established in 50 patients. The CI had revealed a sensitivity, PPV of 100% and 73.5% respectively but non specific in establishing the final diagnosis. ^{18}F-FDG PET/CT revealed positive findings in 58 patients and negative in 10 patients. Regional lymph nodal disease was noticed in 19 patients, regional and distant metastases in 22 patients and only distant metastases in 11 patients. Adrenal lesions were noted in 12 patients. Fifty patients were true positive, eight false positive, nine true negative, and one false negative. ^{18}F-FDG PET/ CT had shown sensitivity, specificity, positive predictive value, negative predictive values and accuracy of 98.0%, 52.9%, 86.2%, 90.0% and 86.7% respectively. On ROC analysis of uptake (SUVmax) in the primary lesion with respect to the results, a cutoff value of SUVmax > 3.2 (sensitivity 92.3%, specificity 76.5% and area under ROC curve 0.89) was obtained to establish the diagnosis. There was a weak correlation between the SUV max values in the primary lesion and distant metastatic disease (Spearman's coefficient rank correlation ρ-0.0180). **CONCLUSIONS:** ^{18}F-FDG PET/CT had shown an

excellent diagnostic performance with high sensitivity, PPV and NPV for establishing the diagnosis of renal cell carcinoma as compared to CI which has no specificity. Additionally ^{18}F-FDG PET/CT also helped in the detection of regional as well as distant metastases.

EP230

Utility of ^{18}F-Choline PET-CT for detection of disease and outcome prediction in castration resistant prostate cancer, compared with PET-CT in patients with biochemical relapse

J. J. Robles-Barba[1], A. Sabaté-Llobera[1], J. Mestres-Martí[1], L. Gràcia-Sánchez[1], E. Llinares-Tello[1], J. L. Vercher-Conejero[1], E. M. Merino-Serra[2], A. M. Ferrer-Artola[3], A. M. Boladeras-Inglada[4], A. Arellano-Tolívar[4], J. F. Suárez-Novo[5], C. Gámez-Cenzano[1]; [1]PET Unit. Department of Nuclear Medicine. IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, (Barcelona), SPAIN, [2]CT Unit. Department of Radiology. IDI. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, (Barcelona), SPAIN, [3]Department of Pharmacy. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, (Barcelona), SPAIN, [4]Department of Radiation Oncology. ICO, L'Hospitalet de Llobregat & Badalona, (Barcelona), SPAIN, [5]Department of Urology. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, (Barcelona), SPAIN.

AIM: To assess the detection rate and recurrence location of ^{18}F-Choline PET-CT (FCH-PET) in castration resistant prostate cancer (CRPC) patients, compared to those with biochemical relapse (BR), as well as evaluate its possible role in outcome prediction. MATERIAL AND METHODS: This prospective study included 220 patients classified in 2 groups: 1) CRPC patients (n=30), 58-83 y.o., median PSA 10.4 ng/mL and the following D'Amico classification: 26 high risk (86%), 2 medium risk (7%), 2 low risk (7%). 2) BR patients (n=190), 50-83 y.o., median PSA 3,7 ng/mL and the following D'Amico Classification: 114 high risk (60%), 50 medium risk (26%) and 26 low risk (14%). All patients underwent FCH-PET scans. Results were categorized as negative or positive, indicating location of the recurrence (exclusively prostatic, pelvic nodes or distant metastasis) and SUVmax of the most FCH-avid lesion. A follow-up of CRPC patients (7-38 months) was performed including PSA levels and imaging studies, with diagnosis of improved/stable disease (SD) or progressive disease/exitus (PD). Outcome was correlated with recurrence location and SUVmax in PET-CT. RESULTS: Detection rate was 100% (30/30) in patients with CRPC and 81% (154/190) in patients with BR. CRPC patients showed also a significant higher percentage of distant metastatic recurrence (73% vs. 16% in BR). Those distant metastasis were more frequently bone/visceral in CRPC group (n=17/22) and nodal in BR group (n=17/31). Regarding BR patients, 36/190 (19%) showed negative FCH-PET studies, 66/190 (35%) presented exclusively prostatic recurrence and 57/190 (30%) pelvic node recurrence. In CPRC patients, 5/30 (17%) showed exclusively prostatic recurrence and 3/30 (10%) pelvic node recurrence. After PET-CT, most CRPC patients underwent treatment with abiraterone acetate +/- enzalutamide, or radiotherapy/surgery if localized disease. During the follow-up, SD was seen in 24/30 patients and PD in 6/30 (1 exitus). Patients with PD presented different FCH-PET patterns compared to patients with SD: percentage of distant metastatic recurrence (83% (n=5/6) vs. 71% (n=17/24) respectively), bone/visceral metastasis (66% (n=4/6) vs. 42% (n=10/24)) and a higher SUVmax (6.5 vs. 4.2). CONCLUSIONS: FCH-PET is a very useful technique for detection of disease in CRPC patients, with a higher detection rate than in BR patients, probably due to the more advanced stage of the disease. The pattern of recurrence in FCH-PET in CRPC patients was very often metastatic. Location of recurrence and a higher SUVmax could predict a worse outcome. Further studies with a larger number of CRPC patients and a longer follow-up are required.

EP231

Value of 18F-choline-PET/CT for re-staging prostate cancer patients with biochemical persistence / relapse: correlation with PSA, PSA doubling time, and Gleason

A. G. GÓMEZ-GRANDE, H. Perez-Montero, A. Campos Bonel, M. Cabeza Rodriguez, A. Rodriguez Antolin, S. Ruiz Solis, P. Sarandeses Fernandez, A. Hernandez Martinez, P. Pilkington Woll, J. Estenoz Alfaro; HOSPITAL UNIVERSITARIO 12 DE OCTUBRE, MADRID, SPAIN, MADRID, SPAIN.

Aims and Purpose:Current NCCN guidelines suggest 18F-choline-PET/CT imaging (18F-Ch-PET) as a diagnostic study for the evaluation of patients with recurrent prostate cancer (PCa). The objective of this study was to evaluate the use of 18F-Ch-PET to restage patients with biochemical relapse (BR) and correlation with PSA, PSA doubling time and Gleason. Material and Methods: This is a prospective study (data collected between February/2014 and April /2016) in a cohort of 54 high-risk PCa patients (based on NCCN criteria) with BR (PSA doubling time (DTPSA) <8 months) after treatment with radiotherapy and/or prostatectomy. Pearson $\chi 2$ test was performed. Results: The mean age of the cohort was of 67 years (range from 46 - 80). Mean PSA was of 3.11 +/-4.2 (0.15 - 21.39). Mean DTPSA of 7.19 +/- 9.1 (0.7 - 61.52). In most cases (57.5%) the Gleason score was $\geq$ 7 (4+3). Positive 18F-Ch-PET results were obtained in 63% of the scans performed, 62% showed local and/or regional disease and 38% had distant metastases. Scans were positive in 33% of patients with PSA<1 ng/mL and in 87% of patients with PSA$\geq$1 ng/mL ($p<0.001$). We found a statistically significant correlation between positive 18-F-Ch-PET studies and Gleason score $\geq$ 7 (4+3) ($p=0.031$). A positive scan and a DTPSA<3 months had a tendency to correlate. All patients with a positive 18F-Ch-PET had a negative TC and bone scan. Conclusions:18F-Ch-PET seems to be a very useful diagnostic test for restaging recurrent PCa in selected group of patients. It can also modify treatment management in an important percentage, identifying which ones can be offered a potential curative treatment. In our series, like in the literature, PSA level is a strong predictive factor for positive 18F-Ch-PET.

EP232

Diagnostic performance of contrast enhanced PET/CT scan for restaging and recurrence in renal cell carcinoma

A. K. Singh, S. Gambhir, P. K. Pradhan, G. Shankar AP, A. Prashanth, M. Ravina, N. Kumar; SGPGI, LUCKNOW, INDIA.

Aim: The role of PET/CT is limited in the evaluation of renal cell carcinoma because of the urinary excretion of ^{18}F 2-fluoro-2 deoxyglucose (FDG). While demonstrating similar accuracy to CT in diagnosing primary renal cell carcinoma (RCC), PET/CT appears to be even more reliable in identifying local recurrence and distant metastasis as well as monitoring progression of disease and response to immunotherapy. The present study was undertaken to emphasis on evaluating the diagnostic performance of contrast PET/CT scan for restaging and recurrence in RCC. **Materials and Methods:** A total of 33 cases of histopathologically proven renal cell carcinoma for restaging and suspected recurrence were included in this study on the basis of clinical and pathological data. The IV contrast agent applied was Ultravist 370 (Bayer, Iopromide 370 mg I/ml, osmolality 607mOsm/kg, density 1.322 g/cm^3 at 37°C).Infusion was given by using Medrad Intego PET/CT Infusion System. For whole body 3.0 ml/sec for 100-125 ml with 50 ml saline, 30 second delay was used. CT images were taken in cranial-caudal over roughly 8-30 seconds. Additional diagnostic contrast CT (CECT) images were obtained with 100 sec and 130 sec delay (Nephrogenic phase and delayed phase)

in region of interest (Top of liver to bottom of kidneys) using CT with 120 mA 120 kvP with 0.5 sec rotation, 4 detector rows, 5.0 mm thickness Pitch 0.8: 1 at a speed 8mm/rotation if required. Immediately after the CECT images were acquired, a PET emission scan was obtained from the vertex to mid-thigh. Two experienced nuclear medicine physicians interpreted the results. **Results:** Out of 33 patients with standard of reference as histopathology, true positive (TP), false positive (FP), false negative (TN) and true negative (TN) results were seen in 22, 1, 2, and 8 cases respectively. The sensitivity, specificity, accuracy, and positive and negative predictive values of the contrast PET/CT for identifying the primary recurrent tumour were 92%, 89%, 90%, 95%, and 80% respectively. **Conclusion:** The contrast PET/CT scan demonstrated a significantly good performance in detecting recurrence and restaging in renal cell carcinoma post-surgery. Based on the above findings combining contrast enhanced CT (CECT) and PET can be considered as a one-stop-shop imaging approach which can detect local and distant metastases with high accuracy in the recurrence of Renal cell carcinoma.

EP233

Evaluation of dualtracer multiparametric PET/MRI parameters in primary prostate cancer

M. Hartenbach[1], P. Baltzer[1], S. Hartenbach[2], M. Susani[3], C. Seitz[4], L. Kenner[3], L. Papp[1], A. Haug[1], W. Wadsak[1], M. Mitterhauser[1], I. Rausch[5], A. Ponholzer[6], M. Lamche[6], S. Shariat[4], M. Hacker[1]; [1]Medical University of Vienna, Dep. of biomed. imaging and image guided therapy, Vienna, AUSTRIA, [2]German Armed Forces Hospital, Institute of Pathology, Ulm, GERMANY, [3]Medical University of Vienna, Institute of Pathology, Vienna, AUSTRIA, [4]Medical University of Vienna, Dep. of Urology, Vienna, AUSTRIA, [5]Medical University of Vienna, Dep. of Medical Physics and biomedical engineering, Vienna, AUSTRIA, [6]Hospital St. John of God, Urology, Vienna, AUSTRIA.

Aim Retrospective analysis of multiparametric ^{68}Ga-PSMA$^{HBED-CC}$ / [^{18}F] Fluorocholine-PET / MRI (mp PSMA/FC-PET/MRI) in terms of detection, characterization and prognosis in primary prostate cancer. Method 43 lesions in 38 prostatectomy patients with preoperative PET/MRI were color-coded in histological whole-mount sections with respect to their Gleason patterns. In so far 18 patients, p14/STAT3-tissue microarrays for risk assessment of early biochemical relapse were performed. SUV, tumor-to-muscle ratios (TBR) and heterogeneity (COV, SUVmax / mean) were determined and percentiles for ADC and DCE (Ktrans, Ve, IAUC and kep). PSMA immunohistochemistry was used to verify PET-PSMA-negative lesions. ROC analyzes discriminated Gleason 3 vs. Gleason >3 pattern and STAT3/p14-loss. FC-SUVmax >3.0, deltaTBR after PSMA application >1.0 and 25th percentile ADC $<1.0 * 10^{-3}mm^2$ / s served as cut-off for positive tumor detection. Results All lesions were FC-positive. 9 lesions each (21%) were PSMA and ADC negative. The AUC for Gleason 3 vs. Gleason> 3 pattern for FC-COV, ADC and dualtracerSUVmax / mean was 0.86, 0.87 and 0.89 ($P < 0.001$). At a cut-off of 1.54, dualtracerSUVmax/mean showed a sens/spec/acc/PPV/NPV of: 84%/75%/81%/88%/69% (P=0.001). A STAT3 and/or p14-loss of the tumor lesion was detected with an AUC of 0.8 by this parameter ($p < 0.05$). iAUCmax demonstrated the largest AUC among DCE parameters: 0.70 ($p = 0.06$). Conclusions All lesions analyzed showed a significant choline metabolism. Significant PSMA-expression and water diffusion restriction was found in 79% of the lesions, however, contributed to a higher accuracy in the assessment of tumor aggressiveness and correlated with prognostic markers for an early biochemical recurrence (STAT3/p14). MRI DCE parameters should be considered critically in the protocol.

EP234

Value and efficacy of sentinel lymph node diagnostics in patients with penile carcinoma with palpable inguinal lymph nodes as a new multimodal, minimally invasive approach

U. Lützen, M. Marx, M. Zuhayra, Y. Zhao, K. Jünemann, M. Naumann; Universitätsklinikum Schleswig-Holstein, KIEL, GERMANY.

Introduction: The international guidelines recommend sentinel lymph node biopsy (SLNB) for lymph node staging in penile cancer with non-palpable inguinal lymph nodes (LN) but it is not recommended with palpable inguinal LN. As a new approach the aim of this study was to evaluate the reliability and morbidity of SLNB with radioactive labelling in combination with an ultrasound-guided resection of suspect inguinal LN as a multimodal, minimally invasive staging-technique in these patients. **Material and Methods:** We performed SLNB in 26 penile cancer patients with 42 palpable inguinal LN after using Tc 99m-nanocolloids. Prior to the combined staging procedures the patients underwent a ultrasound examination of the groins as well as planar lymphatic drainage scintigraphy and SPECT/CT-scans. During the surgical procedure, the radioactive-labelled sentinel lymph nodes (SLN), and in addition, sonographically suspect LN, were resected under ultrasound-guidance. Follow-up screening was done by ultrasound examination of the groins according to the guidelines of the European Association of Urology (EAU). **Results:** Staging of the primary tumor resulted T1: 14, T2: 9 and T3: 3 cases. Tissue differentiation was G1: 2, G2: 19 and G3: 4. For one patient, who had undergone primary surgery ex domo, the degree of tissue differentiation was unknown. 19 groins of 42 preoperatively palpable inguinal findings were histologically tumor-positive. SLNB alone showed lymphogenic metastases in 14 groins. Sonography reveaIed 5 further metastatic groins, which would not have been detected during SLNB due to a tumor-related blockage of lymphatic drainage or a so-called re-routing of the radioactive tracer. During follow-up, none of the 28 groins with tumor-negative LN status showed any LN recurrence in this combined investigation technique. The median follow-up period was 46 (24 to 92) months. Morbidity of this combined procedure was low at 4.76% in relation to the number of groins (2 out of 42) resp. 7.69% in relation to the number of patients (2 out of 26). **Conclusions:** Results from this study show that the combined procedure of SLNB after radioactive LN labelling and ultrasound-guided resection of suspect inguinal LN is a reliable multimodal diagnostic approach for treatment of penile cancer patients with palpable inguinal LN. This combined approach is associated with low morbidity rates. SLNB alone would lead to a significantly higher false-negative rate in these patients.

EP235

To evaluate the role of F 18 FDG PET CT in the metastatic work up in operated cases of penile squamous cell carcinoma

A. K. Jhajharia, A. Bhattacharya, U. K. Mette, N. Kakkar, B. Singh, B. R. Mittal; Post Graduate Institute of Medical Education & Research, Chandigarh, INDIA.

Background: Squamous cell carcinoma is the most common variant of penile cancer and post-surgical recurrence and metastatic disease progression is very frequent. Therefore, a close follow up using clinical examination, biochemical markers and molecular imaging for accurate disease diagnosis for improved prognosis and survival benefits is warranted. **Methods**: We retrospectively reviewed clinical and 18 F-FDG PET/CT data of thirty one patients of SCC penis after partial / total penectomy / circumcision. The reference standard was based on histopathology findings of biopsy/surgery, clinical and/or imaging follow up. **Results:** Thirty-one (mean age 57.6 years; range 35-75 years) operated patients of SCC of penis who were referred between 2010-2015 for PET/CT staging were included in the present study. Twenty-one patients had undergone partial penectomy, 7 complete penectomy and 3 patients underwent circumcision respectively.

Additionally, one patient received chemotherapy , 3 patients received radiotherapy and 9 patients received both chemo-radio treatment. The reconstructed 18 F FDG PET/CT imaging data demonstrated normal scan findings in 6/31 patients and these patients were found to be disease free on clinical follow-up during the follow-up period of 6-months. On the other hand, 13/31 patients were found to have penile residual/recurrent and ilioinguinal lymph nodal metastatic disease. The remaining 12/31 patients were observed to have multiple and distant lymph nodal metastatic disease. Seven (7/12) patients wide spread lymph nodal metastases died during follow-up. PET CT scan findings were false positive in 2 patients as they remained disease free without any intervention during the subsequent follow up. The sensitivity, specificity, PPV, NPV and accuracy of FDG PET/CT in detecting residual / recurrent / metastatic disease in SCC penis in the present were found to be 100%, 75%, 92%, 100% and 82.5% respectively. **Conclusion:** Our result suggest that ^{18}F-FDG PET/CT is a very useful modality in detecting local recurrence, regional and distant lymph nodal metastases in operated cases of SCC of penis. These findings thus may guide the treating urologists in the further management of these patients by using appropriate therapeutic options.

EP236

^{18}F-Fluoromethylcholine (^{18}FCH) PET/CT compared with standard imaging in patients with recurrent prostate cancer

C. Ferrari, A. Niccoli Asabella, V. Lavelli, C. Altini, G. Bianco, N. Merenda, G. Rubini; Nuclear Medicine Unit, D.I.M. – University of Bari "Aldo Moro", Bari, ITALY.

Aim: To assess the utility of 18F-Fluoromethylcholine (^{18}FCH) PET/CT in recurrent prostate cancer compared to guidelines standard imaging (SI): bone scan (BS) and/or morphologic imaging (MI). Methods: 105 patients previously treated for prostate cancer, performed ^{18}FCH-PET/CT and SI (81/105 BS, 57/105 MI and 38/105 both) within a 1-month for suspected recurrence. ^{18}FCH-positive bone lesions were compared to BS while soft tissue lesions, both loco-regional recurrence (LRR) and distant lesions (DL) were compared to MI, by Cohen's K. Results: ^{18}FCH-PET/CT resulted positive in 55/105 (52,4%) patients, SI in 65/105 (61,9%). In 81/105 patients who performed BS, ^{18}FCH-positive bone lesions resulted in 25/81 (30,8%) patients while BS was positive in 34/81 (41,9%). The two methods resulted concordant in 56/81 (69,1%) patients -positive concordant (PC) in 17/81 (21%), negative concordant (NC) in 39/81 (48,1%)- and discordant in 25/81 (30,8%). The strength of agreement was 'fair' (K=0.342). ^{18}FCH-PET/CT showed additional soft tissue lesions in 33/81 (40,7%) patients (LRR in 21/81, DL in 6/81 and both in 6/81). In 57/105 patients who performed MI, ^{18}FCH-positive lesions for LRR were found in 22/57 (38,6%) patients while MI-positive lesions in 20/57 (35,1%). The two methods were concordant in 37/57 (64,9%) patients -PC in 11/57 (19,3%), NC in 26/57 (45,6%)- and discordant in 20/57 (35,1%). The strength of agreement was 'fair' (K=0.247). Considering DL, ^{18}FCH-PET/CT resulted positive in 11/57 (19,3%) patients while MI was positive in 21/57 (36,8%). The two methods were concordant in 41/57 (71,9%) patients -PC in 8/57 (14%), NC in 33/57 (57,9%)- and discordant in 16/57 (28%). The strength of agreement was 'fair' (K=0.330). ^{18}FCH-PET/CT showed additional soft tissue lesions in 13/57 (22,8%) patients (LRR in 8/13, distant lesions in 3/13 and both in 2/13). In 38/105 patients who performed both BS and MI, ^{18}FCH-PET/CT resulted positive in 22/38 (57,9%) patients while SI resulted positive in 32/38 (84,2%). The two methods resulted concordant in 26/38 (68,4%) patients -PC in 21/38 (55,3%), NC in 5/38 (13,1%)- and discordant in 12/38 (31,6%). The strength of agreement was 'fair' (K=0.292). ^{18}FCH-PET/CT showed additional lesions in 11/38 (28,9%) patients (LRR in 8/11, DL in 1/11, and LRR, bone and DL in 2/11 patients). Conclusion: ^{18}FCH-PET/CT showed fair concordance with BS and MI, although it detected additional soft tissue and bone lesions in a significant percentage of patients, respect to SI. Thus, ^{18}FCH-PET/CT could be a more complete whole-body diagnostic tool to evaluate patients with recurrent prostate cancer.

EP237

Should the head be included in 18F- Choline PET/CT scans of patients with prostate cancer ?

A. Nocuñ, B. Chrapko; Chair and Department of Nuclear Medicine, Medical University of Lublin, Poland, LUBLIN, POLAND.

Introduction: There are no definitive procedure guidelines for 18F-Choline (FCH) positron emission tomography/computed tomography (PET/CT) imaging. The acquisition protocols vary between centers. The head is included or not included in the field of view (FOV) on the delayed scans. Inclusion increases the time of imaging and radiation exposure to the patient, however it may be speculated, that it improves the staging accuracy. The aim of the present study was to determine the incidence an clinical significance of abnormalities within the head on FCH PET/CT scans in patients with prostate cancer. Materials and methods: Retrospective analysis included 170 consecutive FCH PET/CT examinations in 150 patients with pathologically proven prostate cancer who underwent FCH PET/CT imaging in our institution between January 2014 and March 2016. Data acquisition was performed using a dedicated PET/CT system Biograph mCT S(64)-4R (Siemens, Germany). The delayed scans were acquired from the top of the skull to the mid-thigh level. Image evaluation was performed visually and by means of maximum standardized uptake values (SUVs). Results: Lesions in the head with increased radiotracer accumulation were seen in 5 patients (2.9% examinations): metastases in the scull (3 cases) and brain tumors (2 cases). In 2 patients with metastases in the scull, multiple lesions in other bones and various organs were observed. In one case, the lesion in the scull was solitary osteolytic metastasis (SUVmax 3.2). The diagnosis of brain tumors was meningioma in one case (SUVmax 3) and metastases from prostate cancer in the second case (four lesions, size from 10mm to 27mm, SUVmax from 5 to 16.1). Brain tumors in both patient were asymptomatic. The staging based on FCH PET/CT with the head in the FOV, was altered in two patients (1.2% examinations) when compared to the FOV from the base of the skull. Conclusions: In patients with prostate cancer examined by means of FCH PET/CT, the abnormalities within the head are very rare, however in some cases detection of such lesions may alter the staging of the disease (1.2% of scans in the present study).

EP238

Detection of local recurrence of prostate cancer after radical prostatectomy in patients with PSA≤2ng/ml: Is there a role for early ^{18}F-FCH PET/CT?

A. Chiaravalloti[1,2], F. Calabria[3], A. Fiorentini[1], D. Di Biagio[1], P. Sannino[2], E. Di Giorgio[4], M. Zinzi[2], M. Tavolozza[1], O. Schillaci[1,2]; [1]Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY, [2]IRCCS Neuromed, Pozzilli, ITALY, [3]Neuromimaging Research Unit, IBFM, National Research Council, Catanzaro, ITALY, [4]IRCCS Neuromed, Rome, ITALY.

Aim: To investigate the diagnostic performance of early acquisition compared to late imaging for the detection of local recurrence of prostate cancer (PC) in a selected population with PSA ≤ 2ng/ml after radical prostatectomy by means of ^{18}F-FCH PET/CT. **Materials and methods:** Forty-five patients (age 68 ± 11 years) with biochemical recurrence of PC following a previous radical prostatectomy were included in this retrospective study. The biochemical relapse was determined as a PSA level of 0.2 ng/mL or greater followed by another increased value during the time. None of the patients was subjected to radiotherapy for local or distant recurrence nor to hormonal therapy prior to PET/CT examination. The PSA level was determined from blood samples obtained during the fasting period 2 weeks (±2 days) prior to PET/CT scan. Early acquisition (8 minutes in dynamic modality, every frame lasting 30s in a 128 x 128 matrix) started after the in bolus injection of ^{18}F-choline intravenously (4

MBq/kg). All patients were asked to empty their bladder before image acquisition. Late acquisition started 40 minutes after the injection of the tracer. First, a low-amperage CT scan for attenuation correction of PET images was taken. Immediately after the low-dose CT scan, whole body PET images were acquired in a 256 x 256 matrix (five to seven bed positions, 3 min/bed position, from the upper thighs to the vertex). **Results:** PSA resulted equal to 1.42±0.40 in the whole population examined. Twenty subjects (PSA=1.31±0.53) out of the 45 examined patients showed positive PET/CT findings for local recurrence. Among them, 4 patients were positive in both modalities (PSA=1.65±0.27), 5 shown a positive early and a negative late acquisition (PSA=1.33±0.86), while 8 shown a negative early and a positive late acquisition (PSA=1.50±0.44). We did not find significant differences in PSA values in subject with a positive PET/CT scan to subjects with a negative PET/CT scan (P=0.8). The analysis of sensitivity, specificity, diagnostic accuracy, positive predictive value and negative predictive value resulted equal to: 53.3%; 96.7%; 82.2%, 88.9 and 80.6% for early acquisition and 66.7%; 93.3%; 84.4%; 83.3% and 84.8% for late acquisition, respectively. Conversely, considering together the results of both scans, results were 93.3%, 90.0%, 91.1%; 82.4% and 96.4% respectively. **Conclusion:** The combination of early acquisition with late acquisition lead to an increase of the diagnostic accuracy of ^{18}F-FCH PET/CT for the diagnosis of local recurrence in PC after RP with PSA ≤ 2ng/ml.

EP239

Radiation dosimetry of ^{68}Ga-PSMA-11 (HBED-CC) and preliminary evaluation of optimal imaging timing

A. Afshar-Oromieh[1], H. Hetzheim[2], W. Kuebler[3], T. Hope[4], C. Kratochwil[1], F. Giesel[1], M. Eder[5], M. Eisenhut[5], K. Kopka[5], U. Haberkorn[1]; [1]University Hospital of Heidelberg, German Cancer Research Center (DKFZ) Heidelberg, Heidelberg, GERMANY, [2]Div. of Medical Physics in Radiology, German Cancer Research Center, Heidelberg, Germany, Heidelberg, GERMANY, [3]Div. of Radiation Protection and Dosimetry, German Cancer Research Center, Heidelberg, Germany, Heidelberg, GERMANY, [4]Dept. of Radiology and Biomedical Imaging, University of California, San Francisco, CA, UNITED STATES, [5]Div. of Radiopharmaceutical Chemistry, German Cancer Research Center, Heidelberg, Germany, Heidelberg, GERMANY.

Aim: The clinical introduction of ^{68}Ga-PSMA-11 ("HBED-CC") ligand targeting the prostate-specific membrane antigen (PSMA) has been regarded as a significant step forward in the diagnosis of prostate cancer (PCa). In this study we provide human dosimetry and data on optimal timing of PET imaging after injection. **Methods:** Four patients with recurrent PCa were referred for ^{68}Ga-PSMA-11 PET/CT. Whole-body PET/CT$_{low\text{-}dose}$ scans were conducted at 5min, 1h, 2h, 3h, 4h and 5h after injection of 152-198 MBq ^{68}Ga-PSMA-11. Organs of moderate to high uptake were used as source organs; their total activity was determined at all measured time points. Time-activity curves were created for each source organ as well as for the remainder. The radiation exposure of a ^{68}Ga-PSMA-11 PET was identified using the OLINDA-EXM software. In addition, tracer uptake was measured in 16 sites of metastases. **Results:** The highest tracer uptake was observed in the kidneys, liver, upper large intestine and the urinary bladder. Mean organ doses were: kidneys 0.262 ± 0.098 mGy/MBq, liver 0.031 ± 0.004 mGy/MBq, upper large intestine 0.054 ± 0.041 mGy/MBq, urinary bladder 0.13 ± 0.059 mGy/MBq. The calculated mean effective dose was 0.023 ± 0.004 mSv/MBq (= 0.085 ± 0.015 rem/mCi). Most tumor lesions (n=16) were visible at 3h p.i., while at all other time points many were not qualitatively present (10/16 visible at 1hr p.i.). **Conclusion:** The mean effective dose of a ^{68}Ga-PSMA-11 PET is 0.023 mSv/MBq. A 3 hour delay after injection was optimal timing for ^{68}Ga-PSMA-11 PET/CT in this patient cohort.

EP240

Diagnostic value of F-18 FDG PET/CT compared to CE-CT for local and distant relapse surveillance in surgically treated RCC patients.

M. A. Abdelwahab, W. Omar, H. Elsayd; National Cancer Institute, Cairo, EGYPT.

Objective: to evaluate the diagnostic performance of combined fluorine-18 fluoro-deoxyglucose (18F-FDG) PET/ computed tomography compared to Ce-CT for the detection of local and distant disease relapse in surgically treated patients with renal cell carcinoma (RCC). Patients and methods: This retrospective study includes 94 patients with a clinical suspicion of renal cell carcinoma tumor recurrence referred to nuclear medicine department, Children's Cancer Hospital, Egypt (CCHE) to perform PET/CT study . Each patient underwent 18F-FDG PET/ computed tomography (CT) with low-dose CT, followed immediately by Ce-CT. Study-based analyses for a total of 94 scans were carried out. For each study, site based analysis was performed. Sites of relapse were categorized into 7 groups: local tumor site, lymph nodes, lung, brain, liver, bone and other soft tissue sites (e.g. adrenal, subcutaneous, intramuscular & pancreas). The final diagnosis of disease status was made on subsequent follow-up by conventional imaging (CT/MRI), 18F-FDG PET/CT, or histopathology whenever possible. Results: Out of the 94 evaluated patients, 69 (73.4 %) studies had local &/or distant recurrent disease and 25 (26.6 %) studies were disease free on the basis of the final diagnosis. 18F-FDG PET/CT and Ce-CT had a sensitivity, specificity, negative predictive value, and positive predictive value of 95.8 versus 100%, 100 % versus 98.5 %, 98.5% versus 100 %, and 100% versus 96 %, respectively for the detection of local recurrence and 92.4 % versus 94 %, 97.4 % versus 62.5 %, 80.9 % versus 78.1 %, and 99.1 % versus 88.1 %, respectively for the detection of distant metastases. 18F-FDG PET/CT was significantly more specific with significantly higher PPV for the detection of distant recurrence (specially in soft tissue sites as intramuscular ,subcutaneous , adrenal, & pancreatic lesions) compared to Ce-CT, with P-values of <0.05 . Conclusion: 18F-FDG PET/CT seems to have added value compared to Ce-CT alone in detection of distant metastatic lesions in the re-staging of surgically treated RCC patients.

EP241

Scintigraphic assessment of pelvic sentinel lymph nodes metastatic spread in oncourologic patients

V. Sukhov[1], K. Zaplatnikov[2], A. Marin[1]; [1]Military Medical Academy, ST. PETERSBURG, RUSSIAN FEDERATION, [2]maz, Nuremberg, GERMANY.

Purpose of the study was to evaluate 99mTc-colloid scintigraphy used as method of clarifying the routs of lymphatic cancer spread for lymph dissection and optimization of radiation therapy. Materials and methods: SLN scintigraphy was performed in 51 patients 17 - 47 y.o. with tumors of the testis (n=17) by administration of 37-74 MBq of 99mTc-colloid beneeth tunica albuginea of the tumor-affected testis prior to its surgical resection or in the stump of spermatic cord, if the patient had earlier undergone orchiectomy and prostate cancer (n=34) - by administration of 37-74 MBq of 99mTc-colloid beneath capsule. Examinations were performed 45-60 minutes p.i. on gamma-camera "E.cam Var" (Siemens) in Anterior, Posterior, Left, Right and perineal projections. Sentinel lymph nodes were seen on scintigrams as foci of intensive accumulation of the radiopharmaceutical most closely to the site of tumor. Results: Pelvic SLN scintigraphy data were helpful for determining of the direction of lymph outflow from tumor-affected testis or the stump of spermatic cord and prostate to sentinel lymph nodes by normal or changed lymph collectors. Thus, SLN scintigraphy led to exact determination of local lymph node dissection or delineation of fields' size and configuration for local

radiation therapy. Conclusions: Clarifying of the lymph outflow routs with 99 mTc-colloid increases the validity of early lymphatic cancer spread detection, including or excluding cases of lymph nodes enlargement. This gives an opportunity to determine precise configuration of radiation fields within sites of 99 mTc-colloid accumulation.

EP242

Introduction of a molecular PI-RADS classification system for ^{68}Ga-PSMA-PET/MR imaging of primary prostate cancer

S. Lütje[1], A. Wetter[2], J. Cohnen[1], L. M. Sawicki[3], A. Bockisch[1], T. D. Poeppel[1], B. Gomez[1]; [1]Clinic for Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [2]Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY, [3]Medical Faculty, Department of Diagnostic and Interventional Radiology, University Dusseldorf, Düsseldorf, GERMANY.

Aim: Multi-parametric magnetic resonance imaging (MRI) is the standard technique for non-invasive tumor staging of primary prostate cancer (PCa). First clinical studies indicate that positron emission tomography (PET)/MRI targeting the prostate-specific membrane antigen (PSMA) is a highly promising new technique for staging of patients with primary PCa. Here, the addition of a molecular component to the standard reporting system PI-RADS was introduced to allow metabolic classification of suspect prostate lesions and their differentiation from benign/inflammatory processes with ^{68}Ga-PSMA-PET/MRI.**Materials and methods:** In a retrospective study, six patients with primary PCa underwent ^{68}Ga-PSMA-PET/MRI for initial staging. Patients received intravenous injections of 113±21 MBq of the ^{68}Ga-labeled PSMA ligand HBED-CC-PSMA at 121±25 min p.i.. All tumor lesions were histologically proven by biopsy. Images were analyzed quantitatively (SUV_{max} and SUV_{mean}) and qualitatively using a three point scale from A (normal tracer accumulation) and B (moderate focal tracer accumulation) to C (suspect focal tracer accumulation) in addition to the original PI-RADS system. **Results:** Seven PET-positive lesions (mean SUV_{max} 6.5, range 3.6-10.5, mean SUV_{mean} 2.9, range 1.8-4.9) were identified with the PET component of ^{68}Ga-PSMA-PET/MRI. All seven lesions were visually concordant to suspect lesions in the MRI component (T2w and DWI) of the PET/MRI system. All visualized suspect lesions where histologically confirmed to be tumor lesions. Six tumor lesions were classified PI-RADS 4 (PCa likely to be present), while one lesion was PI-RADS 3 (presence of PCa is equivocal). All lesions were accompanied by the (m)PI-RADS classification score C as all lesions showed suspect focal tracer accumulation. In the patient with equivocal presence of PCa according to the original PI-RADS classification, ^{68}Ga-PSMA-PET/MRI showed a highly suspect focal tracer accumulation (score C), indicating malignant involvement, which was confirmed by histology. Therefore, the use of the new (m)PI-RADS classification system could clarify unclear findings, by adding a metabolic value to the original score. **Conclusion:** Here, a new (m)PI-RADS system was introduced, which adds a metabolic aspect to the original PI-RADS system, which could facilitate the differentiation between benign and malignant lesions within the prostate.

EP243

Diagnostic impact of 18F-Fluoromethylcholine PET/CT in biochemical relapse of the prostate cancer

A. Alvarez Alonso, C. Vigil Díaz, B. Fernández Llana, A. Álvarez Blanco, N. Martín Fernández, L. Díaz Platas, N. Pérez Castro, O. Rodríguez Fonseca, F. González García; Hospital Universitario Central de Asturias, Oviedo, SPAIN.

Objective: Evaluate the potential diagnostic of the 18F-Fluoromethylcholine (FCH) PET/CT in the diagnosis of the prostate adenocarcinoma recurrence. **Material and methods:** 87 patients with prostate adenocarcinoma treated with curative intent were retrospectively included from October 2014 to January 2016, with a median age of 68 years (range 52-86). Initial treatment was radical prostatectomy in 29 patients (33%), salvage radiotherapy in 51 (59%) and other treatments in 7 (8%). At the time of the study 22 patients were receiving hormonal treatment. The patients were referred for a 18F-FCH PET/CT study due to biochemical relapse (mean PSA: 14,1 ng / ml, 95% CI 9,3-18.9. Final diagnosis of recurrence was confirmed by clinical follow-up (median 188 days). Sensitivity (Se), specificity (Sp), positive (PPV), and negative predictive values were measured for 18F-FCH PET/CT, CT and bone scintigraphy. A T-Student test was performed to compare the value of PSA in patients with or without recurrence in the 18F-FCH PET/CT. **Results:** The 18F-FCH study was positive in 63 patients (72%). 18F-FCH findings showed local recurrence in 19 patients (22%), metastatic lymph nodes in 29 (32%), metastatic bone disease in 17 (22%) and negative in the remaining 20 patients (24%). The Se, Sp, PPV and NPV values for 18F-FCH PET/CT study were 95%, 74%, 94% and 46%, respectively. For CT study 30%, 80%, 87% and 20%, respectively. When the detection of bone metastasis was isolated analyzed, the values obtained were 31%, 99%, 99% and 84%, respectively. Statistically significant differences (p 0.002) between the value of PSA in the negative and positive 18F-FCH studies were observed (4,5; 95% CI: 2-7.1 vs. 17.8; 95% CI: 11,3-24,2). Recurrence was detected more frequently in the group of patients initially treated with radiotherapy (40/51, 78%) than in the group initially treated with radical prostatectomy (15/29, 52%). Recurrence was detected in 20/22 (91%) of patients with hormone treatment and confirmed during the follow-up. **Conclusion:** The findings remarked the accuracy of 18F-Fluoromethylcholine PET/CT in the diagnosis of local and distant relapse of prostate adenocarcinoma, defining the location of the recurrence and surpassing conventional imaging techniques. The study showed a significant association between high levels of PSA and positive 18F-FCH and suggests that the presence of hormonal therapy is not a decisive factor in the outcome of this exploration.

EP244

Effects of Lutetium-177 PSMA-i and Radioiodine Therapy on Salivary and Lacrimal Glands

O. E. Sahin[1], B. Vatankulu[1], R. Akyel[1], J. Nematyazar[1], E. Demirci[2], H. Pehlivan[1], E. Karayel[1], A. Aygun[1], M. Ocak[3], L. Kabasakal[1]; [1]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, İstanbul, TURKEY, [2]Sisli Etfal Training and Research Hospital Department of Nuclerar Medicine, İstanbul, TURKEY, [3]Department of Pharmaceutical Technology,Pharmacy Faculty,Istanbul University, İstanbul, TURKEY.

Aim: Lutetium177- PSMA-i is a new radiopharmaceutical for the treatment of castration-resistant prostate cancer(CRPC). Normal tissue dose rates and absorbed doses are very important to follow-up of the side effects in radionuclide therapy. Lu-177 PSMA-i dosimetry studies showed that absorbed doses of salivary glands and lacrimal glands are higher than kidneys . It is also known that radioiodine has higher uptake in salivary glands. Therefore we aimed to evaluate the effects of radioiodine and Lu-177 PSMAi therapies on salivary and lacrimal glands.**Material-method:** Nineteen prostate cancer patients (mean age : 64 ±8 years) who had PSMA-11 PET/CT imaging before and after Lu177 PSMA-İ therapies (average of Lu177-PSMA dose : 25,4±6,14 GBq) were included into the study .Additionally we included 7 differentiated thyroid cancer patients (mean age:61 ±7 years) who underwent RAI threapy(average of RAI doşe: 26,04±12,8 GBq) and who had PSMA PET for staging. Background corrected SUVmax values of parotid glands, submandibular glands,lacrimal glands,kidneys, liver and spleen

were obtained from initial and posttherapy PSMA PET/CT images of prostate cancer patients and average ratios of tissue/liver SUVmax were calculated and compared with each other by using wilcoxon matched pair test. Additionally, background corrected SUVmax values of aforementioned tissues were obtained from PSMA PET/CT images of thyroid cancer patients and calculated ratios of tissue SUVmax/liver SUVmax . **Results:** The most difference in ratio was seen in lacrimal glands [(Right(R)gland=Before Therapy(BT): 1,02± 0,56-After Therapy(AT): 0,68±0,27,p: 0,01);(Left(L)gland :BT: 0,93±0,41-AT:0,66 ±0,33,p:0,004)] and followed by parotid [(R= BT:1,53±0,62- AF:1,17 ± 0,46,p:0,02);(L= BT: 1,36±0,52 - AT: 1,05±0,37, p: 0,014)] and submandibular glands [(R= BT: 1,69±0,8- AT: 1,38±0,57,p: 0,048);(L=BT: 1,59 ±0,7-AT: 1,29±0,47,p:0,022)].No significant difference was shown in spleen [BT: 1,03±0,31 - AT: 0,94±0,32,p: 0.248] and kidneys [(R= BT: 5,6±3,74 - AT : 5,94±3,05, p: 0.810);(L=BT: 4,97±2,1,AT: 5,48 ±2,35,p:0.248)]. Significant reduction of PSMA uptake were demonstrated in salivary and lacrimal glands of 7 thyroid cancer patients with the ratios of tissue/liver SUVmax [parotis glands (R:0,53;L:0,48),lacrimal glands (R:0,67;L:0,66),submandibular glands (R:0,87;L:0,89),spleen(0,71),kidneys (R:5,81;L:5,73)] **Conclusion:** Lu-177 PSMA and radioiodine show higher uptake in salivary glands and lacrimal glands . It seems that the most effected tissues are salivary glands and lacrimal glands after Lu177-PSMAi therapy. No significant differences were shown in spleen-kidneys . Moreover radioiodine therapy have serious effect on salivary and lacrimal glands.These results show that both therapies can cause lacrimal and salivary gland dysfunctions as xerastomia.

EP245

Biodistribution patterns of Lu177-DKFZ-PSMA617 and Ga68-DKFZ-PSMA11 in the same patient group

N. Yeyin[1], **O. E. Sahin**[1], B. Vatankulu[1], T. Toklu[2], E. Demirci[3], A. Aygun[1], E. Karayel[1], H. Pehlivan[1], N. A. Selcuk[2], M. Ocak[4], L. Kabasakal[1]; [1]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, İstanbul, TURKEY, [2]Department of Nuclear Medicine, Yeditepe University Medical School, İstanbul, TURKEY, [3]Department of Nuclear Medicine,Sisli Etfal Training and Research Hospital, İstanbul, TURKEY, [4]Department of Pharmaceutical Technology,Pharmacy Faculty,Istanbul University, İstanbul, TURKEY.

Aim: Prostate-specific membrane antigen (PSMA) is increasingly recognized as a novel target and 68-Ga-DKFZ-11 (68-Ga-PSMA) has been suggested as a novel tracer for detection of PCa relapses and metastasis. As a theranostic approach its counterpart Lu-177 labelled ligand Ga-68-DKFZ-617 have a potential role for the treatment of castration resistant prostate cancer. However, both agents have different biochemical structures and may have different biochemical distribution. The aim of the study was to compare the biodistribution of Ga-68-DKFZ-11 and Lu-177-DKFZ-617 in patients who underwent Lu-177-PSMA therapy and Ga-68-PSMA imaging. **Material and Method:** For this purpose 10 patients were included to the study. Organ and tissue uptakes of Lu-177-DKFZ-617 were calculated from whole body images obtained at 4, 24, 48 and 120 hour after administration. In order to calculate the activity taken up in the kidneys, liver, parotid glands and left parotid, ROIS were drawn. The geometric mean of anterior and posterior counts were determined through ROI analysis, after that background subtraction and attenuation correction were applied using patients Ga-68-PSMA PET/CT images taking into account. Organ thickness, body thickness and Hounsfield unites from Computed Tomography scan. Average uptake values of organs and lesions at mentioned times were calculated by using activity values per unit. Also average of background corrected SUVmax values of kidneys, liver, parotid glands, lacrimal glands, metastatic lymph nodes (n=5) and bone metastases (n=9) were obtained from PET images. **Results:** Analysing the uptake rates, the highest values were observed in metastatic lymph nodes, followed by bone metastasis, lacrimal glands while low activity were observed in kidneys and liver. When it comes to SUVmax values, highest rates were obtained in kidneys (SUVmax:44.4), in lymph nodes (SUVmax:19.9), bone metastasis (SUVmax:15.9), parotid glands (SUVmax:11.6), liver (SUVmax:8.0) and lacrimal glands (SUVmax:6.2). **Conclusion:** Ga-68 PSMA-11 and Lu-177-PSMA-617 have substantial different bio-distribution patterns., In order to make a therapy plan as a theranostic approach and predicting the therapy response Ga-68-PSMA-11 PET/CT imaging should be interpreted cautiously.

EP246

68Ga-PSMA PET/CT in Biochemical Relapsed Prostate Cancer - Initial Experience

R. Silva[1,2], A. Abrunhosa[2], A. Figueiredo[1], Â. Cruz[2], A. Xavier[2], D. Barroca[2], M. Castelo Branco[2], J. Pedroso de Lima[1,2]; [1]Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL.

AIM: The role of positron emission tomography/computed tomography (PET/CT) in prostate cancer imaging, either with F18-Fluorocholine (F18-FCH) or 68Ga-prostate specific membrane antigen (Ga68-PSMA), is gaining prominence. Current imaging strategies, despite having progressed significantly, have limitations. In particular, they lack sensitivity in the detection of metastatic lymph nodes. 68Ga-PSMA PET/CT has shown encouraging results, particularly in biochemical recurrent disease. In this study we meant to evaluate 68Ga-PSMA PET/CT detection rate in biochemical relapsed prostate cancer. The influence of PSA values was also analysed. MATERIAL AND METHODS: The clinical charts of the 19 patients submitted to 68Ga-PSMA PET/CT scans performed until March 2016 were retrospectively reviewed. Four patients were excluded (3 were scanned for initial staging, and 1 initiated hormonal therapy before scanning). Fifteen prostate cancer patients in biochemical relapse were included (65.2±6.9, 55-74 years). According to the European Association of Urology guidelines, 12 patients were classified as high risk and 2 as low risk for biochemical recurrence (1 patient was not classified due to insufficient information). Seven patients were previously submitted to radical prostatectomy (RP), 2 to radiotherapy (RT) and 6 to both RP and RT. At the time of scanning the average PSA value was of 4.6 (±7.5, 0.1-25) ng/ml. Statistical analysis was performed using IBM© SPSS© Statistics, version 22. RESULTS: Globally, Ga68-PSMA PET/CT detected lesions in 11/15 (73.3%) patients. Not excluding other disease sites, local recurrence was detected in 1/15 (6.7%) patients, pelvic lymph node metastasis in 6/15 (40.0%), distant lymph node metastasis in 5/15 (33.3%) and bone lesions in 5/15 (33.3%). The average PSA values for 68Ga-PSMA PET/CT positive and negative patients was 5.8 (±8.5, 0.1-25) and 1.5 (±1.5, 0.19-2.87) ng/ml, respectively ($p>0.05$, Mann-Whitney U test). In total, distant disease (lymph node metastasis or bone lesions) was detected in 8/15 (53.3%) patients. The average PSA values for patients with local and distant disease was 2.0 (±1.8, 0.2-5.1) and 7 (±9.8, 01-25) ng/ml, respectively ($p>0.05$, Mann-Whitney U test). CONCLUSION: In our sample, Ga68-PSMA PET/CT detection rate in biochemical relapsed prostate cancer was 73.3%. Distant disease, either extra pelvic lymph node metastasis or bone lesions, was detected in 53.3% of cases, with profound implications in treatment strategy. PSA values did not allow the distinction between 68Ga-PSMA PET/CT positive and negative patients or between local and distant disease.

EP247

Early and Late Imaging of Choline PET/CT for the Detection of Prostatic Fossae Recurrences in Prostate Cancer with a Biochemical Failure (PSA< 2 ng/mL)

L. Evangelista[1], M. Hodolic[2], M. Burei[1], E. Pizzirani[3], G. Ramondo[3], G. Saladini[1]; [1]Nuclear Medicine and Molecular Imaging Unit, Veneto Institue of Oncology IOV - IRCCS, Padua, ITALY, [2]Nuclear Medicine Research Department, IASON,, Graz, AUSTRIA, [3]Radiology Unit, Veneto Institue of Oncology IOV - IRCCS, Padua, ITALY.

Introduction: biochemical recurrence of disease represents a failure of treatment in patients with prostate cancer treated with radical prostatectomy. 18F-Choline (FCH) PET/CT is often used to detect the presence of recurrence, although its detection rate is poor in case of prostatic fossae relapse, particularly in those patients with a PSA<2 ng/mL. The aim of the present study was to assess the improvement in the detection rate of FCH PET/CT in the prostatic fossae in patients with low PSA values. **Materials and methods:** from an Institutional database of 100 patients undergoing FCH PET/CT from 1st January to 31st March 2016, we selected those who performed an early scan for the detection of prostate fossae recurrences and had a PSA levels <2 ng/mL at PET time. Thirteen patients met the inclusion criteria (median age: 74 years; range: 45-86 years). All patients underwent an early static (after 2 minutes from the FCH injection; 1 bed; 5 minutes/bed) and late whole-body (after 60 min from FCH injection; 7 beds; 3 minutes/bed) PET/CT acquisition. A correlation among PSA levels, PSA doubling time (PSAdt), PSA velocity (PSAvel) and early/late PET/CT findings were assessed by using non parametric test. A p<0,05 was considered statistically significant. **Results:** the median PSA level, PSAdt and PSAvel at the time of FCH PET/CT were 0.53 ng/mL (0.12-1.9 ng/mL), 8.1 months (2-12.5 months) and 0.5 ng/mL/year (0-1.9 ng/mL/year), respectively. A significant uptake of FCH at the early images was reported and interpreted as a local recurrence of prostate cancer, in 3 patients. However, in these latter subjects, late images were hardly interpreted due to the presence of bladder and therefore considered as negative. Conversely, 10 patients had a negative FCH PET/CT scan, either in the early and late images. The median levels of PSA and PSAvel were significantly higher in patients with a positive early PET/CT scan as compared those with a negative scan (0.88 vs.0.52 ng/mL and 1.1 vs. 0.45 ng/mL/year, respectively; both p<0.05). On the contrary, the median value of PSAdt was similar between positive and negative early scan (7.9 vs. 8.6 months; p=not significant). **Conclusions:** from this preliminary analysis emerges that an early FCH PET/CT acquisition should be considered in patients with very low PSA levels (< 2 ng/mL), low PSAdt (<8 months) and high PSAvel (>1 ng/mL/year), particularly in case of suspicious for prostatic fossae recurrence. However, a prospective, large observational study is warranted for providing final considerations.

EP248

18FDG-PET/CT hypermetabolic renal bed granuloma post-nephrectomy mimicking local recurrence in renal cancer

G. L. BRUNO, **G. L. BRUNO**; FCDN, Buenos Aires, ARGENTINA.

AIM: To raise awareness about the existence of renal bed inflammatory granulomas frequently found in studies of 18FDG-PET/CT after post-surgical nephrectomy for kidney cancer, and try to avoid misinterpretation as local recurrence. MATERIALS AND METHODS: Retrospective study, were it was included and analyzed 20 patients between January 2009 and March 2016 with ages ranging between 36 and 78 years, who underwent radical nephrectomy for renal cancer and 18FDG-PET/CT post-surgically study, either as part of monitoring the disease or for other reasons. The patients presented as the only positive finding related to the disease, the presence of a hypermetabolic pseudonodular solid image in the renal bed. Then the patients underwent biopsy/surgery or clinical follow-up and or conventional diagnostic methods or reexamination with 18FDG-PET/CT. All 18FDG-PET/CT studies were performed on a GE Discovery STE 16, between 4-151 months after surgery. The findings are described and correlated chronologically. RESULTS: The 20 patients selected, presented hypermetabolic pseudonodular solid images in the renal bed, 9 (45%) right-sided and 11 (55%) left-sided, respectively. Of these, 4 patients (20%) underwent confirmatory surgery for local recurrences, showing SUVmax values greater than 5, with an average size of 41.2 mm in diameter. The remaining 80 % (n= 16) patients presented SUVmax values between 1.2 and 6.7 and average size of 15.8 mm in diameter which was statistically significant (p = 0.0004). These patients were followed by clinical and/or conventional diagnostic method; and also some of them underwent 2 or more 18FDG-PET/CT studies showing decreased metabolic activity among subsequence studies, which were interpreted as granulomas. CONCLUSION: Post-nefrectomía inflammatory granuloma is a frequently false positive finding in 18FDG-PET/CT studies during restaging of renal cancer. They are usually difficult to characterized, whether morphologic or metabolically, being often misinterpreted as local recurrence. In our experience it is important to emphasize that lesions less or equal than 15mm in diameter were statistically significant and could guide the diagnosis of inflammatory granulomas, whereas the SUVmax values were not relevant. It may be important to keep in mind these results to avoid misdiagnosis and even sometimes, biopsies and/or unnecessary surgery.

EP249

Value of 18F-FDG PET/CT in patients with castration resistant prostate cancer

M. Grmek, S. Hawlina, L. Lezaic; University Medical Centre Ljubljana, LJUBLJANA, SLOVENIA.

Different nuclear medicine investigations are used in patients with prostate cancer. The primary diagnostic investigations to evaluate disease progression in patients with castration resistant prostate cancer (CRPC) are bone scan, CT of thorax and abdomen. **The aim** of the study is to find out the value of 18F-FDG PET/CT in patients diagnosed with castration resistant prostate cancer. **Patients and methods:** 16 men having CRPC were included in the study. 14 men had Gleason score 9, one Gleason score 8 and one 7. Patients were on average 75±5 years old. In all patients we performed initial 18F-choline PET/CT study followed by 18F-FDG PET/CT study within one week. After 108±12 days we performed control 18F-choline PET/CT study followed by 18F-FDG PET/CT study. Injected activity per study was 2,5 MBq/kg of body weight for 18F-choline and 4 MBq/kg of body weight for 18F-FDG. Acquisition on PET/CT (Siemens, Biograph mCT) started 45 minutes after 18F-choline administration and 1 hour after 18F-FDG administration. A low dose CT scan followed by PET acquisition (two minutes per bed position with 45% overlap) was used. The results of the initial 18F-choline and 18F-FDG study were compared with the follow-up studies and classified in 3 groups - stable, slowly progressive and rapidly progressive disease, Each patient was classified as; Stable, if no new lesions suspected for prostatic cancer metastases were detected or if SUV max wasn't increased more than 25% in any of already known metastases; Slow progress, if combined number of new lesions suspected for metastases and already known metastases with SUV max increase of more than 25% was between one and three; Rapid progress, if combined number of new lesions suspected for metastases and already known metastases with SUV max increase of more than 25% was four or more. **Results:** Initial 18F-choline PET/CT study showed metastases in 12 of 16 patients and initial 18F-FDG PET/CT study in 6 of 16 patients. Results of disease progression are presented in the table. **Conclusion:** 18F-choline PET/CT study is more sensitive than 18F-FDG PET/CT study for metastasis detection in patients having CRPC. However, accuracy to detect patients in whom disease will progress was higher for 18F-FDG PET/CT study. Therefore we suggest that 18F-FDG PET/CT study should be used in therapy planning and follow up of patients with CRPC in addition to 18F-choline PET/CT.

EP250

18F-Choline PET-CT findings in prostate cancer recurrence and treatment modality

L. Mohamed Salem, Sr., A. Abella Tarazona, M. Ibañez Ibañez, V. Godoy Bravo, R. Reyes Marles1, I. Sime Loayza, J. Navarro Fernandez, L. Frutos Esteban, M. Castellón Sanchez, F. Nicolas Ruiz, P. López Cubillana, F. López Soler, P. López González, M. Porras martinez, M. Claver Valderas; Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

AIM: To evaluate the relationship between the 18F-Choline PET-CT findings and treatment method in patients with prostate cancer recurrence after treatment with curative intent and the association between the PSA level and the detection rate. MATERIALS AND METHODS: Together with Urology and Oncological Radiotherapy departments of our Hospital, we study retrospectively 100 patients with prostate cancer (PCa) with biochemical relapse after treatment with curative intent, radical prostatectomy or external radiotherapy and negative conventional imaging techniques, all patients underwent a bone scan and a new determination of PSA level, if they had not one during the last month, PET-CT scan was carried out after I.V. injection of 4 MBq/Kg of 18F-Choline with acquisition of a pelvic bed one minute and a whole body PET-CT 60 minutes after injection. We analyze the association between the treatment method, radical prostatectomy or external radiation therapy (we excluded patients who had both modalities or brachytherapy) and 18F-Choline PET-CT findings in terms of the type of recurrence, wether it is only local or distant with or without local recurrence, as well as the PSA level and the detection rate. RESULTS: Mean PSA is 12,9213 ng/ml, median is 5,5100 ng/ml. 73 patients had a positive scan and 27 patients had a negative scan. Median PSA value was 3 in patients with negative scan and 7,83 in patients with positive one, comparing positive and negative scans according to PSA value, we find strong relationship between PSA value and positive 18F-Choline PET-CT scan, the association is statistically significant P = 0.001, the higher the PSA level is, the higher is the probability to have a positive scan. 32 of 38 (84,21%) patients who was treated by only external radiotherapy, had positive scan. 12 of 24 (50%) patients who was treated by only surgery (radical prostatectomy), had positive scan. 45 patients 0f 73 had local recurrence, which is 61,64% of patients with positive scan. CONCLUSION: There is a strong correlation between PSA level and the probability to have a positive 18F-Choline PET-CT scan. There is more recurrence among patients treated with external radiotherapy, than radical prostatectomy. The most frequent recurrence type is local recurrence.

EP251

Dual-Time Point Evaluation of Prostate Cancer Lesions detected by ^{68}Ga-PSMA PET/CT

L. Sobral Violante, I. Sampaio, J. Teixeira, G. Ferreira, H. Duarte; 1Instituto Português de Oncologia, Porto, PORTUGAL.

Aim: The importance of dual-time point imaging has been described in several studies using ^{18}F-FDG PET/CT. The aim of this study was to evaluate maximum standardized uptake value variation (ΔSUVmax) percentage in malignant lesions detected by ^{68}Ga-PSMA PET/CT in initial and late images and also to evaluate the clinical significance of this parameter. **Methods:** We performed a retrospective analysis on 44 consecutive patients (median age 70±6.7 years) who underwent ^{68}Ga-PSMA PET/CT between October 2015 and April 2016. Clinical indication was biochemical recurrence in the majority of cases (42 patients) and staging (2 patients). Mean prostate-specific antigen (PSA) level was 18.7±32.2 ng/ ml ranging from 0.4 to 144.6 ng/ ml. Gleason score (GSC) range was 6-9. Inclusion criteria: patients with pelvic recurrence/metastasis detected on ^{68}Ga-PSMA PET/CT and confirmed by histology or clinical follow-up. Pelvic region lesions were evaluated in two time points for ΔSUVmax calculation: in the initial imaging (5 minutes bed immediately after radiotracer injection) and in whole-body imaging (acquired approximately 60 minutes post injection). **Results:** In 26 patients (59.1%) at least one lesion indicative of prostate cancer recurrence or pelvic metastasis was detected in ^{68}Ga-PSMA PET/CT scan. From those, 2 patients were excluded due to bladder interference in quantification and lack of histological/clinical confirmation, respectively. In the remaining 24 patients, a total of 27 focal lesions were detected in ^{68}Ga-PSMA PET/CT (16 prostatic bed/region; 8 lymph node; 2 bone; 1 seminal vesicle lesion) with an average SUVmax value of 6.6 (2.9-16.7) in the initial images and 13.5 (4.0-45.9) in the late images. ΔSUVmax Percentage Mean: prostate= 98.4% (22.1%-320.0%); lymph node=81.1% (9.1%-175.8%); bone= 108.8% (71.3%-146.4%). The seminal vesicle lesion SUVmax did not vary with acquisition time. **Conclusion:** The majority of lesions (96.3%) increased their uptake between initial and late acquisitions. These preliminary data suggests that 68Ga-PSMA dual-time point imaging improves identification of local recurrent disease/ metastasis in prostate cancer disease. Further research is necessary to confirm these results.

EP252

Detection of primary and metastatic lesions of urinary tract tumors by ^{18}F-FLT PET/CT

K. Kato[1], Y. Koshiba[1], K. Kunimoto[1], M. Honda[1], A. Murai[1], S. Abe[2], T. Odagawa[1], S. Naganawa[1]; [1]Nagoya University Graduate School of Medicine, Nagoya, JAPAN, [2]Nagoya University Hospital, Nagoya, JAPAN.

Purpose: The aim of this study is to investigate the efficacy of ^{18}F-FLT PET/CT for detection of primary and metastatic lesions of urinary tract tumors. **Methods:** Twenty-two (16 men, 6 women) patients were examined by ^{18}F-FLT PET/CT (Siemens Biograph 16). All the patients received surgical operation or biopsy and the tumor was diagnosed histopathologically. **Results:** In 22 patients examined by ^{18}F-FLT PET/CT, 13 were confirmed histopathologically to be urothelial cell carcinoma, 6 renal cell carcinoma, 2 retroperitoneal liposarcoma, and 1 bladder carcinoma. Five patients had lung metastases, 2 had lymph node metastases, and 1 had gallbladder cancer synchronously. In 7 of the 13 patients with urothelial carcinoma and 1 with bladder carcinoma, the primary tumor could not be detected due to retention of urine in the ureter and urinary excretion of ^{18}F-FLT. In the other 6 patient with urothelial cell carcinoma, 2 with retroperitoneal liposarcoma, and 1 with renal cell carcinoma, the primary tumor could be detected due to lack of urinary excretion of ^{18}F-FLT by renal insufficiency. ^{18}F-FLT uptake in the tumor site expressed as SUVmax in ^{18}F-FLT PET was 2.17-28.99 (mean±S.D. 8.51±11.50) in urothelial cancer, 1.65 in renal cell carcinoma, and 9.35 and 4.24 (6.8±3.61) in retroperitoneal liposarcoma. Lung metastases after nephrectomy for renal cell carcinoma in 5 patients could be detected (SUVmax: 3.24-6.44 (4.45±1.13)). Lymph node metastases in 5 patients also could be detected (SUVmax:2.16-6.35 (4.45 ±1.73)). **Conclusion:** Usually, ^{18}F-FLT PET/CT is not suitable for detection of the primary lesions of urinary tract tumors because of its urinary excretion, whereas their metastatic lesions can be detected by ^{18}F-FLT PET/CT. Nevertheless, in patients whose urinary excretion of ^{18}F-FLT is disturbed by renal failures, ^{18}F-FLT PET/CT is useful for detection of the primary lesions of urinary tract tumors.

EP253

C11-choline PET/CT is an effective tool in prostate cancer diagnosis

I. Garai[1], A. Káplár[1], B. Farkas[1], C. Berczi[2]; [1]ScanoMed Ltd, University of Debrecen, Debrecen, HUNGARY, [2]Department of Urology, University of Debrecen, Debrecen, HUNGARY.

C11 choline PET/CT is a sensitive method to reveal the early recurrence or metastatic spreading of prostatic cancer. C11 choline PET/CT has been introduced in human care since 2014 in Hungary. The aim of this study was to evaluate our experience with C11 choline. Patients and Method:We performed C11 choline PET/CT examinations on 97 patients and analysed the results retrospectively. We grouped the patients based on the primary indications. The groups were as follows: 1. screening (15 patients), 2. primary staging (16 patients) and 3. restaging (66 patients). 700-850 MBq C11 Choline was injected iv. and acquisition was started 5 minutes later with 120 sec./frame using Philips Gemini 64/Tof PET/CT camera from the midthigh to the base of the skull. Low dose CT was also done (120 keV, 150mAs) for attenuation correction and anatomical localisation. We evaluated our results based on clinical data collected from the patients' medical history. Results: In the screening group, we found focal intense choline uptake in the prostate only in 3 cases and the biopsy proved malignancy in those cases. However in some cases, diffused uptake in the prostate caused uncertainty in the diagnosis. Metastasis was absent in this group. In the primary staging group the primary tumor was revealed in all cases on choline PET/CT in the same sites as MRI. Mean SUVmax was 7.4 in the primary lesion. However, the disease was upstaged in 7 cases due to lymphatic and bone metastasis. In the restaging group we classified patients based on sePSA level into three subgroups. Subgroup 1 had 16 patients with PSA<1 ng/ml and there was no pathological uptake. Subgroup 2 had 12 patients with PSA 1-2 ng/ml and in 4 cases showed disease recurrence. Subgroup 3 had 38 patients with PSA> 2 ng/ml and 27 cases showed choline positivity. We found a significant correlation between the choline positivity and PSA level. C11 choline PET/CT is an effective diagnostic method especially in restaging of prostatic cancer in cases of biochemical failure. Furthermore, it can provide additional information in primary staging too.

EP254

The Burden of Castrate-Resistant Prostate Cancer: Making a Case for PSMA Targeted Therapy in Southwest Nigeria

Y. A. Onimode[1,2], A. T. Orunmuyi[1,2], B. O. A. OSIFO[2]; [1]University of Ibadan, Ibadan, NIGERIA, [2]Nuclear Medicine Centre, University College Hospital, Ibadan, NIGERIA.

Introduction: Prostate cancer (PC) is the leading male cancer in Nigeria, with an age-specific incidence rate of 62.35 per 100 000 men. The mean age of diagnosis of cancer in Nigerian men is 50.5 years. Globally, PC is said to be the fifth most common cancer, with a prevalence of 3.2 million. Lu-177-PSMA targeted therapy has recently become available for the treatment of CP. Prostate-specific membrane antigen (PSMA) is an ideal target in management of prostate cancer, which is overexpressed in metastatic PC and (castrate-resistant prostate cancer) CRP. However, Lu-177 PSMA is presently unavailable in Nigeria. **Aim:** To determine the prevalence of castrate-resistant prostate cancer (CRP) patients presenting for bone scintigraphy, to assess bone scan (BS) findings, and make a case for government and private sector provision of PSMA-therapy facilities. **Materials and Methods:** A retrospective review of Tc-99m hydroxymethylene diphosphonate (HMDP) bone scans for PC from 2013-2015 at a tertiary NM facility in South-West Nigeria. **Results:** Of 372 BS, 199 (53.4%) were for patients on anti-androgen therapy (AAT), aged 45 - 87 years. 121 BS showed metastases (60.8%), 30 had suspicious lesions (15.1%), three had metastatic and suspicious lesions (1.5%), while 45 (22.6%) had normal scans. Metastases were most common in the axial skeleton (50.4%), then the lower limbs (23.5%) and upper limbs (16.6%). A significant association was found between type of AAT (medical, surgical or combined) and BS outcome (p=0.003). No significant association was found between BS findings and type of treatment 1 (AAT/prostatectomy/adjunct or combination), between PSA level and duration of AAT, nor between age and bone scan findings. **Conclusion:** Of 199 BS for CRP patients, 61% had metastases despite AAT, of which 63.6% were extensive in nature, mainly involving the axial skeleton. Findings thus suggest that CRP is common among PC patients, and that a potential population exists for Lu-177 PSMA therapy in these patients. 2

EP255

Impact of 18F-Choline PET-CT on the selection of patients with oligometastatic prostate cancer recurrence candidates for local salvage treatments

I. L. Fernandez-Tercero, A. Gomez-Iturriaga, A. Sanchez-Salmon, F. Casquero, A. Urresola, A. I. Ezquerro, R. Llarena, E. Rodeño; Cruces University Hospital, Baracaldo(Bizkaia), SPAIN.

Purpose: Patients with oligometastatic prostate cancer detected by (18F)-Choline PET-CT (Ch-PET) may benefit from targeted high-dose irradiation of the pathologic choline uptake sites associated with a short course of Androgen Deprivation Therapy (ADT). The objective of this study was to select candidates for salvage treatment of oligometastatic prostate cancer recurrence by Ch-PET. **Methods**: From 2013 to 2015, 30 consecutive prostate cancer patients diagnosed with oligometastatic-recurrence on Ch-PET have been prospectively treated. The recurrence occurred after radical prostatectomy in 22 (74%) patients, after radiotherapy(+/-ADT) in 7 (13%),and after cryotherapy in 1(3%) patient. All patients underwent pelvic multiparametric Magnetic Resonance Imaging to assess local failure. All Ch-PET-CT (contrast enhanced) were reviewed by two independent physicians. There was not biopsy confirmation of the pathologic choline uptakes. All patients with biochemical failure after salvage treatment were re-staged by Ch-PET scan. **Results**: Median follow-up was 12 months (range 8-26). The median prePET PSA was 3.96 ng/ml (1.51-36.4) and median prePET PSA-doubling-time was 4.5 months (1-47.4). Ch-PET showed pathologic uptake consistent with recurrence in lymph-nodes in 24 (80%) patients, bone in 4 (14%) patients, bone and nodes in 1 (3%) patient, and bone and prostate in 1 (3%) patient. A total of 64 lesions have been treated. The treatments administered to the initial oligo-recurrence uptakes were Intensity-Modulated-Therapy (IMRT) +/- ADT (23 patients; 77%) and Stereotactic- Body-Radiation (SABR) +/- ADT (7 patients; 23%). ADT was administered for no longer than 6 months in 18 patients. At last follow-up, 18 patients are free from biochemical failure and 12 patients showed biochemical failure. Median time to biochemical failure from first salvage treatment was 8 months (2-14). Four (30%) (3 nodal, 1 bone) out of the 12 patients with biochemical failure presented on a repeated Ch-PET oligometastatic disease, and were treated with a second salvage treatment (1 IMRT, 3 SABR). Two of them, are free from biochemical failure at last follow-up. Seven (58%) out of the 12 patients with biochemical failure developed progression on a repeated Ch-PET scan, and in one of them, macroscopic recurrence was not found. **Conclusion**: Early detection of oligometastatic prostate cancer recurrences with Ch-PET allows guiding local salvage radiation treatments Follow up with Ch-PET in patients with biochemical failure detects subsequent oligometastatic recurrences suitable for further salvage treatment

EP256

qPET Distribution in Prostate, Lymphonodular and Skeletal FCH-PET Positivities in Biological Relapse of Prostate Carcinoma

c. Olianti[1], M. Di Russo[1], I. Laghai[1], M. R. Raspollini[2], F. Sessa[3], A. Minervini[3]; [1]Nuclear Medicine Unit, FLORENCE, ITALY, [2]Pathologic Histology Unit, FLORENCE, ITALY, [3]Clinic Urology Unit, FLORENCE, ITALY.

We retrospectively evaluated 100 male asymptomatic patients [median age : 75 y - range : 54-91 y; PSA (ng/ml) median : 2,3 ; range: 0,13 - 203] with biological relapse of prostate carcinoma undergone to FluoroCholine-Positron Emission Tomography (FCH-PET). Of them 43 pts. (43%) had negative FCH-PET and 57 pts. (57%) had positive FCH-PET , on prostate 28% (P), lymph nodes 43% (LN) and bone 29% (SK). For each FCH-positivities we extracted qPet 3D value by an automatic selection of Voxel with highest SUV and subsequent extraction of mean SUV in a 4 voxel VOI around the highest SUV. Analysis of variance found significant differences

in qPet SUV mean VOI values (qPet) among P (mean +/- SD: 7.4 +/- 3.4), LN (mean +/- SD: 5.4 +/- 2.4) and SK (mean +/- SD: 4.2 +/- 2.5) positivities, $p < 0.001$ among all groups ; Post Hoc test HSD di Tukey found significant differences between SK and Ln qPet with $p < 0.05$, between SK and P qPet with $p < 0.001$, between Ln and P qPet with $p < 0.02$. We also found on the basis of FCH-PET results a significative difference in mean PSA of patients with FCH-Pet positive and patients with FCH-Pet negative) non parametric test of Kolmogorov - Smirnov $Z = 2,8$; $p < 0.001$. RocAnalysis found a PSA cutoff-value between positive and negative FCH-Pet results corresponding to 2.845 ng/ml with a sensibility of 67 %, specificity of 80% and accuracy of 73%; VPP = 80 %; VPN = 67 %. We conclude that a qPet value seems correlated to a more FCH-expression in local relapse, than in LN and SK metastasis. Also PSA, as note in literature , is and useful index of presence of disease relapse or metastatic illness.

EP257

Computer-assisted analysis of skeletal lesions in the staging of prostate cancer: Prospective multicenter study

L. J. Petersen[1], J. C. Mortensen[2], H. Bertelsen[1], H. D. Zacho[1]; [1]Aalborg University Hospital, Aalborg, DENMARK, [2]Regional Hospital West Jutland, Herning, DENMARK.

Aim The purpose of this study was to compare the diagnostic properties of EXINI Bone^{BSI} versus expert reading in the initial bone metastasis staging in prostate cancer. **Materials and Methods** Bone scintigraphy was performed in 342 consecutive patients referred for the staging of newly diagnosed prostate cancer in a multi-center trial. The bone scan index (BSI) and the number of malignant lesions (hot spots) was calculated by EXINI Bone^{BSI}. Three imaging experts independently classified bone status by a dichotomous outcome (M1 for bone metastasis, M0 for no bone metastasis). **Results** The diagnostic characteristics of BSI>0/BSI=0 versus expert M1/M0 classification showed excellent sensitivity and negative predictive value (NPV) (96 - 98 %) but low to modest specificity (38 %) and low positive predictive value (PPV) (21 %). A BSI value of 0.3 was identified as the optimal diagnostic cut off by which sensitivity was 88 %, specificity 86 %, PPV 51 %, and NPV 98 %. Stratification based on individual risk classification did not improve the diagnostic performance of the software. A subgroup of patients were classified as true M0 (n=130) or M1 (n=12) based on supplementary imaging and/or clinical follow up. The software incorrectly showed malignant lesions in 64 % of the M0 patients but correctly identified malignant skeletal lesions in all M1 patients. **Conclusion** EXINI Bone^{BSI} presented excellent sensitivity and NPV, but specificity was modest, and PPV was low to modest. The diagnostic value of EXINI Bone^{BSI} in staging of newly diagnosed prostate cancer is limited.

EP258

The importance of whole body PET/CT with 18F-Choline in detecting unsuspected brain lesions in patients with prostatic cancer

L. Massi[1], A. Franceschetto[1], V. Rossetti[1], A. Bruni[2], F. Lohr[2], N. Prandini[1]; [1]Nuclear Medicine, Modena, ITALY, [2]Radiation Oncology, Modena, ITALY.

Aims: 18F-Choline (FCH) PET/CT is routinely performed in patients with biochemical relapse of prostate cancer. The PET/CT scan is usually performed from base of the skull to midthigh. In this study we report our experience of PET/CT whole body scan, including the skull vertex, looking for brain metastates from prostate cancer. Matherials and Methods: A total of 485 whole body 18F-CH PET/CT in patients with prostatic cancer and biochemical recurrence were performed from january 2013 to december 2015. All the patients were i.v. injected with 3.7 MBq/Kg of 18F-CH and immediately underwent to a PET/CT scan of the pelvis: 50 minutes later a PET/CT whole body scan including the head vertex was obtained. In five patiens a focal brain uptake of 18F-CH was found. In 2 patients the FCH uptake was in sella turcica, in 1 patient was in left corpo callosum region, in 1 patient in the left frontal region and in 1 patient in fronto-parietal bilateral regions. Results: All 5 patients were studied by brain MRI: in two of them an histological examination of the lesions was obtained whereas the remaining 3 pts underwent to a clinical and instrumental management. The final diagnosis was of two meningiomas and two pituitary adenomas (one resulted a prolactinoma at biopsy). The patient with prolactinoma was treated with medical therapy with subsequent reduction of the lesion at MRI imaging. The fifth patient had an uptake of 18F-CH in the left side of corpus callosum without other pathological uptake in the body; the MRI showed a cystic-necrotic parasagittal lesion (diameter of about 3 cm) with a compression in the frontal horn of the lateral ventricle with deviation of septum pellucidum suspected for an high grade glioma. The subsequent brain stereotactic biopsy has demonstrated a metastasis of prostatic adenocarcinoma. The lesion was then treated with stereotactic ablative radiotherapy. Conclusions: In the normal brain parenchyma FCH uptake is low. The inclusion of the brain study in 18F-CH PET/CT can detect unknown brain lesions, which sometimes are the only secondary localization of prostatic cancer.

EP259

Detection of bone metastases in patients with PSA Detection of bone metastases in patients with PSA progression: comparison [18F]Choline PET/CT with bone scintigraphy; our experience

M. Grivet Fojaja[1], B. Carabellese[1], M. Lago[1], F. Scarabeo[2], G. Giglio[3]; [1]Nuclear Medicine department "A.Cardarelli" Hospital, Campobasso, ITALY, [2]Diagnostic Imaging department "A.Cardarelli" Hospital, Campobasso, ITALY, [3]Oncology department "A.Cardarelli" Hospital, Campobasso, ITALY.

AIM: The purpose of this study was to evaluate the clinical usefulness of [18F]choline positron emission tomography PET/CT in comparison with bone scintigraphy (BS) in detecting bone metastases (BM) of patients with biochemical progression after radical treatment for prostate cancer. MATERIALS AND METHODS: 27 consecutive patients (mean age 74 years; range 56-84) with a biochemical relapse after radical prostatectomy were included in our retrospective study. These patients underwent a both [18F]Choline PET/CT and bone scintigraphy (BS) for restaging (range: 1 week to 8 months; mean: 3 months). The imaging were retrospectively analyzed using morphological and/or follow-up imaging as standards of reference. Validation of positive results for bone metastasis was established by a positive subsequent BS and/or 18F-holine PET/CT, and a normalization of 18F-choline bone uptake after systemic therapy. RESULTS: in 19/27 patients positive bone disease were finding, both on [18F]Choline PET/CT and on BS; equivocal findings occurred in 2/27 patients on 18F-choline PET/CT, no equivocal finding occurred on BS; 6/27 negative patients for bone metastasis were findings on [18F]Choline PET/CT; in 8/27 patients negative bone disease on BS were findings. [18F]Choline PET/CT findings 164 bone metastatic localization vs 123 bone metastatic localization findings with BS. Concordant findings between [18F]Choline PET/CT and BS occurred in 20 of 27 (74%). Concordance rate for negative metastatic bone disease was 75%; concordance rate for positive metastatic bone disease was 84%. Sensitivity and specificity for [18F]Choline PET/CT and BS were 86%, 83% and 95%, 77%, respectively. For 3/27 patients (11%), with biochemical progression, BS and [18F]Choline PET/CT were negative ([18F]Choline PET/CT for no bone lesions too). For 2/27 patients (7%), with biochemical progression, BS and [18F]Choline PET/CT were negative for bone lesions but positive on [18F]Choline PET/CT for no bone lesions (lymphnodes and local recurrence) CONCLUSION: In clinical practice, [18F]Choline PET/CT may not replace BS because of its lower sensitivity. However, for its high specificity, [18F]Choline PET/CT, positive findings may accurately predict presence of bone metastasis. Also, there where the negativity for bone metastases does not explain the increased laboratory data, [18F]Choline PET/CT allows simultaneously the parenchyma and lymphnodes evaluation.

EP260

Is there a Role for 68-GaDOTATOC PET/CT in renal cell carcinoma? Our preliminary experience

L. Locantore, D. Grigolato, M. Zuffante, M. Cucca, F. Sciumè, M. Ferdeghini; Nuclear Medicine Unit, University Hospital of Verona, Verona, ITALY.

Background/Aim: Renal cell carcinoma (RCC) may be a target for somatostatin receptor (SSTR) imaging, due to the reported SSTRs expression. Moreover, most of RCC are not 18F-FDG avid. PET/CT using 68Ga-labelled DOTA0 -Tyr3 octreotide (DOTATOC) is one of the diagnostic imaging tools in SSTR imaging. We assessed if DOTATOC PET/CT could be helpful in patients with recurrent or metastatic RCC. Patients/Methods: Five consecutive patients (mean age 61.5 years, range 52-71) who had surgery for RCC, underwent 68Ga-DOTATOC PET/CT due to suspicion of recurrent/ metastatic lesions. Suspected relapse occurred at a median of 10 years after surgery. 68Ga-DOTATOC PET/CT was performed after contrast-enhanced CT (ceCT) scan; four patients also underwent 18F-FDG PET/CT (FDG) prior to 68Ga-DOTATOC PET/CT scan. Images were acquired 1 hour after 68Ga-DOTATOC intravenous administration with a PET/CT Philips Gemini TF Big Bore scanner (3 minutes/bed position, from skull-vertex to mid-thigh level). Images were analyzed both qualitatively and semiquantitatively (SUVmax). Results were compared both to ceCT and FDG PET/CT findings. Clinical and radiological follow-up data were also assessed. Results: 68Ga-DOTATOC PET/CT was positive in 3 patients, confirming disease in pancreas (=2) and lung (=1). Two patients had 68Ga-DOTATOC PET/CT scan negative (lung was the site of CT suspected recurrence). No uncertain results were found. SUV max of the lesions ranged from 4,3 to 19 (mean 9). In one patient an additional site of possible recurrent disease (parotid gland) was found. Compared to 18F-FDG PET/CT results, 2/4 patients were positive at 68Ga-DOTATOC PET/CT but negative at FDG scan (1 lung and 1 pancreas); 1 patient was classified as positive at DOTATOC but indeterminate at FDG (lung). One patient had both FDG and DOTATOC PET/CT scan negative (lung). Totally, 3/4 patients had FDG negative scan; in one case FDG results were rated as doubtful. 68Ga-DOTATOC PET/CT findings changed patients management in 4/5 cases. In patients candidated to surgery, hystologic evaluation confirmed RCC origin in 100% of the lesions. One patient with negative DOTATOC underwent cytologic examination (lung), with negative results (1 year radiologic follow-up showed lesion stability, referable to non-neoplastic aetiology). Conclusions: At this time, experience with DOTATOC PET/CT in RCC is limited. When inconclusive findings are obtained by conventional imaging, 68Ga-DOTATOC PET/CT could be useful for confirming or excluding renal origin of the lesions. Thus, in our patient population the use of DOTATOC PET/CT leaded to a more accurate staging, impacting patients treatment-decision making.

Background: The Zeus/SPCG11 study is a randomized controlled clinical trial with the aim to assess the efficacy of zoledronic acid (ZA) in preventing bone metastases in high-risk prostate cancer (PCa) patients. Automated Bone Scan Index (aBSI) reflects the tumour burden in bone calculated from bone scintigraphy, and has recently been validated as an imaging biomarker in metastatic PCa patients. The purpose of this study was to investigate if change in aBSI during treatment may serve as a useful imaging biomarker to predict clinical outcome in the Zeus/SPCG11 study population. ***Methods:*** We retrospectively selected as our aBSI-study group all patients with bone scan image data of sufficient quality to allow for both baseline and 48-months follow-up aBSI-assessments. aBSI data from the resulting cohort was later obtained by using the automated quantification software EXINI bone^{BSI}, in a blind fashion, without knowledge of any clinical data or treatment randomization. Clinical data on age, overall survival (OS) and prostate-specific antigen (PSA) concentration in blood at baseline and upon follow-up was collected separately. Association between clinical data and aBSI-change during treatment was evaluated using Cox proportional-hazards regression models, Kaplan-Meier estimates of the survival function and Log rank test. Discrimination between prognostic variables was assessed using the concordance index (C-index). ***Results:*** From a total of 1,433 high-risk PCa patients who participated in the Zeus/SPCG11 study, 176 fulfilled the inclusion criteria. The patient-characteristics of the aBSI-study group (n=176) showed baseline characteristics similar to those of the final total Zeus study population (p=0.83). In our aBSI-study cohort (N=176), patients with a aBSI-change $\leq$ 0.3 had a significantly longer median survival time compared to patients with aBSI-change of > 0.3 (32.3 months and 18.2 months respectively) (p< 0.001). In the Cox analysis aBSI-change from baseline to follow-up was significantly associated with OS (p<0.01 and C-index=0.6) while age and PSA change were not significantly associated with OS. ***Conclusions:*** aBSI-change during treatment was associated with OS in high-risk PCa patients from the Zeus/SPCG11 study. aBSI may be a useful imaging biomarker in future clinical trials involving PCa patients with bone metastases.

EP262

18F-choline PET/CT physiological distribution and pitfalls: a multicenter Southern Italian experience on 1000 patients examined for Prostate Cancer

F. CALABRIA[1], A. Chiaravalloti[2], C. Cicciò[3], V. Gangemi[4], G. L. Cascini[4], O. Schillaci[2,5]; [1]IBFM Italian National Research Council - PET/MRI Unit., Catanzaro, ITALY, [2]Department of Biomedicine and Prevention, University "Tor Vergata"., Rome, ITALY, [3]Department of Diagnostic Imaging, Sacro Cuore Hospital "Don Calabria"., Verona, ITALY, [4]Department of Diagnostic Imaging, Nuclear Medicine Unit, Magna Graecia University., Catanzaro, ITALY, [5]IRCCS INM Neuromed, Molise, ITALY.

Introduction. The (^{11}C or ^{18}F) labeled choline has become one of the mostly useful PET/CT radiopharmaceuticals, due to its capability to be enhanced in neoplastic lesions with low rate of glucose metabolism, as for prostate cancer (PC) cells. Similarly to the ^{18}F-FDG, choline uptake can be observed in several physiological conditions, inflammatory processes and tumors other than PC. A satisfactory knowledge on the "*in vivo*" biodistribution of the radiolabeled choline is essential for nuclear physicians, in order to recognize possible physiologic variants or pathologic false

positive findings. Moreover, being the experience with radiolabeled choline PET/CT largely linked to studies on PC patients, few information are available on the "*in vivo*" bio-distribution of this tracer in female patients. The aim of our study was to show and discuss false positive findings and diagnostic pitfalls documented in a multicenter experience in Southern Italy with ^{18}F-choline PET/CT in PC patients. Our secondary aim was to describe the "*in vivo*" ^{18}F-choline physiological bio-distribution in the female body. **Materials and Methods**. We collected a large series of false positive cases and diagnostic pitfalls in three PET centers performing PET/CT with ^{18}F-choline on an overall population of 1000 PC patients. Moreover, we performed a whole body PET/CT in 5 female patients undergoing brain PET/CT for suspicion of brain tumor relapse. Diagnostic pitfalls was ensured by follow-up, correlative imaging and/or histological sample. SUVmax analysis of the ^{18}F-choline uptake in the female body was done. **Results**. 169/1000 (16.9%) PC patients showed abnormal and unexpected PET/CT findings not owing to PC localizations. The majority of these findings were owing to inflammation. Few benign tumors were also observed. In a minority PC patients (1%) a concomitant malignant tumor was found (lymphoma, primitive bladder cancer, colon cancer, multiple myeloma, low-grade brain tumor, mesothelioma). SUVmax was significantly higher in malignant tumors than in inflammation and benign lesions. In the female body, the breast showed mild/low physiological uptake. **Conclusion**. A more confident diagnosis of PC secondary localizations can be achieved by nuclear physicians by the accurate knowledge of the bio-distribution, physiological variants and potential diagnostic pitfalls of ^{18}F-choline PET/CT. Semi-quantitative measurement of SUVmax can help to reach the final diagnosis but, especially when observing ^{18}F-choline uptake in lymphadenopaties and colon, correlative imaging and histological exam are of the utmost importance. In women, the uptake in the breast is physiologically due to the high gradient of ^{18}F-choline uptake in the exocrine glands.

EP263

Full-bladder with "cold" urine whole-body protocol for 18F-fluorocholine PET/CT in patient with prostatic cancer

M. Gauthé, V. Huchet, J. Ohnona, O. Belissant, J. Zhang Yin, K. Kerrou, S. Balogova, F. Montravers, J. Talbot; Hôpital Tenon, Paris, FRANCE.

Purpose: to assess the feasibility and efficacy of a 18F-fluorocholine (FCH) PET/CT whole-body acquisition without previous voiding of the bladder, in order to optimize image analysis of the pelvis, in patients with prostate cancer (PC). Methods: Patients with PC referred for FCH-PET/CT were prospectively evaluated. Two acquisition protocols were considered. The proposed "full bladder" protocol consisted in a starting PET acquisition immediately after FCH administration without previous voiding of the bladder, patient being positioned supine with arms crossed above head, speed 2 minutes per bed position, the upper limit of the first step being centered on the ischial tuberosity. The standard protocol consisted in a starting acquisition 10 minutes after FCH administration, patient having voided, positioned supine with arms crossed above head, from mid thighs to vertex, same speed. The interference of radioactive urine on visualization and quantification of uptake by foci was classified by two masked readers according to a 4-points scale, from no to major interference. This quotation was applied on 3 pelvic areas: prostatic bed, right and left ilio-obturator lymph nodes. The presence of radioactive urine and the radioactive urine interference on quantification between the acquisition protocols were compared using the non-parametric Kuskal-Wallis test, and the reproducibility of the reading between readers using non non parametric Wilcoxon matched pairs test. Results: 147 patients with PC were included. Thirty-seven (25.2%) underwent FCH-PET/CT for initial workup, 49 (33.3%) for biochemical recurrence, 32 (21.8%) for evaluation of therapeutic efficacy and 29 (19.7%) for another indication. Forty-one (27.9%) patients had history of prostatectomy. Fifty-one PET/CTs (34.7%) were performed according to the "full bladder" protocol. "Full bladder" protocol resulted in a significant reduction in radioactive urine interferences compared to standard protocols, in all pelvic areas for both readers ($p<0.001$). "Full bladder" protocol resulted in fewer urinary artifacts in the prostatic bed and fewer urinary artifacts in all pelvic areas when considering the whole group of patients and the biochemical recurrence subgroup respectively. In the subgroup of patients who underwent prostatectomy, "full bladder" protocol demonstrated less radioactive urine interferences than standard protocol, in all pelvic area for both readers ($p=0.03$). Conclusion: the "full bladder" protocol allowed a better certainty in reading image of the pelvis by suppressing physiologic urinary accumulation in the bladder that can compromise the evaluation. It seems to be particularly interesting in patients presenting for biochemical recurrence and/or patients with history of prostatectomy.

EP264

Detection of liver lesions during 11C-Choline PET/CT in relapsing prostate cancer patients

P. Ghedini[1], I. Bossert[1], T. Graziani[1], F. Ceci[1], F. Massari[2], E. Nobili[2], B. Melotti[2], P. Castellucci[1], S. Fanti[1], C. Nanni[1]; [1]Nuclear Medicine Department, University Hospital S.Orsola-Malpighi, Bologna, ITALY, [2]Medical Oncology Unit, University Hospital S.Orsola-Malpighi, Bologna, ITALY.

Aim: During our daily clinical practice using 11C-Choline PET/CT for restaging patients affected by relapsing prostate cancer (rPCa) we noticed an unusual but significant occurrence of hypodense hepatic lesions with a different tracer uptake. Thus we decided to evaluate the possible correlation between rPCa and these lesions as possible hepatic metastasis. **Materials and Methods**: We retrospectively enrolled 528 patients (mean age 71yr) diagnosed with rPCa in biochemical relapse after a radical treatment (surgery and/or radiotherapy). Among these, 47 patients were excluded due to the occurrence of a second tumour or other benign hepatic diseases. All patients underwent 11C-Choline PET/CT during the standard restaging workup of their disease. We analyzed CT images to evaluate the presence of hypodense lesions, and PET images to identify the relative tracer uptake. Patients were divided into 5 groups: 1-absence of lesions; 2-only one exam available, showing suspected lesions; 3-stable lesions in more than one PET/CT; 4-lesions showing modified dimensions/morphology on subsequent scans; 5-lesions confirmed as prostate liver metastasis by histopathology, triphasic CT, CEUS and clinical or biochemical evaluation. Furthermore we evaluated the relationship between these groups and PSA level at time of scan, SUVmax of lesions, presence of local relapse or non hepatic metastasis (lymphnodes, bone, other parenchyma), and presence of renal cystis. We also analyzed the ratio between SUVmax of the main lesion and SUVmean of the liver (SUVmax/SUVliv). **Results**: 396 (82,3%) patients were included in group 1, while 85 (17,7%) presented hepatic findings. Among these patients 19/481 (3,95%) were included in group 2, 12/481 (2,49%) in group 3, 37/481 (7,69%) in group 4, and 17/481 (3.5) in group 5. The mean SUVmax/SUVliv and PSA level were respectively: 4.5/8.4 and 7.9 for group 2; 4.2/7.3 and 10.4 for group 3; 4.8/7.4 and 14.4 for group 4; 5.9/8.8 and 14.7 for group 5; mean PSA of group 1 was 6.9 and mean SUVliv was 7.5. Though the majority of lesion was colder than SUVliv, in 3 patients lesions showed a higher SUVmax value. Presence of liver metastasis did not correlate with PSA levels, local relapse or other distant metastasis. **Conclusions**: Our results state that liver metastasis in relapsing prostate cancer occur, during restaging, with a significant incidence up to 17,6% (3,5% was confirmed by other techniques, and 14,1% was strongly suspected). On this basis we suggest to always investigate hepatic hypodense areas at 11C-Choline PET/CT, given that a similar finding can radically change patient management.

EP265

The role of 18F-FACBC PET/CT in localizing aggressive intra-prostatic lesions in high-risk primary prostate cancer: comparison with MRI and 11C-Choline PET/CT

L. Zanoni[1], I. Bossert[1], C. Nanni[1], C. Pultrone[2], R. Schiavina[2], F. Giunchi[3], M. Fiorentino[3], C. Fonti[1], C. Gaudiano[4], R. Golfieri[4], L. Bianchi[2], A. Porreca[5], E. Brunocilla[2], A. D'Errico[3], S. Fanti[1]; [1]Nuclear Medicine, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [2]Urology, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [3]Pathology, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [4]Radiology, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [5]Urology, Policlinico Abano Terme, Abano (PD), ITALY.

AIM: To assess whether 18F-FACBC PET/CT could identify the most aggressive intra-prostatic malignant lesion in high risk prostate cancer (PCa) scheduled for radical surgery, compared to endorectal-MRI and 11C-Choline PET/CT. **MATERIALS AND METHODS:** 65 patients (pts) with biopsy-proven high risk primary PCa prospectively underwent 18F-FACBC-PET/CT prior to radical surgery. All pts received standard staging workup, including 11C-Choline-PET/CT in all cases and MRI in 36. Lesion location was assessed in PET by prostate-uptake-pattern (diffuse/focal; inhomogeneous/homogeneous) and SUVmax laterality, whereas in MRI by site of suspected predominant nodule, and finally confirmed by available prostatectomy pathology specimens. Readers were aware of full clinical history but blinded to histopathology. Overall, 20 pts were evaluable for analysis. **RESULTS**: Pts characteristics (20pts): Age: mean 65; median 66; range 47-75. PSA: mean 9,1 ; median 7,3; range 3,7-27,4. cT: cT2 n.s 6; cT2c 8; cT3 6. *Biopsy.* %positive-cores: mean 43; median 43; range 8-83. GS: 3+4 1; 4+3 1; 4+4 12; 4+5 6. *MRI.* Size predominant nodule (14pts): mean 17mm; median 16; range 5-30. PIRADS (13pts): mean 4; median 4; range 3-5. ECE (18pts): 11 neg; 7 pos. SVI (18pts): 17 neg; 1 pos. Perfusion-curves (6 pts): type2. *Histopathology.* Acinar (1 acinar+neuroendocrine) PCa. pT: pT2b 1; pT2c 7; pT3a 10; pT3b 2. Tumor (%): mean 24; median 20; range 6-60. Size predominant nodule (10pts): mean 25mm; median: 22,5 ; range 13-40. EPE (18pts): 9 neg; 5 focal; 4 extensive. Perineural invasion: 3 neg; 17 pos. 11 R0 and 9 R1. GSmax: 3+4 1; 4+3 4; 4+4 2; 4+5 8; 3+5 1; 4+3 (tertiary 5) 2; 4+4 (tertiary 5) 2. FACBC prostate pattern was very comparable to Choline (except for 1 case), differed in SUVmax and estimated disease extent (focal vs multifocal) in 16/20 pts. FACBC revealed the most aggressive malignant lesion in 14 pts (70%), Choline in 15 (75%) and MRI in 16 (80%), respectively. The 3 imaging modalities were all in agreement with pathological findings in 13 pts (65%). Among the 7 pts with discrepancies, all methods failed in 3, whereas MRI performed better than PET in 2, both Choline and MRI better than FACBC in 1 and PET better than MRI in 1. **CONCLUSION:** 18F-FACBC PET/CT may support intra-prostatic localization of the most aggressive PCa lesion. However combined clinical, morphological and functional modalities are warranted for better localization and risk stratification at initial staging. Enrolment and further semi-quantitative and predictive analyses are ongoing.

EP266

PSMA PET Index - Introduction of a new imaging quantitative biomarker for assessment of osseous tumor burden in patients with metastatic castration-resistant prostate cancer

M. Krönke[1], M. Bieth[1,2], R. Tauber[3], M. Retz[3], B. Menze[2], J. Gschwend[3], T. Maurer[3], M. Schwaiger[1], M. Eiber[1]; [1]Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY, [2]Department of Computer Science, Technical University of Munich, Munich, GERMANY, [3]Department of Urology, Technical University of Munich, Munich, GERMANY.

Introduction & Objectives Bone scintigraphy (BS) is performed in prostate cancer (PC) patients to evaluate osseous lesions and has been recommended for therapy response evaluation in patients treated with radium223. 68Ga-PSMA-PET/CT is an emerging technique for re-staging of PC offering a higher spatial resolution as well a superb specificity. Aim of this project was to create a semi-automatic und quantitative tool for assessment of patients' osseous tumor burden and compare it to the current standard of the bone scan using the bone scan index (BSI). **Material & Methods** 45 patients with castration resistant prostate cancer (mCRPC) underwent 68Ga-PSMA-PET/CT before initiation and after 3 or 6 cycles of Radium223-dichloride. 35 patients underwent additional BS. BSI was computed using the commercially available EXINI Bone BSI. An in-house developed software first segmenting the skeleton and secondly extracting the osseous tumor load was used for determining a PSMA-PET- Index (PPI). PPI(VOL) is defined as the percental bone volume affected by bone metastases. PPI(SUV) considers additionally the PSMA-expression measured by SUV in every voxel. The threshold for automatically identifying bone metastasis was determined by analysis of 15 patients without bone metastasis with the assumption that less than 0.1% false positive voxels would be accepted. Correlation between different thresholds, PPI(VOL) and PPI(SUV), PPI and BSI were performed. **Results** Semiautomatic identification of total bone volume as well as metastatic affected bone was feasible. A small amount of manual correction was necessary especially due to misalignment, calcification and endoprosthesis. There was a very high correlation between the PPIs(VOL) for different SUV-cutoffs ($r=0.95$, $p<0.0001$), PPIs(SUV) for different SUV-cutoffs ($r=0.99$, $p<0.0001$). PPI(SUV) and PPI(VOL) showed a high correlation ($r=0.89$, $p<0.0001$). The new volumetric parameter for 68Ga-PSMA-PET PPI(VOL) showed a highly statistical moderate correlation to the established BSI ($r=0.77$, $p<0.0001$). A weak to moderate correlation was found between the change in BSI and PPI(VOL) during Radium223-dichlorid treatment ($r=0.52$, $p< 0.001$). **Conclusion** The assessment of bone metastases in PC using a novel semi-automatic tool for evaluation of PSMA PET as a new imaging biomarker is feasible. Preliminary analysis shows a good correlation between a newly introduced PSMA PET Index and the traditional Bone Scan Index regarding osseous bone involvement. Changes of both parameters during therapy seem to be less correlated. Further study evaluating the value of this new quantitative biomarker for 68Ga-PSMA-PET with clinical outcome in mCRPC are mandatory and ongoing.

EP267

Clinical impact of PSMA PET/CT for evaluation of patients with biochemical recurrence of prostate cancer

A. Santos, **M. Queiroz**, P. Viana, F. Barbosa, A. Vicente, G. Cerri, E. Etchebehere; Hospital Sirio-Libanes, Sao Paulo, BRAZIL.

Purpose Analyze the clinical impact of PSMA PET/CT in patients with biochemical recurrence prostate cancer. **Materials and Methods** Twenty-four patients were included in the retrospective analysis approved by the local ethic committee. The inclusion criteria were biochemical recurrence of prostate cancer (defined as PSA > 0.2 ng/dL; three consecutive rises of serum PSA; PSA doubling time less than 6 months) and negative findings on conventional imaging diagnostic work-up (Bone scintigraphy, US, CT, MR and/or FDG PET/CT). All patients underwent a whole-body PET/CT 30 minutes after the injection of 185 MBq of PSMA-^{68}Ga. Positive lesions detected by PSMA PET/CT were confirmed by histopathology. Clinical impact was measured through a structured form applied to the referring physician and it was categorized as high, medium, low or nule, according to the therapeutic change determined by PSMA PET/CT. **Results** Twenty-four patients (mean age of 68 ± 10.8 years) were included. Mean PSA serum level was 3.98 (± 4,42). In 18 out of 24 patients (75%), PET/CT was detected lesions with abnormal PSMA uptake. Histopathology was available in 22/24 patients. The

detection rate for local recurrence was 14%, for regional lymph node metastasis 41% and for distant metastasis 36%. PSMA PET/CT determined change in therapeutic management in 82% of patients, all of them with high impact. Any adverse event was evinced. **Conclusion** PSMA PET/CT is capable to determine local, regional and distant recurrence in patients with biochemical recurrence of prostate cancer and equivocal findings in conventional diagnostic work-up. PSMA PET/CT has a high clinical impact in the therapeutic management.

EP268

F-18 PSMA-1007 - histopathological verification of a novel fluorinated low-molecular weight PSMA targeting PET tracer

F. Giesel[1], J. Cardinale[2], C. Kratochwil[1], J. Radtke[3], B. Hadaschik[3], K. Kopka[2], U. Haberkorn[1]; [1]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY, [2]Division for Radiopharmaceutical Chemistry, German Cancer Research Center (dkfz), Heidelberg, GERMANY, [3]Clinic of Urology, University Hospital Heidelberg, Heidelberg, GERMANY.

Introduction: The new PET tracer F-18 PSMA-1007 was chosen from a series of pre-clinically evaluated radiofluorinated PSMA ligands to demonstrate favorable characteristics in regard to tumor uptake and physiological biodistribution in comparison to Ga-68 PSMA-11. Methods: In this investigation about men (n=5) with prostate cancer at high risk F-18 PSMA-1007 PET/CT 1h and 3h p.i. were performed prior to surgery, which included pelvic lymphadenectomy. The diagnostic findings regarding localization of the dominant intra-prostatic lesion as well as lymphnode metastases were correlated with histopathology. Results: Already 1h p.i. F-18 PSMA-1007 presented with sufficient tumor-to-background ratios. In comparison to Ga-68 PSMA-11 the here presented new radiofluorinated PSMA ligand presented a significant portion of hepatobiliar excretion and in exchange a lower clearance in the urinary bladder. This presents preferable for diagnostics of primary tumors in the central or transitional zone of the prostate and pelvic lymph node metastases. Conclusion: F-18 PSMA-1007 seems a feasible alternative to Ga-68 PSMA-11 and could be produced in larger amounts if an on-site cyclotron is available to reduce the demand for multiple tracer synthesis per week.

EP269

Preliminary experience with Cu64PSMA PETCT in patients with intermediate and high risk prostate cancer (PC) before prostatectomy

V. Gangemi[1], R. Damiano[2], F. Calabria[3], F. Barbato[4], G. L. Cascini[1]; [1]Nuclear Medicine- Università Magna Graecia, Catanzaro, ITALY, [2]Urology- Università Magna Graecia, Catanzaro, ITALY, [3]Institute of Molecular Bioimaging and Physiology, National Research Council, Catanzaro, Catanzaro, ITALY, [4]Nuclear Medicine, Napoli, ITALY.

Aim To analyze the diagnostic performances of PET with PSMA labeled with Copper 64 (Cu64PSMA/PET) during the staging of patients with PC scheduled for radical prostatectomy (RP). Materials and methods From November 2015, 13 patients (age range, 67-81; median 71) with biopsy proven PC were enrolled into the study. Sums of Gleason Score (GS) were 9 in 2/13, 8 in 2/13, 7 in 4/13, and 6 in the other 5 pts. All patients were drug-naïve. PSA values were ranged between 2.9-65.0 median 7.1. Six pts were classified as High Risk (HR) whereas 7 as intermediate or Low Risk group (LR). Hybrid Cu64PSMA-PET/CT acquisition included static scan of the pelvis at the time of the injection (early images), and whole body scan after 1 and 4 hours by using a 5 min/bed duration. The administered dose was ranged between 259-370 MBq. SUVmax on early and delayed images was measured for any focal area of pathological uptake and into the liver as reference with a regular 1.5 cm ROI. Changes SUVmax were analyzed. Results All pts underwent RP within 21 days from PET scan. In 6 pts according to the risk stratification extended pelvic lymph node (LN) dissection were performed. In all pts Cu64PSMA-PET detected an intense, focal hot spot into the prostate with an SUVmax ranged between 4-14, median 6.6. All focal areas were considered pathologic because of low physiological prostate uptake and low urinary excretion, particularly on 4h images. The SUVmax of primary prostatic lesions progressively increased from early to delayed images (30%) with an optimal tumor-background ratio at 4h. Median SUVmax of liver was 27.1 (range 19.5-40.5). PET findings well correlated to the site of primary tumor as well as to the lesion dimensions, GS and PSA values. In 3 out of 6 HR pts were also detected a focal PSMA uptake corresponding to 6 regional LNs on 1h and 4h images both. The average SUVmax was 5.2 (range 4.1-6.2). The LNs involvement detected by PET were confirmed by histology after the surgical removal in all patients and for all lesions. The average of LN dimensions were 1.0 mm (range 0.6-1.5). A false negative micrometastatic LN was reported. None of 13 pts showed distant pathological uptake. Conclusion Cu64PSMA-PET may represent an alternative to Ga68-PSMA in patients with PC because high quality delayed images due to low urinary excretion and the good physical properties.

EP270

F-18 PSMA-1007 - a novel fluorinated PET tracer structural similar to PSMA-617 as a theragnostic tandem

F. Giesel[1], J. Cardinale[2], O. Neels[2], C. Kratochwil[1], U. Haberkorn[1], K. Kopka[2]; [1]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY, [2]Division for Radiopharmaceutical Chemistry, German Cancer Research Center (dkfz), Heidelberg, GERMANY.

Introduction: Lu-177 PSMA-617 was recently clinically introduced as promising option for the treatment of mCRPC. The currently most used fluorinated PSMA ligand F-18-DCFPyl differs significantly in chemical structure. In contrast, PSMA-1007 shares structural similarity with PSMA-617 and, thus, we suggest PSMA-1007 to be a closer analogue to form a theragnostic tandem with PSMA-617. Methods: In this ongoing investigation, patients scheduled to PSMA targeted radioligand therapy with Lu-177-PSMA-617 received PSMA-PET/CT 1h and 3h p.i. after i.v. injection of 300-350 MBq F-18 PSMA-1007. The PET-scans were compared to the post therapeutic emission scans of the succeeding Lu-177 PSMA-617 therapy and the last PSMA targeted previous imaging (Ga-68 PSMA-11 PET or Tc-99m MIP-1427 SPECT). Results: The fluorinated PSMA ligand F-18 PSMA-1007 demonstrated a good agreement with the biodistribution of Lu-177 PSMA-617 in both tumor targeting and normal organs. In contrast, the other diagnostic compounds differed significantly regarding liver and kidney uptake. In regard to tumor delineation, the additive value of F-18 PSMA-1007 should be based on the physical advantages of F-18-PET (lower positron energy then Ga-68) rather than differences in targeting. Conclusion: A related chemical structure and similar biodistribution in men suggest F-18 PSMA-1007 as suitable theragnostic analogue to tailor patients for or against Lu-177 PSMA-617 therapy. Its diagnostic potential in comparison to other PCa PET-diagnostics has still to be evaluated.

EP271

Diagnostic efficacy of Ga-68 labelled PSMA ligand PET/CT in clinically and/or radiologically suspected cases of prostate cancer - A prospective study

B. R. Mittal, R. Kumar, S. K. Singh, J. Shukla, A. Bhattacharya, A. K. Mandal; Postgraduate Institute of Medical Education & Research, CHANDIGARH, INDIA.

Objective: To evaluate the diagnostic performance of Ga-68 labelled PSMA ligand PET/CT in patients with clinical and/or radiological suspicion of prostate cancer and a possible association between different clinical variables and the imaging results. **Material and Methods:** In this prospective study we evaluated 38 patients aged 45-80 years (median 66.4) with the clinical and/or radiological suspicion of prostate cancer and with raised PSA levels. All the patients underwent Ga-68 labelled PSMA ligand PET/CT imaging and the data was evaluated by two expert nuclear medicine physicians. Any abnormal tracer uptake on PET images was correlated with the corresponding CT images. SUVmax was measured in prostate region, pelvic and abdominal lymph nodes, bone and other lesions. The target to background ratio for all lesions was also evaluated. Histopathological examination was taken as gold standard to compare the results. PSA levels were also correlated with the PET results. **Results**: Histopathological examination showed prostatic carcinoma in 20 patients and no evidence of malignancy in 18 patients. PET/CT revealed positive findings in 26/38 patients (68.4%) while 12/38 patients (31.6%) were negative. Apart from primary lesion in the prostate, locoregional disease was noticed in 12 patients and distant metastases in 13 patients. On comparing the PSMA ligand PET/CT findings with HPE, 19 patients were true-positive, 7 false-positive, 11 true-negative and one false-negative. PET had shown a sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of 95.00%, 61.1%, 73.08%, 91.67% and 78.9% respectively. We noticed a good correlation between PET findings and final diagnosis (P=0.001). The mean SUVmax value in the prostate in the prostate cancer group was 15.4 (3.3-61.3) while it was 4.4 (2.1-8.1) in benign group and there was strong correlation between SUVmax and final diagnosis (P=0.003). By ROC curve analysis we found that SUVmax >5.2 had a sensitivity and specificity of 85.0% and 88.2% respectively (AUC 0.90). Similarly lesion to background ratio >5.9 had a sensitivity and specificity of 100.0% and 88.2% respectively (AUC 0.92). The mean PSA value in the prostate cancer group was 92.8ng/ml (4.7-863.0 ng/ml) while 11.3ng/ml (0.3-36.3 ng/ml) in benign group. **Conclusion**: 68Ga-PSMA PET/CT has a high sensitivity in detecting prostate cancer in clinically or radiological suspected cases. It also localizes distant metastases helping in management startegy. More studies with larger patient population are required for further evaluating the diagnostic accuracy of 68Ga-PSMA ligand PET/CT imaging clinically suspected cases of prostate cancer.

EP272

Ga-68 PSMA PET/CT in metastatic or locally recurrent prostate cancer: Comparison to bone scan, CT or MRI

E. Acar, R. Bekiş, Ö. Özdoğan, B. Polack; Dokuz Eylül University, School of Medicine, Department of Nuclear Medicine, İzmir, TURKEY.

Aim: The purpose of this study was to evaluate the diagnostic role of Ga-68 PSMA PET/CT and to investigate its' complementary role to the other imaging modalities such as bone scan, CT and MRI in local recurrence/metastatic prostate cancer patients. **Material and Method:** We retrospectively analyzed a total of 57 patients (the mean age 68.8 (range: 48-89), Gleason score 7.86 (range: 6-10), PSA level 214±455 (0.01-1740) ng/ml who were referred to our department to investigate metastatic foci or recurrent disease. Patient based analyses were performed and compared to other images such as bone scan, CT and/or MRI. All scans of the each patient were performed within one month period. Bone scans, CT and MRI were available for comparison, in 31/57, 45/57 and 10/57 patients, respectively. **Results:** There was no abnormal Ga-68 PSMA uptake in 11 patients (19%). The mean PSA level of these patients was 2.6 (0-15.9) ng/mL. Ga-68 PSMA PET/CT showed increased uptake which was considered as metastatic or recurrent foci in 46 out of 57 (81%) patients. Lymph node, bone, liver, lung and adrenal gland metastases were detected in 24 (42%), 17 (30%), 6 (10%), 4 (7%), 3 (5%) patients, respectively. Local recurrence was found in 8 patients. Peritoneal, penile and scrotal metastases were found in one of each patient. Ga-68 PSMA showed increased uptake in primary lesion in 3 patients who did not have a prostatectomy. All the lesions were detected by Ga-68 PSMA PET/CT were either suspicious for metastatic foci in the other imaging modalities or unknown for the clinicians. In one patient, a liver lesion evaluated as metastases by MRI did not show Ga-68 PSMA uptake. **Conclusion:** Ga-68 PSMA PET/CT seems to be a valuable imaging modality to evaluate local recurrence and/or metastatic disease in patients with prostate cancer patients who has a high PSA level and radiologically suspicious or negative for metastases.

EP273

Diagnostic Accuracy Of ^{68}Ga PSMA In High Risk Prostate Cancer & Its Comparison With CECT

V. Rangarajan, A. Agrawal, A. N, N. Purandare, S. Shah, G. Bakshi, G. Prakash, U. Mahantshetty, V. Murthy, S. Menon, A. Joshi; Tata Memorial centre, Mumbai, INDIA.

Aim - In the past few years ^{68}Ga PSMA has emerged as a useful investigational tool in evaluation of disease recurrence post biochemical relapse. It usefulness lies in detection of small nodal disease which remains undetected by morphologic imaging like CT or MRI. The aim of this study was to evaluate the diagnostic efficiency of ^{68}Ga PSMA and compare its efficiency with CECT (contrast enhanced CT) in high risk prostate cancer. Materials and Methods- 75 consecutive patients with carcinoma prostate who underwent ^{68}Ga-PSMA PET/CECT at initial staging were retrospectively analyzed. All were high risk prostate cancer with PSA level >20 ng/ml. The age range was between 47-83 years. 68Ga PSMA scans were analyzed to look for lymph nodal and visceral metastases. Increased uptake more than the background which did not correlate with physiological uptake was taken as a positive finding on PSMA scan. On CECT - the following criteria were taken for node positivity - >1 cm size in short axis and/or, rounded shape and/or, enhancement and/or, presence of necrosis. Results - PSMA was positive for locoregional nodes in 11 patients and CECT in 5. PSMA was positive for metastatic disease in 51 patients - by virtue of retroperitoneal nodes in 33 and by CECT in 28. The remaining 18 patients had only skeletal metastases. None of the patients had visceral metastases. The detection rates (DR) of PSMA were 100% for the primary (75/75). CT was not assessed for this as MRI is the imaging modality of choice. DR of PSMA was 15% (11/75) for locoregional nodes and 6% for CECT (5/75). DR rate of PSMA was 44% (33/75) for metastatic retroperitoneal nodes and 37% (28/75) for CECT. PSMA PET/CT had incremental value over CT in 14 % (11/75) of patients. It upstaged the disease from organ confined to Loco-regional in 8% (6/75) patients and loco-regional to metastatic in 6% (5/75) patients. Conclusion - ^{68}Ga PSMA proved to have better diagnostic accuracy in detection of locoregional and metastatic adenopathy over CECT in high risk prostate cancer.

EP274

Detection efficacy of hybrid ^{68}Ga-PSMA ligand PET/CT in 129 prostate cancer patients with suspected recurrence after primary radiation therapy

I. Einspieler, C. Hacker, I. Rauscher, M. Krönke, C. Rischpler, T. Maurer, M. Schwaiger, M. Eiber; TU München, München, GERMANY.

Purpose: The aim of this study was to investigate the detection rate of ^{68}Ga-PSMA PET/CT in a population of patients with suspected recurrence of prostate cancer, exclusively treated with external (photon or proton therapy) or internal beam therapy (brachytherapy) as primary treatment. Methods: We enrolled 129 patients for a retrospective analysis with proven biochemical recurrence using the ASTRO criteria. Median prostate-specific antigen (PSA) level was 6.1 ng/mL (range, 0-158 ng/mL). 87 and 42 patients had been treated by external (73 by photon and

14 by proton therapy) or internal radiation therapy, respectively. Of the 129 patients, 62 were receiving antihormonal treatment within at least 6 months prior to the PET/CT scan. The detection rates were correlated with different PSA levels. The contribution of primary Gleason score and antihormonal treatment to the final diagnosis was assessed. Results: 114 (88.4%) patients showed pathologic findings in ^{68}Ga-PSMA ligand PET/CT. The detection rates were 93.9% (31/33), 93.0% (40/43), 78.6% (33/42) and 90.9% (10/11) for PSA levels of ≥10, 5 to <10, 2 to <5 and 0 to <2 ng/mL, respectively. Remarkably, with regard to the ASTRO criteria, all patients with a PSA-value <2 ng/mL received antiandrogen therapy. ^{68}Ga-PSMA ligand PET/CT indicated local recurrence in 48 cases (42.1%), local and distant relapse in 28 cases (24.6%), only distant relapse in 38 cases (33.3%) and distant relapse with/without local recurrence in overall 66 cases (57.9%). No significant difference in detection efficacy was present regarding Gleason score (p =0.4421) and antiandrogen therapy (p = 0.2245). Conclusion: Hybrid ^{68}Ga-PSMA ligand PET/CT demonstrates substantially high detection rates in patients with suspected recurrence of prostate cancer after primary radiation therapy. It was able to detect extraprostatic disease in 57.9% of patients, potentially having substantial impact on further clinical management.

EP275

The PSMA-Agent Tc-99m-MIP-1404 in the Primary Staging of Biopsy Proven Prostate Cancer - Preliminary Results

M. Beck[1], J. Reinfelder[1], P. Ritt[1], J. Sanders[1], T. Bartschat[2], P. Goebell[1], T. Kuwert[1]; [1]University Erlangen-Nuremberg, Erlangen, GERMANY, [2]Hospital Martha-Maria Nuremberg, Nuremberg, GERMANY.

Purpose: The prostate specific membrane antigen (PSMA) is a relatively new target for molecular imaging. The purpose of our study was to investigate the potential of the PSMA-ligand Tc-99m-MIP-1404 in biopsy proven prostate cancer (PC) prior to therapy. **Methods:** Thirty patients with biopsy-proven medium- and high-risk PC (median PSA 8.8 ;Range 4.5 - 59) were referred for PSMA whole-body scintigraphy and SPECT/CT of the abdomen prior to planned surgery. Scans were performed 3 to 4 hours after injection of 740±19 MBq Tc-99m-MIP-1404. Two observers read the images for pathological uptake in the prostate, as well as for visceral and osseous metastases. Furthermore, standardized uptake values (SUV) were calculated based on quantitative SPECT/CT images. **Results:** The measured background activity in bone (SUV_{mean} 1.1±0.1) and soft tissue (SUV_{mean} 0.5±0.1) was low. In 28 patients, an increased focal or diffuse tracer uptake in the prostate gland was identified, with an average SUV_{max} of 16.5±18.9 (Range 4.4 - 107.3). Prostate SUV_{max} correlated significantly with the serum concentration of prostate specific antigen (PSA; r = 0.76, p < 0.01). Lymph node filiae (SUV_{max} 12.7±8.7) were suspected in three patients and confirmed by histology or CT in two. One patient had PSMA-positive bone metastases in a thoracic vertebral body (SUV_{max} 49.5) and the pelvic region; another patient had diffusely increased skeletal uptake caused by polycythemia vera (left femoral head SUV_{mean} 5.9). An additional seventeen patients in whom pelvic lymph node dissection was performed had no evidence of lymph node metastasis in imaging, which was confirmed by histology. **Conclusion:** Tc-99m-MIP-1404 is a promising PSMA agent with high tracer uptake in prostate cancer and the potential to inform preoperative staging of PC.

EP276

Is the ^{68}Ga-PSMA PET-CT the new benchmark for lymphnode staging in high risk prostate cancer patients:A comparative study with MRI?

M. Gupta, P. S. Choudhury, D. Hazarika, S. Rawal; Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA.

Abstract: Introduction: Lymphnode staging is an important step in high risk prostate cancer patients before a potentially curative treatment. Using size criteria Computed Tomography (CT) and Magnetic Resonance Imaging (MRI) perform similarly with a poor sensitivity for metastatic pelvic lymphnode. We compared lymphnode detectability of ^{68}Ga-PSMA PET-CT to MRI in high risk prostate cancer patients tacking histopathology as standard. Method: 39 high risk prostate cancer patients underwent staging ^{68}Ga-PSMA PET-CT in-between Dec-2014 to Dec-2015. 5 received radiotherapy & 2 high intensity focused ultrasound (HIFU) as primary treatments and 20 patients with distant metastasis on PSMA PET were excluded. 12 patients with radical prostatectomy (RP) with extended pelvic lymphnode dissection were analysed. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of ^{68}Ga-PSMA PET-CT and MRI were calculated for numbers of patients and lymphnode metastasis. Chi Square test, McNemar's test and ROC analysis were also done. Results: ^{68}Ga-PSMA PET-CT and MRI diagnostic sensitivity, specificity, PPV, NPV and accuracy for number of patients detection were 100%, 80%, 87.5%, 100%, 91.67% and 57.14% 80%, 80%, 57.4%, 66.67% respectively. For metastatic lymphnode detection findings were 66.67%, 98.61%, 85.71%, 95.95%, 95.06% and 25.93%, 98.61%, 70%, 91.42%, 90.53% respectively. Lymphnode detectability was better and statistically significant on Chi square test for ^{68}Ga-PSMA PET-CT. On McNemar's test, *P* value was insignificant for number of patient detection (*P* value 0.250) but significant for lymphnode detection (*P* value 0.001) for ^{68}Ga-PET-CT. In ROC analysis, AUC was also significantly high for lymphnode detectability by ^{68}Ga-PSMA PET-CT. Conclusion: We conclude, ^{68}Ga-PSMA PET-CT is a promising imaging modality for lymphnode staging in high risk prostate cancer with overall sensitivity (66.67%). It has the potential to impact patient's initial management and can upstage and down stage the disease. Therefore, it's worthwhile to use it before RP to assess disease volume and distribution in high risk patients. Key Words: ^{68}Ga-PSMA PET-CT, MRI, High risk prostate cancer, pelvic lymphnode comparison

EP277

Utility of 68Ga-PSMA-PET/CT in Prostate Cancer with Biochemical Recurrence with PSA≤1

L. Geraldo[1], C. Uprimny[1], D. Kendler[1], A. Kroiss[1], B. Nilica[1], L. Scarpa[1], C. Decristoforo[2], A. Griesmacher[3], P. Lukas[4], W. Horninger[5], I. Virgolini[1]; [1]Nuklearmedizin Universitätsklinik Innsbruck, Innsbruck, AUSTRIA, [2]Radiopharmazie Universitätsklinik Innsbruck, Innsbruck, AUSTRIA, [3]Labordiagnostik Universitätsklinik Innsbruck, Innsbruck, AUSTRIA, [4]Strahlentherapie Universitätsklinik Innsbruck, Innsbruck, AUSTRIA, [5]Urologie Universitätsklinik Innsbruck, Innsbruck, AUSTRIA.

Aim ^{68}Ga-Prostate Specific Membrane Antigen (PSMA)-ligand-PET/CT is a new imaging method that allows the exploration of patients with biochemical recurrence (BR) of PC after curative primary treatment (mainly radical prostatectomy (RP) and radiation therapy (RT)). Up to 40% of PC patients will develop BR, evidenced by a rise in serum prostate-specific antigen (PSA) levels within 10 years after primary treatment. Hence, the importance of early detection and localization of recurrent disease. In this study we evaluated the utility of ^{68}Ga-PSMA-HPED-CC-ligand PET-CT in the detection of lesions in patients with PC and BCR with a PSA≤1. **Methods** 32 consecutive patients with recurrent PC after curative primary treatment and PSA≤1 were included (mean age: 67, range: 40-81 years); mean time from initial diagnosis: 6 years). All patients underwent a ^{68}Ga-PSMA-HPED-CC-ligand-PET/CT whole-body acquisition at 60 min after intravenous injection of ^{68}Ga-PSMA-HPED-CC-ligand-PET/CT (mean dose 140, range: 103-159 MBq). 19/32 patients (26%) had PSA≤0.5. 31 patients had RP and 11 local RT as curative treatment after initial diagnosis. **Results** 14/32 patients (44%) demonstrated pathologic lesions in ^{68}Ga-PSMA-HPED-CC-ligand-PET/CT,

1/32 (3%) local relapse, 9/32 (28%) showed lymph node relapse and 4/32 (13%) patients had distant metastases. In 8 patients a doubtful uptake in the prostatic PET was observed, not considered as clear local relapse. 5/19 patients (26%) with PSA≤0.5 were pathological in ^{68}Ga-PSMA-HPED-CC-ligand-PET/CT imaging, 4/5 showed positive lymph nodes, and only one had a distant metastasis. **Conclusion** ^{68}Ga-PSMA-HPED-CC-ligand-PET/CT imaging can help to identify BR in PC patients, even with PSA≤1, and therefore has a significant implication for treatment strategy, also in this subgroup of patients.

EP278

Impact of 68Ga-PSMA PET/CT in the Assessment of Prostate Cancer Patients with Biochemical Recurrence

M. Beheshti[1], C. Schiller[1], B. Aschacher[2], H. Geinitz[2], L. Imamovic[1], J. Kaufmann[1], C. Pirich[3], W. Loidl[4], W. Langsteger[1]; [1]PET-CT Center Linz, St. Vincent's Hospital, Linz, AUSTRIA, [2]Department of Radiation Oncology, St. Vincent's Hospital, Linz, AUSTRIA, [3]Department of Nuclear Medicine, Paracelsus Medical University, Salzburg, AUSTRIA, [4]Prostate Cancer Center Linz, Department of Urology, St. Vincent's Hospital, Linz, AUSTRIA.

Aim 68Ga-PSMA (PSMA) PET/CT is introduced as promising imaging in assessment of prostate cancer (PCa). This study is planned to evaluate the value of 68Ga-PSMA PET/CT in prostate cancer (PCa) patients with evidence of biochemical recurrence (BCR). **Material & Methods** In this prospective study 100 consecutive PCa patients (mean age 68 ± 8) with evidence of BCR underwent 68Ga-PSMA PET/CT. Radiotherapy and/or hormone therapy was performed in 36 patients while 54 patients had no treatment after radical prostatectomy (RPE). PET/CT imaging was performed 60 min. after intravenous injection of 140 MBq Glu-NH-CO-NH-Lys-(Ahx)-[68Ga(HBED-CC)] (68Ga-PSMA) with 3min./bed position acquisition time. Pathologic findings in each imaging modalities have to be clarified histopathologically or by conventional imaging modalities and/or clinical follow-up. **Results** 68Ga-PSMA PET/CT was able to localize recurrent disease in 83% (83/100; 47 pts without previous treatment & 36 pts with previous and/or ongoing therapy; PSA range: 0.01 - 56.6 ng/ml) of the patients. PSA value was ≤ 0.5, 0.6 - 1.0, 1.0 - 2.0 and > 2.0 ng/ml in 24 %, 7 %, 11 % and 40 %, respectively, in ^{68}Ga-PSMA PET-positive patients. 68Ga-PSMA PET/CT was negative in 17 % of the patients with a PSA range of 0.01 - 3.7 (10 pts under hormone therapy and 7 patients without any ongoing treatment). It was able to detect local recurrence (LR) in 33 %, lymph node metastases (LNM) in 35 % and bone metastases (BM) in 11 % of the patients. In 4 % of the cases all LR, LNM and BM were detected. **Conclusion** 68Ga-PSMA PET/CT showed a sensitivity of 83 % in the detection of recurrent disease in prostate cancer. It seems to be a very promising diagnostic procedure even in low PSA level ≤ 0.5.

The Value of SPECT Lymphoscintigraphy for Sentinel Lymph Node (SLN) mapping in melanoma

A. Velidaki, A. Kolindou, M. Karkani, N. Prosotsianiotis, E. Dagrakis, E. Kitsou; Nuclear Medicine Dept,, Laiko General Hospital of Athens, ATHENS, GREECE.

Introduction: Lymphoscintigraphy is a sensitive, inexpensive, non-invasive imaging modality that allows SLN identification in patients with malignant melanoma. Several techniques have been described: planar imaging (PL), tomographic imaging (SPECT) and more recently (where available) SPECT/CT imaging. The aim of our study was to assess the benefit of SPECT to PL lymphoscintigraphy in presurgical SLN mapping. Materials and method: We studied 73 patients with melanoma (24women, 49 men, age 30 to 80 y.o.). The technique involved the peritumoral injection of 1-2 mCi Tc-99m-nanocolloid. Planar images according to the expected sites of SLN were obtained 5 minutes p.i. The first hot spot in the lymphatic drainage represents the SLN and it was marked to the skin as a guide to the surgeon. The same was performed if more than one SLN were detected. Sequentially, SPECT imaging was performed and the number of the SLNs detected from the reconstructed images was evaluated. PL and SPECT results were compared to the findings of the surgery. Results: A total of 196 SLNs were surgically resected in all 73 pts (1 SLN in 22 pts, 2 in 19 pts, 3 in 17 pts and >3 in 17 pts). The total number of SLNs identified by PL was 138 and by SPECT imaging was 189; 13/189 detected SLNs were near the injection site and they were not detected by PL. SPECT accurately identified at least 1 SLN in all 73 patients (identification rate of 100%). In a single case PL failed to image any SLN. Agreement between surgery and PL regarding the number of SLNs was in 32/73 pts, while SPECT accurately predicted the number of surgically identified SLNs in 64/73 pts. Conclusion: SPECT imaging detects more sentinel nodes than conventional planar imaging. Nodes near the injection site are more clearly identified with SPECT.

EP280

Selective lymph node biopsy in patients with adenocarcinoma of the prostate with intermediate and high-risk our experience

V. Vera Pinto; Hospital Universitario y Politécnico La Fe, Valencia, SPAIN.

OBJECTIVE To determine the effectiveness of Selective Lymph Node Biopsy (SLNB) in patients with adenocarcinoma of the prostate with intermediate and high risk. MATERIAL AND METHODS Descriptive study of 55 patients with mean age of 64,8 (50-75 years old) in which SLNB was performed between August 2012 to january 2016 after ruling out distant metastases with bone scintigraphy. All patients were diagnosed with prostate adenocarcinoma in intermediate or high risk stages with a mean serum PSA of 9.65ng/ml (range 4 - 46,39 ng/ml). The day before surgery, 10 mCi (370 MBq) of nanocolloids labelled with ^{99m}Tc were injected within the prostate guided by transrectal ultrasound while simultaneously abdominopelvic acquisitions were made with portable gamma camera (Sentinella®) to ensure intraprostatic deposit of the tracer. 2 hours later planar abdominopelvic acquisitions and SPECT / CT (Phillips BrightView XCT®) were performed to obtain definitive lymph node mapping. In all cases, standard pelvic lymphadenectomy was performed by Laparoscopic technique, however, it will become extended in cases where migration of the tracer reaches unusual lymphatic territories. Abdominopelvic acquisitions with Sentinella®, pre and post lymphadenectomy were also done in the operation room. All sentinel lymph nodes (SLNs) were removed and examined with haematoxylin and eosin staining and immunohistochemical techniques RESULTS In 100% of cases there was migration of the radiotracer with positive scintigraphy. 25.4 % (14/55) of patients presented metastatic SLN infiltration. 74.5 % of patients (41/55) were true negatives, obtaining negative predictive value of 100%. 41 patients (74,5%) present unusual lymphatic drainage to paraaortic chains 41,8 %, , presacral chains 36,3 % and 43.8% common iliac chain. In this group of patients, 7.3% (3/41) presented metastatic infiltration of atypical SLN. CONCLUSION SLNB in prostate cancer is a reliable and useful tool, capable to identify first landing lymphatic chains of the prostate, allowing properly assessment of lymph node involvement in prostate cancer. It is also a useful technique to detect patients with atypical prostate lymphatic drainage. If SLNB wasn´t performed a potential metastatic node would be involved but not resected, and that allows the surgeon to recognize when to perform an extended lymphadenectomy.

EP281

Radioguided Occult Lesion Localization in Reoperative Procedures of Patients with Locoregional Metastases of Papillary Thyroid Cancer

I. SAHINER[1], G. U. VURAL[1], M. A. GULCELIK[1], I. KERIMEL[1], T. SENGEZER[2], S. ILGAN[2]; [1]Ankara Oncology Research And Training Hospital, ANKARA, TURKEY, [2]Ankara Güven Hospital, ANKARA, TURKEY.

Purpose/Introduction : Surgery is the preferred modality of treatment in locoregional recurrences of papillary thyroid cancer(PTC) providing improved disease control. However, reoperative surgery in patients with previous neck exploration in either central and/or lateral compartments carries increased risks associated with surgery in addition to diminished operative success. The aim of our study was to determine if radioguided occult lesion localization(ROLL) technique was feasible in terms of surgical success and reduction in complication rates in reoperations of PTC recurrences. Subjects and methods:Sixteen consecutive patients (12 female, 4 male) who were previously operated for PTC with cytological proof of locoregional recurrences in the previously operated neck compartments were included in the study. Preoperative mapping and injection of Tc-99m labeled macroaggregated albumin into selected lesions were performed under guidance of ultrasonography (US). Surgical exploration was carried out according to the US map and labeled lesions were localized with a handheld gamma probe intraoperatively. After the excision of lesions; counts from the background, lesion and postexcisional site were compared to confirm the success of the procedure. All excised specimens were evaluated histopathologically and serum levels of thyrotropin(TSH), thyroglobulin(Tg), anti-Tg antibodies and calcium were recorded for each patient before and (minimum 45 days) after the surgical procedure. Results: Mean patient age was 47 (range: 17-69). Thirteen of the patients had previous therapies with radioiodine (cumulative activity range:100-1150mCi, median:250mCi). The smallest lesion injected was 5x5mm and the largest was 16x18mm in two dimensions. An average of 2.13 injections were performed per patient (range:1-5). A total of 79 suspicious lesions were detected preoperatively, 143 lesions were excised and 75 were histopathologically proven to be infiltrated by PTC. Serum Tg and/or anti-Tg levels of 14 patients displayed reductions on similar pre- and post-operative TSH levels, whereas serum Tg levels of one patient rised after the surgery and lung metastases were detected in follow up. In the remaining no rise in Tg and/or anti-Tg serum levels were present before and after the surgery. Ductus thoracicus injury occured only in 2 patients, without any chyle leak in the follow up period. Discussion/ Conclusion: ROLL technique and lesion mapping under preoperative US guidance is a safe and efficient method in terms of surgical success with reasonable complication rates in reoperations of locoregional PTC recurrences.

EP282

Preoperative sentinel node visualisation in breast cancer using portable gamma cameras

D. M. V. Huizing[1,2], L. J. de Wit - van der Veen[1], B. Pouw[1], C. H. Slump[2], M. P. M. Stokkel[1]; [1]Netherlands Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS.

Aim Portable gamma cameras (PGCs) are routinely used during surgical radio-guided sentinel node (SN) procedures in our hospital. The high spatial resolution and sensitivity of these real-time imaging systems ensure precise visualisation of SNs during resection. Up-to-now the role of PGCs in a preoperative setting has been limited. Accordingly the aim of this study was to assess if PGC imaging could substitute conventional gamma imaging in preoperative breast cancer SN detection. **Materials and methods** Sixteen patients scheduled for breast conserving surgery (BCS) and SN procedure were prospectively included. Conventional lymphoscintigraphy was performed 15 minutes and 3 hours after intratumoural injection of ± 140 MBq Tc-99m albumin nanocolloid. PGC acquisition and image interpretation were performed 2.5 hours post-injection by an experienced user blinded for conventional gamma imaging results. Additional PGC imaging was performed 22 hours (shortly before surgery) post-injection to evaluate the visibility of the SNs. The breast, axillary and parasternal regions were imaged from 15 cm distance (field-of-view 20x20 cm) and close to the skin. **Results** SNs were visualised in 81% of the patients by PGC, where conventional imaging showed nodes in 69% of the patients, performed 2.5 and 3 hours post-injection respectively. PGC visualised 9/10 axillary nodes detected by the conventional gamma camera. In two patients, PGC imaging showed an axillary SN which was not visualised on the conventional gamma camera. Axillary nodes were most important, since parasternal and intramammary nodes generally are not surgically removed in this group of patients. Twenty-two hours post-injection, SNs were visible in 56% of the patients using PGC. The main advantage of using the PGC for preoperative imaging was to assess the number and location of SNs, however intraoperative benefit of the PGC was limited. Preoperative breast cancer SN imaging using a PGC reduces time and costs compared to conventional gamma imaging. Furthermore, extra acquisition time for more complex gamma imaging is created. For this reason, PGC imaging would be best performed at the Nuclear Medicine department, and in this way also the possibility for reinjections remains. **Conclusion** The sensitivity of PGC imaging for SN detection in breast cancer patients is comparable to conventional gamma imaging; both performed 2.5 to 3 hours post-injection after ± 140 MBq of radiotracer administration. Preoperative SN detection using the PGC at the department of Nuclear Medicine reduces time and costs compared to conventional gamma imaging, enabling more conventional gamma acquisitions for other indications.

EP283

Feasibility of ^{18}F-FDG PET/CT-guided Cytoreductive Surgery (CRS) and Hyperthermic Intraperitoneal Chemotherapy (HIPEC) in patients with pertioneal carcinomatosis : a Preliminary Experience

S. Lee[1,2], D. Lee[3], K. Oh[4], D. Jeong[4], C. Lee[5], E. Kim[3], S. Oh[6], J. Choe[2,7]; [1]Department of Nuclear Medicine, G Sam Hospital, Hyosan Medical Foundation, Gyeonggi-do, KOREA, REPUBLIC OF, [2]Department of Medicine, Graduate School, Korea University, Seoul, KOREA, REPUBLIC OF, [3]Department of Medical Oncology, G Sam Hospital, Hyosan Medical Foundation, Gyeonggi-do, KOREA, REPUBLIC OF, [4]Department of General Surgery, G Sam Hospital, Hyosan Medical Foundation, Gyeonggi-do, KOREA, REPUBLIC OF, [5]Department of Oncologic Surgery, G Sam Hospital, Hyosan Medical Foundation, Gyeonggi-do, KOREA, REPUBLIC OF, [6]Department of Nuclear Medicine, National Police Hospital, Seoul, KOREA, REPUBLIC OF, [7]Deptment of Nuclear Medicine, Korea University Anam Hospital, Seoul, KOREA, REPUBLIC OF.

The prognosis of patients with secondary peritoneal carcinomatosis (PC) remains poor, despite of the variable best standard treatment options. Recently, cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) has been developed to treat PC. But there reported considerable complications, morbidity, and mortality owing to the aggressiveness of the surgery. Therefore, exact pre-surgical determination of localization and extent of PC is crucial for the clinical outcome. This study aims to review our preliminary experience with ^{18}F-Fluorodeoxyglucose (^{18}F-FDG) PET/CT-guided CRS and HIPEC in patients with PC, which could be expected as less invasive technical procedures in the way that pre-surgical mapping and planning surgical procedure are possible. Seven patients (3 men and 4 women; mean age 62.3 years; range 60-72) with secondary PC from April 2015 to March 2016 were enrolled in this study. Underlying primary malignancy sites were ovarian cancer (n=2), colorectal cancer

(n=2), malignant peritoneal mesothelioma (n=1), and pancreatic cancer (n=2). All patients had been examined on pre-operative staging ^{18}F-FDG PET/CT. PET/CT image were assessed and analysed as positive or negative, regarding presence and localization of PC manifestations based on the peritoneal cancer index (PCI) by Sugarbaker et al.. Patients underwent CRS and HIPEC within 10 days afterward of pre-op PET/CT. PET/CT images were assessed and correlated with surgical reports and pathologic confirmation. Post-surgical PET/CT exams were performed on one-month later for assessment of the residual tumor burden in three patients. Total 79 peritoneal segments in 7 patients were surgically removed and sampled during CRS HIPEC (PET positive segment n=62, PET negative segment n=17). PET/CT provided a reliable detection of PC. In summary, 1 peritoneal segment was classified as a false positive and 5 segments were as false negative group. Diagnostic performance of ^{18}F-FDG PET/CT-guided CRS HIPEC in patients with PC was sensitivity 92%, specificity 94%, PPV 98%, NPV 77%, and diagnostic accuracy 92 % with lesion-by lesion analysis. Moreover, we could be notified a dramatically decreased metabolic tumor burden of PC after CRS HIPEC with comparison of pre- and post-surgical ^{18}F-FDG PET/CT in three patients who underwent post-surgical PET/CT examination. ^{18}F-FDG PET/CT-guided CRS HIPEC appears to be technically feasible and effective in patients with excessive pertitoneal metastases. This is a pilot study with limited number so further studies are needed to elucidate its precise role in the patient-tailored multimodality management.

A novel device for true PET guided biopsies: First accuracy tests

J. Cortes-Rodicio[1], G. Sanchez-Merino[1], I. Tobalina Larrea[2], M. Garcia-Fidalgo[1]; [1]S° Fisica Medica, OSI Araba, Hospital Txagorritxu, Vitoria-Gasteiz, SPAIN, [2]S° Medicina Nuclear, OSI Araba, Hospital Santiago, Vitoria-Gasteiz, SPAIN.

INTRODUCTION AND OBJETIVES: PET/CT guided biopsy is a relative new technique in which metabolic information from a previously acquired PET/CT scan is integrated into a CT guided biopsy procedure. Besides, there are examples of real PET guided biopsy procedures in which a radioactive source is coupled to the biopsy needle and is introduced into the patient. Many drawbacks arise from both procedures: incorrect positioning of the patient, sterilization of radioactive needles, expensive radioactive sources, radiation protection of patients and staff… In this work we present a novel device to perform true PET guided biopsies avoiding the problems of previous procedures and improving the biopsy process. **METHODS AND MATERIALS:** A first prototype of the stereotactic frame has been built with a 3D printer. It consists of four main components: A fixed circular base, an outer circular rotating crown with a U-shaped fixed piece, a header that moves along the U-shaped piece and a needle holder. The primary base constrains three holders where radioactive markers doped with 18-FDG are introduced. Another marker is attached to the outer end of the needle. These four markers will be the only visible points of the device in PET images. Once the device is mounted, a spherical coordinate system is built with the entrance needle point in the skin as the origin of coordinates. Two in-house software programs have been written in ImageJ macro language. The first one obtains the spherical coordinates (θ, φ and *depth*) of the tumour tissue that want to be punctured with respect the stereotactic frame. After the puncture, a biopsy verification is performed to assess that the needle is placed at the desired point. To this end, the second program draws the inner end of the needle in the PET image. **RESULTS:** For testing purposes of the prototype, a gel tumour phantom was built to test the PET guiding device. It consists on a dissolution of FDG (2.5kBq/ml) in which a sphere of 10mm of diameter and an activity concentration of 4:1 with respect the background is settled. After all biopsy procedures we found the needle tip inside the tumour, with an accuracy of less than 5mm with respect the center of the sphere. **CONCLUSIONS:** A first prototype has been built and tested successfully. Anyway some improvements have to be developed and more trials have to be done to further characterize the device

EP285

Lymphatic drainage patterns in breast cancer recurrence with previous surgical interventions - our experience

A. Fernandes, T. Faria, A. Oliveira, M. Perez, V. Alves, A. Pinto, J. Pereira; Hospital São João, Porto, PORTUGAL.

Aim: The aim of this study was to determine the drainage patterns in patients with breast cancer recurrence who had been submitted to previous surgical interventions, and underwent a sentinel node procedure at our department. **Introduction:** Lymphoscintigraphy determines lymphatic drainage of the breast and identifies the sentinel node(s) (SLN). Lymphatic drainage of the breasts occurs predominantly to the ipsilateral axilla, but it can occur to other locations, especially in patients with prior interventions, like chest and axillary surgery. **Materials and Methods:** We reviewed data from all patients who underwent lymphoscintigraphy at our department from November 2009 to March 2016 (n=560), and selected the patients with breast cancer recurrence that had been submitted to previous surgical intervention. A total of 33 patients were enrolled. **Results:** In 11 of the 33 patients reviewed, no drainage was observed. The other 22 (detection rate of 67%) showed multiple drainage patterns: 13 ipsilateral axillary nodes, 7 contralateral axillary nodes, 6 ipsilateral internal mammary nodes, 1 contralateral internal mammary node, 3 intramammary nodes, 1 supraclavicular node, 1 infraclavicular, 2 intercostal nodes and 1 pectoral node. **Conclusion:** Our results demonstrate a diversity of drainage patterns in the patients with breast cancer recurrence who had been submitted to previous surgical intervention. Routine lymphoscintigraphy should therefore be mandatory in this group, as it may significantly impact staging, therapy approach and prognosis.

Clinical outcomes of sentinel lymph node biopsy in breast cancer patients. Our follow up experience

S. M. Nieves Maldonado[1], S. Argibay Vázquez[2], M. Garrido Pumar[1], P. Fierro Alanis[1], L. Souto[3], B. Vidal[4], V. Pubul Nuñez[2], B. Fernández[5], O. D. Rodríguez Fónseca[6], Á. Ruibal Morell[2]; [1]Nuclear Medicine Department. Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, SPAIN, [2]Nuclear Medicine Department. Hospital Clínico Universitario de Santiago de Compostela. Grupo de Imagen Molecular e Oncología, Instituto de Investigación Sanitarias (IDIS), Santiago de Compostela, SPAIN, [3]Gynecology Department. Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, SPAIN, [4]General Surgery Department. Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, SPAIN, [5]Pathologic Anatomy Department. Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, SPAIN, [6]Nuclear Medicine Department. Hospital Central de Asturias., Oviedo, SPAIN.

Purpose: Our aim is to evaluate the clinical outcomes after a sentinel node biopsy in patients with breast cancer followed up at our institution. Methods: Our study involved 828 consecutive breast cancer patients who underwent isotopic detection of SLN in our department. Lymphoscintigraphic images were acquired after injection of 111 MBq of Tc^{99m} nanocolloid for SLN mapping. SLN localization at surgery was performed using a hand-held gamma probe. Sentinel nodes were studied intraoperatively and axillary lymphadenectomy was indicated in SLN positive cases. Results: The median follow-up time for the study was 4.5 years (range 1-9 years). The mean age of patients was 58 years (range 28- 88 years), most of them were staged as I (47%, n: 386) and IIa (29%, n 237) according to TNM 7th edition. The most prevalent tumor type was infiltrating ductal carcinoma (77%), and the most frequent molecular diagnosis was Luminal A (68 %). The pre-surgical lymphoscintigraphic images showed tracer migration to the SLN in 91% of patients included

(755), showing lymphatic drainage to axillary region (n: 751 - 99.5 %), as well as the internal mammary chain (10%), clavicular region (6 %) and intramammary region (5%). A mean of 2,6 sentinel lymph nodes were resected per patient (range 1-6 SLN).The pathology results were negative for malignancy in 63% of cases (478). From the 277 positive for malignancy SLN, 108 presented micrometastases. Lymphadenectomies were performed in 268 positive for malignancy patients. The 32% of these lymphadenectomies were positive for malignancy (86). The breast cancer committee decided that 9 patients with micrometatsis should not recieve lymphadenectomy, 5 of them were SLNB prior to neodajuvant chemotherapy cases and the remaining 4 were derived to radiotherapy. Almost every patient included in the study presented a favorable follow up 94 % (780), 6 developed local recurrence (0.7%). Only one patient presented axillary recurrence (0, 1%), it was a positive for malignancy SN due to micrometastasis which was not considered for lymphadenectomy, and was detected as a recurrence at the sixth year of follow-up. Metastases appeared over time in 16 patients (1.9%). The 3% of patients died (25) due to different reasons, and only 8 of the deaths were secondary to the breast cancer. Conclusion: Our results allow us to indicate that adequate local control is achieved with favorable outcomes after many years of follow up by application of the SLN techniques as lymphatic staging tools for breast cancer patients.

EP287

Sentinel node biopsy after neoadjuvant therapy in breast cancer patients

J. Duch, F. Ascencio, B. García Valdecasas, E. Capdevila, A. Moral, A. Domènech, D. López, I. Carrió; Hospital de la Santa Creu i Sant Pau, Barcelona, Barcelona, SPAIN.

Aim: We previously validated sentinel lymph node dissection (SLND) after neoadjuvant therapy (NT) in a group of 30 breast cancer patients. We have evaluated the results 6 years after validation. **Methods:** Between february 2010 - december 2015, 170 breast cancer patients (T2-3, N0-1, M0) were treated with NT. After then all patients were N0. After the SLND, complete axillary lymph node dissection (ALND) was only performed in those with sentinel node metastases or not located. **Results:** 81 patients (48%) were N1 before NT, but all were N0 when the treatment was finished. Whole SLND identification rate was 92% (85% in initial N1 patients and 98% in initial N0 patients). In 14 patients (2 N0 and 12 N1) SLND was not found. Only 7 of these ALND was positive. Among located SN, 36 of them were positive. Among the 170 patients we have been able to avoid 120 axillary dissections (70%) (37 of them were initially N1). With the follow-up, only 1 patient has developed local recurrence and 11 patients distant metastases, but none of them has developed axillary recurrence. **Conclusion:** SLND after NT is safe and feasible in breast cancer patients, not only in initially N0 but also in initially N1. It accurately predicts the status of the axilla and avoids unnecessary ALND.

The clinical management of a suspect lesion relies not only on diagnosis of benign vs malignant, but also on tumor grading, immunohistochemistry and genetic information. Biopsy of suspect tissues is required for diagnosis and planning an adequate treatment. Open incisional biopsy (OIB) is traditionally the method of choice, providing an accuracy of approximately 100%, neverthless is associated with several drawbacks. The development of imaging-guided biopsies (CT,US) has almost overcome these disadvantages: safe, easy to perform, less invasive and with a good accuracy. However, in recent literature a variable amount of non-diagnostic imaging guided procedures is reported. FDG PET/CT is a functional imaging technique capable of interrogating the metabolic characteristics of masses, with a very high sensitivity. Inherent advantages include early detection of malignancy, (sometimes before changes are evident morphologically), and concerning inhomogeneous tumors, FDG uptake is higher in the most malignant part of the lesion, lower in the most differentiated components and absent in necrotic/fibrotic areas. In the period 11/2014-10/2015 were selected 11 patients with unclear hypermetabolic findings (more lesions with variable SUVmax, small lesions, large inhomogeneous masses; 7F,4M, mean age 56). 9/11 had a suspect malignancy relapse (4 anorectal, 2NHL, 2 gynecologic, 1 Langherans Histiocytosis), 2/11 was a first diagnosis. 5/11 had a previous non diagnostic CT-guided biopsy. FDG PET/CT guided biopsy was performed by trained doctors (interventional radiologist/orthopedic, nuclear medicine and pathologist): after a PET/CT target on the lesion were identified its skin projections and local anaesthesia was performed. The biopsy needle was tracked by driving its progression towards the highest SUVmax through seriated PET/CT acquisition (1bed/position; acquisition time 1'). On average, the procedure lasted 1h/patient. The sample was laid down on adhesive glass slide for cytological extemporaneous exam, were tested its adequacy (if not, repeated) and, sometimes, for an immediate diagnosis. 9/11 pts had a definitive diagnosis after PET/CT biopsy (1TBC, 1 sacral chordoma, 2 rectal ca relapse, 2NHL, 2 gynecological ca, 1 Langherans Histiocytosis) while 2 pt with suspect rectal relapse had non pathological findings (1 post-RT scar tissue, 1 muscular tissue). These pt are currently negative after 18 months follow-up. No pts had complications. FDG PET/CT guided biopsy is feasible and safe in the clinical practice. It impacted positively on the time to treatment onset, especially in pt with a previous non diagnostic procedure. Further issues to be discussed are the dose (pt and operators), scanner occupancy, real time/non real time acquisition, non FDG tracers.

EP289

The diagnostic performance of sentinel lymph node biopsy after neoadjuvant chemotherapy in patients with node negative and node positive breast cancer: prospective single centre trial

S. N. Novikov, S. Kanaev, P. Krivorotko, E. Trufanova, P. Krzhivitskiy, L. Jukova; N.N. Petrov Institute Oncology, St Petersburg, RUSSIAN FEDERATION.

Purpose: to evaluate diagnostic accuracy of sentinel lymph node (LN) biopsy (SLNB) after neoadjuvant chemotherapy (NAC) in patients with breast cancer (BC). The secondary end point was to determine whether SPECT-CT with 99mTc-MIBI can guide patient selection for SLNB. **Material & Methods:** From May 2014 to March 2016, 62 women with BC were accrued to the study. Before the start of NAC all patients underwent routine clinical staging with obligatory addition of SPECT-CT scintimammography (SMG) with 99mTc-MIBI. In 44 women with suspiciously abnormal axillary LN ultrasound examination was supported by

aspiration biopsy. According to clinical examinations 40 women were node-positive and 22 - node-negative. After 2-3 cycles of NAC and before surgery efficacy of treatment was evaluated by ultrasound and SMG. In all cases accuracy of SNLB was verified by standard axillary LN dissection. **Results:** All 62 women included in analysis underwent successful SLNB: metastases in SLN were revealed in 26 cases, false negative results obtained in 4, true negative - in 31patients. False negative rate (FNR) was 13%. Average number of positive LN in SLNB positive group was 3.92: on axillary dissection 16 of 26 (61.5%) patients had 3 or more metastatic LN. In 25 women with prominent and complete scintigraphic response to NAC sentinel LN were positive in 7 cases, SLNB was true negative in remained 18 women, FNR - 0%. In 31 patients with negative LN on pre-surgery SMG SLNB revealed metastases in 6 of 7 women with positive LN diagnosed on axillary dissection: FNR - 14%. **Conclusion:** 1) High FNR of SLNB after NAC dramatically reduced to zero in women with prominent-complete BC response detected by SMG at the end of NAC. 2) Axillary dissection should be recommended in all patients with positive SLNB after NAC.

EP290

Sentinel Lymph Node Biopsy in penile squamous cell carcinoma: review of our experience

J. Rodríguez-Rubio Corona, R. Jaller Vanegas, J. Suils Ramón, M. Boya-Román, G. Martínez-Pimienta, A. Benítez Segura, E. Noriega Álvarez, J. Suárez Novo, J. Mora Salvadó, M. Bajén Lázaro; Hospital Universitari de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, SPAIN.

AIM: To analyse our experience in the applicability of sentinel lymph node biopsy (SNLB) in patients with squamous cell carcinoma METHOD: Retrospective review. 18 p with previous primary surgery for penile cancer (T_{1-4}, G_{1-2}) were included (June 2002-April 2016). Two groups were performed based on clinical groin lymph node status previous SLNB: group A (patients with clinically negative lymph node, cN0) and group B (patients with unilateral clinically groin nodes metastases (cN+). All patients underwent preoperative lymphoscintigraphy with 99mTc-Nanocolloid and radioguided surgery to evaluate the nodal status in group A, and contralateral nodal status in group B. Ipsilateral lymphadenectomy was performed in patients who had positive sentinel lymph node (SLN). Parameters analyzed: scintigraphy and surgical sentinel node detection; SLN status and lymphadenectomy status when it was performed, and lymph node recurrence in both groups after a median follow-up of 84,5 months (1 month - 168 months). RESULTS: 10/18 patients (p) (55.6%) were cN0 and SLNB was requested to study bilateral groin (group A). 8/18 p (44.4%) had unilateral cN + and SLNB was requested to study contralateral groin (group B). Scintigraphic and surgical detection was 100% in both groups. SLN was negative in 8/10p (80%) in group A and in 7/8p (87.5%) in group B. SLN was positive in 3/18p (16.7%) (2p in group A and 1p in group B) and lymphadenectomy was performed in 2/3 (only 1p had positive nodes). 1p of group B developed lymph node recurrence 6 months after SLNB. The scintigraphy showed multiple hot spots, but only two SLN were biopsied at surgery, so residual activity remained (>10%). CONCLUSION:Despite the short series of patients studied, SLNB is applicable in cN0 patients to stage bilateral lymph node involvement, and in unilateral cN+ patients to stage contralateral lymph node involvement. Both groups benefit of less morbidity associated to SLNB technique.

EP291

Usefulness of Radioguided Occult Lesion Localization for small intraparenchymal or non palpable lung lesions. Preliminary results

s. fuertes, J. Sanchez, J. Moradiellos, A. Villalba, S. Amor, M. Velasco, A. Varela, A. Maldonado; Quiron Madrid University Hospital, Pozuelo de Alarcon (Madrid), SPAIN.

Objectives: Peripheral subpleural solitary pulmonary nodules can be visualized and resected easily at thoracoscopy , but it is very difficult to localize deep non-palpable pulmonary nodules that lie in lung parenchyma. The aim of this study is to evaluate usefulness of Radioguided Occult Lesion Localization (ROLL) for intraparenchymal or non-palpable lung lesions. **Methods**: This is a prospective study performed from August 2014 to February 2016. 11 patients with suspicious small intraparenchymal or non-palpable lung lesions were offered and consented to the procedure as part of a single diagnostic-therapeutic minimally-invasive surgical approach. The day before or the same day, underwent computed tomography (CT)-guided injection of a solution, composed of 0.2 ml 99mTc-labeled human serum albumin microspheres (1-5 mCi) and 0.1 ml nonionic contrast, into the nodule or into the area just in contact with it, using a 25 G needle. The site of injection were confirmed by CT scan and scintigraphy image. Intraoperative lesions were localized and excised during surgery using a laparoscopic gamma probe, followed by frozen-section analysis. **Results:** No complications were reported after the injection. The diameter of lung lesions ranged from 4-23 mm as measured by CT. In 10/11 cases the gamma-detection was successful and 1 case was considered unsuccessful because the most of the activity was detected in the chest wall but a puncture mark in the lung allowed for a successful localization of the lesion. 4 of 11 cases, who revealed primary lung cancer after frozen-section examination underwent video-assisted thoracoscopic lobectomy except one case lobectomy were performed with a full robotic technique. 4 cases showed metastasis and 3 cases revealed benign lesion. **Conclusions:** Our initial results demonstrate that ROLL guided by CT is useful and simple technique for complete excision undiagnosed lung lesions, particularly in small intraparenchymal or non-palpable ones. It avoids problems such as wire-guide dislodgment and dye diffusion and it may be particularly useful for fully-VATS or robotic approaches, without need for digital palpation.

EP292

ROLL and SNOLL in breast carcinoma patients after NeoAdjuvant Chemotherapy (NAC) treatment

S. Maccafeo[1], S. Chiusaroli[1], F. Fiore Melacrinis[1], S. Ghinassi[1], A. Massari[1], A. Piccinetti[1], A. Ricci[2], E. Ruggeri[1], E. Pofi[1], P. Frittelli[1], R. Schiavo[1]; [1]Belcolle Hospital, Breast Unit, Viterbo, ITALY, [2]Belcolle Hospital, Medical Physics Unit, Viterbo, ITALY.

Aim: Surgical planning after NAC in breast cancer patients may be difficult as the clinical impact of imaging techniques based on pre-treatment "marker" insertion after a complete treatment response may be cumbersome in helping the surgeon to clearly detect the tumoral bed and perform total excision. The feasibility of ROLL (Radioguided Occult Lesion Localization) and SNOLL (Sentinel Node biopsy and Occult Lesion Localization) techniques in these settings was evaluated. Methods: From 2009 to 2015 we studied 26 patients (pts) undergoing breast cancer surgery after NAC. ROLL (9 pts) and SNOLL (17 pts) surgery was performed, after radiopharmaceutical administration (99mTc-albumin macroaggregate for ROLL, 99mTc-albumin nanocolloid for SNOLL). A 1-2 mCi activity was directly injected as close as possible to the pre-treatment "marker" using an ultrasound guide (12 pts) or a stereotactic mammography (14 pts). Scintigraphic images were then acquired in all pts to verify the absence of anomalous activity diffusion and the correct lymph node detection: subdermal periareolar 99mTc-nanocolloids were administrated in SNOLL pts with no lymph node activity (4 pts) after deep interstitial injection. Results: In all treated pts (26/26), intraoperative detection was successful and allowed a precise tumoral bed excision. Sentinel node biopsy was correctly performed in 15/17 SNOLL pts: no significant lymphatic drainage was observed in 2 pts even after subdermal periareolar administration. Conclusions: ROLL and SNOLL techniques are both feasible in pts undergoing breast cancer surgery after a complete response to the NAC treatment. NAC-inducted drainage derangements or secondary lymphatic involvement should be taken in account for those pts with a negative sentinel node identification.

EP293

Starting a ^{125}I radioactive seed localization program in nonpalpable breast lesions

R. SANCHEZ SANCHEZ, A. GONZALEZ JIMENEZ, A. C. REBOLLO AGUIRRE, E. M. TRIVIÑO IBAÑEZ, N. TESTART DARDEL, S. MENJON BELTRAN, J. M. LLAMAS ELVIRA; Hospital Virgen de las Nieves, GRANADA, SPAIN.

AIM: To show our preliminary result in using of ^{125}I radioactive seed (RSL) for guidance during surgical resection of nonpalpable breast lesions. *METHODS*: Patients undergoing breast procedures after radiologic localization were included. RSL was performed with a 4.5 mm by 0.8 mm titanium seed containing 3.7-11.1 MBq of iodine 125. The radioactive seed is loaded into and 18G spinal needle after occluding the tip with sterile bone wax. RSL were preferentially conducted under ultrasound guidance and were performed under mammographic guidance if the lesion was no sonographically visible. The day selected was determined by radiology and operative suite scheduling (up to five days). At the time of operation a gamma probe is set to detect 27 KeV (^{125}I) source. The incision was made at the point of greatest activity. Seed removal within the specimen is assured by detecting the ^{125}I source of radioactivity within the excised specimen and no ^{125}I source remaining within the wound. Sentinel lymph node were performed in patients with no contraindication. Margins of excision were assessed delayed. Margins were considered negative if all were ≥ 1mm from invasive carcinoma and ductal carcinoma in situ on final histology. *RESULTS*: A total of 16 consecutive patients with nonpalpable breast lesions were included. Five of them received neoadjuvant therapy previously. The patient characteristics were: mean age (years)- 60.43, malignant tumor size (cm) mean-1.4, Invasive ductal carcinoma-81.3%, Invasive lobular carcinoma- 12.5% and other histology- 6.3%. Concomitant SLN mapping and biopsy was performed in 14/16. SLN metastases were identified in one patient. In one patient there was an erroneous placement of the seed, a wire was successfully placed to localize the lesion correctly. No major complications occurred during surgery. All seed were removed. Specimen size mean was 4.8 cm; malignant tumor size mean was 1.44 cm. Margins in first specimen were negative in 14/16 (87.5%). Two patients showed margins affected but only one required a reoperation. *CONCLUSION:* In our institution RSL is a feasible procedure that shows promising results. RSL seems to improve our rate of negative margins of excision and shows advantages in scheduling surgery. It is necessary increased the number of patient and good preliminary results encourage us to continue working on it.

EP294

Pulmonary nodules radioguided surgery with gammadetector probe

J. Suils Ramon[1], R. Jaller[1], I. Romero[2], J. G. Rojas[1], A. Rodriguez-Gasen[1], E. Noriega[1], G. A. Martinez-Pimienta[1], P. Boya[1], J. Rodriguez-Rubio[1], E. Carreño[3], F. Rivas[4], A. M. Benitez[1], M. Bajen[1], J. Mora[1]; [1]Nuclear Medicine Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Radiopharmacy and PETs Units. Nuclear Medicine. IDI. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Radiodiagnostic Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [4]Toracic Surgery Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.

AIM: Assessment of radioguided surgery (ROLL) utility in the resection of pulmonary nodules. METHODS: Retrospective review of 56 pulmonary ROLL in 47 patients, since 30/03/2012 until 05/11/2015, with a pulmonary lesion potentially resectable. 14 patients without oncologic antecedent. Middle age 60,12 years old (range 34 - 82 y). 2 patients were excluded by disease progression. All patients had a thoracic CT between 2 days and 3 moths before the surgical procedure. Scintigraphy detection (planar projection +/- SPECT - CT) and radioguided surgery after intra or peritumoral administration of the radiotracer (1,5 - 3 mCi / 0.2 mL / 0.3 mL air 99mTc-MAA) guided by CT the same or previous day before the surgery. We analyzed the scintigraphy detection, surgery detection, histological results and the size of the pulmonary lesion. RESULTS: Radiotracer administration could not be performed in 2 pacients due to retrocostal localization in one patient and moderate symptomatic pneumothorax caused by puncture in other patient. Presurgical scintigraphy showed intrapulmonary focal uptake in 50/54 ROLL (94%), absence of pulmonary uptake in one patient caused by radiotracer pass to systemic circulation, and other patient showed pleural diffusion. In first studies we performed SPECT - TC which did not provided additional information and did not help in the surgical detection respect to planar images, for that reason only it was used in the establishment of the technique and in doubtful cases. The nodal surgical detection was possible in the 49/54 ROLL (90, 70%). The pathology anatomy results showed benignity in 14 nodules. The extracted nodules presented sizes between 4 and 17 mm (medium: 8 mm). CONCLUSIONS: ROLL technique in pulmonary nodule is easy and allow the localization of small nodules with safety resection margins. Planar scintigraphy is enough for surgical planning, SPECT - CT is useful in doubtful cases.

EP295

Lymphoscintigraphy (LS) in Oral Cavity Cancer (OCC) as a tool for a tailored surgical approach through selective and modified lymphadenectomy: preliminary report

S. Panareo[1], N. Malagutti[2], I. Santi[1], I. Rambaldi[1], S. Taralli[1], S. Pelucchi[2], A. Pastore[2], C. Cittanti[1]; [1]University Hospital - Nuclear Medicine Unit, FERRARA, ITALY, [2]University Hospital - Othorynolaringoiatry Section, FERRARA, ITALY.

Aim: The purpose of the study was to assess the role of LS as a simple and widely accessible method with a favorable cost/benefit ratio in improving OCC staging and surgical appropriateness and implementing a tailored surgical approach to cervical lymph node dissection. The aim was to assess the lymphatic drainage in OCC through LS, in order to identify the percentage of patients with a lymphatic drainage beyond the compartments classically included in tumor surgery, and extend lymphadenectomy to the side of abnormal lymphatic drainage evaluating the metastatic status of excised lymph nodes. Method: we enrolled 7 consecutive patients (4 female, 3 male, median age 74±4.2 yo) affected by OCC scheduled for surgery. The day before surgery all patients underwent LS with planar and SPECT/CT images acquisition comprising head and neck regions, after the administration of 99mTc-nanocoll (median 74±2.1 MBq) divided into injections (median 3±1) performed around the OCC, with lymph nodal drainage identification. Patients underwent tumor ecxision and lymphadenectomy of usual laterocervical compartment (depending on tumor localization) and radioguided surgery of additional sites of lymphatic drainage as shown by LS. Anatomo-pathological analysis of tumor and lymph nodes was performed. Results: in 4 cases the tumor was in the tongue; in 1 case in the upper right dental arch and in 2 cases in the palate. Out of 7 patients, 3 (42%) showed laterocervical lymphatic drainage both ipsilateral and contralateral (LII, LIV and LIII respectively) to tumor. In 1 of these 3 cases (33%), metastasis was identified in the contralateral cervical lymph nodes (LIII). In the remaining 4 cases the lymphatic drainage was only ipsilateral to tumor and lymph nodes metastases were observed in 2 cases (50%). Conclusions: Although the results of this study are limited and preliminary, it has been possible to observe that the lymphatic drainage from OCC can be abnormal, namely contralateral to tumor site in cervical region, in a non-negligible percentage of cases (42% overall), with possible cervical lymph nodes metastatic involvement (33% of cases and 14% overall). Therefore LS could be a useful tool to properly map the lymphatic drainage from OCC, in order to perform a selective and modified

lymphadenectomy (different from classical one) with potential benefits for patients in terms of more accurate cancer staging and better disease control, and for health service in terms of costs. Of course, our data should be increased in order to obtain more reliable and reproducible results.

EP296

Is reliable Sentinel lymph node biopsy in axillary node-positive breast cancer patients after neoadjuvant chemotherapy?. Preliminary results

S. Fuertes, G. Hernandez, M. Velasco, S. Linares, R. Sainz de la Cuesta, V. Martínez de Vega, L. Gonzalez, A. Maldonado; Quiron Madrid University Hospital, Pozuelo de Alarcon (Madrid), SPAIN.

Aim: Sentinel lymph node biopsy (SLNB) has replaced conventional axillary lymph node dissection (ALND) in axillary node-negative breast cancer patients, but the use of SLNB remains controversial in patients after neoadjuvant chemotherapy (NAC). The aim of this study is to evaluate if is reliable SLNB after NAC in axillary node-positive breast cancer patients. **Material and methods:** This is a prospective study performed from April 2012 to February 2016. 23 breast cancer patients (p.) diagnosed with metastasis of the axillary lymph node by fine needle aspiration were enrolled in this study. All patients scheduled to receive NAC and patients undergoing SLNB after NAC, followed by ALND. The day before surgery an intralesional (21 p.) dose of 99mTc-nanocolloid (activity of 4 mCi and 0.2 ml volume) was injected guided with MRI (18 p.) or ultrasonography (3 p.) or periareolar (2 p.) . The site of injection and lymphatic drainage were confirmed by scintigraphy image. Intraoperative lesion and sentinel lymph node were localized and excised during surgery using a gamma probe. **Results:** Sentinel nodes were identified in 19 p. (identification rate, 82.6%). The number of resection SLN were 36 (1.9 per p.). In 7 p. the SLN was positive however ALND showed metastasis in 5/7p. In 12 p. the SLN was negative with post-chemotherapy changes. In these cases, the ALND was negative with post-chemotherapy changes. The false negative rate was 0%. 4 p. didn´t show lymphatic drainage. In 3 p. the ALND was negative with post-chemotherapy changes and 1 p. the ALND showed metastasis.**Conclusions:** Our results demonstrate that SLNB is reliable after NAC for node-positive breast cancer, with an acceptable identification rate.

EP297

Promising Results of RSL Technique to localize non palpable breast lesions

O. Ajuria Illarramendi, A. L. Santos Carreño, A. P. Ortega Manrique, M. E. Rioja Martin, P. Paredes Rodriguez, J. M. Castro Beiras; Hospital Ramon y Cajal, Madrid, SPAIN.

The increase of the screening mammography rates and the improvement in breast cancer imaging has led to localize non palpable breast lesions (under 1mm). Radioguided Seed Localization (RSL) is a new technique that has replaced WL to localize these lesions. AIM Review of the experience of our Breast Cancer Unit in localization of non palpable breast lesions using Radioguided Seed Localization (RSL). MATERIAL AND METHOD All the patients in our database that underwent RSL surgery between 2013-2015 were considered. Specifically, 275 cases of RSL were reviewed, from which 226 were breast non palpable lesions. Out of these 226 cases, in 192 (84, 96%) the seed was deployed intratumour helped by ultrasonography, while in 29 (12, 83%) cases, radiography (either mammography, CT or MRI) was the elected technique. Just in 3 cases was necessary the combination of both techniques and there were 2 cases were the technique was not reported. RESULTS It must be highlighted that out of the 226 cases, 87,17% were correctly deployed in the middle of the lesion, 5,75% where left on the tumour margin and only at 8 cases the RSL technique failed. When comparing the rates of deployment obtained with respect to the radiological technique, we observed that 90,63% where correctly set by using ultrasound, 5,21% were marginally set and only in 2,08% cases failed. When the procedure was guided by radiography technique, 68,97% were correctly set, 10,34% marginally, and the rate of failure amounts to 13,79%. It stands out a low rate of affected margins, being necessary to amplify them in only 54 cases and what is more relevant, reintervention was only needed at 6,64% of the cases. When the reintervention rates are analyzed concerning the radiological techniques, it can be noticed, on one hand that when ultrasonography was the elected technique, only 6,25% cases needed another surgery, while on the other hand, when radiography imaging was the preferred technique the rate of reintervention was slightly higher been of 10,34%.CONCLUSION To sum up, RSL is a novel procedure that has become the preferred technique among the surgeons due to the good outcomes, low rate of reintervention, its accuracy and safety. Furthermore, when using RSL guided by ultrasound, results were outstanding.

EP298

Comparison of first day and second day imaging in evaluating sentinel lymph node with SPECT/CT in breast cancer

B. Vatankulu[1], E. Akgün[1], M. Velidedeoğlu[2], S. Sağer[1], M. Halaç[1], K. Sönmezoğlu[1]; [1]İstanbul University Cerrahpaşa Medical Faculty Department of Nuclear Medicine, İstanbul, TURKEY, [2]İstanbul University Cerrahpaşa Medical Faculty Department of General surgery, İstanbul, TURKEY.

Aim: Although sentinel lymph node biopsy (SLNB) is a certain method, the protocol of sentinel lymph node scintigraphy (SLNS) is not clear. Studies against the late imaging emphasised that washout of the activity from the lymph node was the main problem. On the other hand, several studies supported the second day imaging after SLNS that make surgeons free to decide the timing of surgery. We compared first day early imaging and second day late imaging in breast cancer patients who had SLNS with SPECT/CT. **Materials and methods:** Thirty-eight patients who referred to our clinic for SLNS before SLNB were included into the study. For whole patients, after injection of 1mCi Tc-99m nanocolloid dynamic imaging followed by first day early SPECT/CT and second day late SPECT/CT imaging were performed. The presence, morphology and activity uptake intensity of SLN and nonSLN were recorded in all imaging. Patients were divided into the two groups as early imaging (group A) and late imaging (group B). Each group were compared by using McNemar test. **Results:** SLN was detected in 18% of patients with dynamic imaging after injection and SLN was detected with late SLNS in whole patients. The number of lymph node compatible with SLN was equal in both group A and B. Although no significant differences in visual analysis of activity uptake intensity were seen in both groups, activity uptake intensity of SLN and nonSLN were decreased in group B patients (p=0.08). Moreover despite the number of nonSLN were higher in group A, no significant difference was showed (p=0.09). There is no difference of the localizations of lymph nodes compatible with SLN between group A and B. The localizations for SLN were; intra+internalmammarial in 1 patient, level II in 1 patient and level I in 94% of patients. **Conclusions:** In the present study, no significant differences were observed in the number of SLN and activity uptake intensity between first and second day imaging. It is suggested that imaging performed 1 day before the surgery may help the surgeon free to decide the timing of SLNB.

TRAP substudy: assessment of 18-FLT PET/CT to examine tumour proliferation in patients with ASS1-deficient thoracic cancers treated with arginine deiminase (ADI)-PEG20, pemetrexed and cisplatin

T. A. Szyszko[1], J. S. Bomalaski[2], V. Goh[3], S. F. Barrington[3], **G. J. R. Cook**[3], P. W. Szlosarek[4]; [1]KCL and Guys and St Thomas PET Centre, London, UNITED KINGDOM, [2]Polaris Pharmaceuticals Inc, San Diego, CA, UNITED STATES, [3]Division of Imaging Sciences and Biomedical Engineering, KCL, London, UNITED KINGDOM, [4]St Bartholomew's Hospital, London, UNITED KINGDOM.

Aim: Loss of argininosuccinate synthetase 1 (ASS1) sensitises malignant pleural mesothelioma (MPM) and non small cell lung carcinoma (NSCLC) cells to apoptosis following arginine (L-Arg) deprivation. L-Arg depletor pegylated arginine deiminase (ADI-PEG20, ADI) enhances the cytotoxic effect of pemetrexed (PEM) and cisplatin (CIS) in ASS1-negative tumour cells involving suppression of pyrimidine synthesis and the salvage pathway. The aim of this study was to explore the role of 3'-Deoxy-3'-(18)F-fluorothymidine (18-FLT-PET) as a biomarker for assessing disease response to ADI, PEM and CIS (ADIPEMCIS) compared to CT response using RECIST 1.1 criteria in NSCLC and MPM. Materials and Methods: 18-FLT-PET was performed to assess tumour proliferation at baseline (scan 1), 24 hours post first dose of ADI and prior to PEMCIS on day 3 (scan 2), post first cycle ADIPEMCIS and before cycle 2 on day 15 (scan 3) and at end of ADIPEMCIS (@ day 120) (scan 4). Baseline imaging was performed in 10 patients with MPM and 4 patients with NSCLC. 3 patients did not complete the study, due to ill health. This was a substudy of a larger phase 1 clinical trial (TRAP). Treatment response was measured using EORTC based PET response criteria (partial response or PR, stable disease or SD, progressive disease or PD). This was compared with the response on diagnostic CT using RECIST 1.1 (NSCLC) and modified RECIST (MPM) criteria at day 15 and also at the end of treatment. Results: At the end of cycle one, PET response in 11 patients (8 MPM and 3 NSCLC) was PR in 4/11 (36%) SD in 6/11 (55%) and PD in 1/11 (9%) CT (RECIST 1.1) response in the same 11 patients was PR in 4/11(36%) and SD in 7/11(64%). At the end of treatment, a complete data was only available for both PET and CT in 7 patients and in these PET revealed a PR in 6/7 (86%) and SD in 1/7(14%) whereas CT revealed a PR in 4/7 (57%), SD in 2/7 (29%) and PD in 1/7 (14%). Conclusion: 18-FLT-PET may provide early evidence of response to ADI therapy in ASS1-deficient thoracic tumours, equivalent to RECIST 1.1 response rate. The rate of metabolic PRs is maintained at the end of treatment. Our study confirms that L-Arg depletion impacts on tumour proliferation and warrants further investigation as a novel antimetabolite strategy with antifolate drugs for cancer therapy.

EP300

Role of GLCM-based Texture Analysis using FDG PET/CT in Evaluation of Response to Neoadjuvant Therapy in Patients with Locally Advanced Breast Cancer

G. Kumar, A. K. Pandey, R. Kumar; All India Institute of Medical Sciences, New Delhi, INDIA.

Introduction Tumor heterogeneity assessment using texture analysis in various imaging modalities including PET/CT is evolving as an attractive option in in various aspects of Oncology practice. **Aim**Our study assesses the possible role of texture parameters obtained on from FDG PET/CT using Gray Level Co-occurrence Matrices (GLCM) in evaluation of response in patients undergoing neoadjuvant chemo/hormonal therapy for locally advanced breast cancer (LABC). **Material and Methodology** Thirty female patients with histopathologically confirmed breast cancer were enrolled in this prospective study. At baseline FDG PET/CT evaluation, 13 patients had TNM stage II disease while 17 had stage III disease. Following completion of three cycles of neo-adjuvant therapy, each patient subsequently underwent a post-therapy PET/CT. From each PET/CT scan, the following GLCM-based texture parameters were obtained from gray-scale image of that section of primary tumor with longest diameter: Angular Second Moment (ASM), Inverse Differential Moment (IDM), Contrast, Entropy and Correlation. Each texture parameter was extracted twice for test-retest reliability analysis. For comparison, routinely used metabolic parameters viz. SUVmax, SUVmean, Primary lesion metabolic Tumor Volume (PTV) and whole-body Metabolic Tumor Volume (MTV) were obtained. Appropriate statistical methods were further applied and results were obtained; P value of less than 0.05 was considered statistically significant. **Results** On test-retest reliability analysis, there was excellent linear correlation (Spearman's rho) and ranked correlation (Pearson's r) for all texture parameters with values approaching Unity in all of them. Response to therapy was assessed based on RECIST 1.1 criteria. Accordingly there were 16 responders (Partial Response=15, Complete Remission=1) and 14 non-responders (Stable Disease=6, Progressive Disease=8). On applying Mann Whitney U test, Contrast and Entropy, were statistically significant ($P < 0.0001$) between the responders and non-responders compared to the other three texture parameters. 'Delta' value (percent change between post-therapy and pre-therapy value) of each texture parameter was calculated and employed for ROC curve analysis. On ROC analysis, texture Entropy (AUC=0.902) and Contrast (AUC=0.879) again outperformed the other three texture parameters. Among the metabolic parameters, SUVmean (AUC=0.888), SUVmax (AUC=0.857) and MTV (AUC=0.821) outperformed PTV. Contrast, Entropy, SUVmean and SUVmax were employed as covariates for binary logistic regression analysis for predicting non-responders. The resulting model correctly classified 86.67% of patients ($P=0.0003$). Only texture contrast was statistically significant ($P=0.0407$) in predicting the non-responders. **Conclusion** Our study shows that GLCM-based texture parameters extracted using FDG PET/CT are reproducible, accurate and are valuable in identifying the non-responders in patients with LABC undergoing neo-adjuvant therapy.

EP301

Evaluation of metabolic response with 18F-FDG PET-CT in patients with advanced or recurrent thymic epithelial tumors

S. Segreto[1], R. Fonti[2], M. Ottaviano[3], S. Pellegrino[1], G. Palmieri[3], **S. Del Vecchio**[1]; [1]University of Naples Federico II, Naples, ITALY, [2]Institute of Biostructures and Bioimages, National Research Council, Naples, ITALY, [3]Rare Tumors Excellence Center, University Hospital Federico II, Naples, ITALY.

Aim: Thymic epithelial tumors are rare malignancies arising in the anterior mediastinum. Although surgery is the mainstay treatment, most of these tumors are unresectable or in advanced stage at diagnosis and require chemotherapy. Furthermore, despite radical resection, recurrence is common in those patients and multicourse therapy is often necessary. The aim of this retrospective study is to evaluate the usefulness of 18F-FDG PET-CT to monitor chemotherapy efficacy in patients with advanced or recurrent thymic epithelial tumors and to compare metabolic response with morphovolumetric reduction of tumor burden as assessed by RECIST criteria. **Materials and Methods**: We evaluated 27 consecutive patients (18 male and 9 female; age 56±11 y) with advanced (16 patients, Masaoka stage III, IVa and IVb) or recurrent (11 patients) thymic epithelial tumors. All patients underwent 18F-FDG PET-CT before and after at least 3 cycles of chemotherapy. 18F-FDG PET-CT scans were acquired after fasting for 8 h and 60 min after i.v. injection of 370 MBq of 18F-FDG using an integrated PET-CT system. SUVmax of all detected lesions was recorded and the most 18F-FDG avid lesion in each patient was selected for determination of percentage change in 18F-FDG uptake using the following formula: deltaSUVmax = SUVmax post - SUVmax pre/SUVmax pre. Contrast-enhanced CT was performed at baseline and

at the end of the planned regimen to assess tumor response. On the basis of RECIST criteria, patients were allocated in classes of complete response (CR), partial response (PR), stable disease (SD) or progressive disease (PD). ROC curve analysis was performed to define the optimal threshold of deltaSUVmax discriminating responders (CR+PR) from nonresponders (SD+PD). **Results**: Objective response was observed in 17 patients (2 CR and 15 PR) whereas in the remaining patients, 8 showed SD and 2 had PD. Metabolic response expressed as deltaSUVmax was significantly correlated to morphovolumetric response (r= 0.645, p=0.001). ROC curve analysis showed that a deltaSUVmax value of -25% could discriminate responders from nonresponders with a sensitivity of 88% and a specificity of 80%. Conversely, basal SUVmax values, although significantly correlated with the stage of disease (r=0.521, p=0.008), were not predictive of morphovolumetric tumor response. **Conclusion:** Our findings indicate that metabolic response assessed by 18F-FDG PET-CT may allow early identification of responders and non-responders thus guiding adaptation of therapy in patients with advanced or recurrent thymic epithelial tumors.

EP302

Early evaluation with 18FCH-PET/CT for response assessment among patients with metastatic castration-resistant prostate cancer treated with abiraterone

L. Pailhas[1], L. Vercellino[2], D. Pouessel[3], C. Balouzet[1], E. Barré[1], C. Hennequin[4], S. Culine[3], P. Merlet[2]; [1]Radiopharmacy Unit, APHP, Hôpital Saint Louis, Paris, FRANCE, [2]Department of Nuclear Medicine, APHP, Hôpital Saint Louis, Paris, FRANCE, [3]Department of Medical Oncology, APHP, Hôpital Saint Louis, Paris, FRANCE, [4]Department of Radiotherapy, APHP, Hôpital Saint Louis, Paris, FRANCE.

Abiraterone is a selective inhibitor of androgen biosynthesis used in metastatic castration-resistant prostate cancer manifesting disease progression during and after docetaxel chemotherapy. 18F-Fluorocholine (18FCH) is a cell membrane biosynthesis marker. 18FCH-PET/CT shows better sensibility and specificity than 18FDG-PET/CT in prostate cancer. Metabolic imaging with 18FCH-PET/CT could be an early indicator of therapeutic evolution in comparison to anatomic imaging.The aim of our study is to evaluate the prognostic value of 18FCH-PET/CT in response to abiraterone and its correlation with therapeutic responses. A retrospective study was conducted from January 2011 to December 2014 on patients treated with abiraterone. Patients had two 18FCH-PET/CTs: just before abiraterone treatment instauration and six weeks later. The Standard Uptake Value (SUVmax) relative variation between the two exams (ΔSUVmax) enables the evaluation of tumor response using criteria from the European Organisation for Research and Treatment of Cancer (EORTC). The therapeutic evaluation was conducted following the Prostate Cancer Working Group 2 (PCWG2) recommendations using the following criteria: biologic (Prostate Specific Antigen (PSA) level variation), clinical (treatment tolerance, pain, performance status) and imaging (bone scintigraphy, CT) twelve weeks after abiraterone initiation. Eight patients were identified. 18FCH-PET/CT results are consistent with therapeutic response for 6/8 patients: progressive disease (EORTC criteria) and non-responding (PCWG2 criteria) for 2/6, or stable (EORTC criteria) and responsive (PCWG2 criteria) for 4/6. Two patients' results are inconsistent. In one case, PSA level variation presents a stability indication value (ΔPSA= -12 percent) whereas PET interpretation gives a partial response. In the other, ΔPSA= +90 percent shows a biologic progression whereas the PET indicates stable disease. Average survival without progression is 4.4 months. Average duration of abiraterone treatment is 6.2 months. Causes for interrupting abiraterone treatment are biologic and/or radiologic progression for seven patients. One died. After interruption, patients are treated with cabazitaxel (4/8), docetaxel (1/8) or hormonotherapy (1/8). One patient was lost from sight after abiraterone interruption. Economically, although the 18FCH-PET/CT exam is expensive (550-1000€) it is justified if its predictive value is confirmed, compared to the monthly cost of abiraterone treatment (3200€). 18FCH-PET/CT seems to correctly identify responsive and non-responsive patients at an early stage, but some results show inconsistency. 18FCH-PET/CT and the clinical evaluation will remain complementary. A prospective study and a higher number of patients could give more exhaustive data and statistically confirm this tendency as found in literature.

EP303

Usefulness of 18F FDG PET CT in the assessment of neoadjuvant chemotherapy in Esophageal Cancer

J. Navarro Fernandez[1], L. Frutos Esteban[1], L. Mohamed Salem[1], M. Porras Martinez[1], V. Munitis[1], G. Ruiz Merino[1], M. Marin Vera[1], M. Alcaraz Baños[2], M. Claver Valderas[1]; [1]HCU VIRGEN DE LA ARRIXACA, 30120, SPAIN, [2]Universidad de Murcia, 30120, SPAIN.

Although 18F-FDG PET CT has a well-established role in the diagnosis and staging of esophageal carcinoma, is should not yet be used in routine practice to guide neoadyuvant chemoradiotherapy (NACR) decision in patients with this desease. Predicting complete pathologic response (CPR) preoperatively can significantly affect surgical decision making. Aim: to determine is 18F-FDG PET CT characteristics are associated with CPR in patients undergoing trimodality treatment for esophageal cancer. Materials and methods This is a retrospective analysis of 20 patients with Locally advanced oesophageal or junctional cancer underwent 18F-FDG PET CT at basaline and after NACR prior to planned surgical resection. Quantitative measurements of tumor FDG uptake were correlated with histopathologic response. Results On surgical pathology , there was complete or near complete regression of tumor in 12 patients (60% responders) and lack regression or partial response in 8 patients (40% no responders) The median of SUV decrease after finished of therapy was 0.6+-0.9 for histopathologic responders and 0.42+-0.23 for nonresponders (p<0.077). In receiver operating characteristic analysis, the area under the curve was 0.719 At a thresthold of 43% decrease of FDG uptake compared with baseline, sensitivity to detect response was 83.3, with a corresponding specificity of 62.5. The positive and negative predictive values were 82% and 62% respectively. Conclusion FDG PET is a valuable tool for the noninvasive assessment of histopathologic tumor response after NACR.

EP304

Value of 18F-FDG PET/CT in the characterization of indeterminate adrenal lesions

L. Zanoni[1], C. Nanni[1], A. Farolfi[1], E. Casadio[2], V. Vicennati[2], G. Zavatta[2], R. Pasquali[2], S. Fanti[1]; [1]Nuclear Medicine, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [2]Endocrinology, Azienda ospedaliero-universitaria di Bologna, Policlinico S.Orsola-Malpighi, Bologna, ITALY.

AIM: To assess the value of 18F-FDG PET/CT for the characterization of indeterminate adrenal lesions. **MATERIALS AND METHODS:** Records of patients (pts) referred to the Endocrinology Unit, between 2006 and 2016, for indeterminate adrenal lesions were retrospectively collected (113 pts). Only pts with at least one 18F-FDG PET/CT performed before diagnosis, available dicom files, histological proofs (or clinical diagnosis) of adrenal findings as Standard of Reference, were included for the analysis (48/113 pts). PET were blindly revised for visual uptake (negative or positive for malignancy, lesion laterality, homogeneity and focality) and semi-quantitative parameters (adrenal SUVmax, SUVmean; adrenal-to-liver-ratio (AL) using liver SUVmean; adrenal-to-controlateral-adrenal-SUVmax-ratio (AA). Adrenal enlargement was considered only when significant on corresponding low-dose CT images. Diagnostic performance was evaluated, cut-off values for optimal separation of benign from malignant

glands were proposed (ROC). **RESULTS:** Using visual interpretation PET resulted negative in 30 pts (all true-negative) whereas positive in 18 (8 true-positive, 10 false-positive) out of 48: sensitivity was 100%, specificity 75%, PPV 44%; NPV 100%, accuracy 79%. The population comprised 40 benign (25 adenoma, 12 hyperplasia, 1 Schwannoma, 2 eumorphic adrenals) and 8 malignant lesions (5 carcinoma, 2 pheochromocytoma, 1 lymphoma). In particular the 10 FP cases (mean SUVmax 6,5) were 4 atypical adenoma, 2 nonfunctioning adenoma, 4 bilateral macro-nodular hyperplasia. Malignant adrenal glands were all significantly enlarged and presented with diffuse and inhomogeneous pattern (1 homogeneous). Mean SUVmax was 10, 5 (median 10,6; range 3,3-18,5); mean SUVmean was 5,9 (median 5,7; range 2-9,7); mean AL-ratio was 4,8 (median 5; range 1,3-7,5); mean AA-ratio was 5,8 (median 4; range 2,5-16,8). On the other side benign lesion showed: mean SUVmax 3,3 (median 2,4; range 0,8-8,5); mean SUVmean 2,1 (median 1,6; range 0,4-5,4); mean AL-ratio 1,5 (median 1,2; range 0,4-3,9); mean AA-ratio 1,7 (median 1,4; range 0,9-3,7). These PET indices were significantly higher in malignant than in benign lesions (Mann-Whitney-U-test: SUVmax p= 0,0006; SUVmean p=0,0007; AL-ratio p= 0,0002; AA-ratio p< 0,0001). SUVmax cut-off of 3 resulted in 100% sensitivity but 65% specificity; AL-ratio cut-off of 2,5 in 87,5% for both sensitivity and specificity whereas AA-ratio of 2,3 in 87,5% and 82,5% respectively. Their performance was similar (AUC 0,886; 0,923; 0,848; p>0,4). **CONCLUSION:** Our preliminary results suggest that 18F-FDG PET/CT is helpful in assessing the malignant potential of indeterminate adrenal lesions. However a "grey-zone" of benign avid lesions exists. Further analyses (including contrast-enhanced-CT features and hormonal profile) for more accurate multidisciplinary characterization, are ongoing.

EP305

18F-FDG PET/CT versus contrast enhanced (ce) CT versus PET/ceCT in patients with peritoneal carcinomatosis candidates to Hyperthermic Intraperitoneal Chemotherapy (HIPEC)

L. Evangelista[1], A. Cervino[1], G. Pintacuda[2], G. Ramondo[2], A. Sommariva[3]; [1]Nuclear Medicine and Molecular Imaging Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY, [2]Radiology Oncology Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY, [3]Surgery Oncology Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY.

Introduction: to investigate the relationships between 18F-FDG PET/CT, ceCT, PET/ceCT and surgical evaluation in patients with peritoneal carcinomatosis from mucinous/non mucinous malignancies who were candidates to HIPEC. **Materials and methods:** from 2012 to 2016 we prospectively collected data from 27 patients (median age: 52 years; male: 13) with a clinical suspicious of peritoneal carcinomatosis candidates to HIPEC for the resolution of the disease (18 patients with no-mucinous and 9 with mucinous cancer). All patients underwent FDG PET/ceCT in a single session. The acquisition was started after 60 minutes from the administration of FDG. Two nuclear medicine physicians and 2 radiologists independently evaluated PET/CT and ceCT imaging, respectively. In case of discordance, the consensus was reached by a discussion between the specialists. Moreover, the combined images were evaluated by all the specialists in consensus. The images were qualitatively and quantitative analyses, by using the peritoneal cancer index (PCI). A 39-score was used. The PCIs obtained from surgical look, PET/CT, ceCT and PET/ceCT were compared each other. The coefficients of correlation (r) were calculated. **Results:** PET/CT showed a significant uptake of FDG in 20/27 (74%) patients, being focal in 11 cases, diffuse in 5 and focal+diffuse in 4. The r coefficients were 0.641, 0.639 and 0.99 between PCI at PET/CT vs. ceCT, PCI PET/CT vs. PET/ceCT and PCI PET/ceCT vs ceCT, respectively. Surgical PCI was available in 21 patients, due to a progression of disease in 6 subjects. The r coefficients between surgical PCI, PET/CT, ceCT and PET/ceCT were respectively, 0.528, 0.876 and 0.878. Out of 21 patients who underwent surgical look, 12 had a non-mucinous cancer and 9 a mucinous one. The r coefficient between surgical PCI and PET/CT was higher in patients with a non-mucinous cancer than the counterpart (0.601 vs. 0.303) and the addition of ceCT significantly increase the correlation (r= 0.953) (see Table 1). Moreover, at FDG PET/CT, peritoneal carcinomatosis from mucinous cancer showed more often a focal pattern. Conversely, the peritoneal carcinomatosis of non-mucinous cancer had a both a focal and diffuse FDG uptake. **Conclusions:** PET/ceCT as single examination seems more accurate than PET/CT and ceCT alone for the definition of PCI in patients candidates to HIPEC. However, a careful selection of histological pattern should be warranted, although a negative PET/CT scan would provide important prognostic information.

EP306

Characterization of malignant pleural effusion (MPE) with 11C-Methionine PET/CT before and after talc pleurodesis: interim evaluation of a prospective clinical trial

E. Lopci[1], P. Zucali[1], G. Ceresoli[2], A. Testori[1], E. Voulaz[1], K. Marzo[1], L. Leonardi[1], L. Olivari[3], G. Ferraroli[1], E. Bottoni[1], A. Galeassi[4], G. Veronesi[5], M. Alloisio[1], A. Santoro[1], A. Chiti[1]; [1]Humanitas Clinical and Research Hospital, Milano, ITALY, [2]Humanitas Gavazzeni, Bergamo, ITALY, [3]Milano University, Milano, ITALY, [4]Humanitas Castellanza, Castellanza, ITALY, [5]Humanitas Research Hospital, Rozzano, ITALY.

Purpose: Malignant pleural effusion (MPE) is a pathological condition associated to cancer and one the most frequent signs of mesothelioma presentation. 18F-FDG PET/CT has proved to be useful in detecting malignant pleural lesions, although unreliable results have been reported in early epithelioid mesothelioma and in patients receiving talc pleurodesis. 11C-methionine is expected to be less influenced by inflammatory reaction to pleurodesis. In this study we aimed to define the role of 11C-Methionine PET/CT in the characterization of MPE before and after talc pleurodesis. **Materials and Methods:** From September 2014 to February 2016, 30 consecutive patients referred to our Institution for MPE were prospectively enrolled. Patients were evaluated at baseline and after talc pleurodesis with two consecutive PET/CT investigations: 11C-methionine (experimental) and 18F-FDG (standard in our Institution). Semi-quantitative PET parameters were defined for both examinations: i.e. SUVmax, SUVmean, metabolic tumor volume (MTV) and metabolic tumor burden (MTB=MTV x SUVmean). During video-thoracoscopy for pleurodesis, all patients underwent pleural biopsy and imaging parameters were compared to pathological findings. A statistical analysis was performed to compare the impact of talc pleurodesis on 11C-Methionine and 18F-FDG PET. **Results:** The interim analysis was completed in 15 out of 30 patients (M:F= 13:2; mean age 73 years), all affected by malignant mesothelioma (12 epithelioid, 3 non-epithelioid). All tumors showed increased uptake of 11C-methionine at baseline: median SUVmax, SUVmean, MTV and MTB were 4.7 (range 3-10.1), 2.8 (range 1.5-4.6), 19.5 (range 0.9-464.3) and 45.2 (range 2-2052.2), respectively. MTV and MTB were significantly higher in non-epithelioid tumors compared to epithelioid histotype (p=0.022 and 0.03, respectively). For 11C-methionine PET, the median percentage of variation before and after talc pleurodesis was 12.8 for SUVmax (%ΔSUV) and 29.9 for MTB (%ΔMTB). Compared to 18F-FDG PET, the percentage of variation for MTB resulted significantly lower for 11C-methionine (p<0.001), but not for SUVmax. Interestingly, there was an inverse linear correlation between MTV for 18F-FDG PET at baseline and %ΔSUV or %ΔMTB after pleurodesis (p<0.01), whereas for 11C-methionine only for%ΔSUV. **Conclusion:** 11C-methionine PET/CT appears to be able to characterise malignant pleural effusion. This preliminary analyses shows that it might be less influenced by inflammatory reaction related to talc pleurodesis compared to 18F-FDG PET/CT.

EP307

A Paradigm Shift in PET Imaging Reconstruction Inspired by Digital PET

M. V. Knopp, K. Binzel, A. Siva, R. Moore, C. L. Wright, J. Zhang; The Ohio State University, Columbus, OH, UNITED STATES.

Aim: Despite many advances in PET technology and reconstruction, as we moved from filtered back projection to iterative with time of flight correction, the image voxel volume remained unchanged using a 3-4 mm voxel length. Prior attempts to increase the reconstruction matrix, thus reducing the voxel volume, were impeded by the rapid increase in noise. With the introduction of solid state detectors, we realized that iterative convergence is strongly dependent upon count densities and changes in voxel volume may thus require a re-optimization of reconstruction parameters. With this experience, we reassessed the possibility of substantially improving image quality, even on conventional time of flight PET systems through rigorous reconstruction optimization. **Materials and Methods:** 30 previously acquired FDG whole body oncologic PET scans performed within standard of care and archived with complete listmode data were included in an optimization / assessment study. 10 cases were used for rigorous analysis by reconstructing listmode data using a 2mm voxel / 288x288 reconstruction matrix, using a comprehensive set of iterative reconstruction parameters. These images were compared against each other as well as the default 4mm voxel / 144x144 matrix images using visual and quantitative assessments. The ROC methodology was used to define the optimized parameter set that was subsequently utilized in 20 cases for intra-individual comparisons. **Results:** Surprisingly, higher matrix reconstruction was readily accomplished with improved and preferable image quality from standard clinical acquisitions. High definition reconstruction simply requires a re-optimization of iterative reconstruction parameters, as the reconstruction dependent image noise level otherwise impedes the benefits of reduced partial volume effects. Without optimization, decreasing voxel size leads to spuriously poor image quality. We found that reducing the number of iterative subsets reliably produces excellent image quality while simultaneously maintaining quantitative accuracy. **Conclusion:** Image quality can be considerably refined, even on current generation conventional time of flight PET/CT systems, if smaller voxel volume reconstructions are being used based on utilizing re-optimized reconstruction parameters. While the future of PET is evolving into solid state digital detection, which has many benefits, existing technologies still hold great potential for improving image quality through optimization of reconstruction.

EP308

Are the Clinical Indications Easily Retrieved from ^{18}F-FDG PET-CT Request-Forms? Analysis of 200 ^{18}F-FDG PET-CT Request-Forms from a Single PET-CT Centre

M. Mattoli[1], V. Scolozzi[1], D. Ripani[1], L. Indovina[2], V. Rufini[1], A. Giordano[1], M. Calcagni[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [2]Institute of Physics, Università Cattolica del Sacro Cuore, Rome, ITALY.

Introduction: In oncologic patients, the identification of clinical indication is of paramount importance to evaluate whether PET-CT is appropriate or not according to the EANM guidelines. Aims: to assess the accuracy of ^{18}F-FDG PET-CT request-forms; to analyse the practical-organizational aspects. Materials and methods: We retrospectively evaluated 200 consecutive oncological ^{18}F-FDG PET-CT request-forms. We assessed the accuracy of the request-forms (consisting on the form and the clinical information attached) and the clarity of the clinical indication reported on it. The request-form was defined as "correct" when filled-out in all parts or at least in those essential to identify the clinical indication; the clinical indication was defined as "clear" when it was well identified. In addition, we assessed the following practical-organizational aspects: presence of information attached; amount of in-patients/out-patients; PET-CT requests with CT contrast medium; urgency. Results: Patients characteristics: 90 males; mean age 64±13years. Anatomical districts involved: lung (n=53), breast (n=33), gastrointestinal (n=33), pelvic (n=29), haematological (n=25), head-neck (n=11), double district (n=6); excretory system (n=5), skin (n=3), unknown primary malignancy (n=2). Request-forms judged as correct: 115/200 (58%); clear clinical indications: 124/200 (62%); correct request-forms with clear clinical indications: 111/200 (56%); correct request-forms with unclear clinical indications: 4/200 (2%); non-correct request-forms with unclear clinical indications: 72/200 (36%); non-correct request-forms with clear clinical indications: 13/200 (6%). Information attached: 74/200 (37%); in-patients: 3/200 (1.5%); contrast medium: 10/200 (5%); urgency (to be performed within 15days): 51/200 (25%). Conclusion: In our clinical practice, the accuracy of the request-forms was low because only half of them was properly filled-in. This can be attributed to a poor compliance of the referring clinician who selected none or more than one clinical indication. Inaccuracy implies an overload work for nuclear physicians to retrieve necessary information. Finally, PET-CT is a second-line exam, as demonstrated by the low requests of PET-CT with contrast medium (diagnostic CT had already been performed), and by the small number of PET-CT performed for in-patients. The need to perform PET-CT within 15 days is low, suggesting that the clinical indications considered really urgent (<15days) are few, such as staging, guiding biopsy, and unknown primary tumor. On the contrary, treatment evaluation and characterization of pulmonary nodule can be considered "not urgent", while restaging can be performed within 15days, as well as after. This analysis allows to improve the organization of the PET-CT departments, and to reduce the waiting-list.

EP309

Repeatability of Quantitative ^{18}F-FLT Uptake Measurements in Solid Tumors: A multi-centre Meta-Analysis

G. M. Kramer[1], Y. Liu[2], A. J. de Langen[3], E. P. Jansma[4], I. Trigonis[5], M. Asselin[5], A. Jackson[5], L. Kenny[6], E. Aboagye[6], O. S. Hoekstra[1], R. Boellaard[1], QuIC-ConCePT consortium; [1]Department of Radiology and Nuclear Medicine, VU university medical center, Amsterdam, NETHERLANDS, [2]European Organisation for Research and Treatment for Cancer (EORTC), Headquarters, Brussels, BELGIUM, [3]Department of Pulmonology, VU university medical center, Amsterdam, NETHERLANDS, [4]Medical Library, VU university medical center, Amsterdam, NETHERLANDS, [5]Institute of Population Health, Wolfson Molecular Imaging Centre, Manchester Academic Health Sciences Centre, The University of Manchester, Manchester, UNITED KINGDOM, [6]Department of Surgery and Cancer, Imperial College London, Hammersmith Hospital, Lodon, UNITED KINGDOM.

Objectives. ^{18}F-Fluorothymidine (^{18}F-FLT) positron emission tomography (PET) has potential as imaging biomarker of response to antitumor therapy. Before quantitative ^{18}F-FLT uptake metrics can be used for evaluation of proliferative response, repeatability of these metrics have to be established. The aim of this study was therefore to determine repeatability of several ^{18}F-FLT uptake metrics by analyzing available patient data from previously published reports. **Materials and Methods:** A systemic search was performed in PubMed and EMBASE.com from inception-January 2015 and revealed five ^{18}F-FLT repeatability cohorts in solid tumors. ^{18}F-FLT avid lesions were delineated using a 50% isocontour adapted for local background on the test and retest scans (in-house developed software). SUVmax (maximum SUV), SUVpeak (1.2cm^3 spherical region positioned to maximize its mean value), SUVmean (mean SUV), proliferative volume (50% threshold of SUVpeak corrected for local background) and total lesion proliferation (TLP) (product of SUVmean and proliferative volume) were calculated. Repeatability of quantitative uptake metrics was assessed using repeatability coefficients (RC) calculated as 1.96 * SD, linear regression analysis and intraclass correlation coefficients (ICC). Analyses were performed to investigate the impact of different lesion selection criteria.

Results: Images from four datasets containing 30 patients with 52 lesions were obtained and analyzed (10 in breast cancer, 9 in head and neck squamous cell carcinoma and 33 in non-small cell lung cancer patients). Repeatability of SUV (RCs of 29.4% - 33.5%) was better than of TLP (76.4%) and proliferative volume (79.2%). Patients did not receive any therapeutic treatment between the test and test scans (interval <8 days). No significant differences in RCs were found between the different SUV metrics. With exception of proliferative volume, a good correlation was found between test and retest data for all ^{18}F-FLT uptake metrics ($R^2 > 0.86$; ICC > 0.91). Lesion selection methods based on size (tumor >4.2mL), SUV (> 4.0), hottest lesion or primary tumor did not influence repeatability of any of the ^{18}F-FLT uptake metrics. **Conclusion:** We show that ^{18}F-FLT SUV metrics are acceptably repeatable in the meta-analysis of a multi-centre dataset, with proliferative volume and TLP being less repeatable. A ≥30% change in SUV metrics represents a true change in ^{18}F-FLT uptake independent of the lesion selection strategy.

EP310

Diagnostic Value Of 18F-FDG PET/CT In Fever Of Unknown Origin. Our Experience

M. Fernández Rodríguez, P. García Alonso, C. Sandoval Moreno, A. Herrero Muñoz, L. Castillejos Rodríguez, C. Paniagua Correa, M. Balsa Bretón, A. Ortega Valle, F. Penín González; Hospital Universitario de Getafe, Getafe, SPAIN.

AIM: To assess diagnostic contribution of 18F-FDG PET/CT for evaluation of fever of unknown origin (FUO). **MATERIALS AND METHODS:** We retrospectively evaluated (August 2013-March 2016) 54 cases of patients investigated for FUO. All fulfilled the Durack and Street modified criteria for FUO and underwent a 18F FDG PET/CT. 12 patients were excluded by lack of data under follow-up. 42 cases were included in the analysis: 22 women (52.38%) and 20 men (47.62%); aged 59 ± 27. Final diagnoses were based on integration of clinical, microbiological, radiological and histological data at follow-up (mean follow-up time 6.54 months). Studies showing at least one area of pathological FDG uptake (SUVmax > 2.5) were defined as PET positive. Studies showing FDG activity only in areas of physiologic tracer biodistribution were considered as negative. A PET/CT study demonstrating a focal, localized disease process confirmed by additional conventional techniques as representing the cause of FUO was considered as contributory for diagnoses and defined as true-positive (TP). A PET/CT study showing normal findings, when no localized disease process was further diagnosed by additional techniques, and there was no evidence of disease following at least 6 months of clinical follow-up, was regarded as contributory in excluding focal disease and defined as true-negative (TN). **RESULTS:** 19 (45.24%) PET/CT studies demonstrated pathological FDG uptake and were considered abnormal. 17 studies were considered TP (40.48%) and final diagnoses were: 9 infectious diseases (1 osteomyelitis, 1 pancreatitis, 1 hepatic abscess, 1 spondylodiscitis, 1 prosthetic joint infection, 3 vascular graft infections and 1 tuberculosis), 9 inflammatory/autoinmune diseases (3 lymphadenopathy of uncertain clinical significance, 2 temporal arteritis, 2 sarcoidosis, 1 Wegener's granulomatosis, 1 Ig G4-related disease) and 1 neoplasm (thymic carcinoma). FP included 2 cases: 1 increased FDG uptake in anal region (ultrasound and MRI demonstrated no pathological process) and 1 uptake in left ventricular outflow tract (normal cardiac MRI). PET/CT showed no pathological FDG uptake in 23 cases (54.76%): 19 (45.24%) were considered TN (FUO resolved with no etiologic diagnoses and no evidence of disease during at least a 6-month follow-up) and 4 FN (9.52%): 2 endocarditis, 1 renal vasculitis, and 1 patient died with no diagnosis. PET/CT had: accuracy 85.71%, sensitivity 80.95%, specificity 90.48%, a positive predictive value 89.47% and negative predictive value 82.61%. In 85.71% cases PET/CT was considered clinically helpful and contributory to diagnosis. **CONCLUSION:** PET/CT is a noninvasive diagnostic tool useful for the diagnosis of patients with FUO.

EP311

Is the Amount of Doubtful Reports Dependent on the Appropriateness of Clinical Indication? Analysis of 200 ^{18}F-FDG PET-CT Reports from a Single PET-CT Centre

M. Mattoli[1], V. Scolozzi[1], D. Ripani[1], L. Indovina[2], V. Rufini[1], A. Giordano[1], M. Calcagni[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [2]Institute of Physics, Università Cattolica del Sacro Cuore, Rome, ITALY.

Introduction: PET-CT report is the most important final step in the diagnostic work-up. It can be positive, negative, or doubtful for malignancy. Since PET-CT is a second-line exam, the rate of doubtful reports should be low. Aims: to evaluate the rate of doubtful ^{18}F-FDG PET-CT reports; to match the report with the appropriateness categories according to EANM guidelines 2010 (v.1.0) and 2015 (v.2.0). Materials: We retrospectively classified as positive, negative, and doubtful for malignancy 200 consecutive oncological ^{18}F-FDG PET-CT reports draft by six nuclear physicians. We matched them with the appropriateness categories, and the doubtful reports with clinical indications. Results: Overall, 92/200 (46%) PET-CT reports were positive, 92/200 (46%) negative,16/200 (8%) doubtful. According to EANM guidelines v.1.0: 61/200 (31%) PET-CT were appropriate, 124/200 (62%) inappropriate, 15/200 (7%) promising. The reports of appropriate PET-CT group were positive in 34/61 (56%), negative in 22/61 (36%), doubtful in 5/61 (8%: all restaging). The reports of inappropriate PET-CT group were positive in 47/124 (38%), negative in 67/124 (8%), doubtful in 10/124 (8%: 7 follow-up, 1 restaging, 1 treatment response, 1 staging). The reports of appropriate PET-CT group were positive in 11/15 (73%), negative in 3/15 (20%), doubtful in 1/15 (7%: response evaluation). According to EANM guidelines v.2.0: 127/200 (64%) PET-CT were appropriate, 73/200 inappropriate. The reports of appropriate PET-CT group were positive in 78/127 (61%), negative in 40/127 (32%), doubtful in 9/127 (7%: 6 restaging, 2 treatment response, 1 staging). The reports of inappropriate PET-CT group were positive in 14/73 (19%), negative in 52/73 (71%), doubtful in 7/73 (10%: follow-up). Conclusions: Overall, the rate of doubtful PET-CT reports is very low (overall 8%) despite the reports were drafted by several nuclear physicians. This finding confirms that when all previous exams are available (PET-CT is a second-line exam) and clinic-anamnestic information are known, the chance to draft a doubtful PET-CT report is very low. The doubtful reports rate in each appropriateness category is almost equal, either for guidelines v.1.0 or v.2.0. The major incidence of doubtful reports were in follow-up and restaging and not in other clinical indications. Two examples for explaining these findings: during follow-up, a ^{18}F-FDG uptake without a corresponding morphological alteration not supported by clinical/instrumental suspicion can be doubt; for restaging, a ^{18}F-FDG uptake in a morphological alteration around the prosthesis implanted for previous malignancy can be doubt. Finally, the nuclear physician experience and temperament play an important role in the reporting.

EP312

Clinical implication of F-18 FDG PET/CT with Philadelphia chromosome-negative myeloproliferative neoplasms

S. Kang[1], J. Kim[2], H. Bom[1], J. Min[1], H. Song[2]; [1]Department of Nuclear Medicine, Chonnam National Unuversity Hwasun Hospital, Hwasun-Gun, KOREA, REPUBLIC OF, [2]Department of Nuclear Medicine, Chonnam National Unuversity Hospital, Gwangju, KOREA, REPUBLIC OF.

Background: The objective of this study was to investigate the clinical implication of ^{18}F-FDG PET/CT in patients with Philadelphia chromosome-negative myeloproliferative neoplasms (MPNs). **Materials and methods**: Twenty-eight patients diagnosed with Philadelphia chromosome-negative MPNs who underwent FDG PET/CT from 2007 to 2013 were enrolled; 6 polycythemia vera (PV), 16 essential

thrombocythemia (ET), 6 primary myelofibrosis (PMF). All patients underwent FDG PET/CT, hematologic tests, and bone marrow biopsy. FDG uptake was semi-quantitatively assessed using mean standardized uptake values (SUVmean) in the lower thoracic and lumbar vertebrae and mediastinal blood pool. The correlation between PET and clinical parameters were determined. The prognostic significance of following parameters were evaluated: age, sex, laboratory parameters, JAK2V617F mutation, splenomegaly, and bone marrow FDG uptake. **Result:** Among parameters, only the presence of JAK2V617F mutation and WBC count ($x10^3/mm^3$) were correlated with bone marrow FDG uptake. Bone marrow SUVmean to mediastinal blood pool SUVmean ratio ($SUV_{BM/M}$) was significantly higher in patients with JAK2V617F mutation and in patients with higher WBC count; 1.73±0.37 vs. 1.06±0.23 in $SUV_{BM/M}$ ($p<0.0001$), 1.72±0.38 vs. 1.32 ±0.40 in $SUV_{BM/M}$ ($p=0.007$), respectively. Furthermore, $SUV_{BM/M}$ showed a strong positive correlation with the allele burden of JAK2V617F (rho=0.702, p=0.005) and the WBC count (rho=0.643, $p<0.0001$). However, the allele burden of JAK2V617F was not correlated with the WBC count (rho=0.344, p=0.250). High $SUV_{BM/M}$ ($p=0.021$, log-rank test) and presence of JAK2V617F mutation ($p=0.023$) were statistically significant poor prognostic factors in overall survival analysis but not in event free survival analysis (p=0.275, p=0.087, respectively). **Conclusion:** In Philadelphia chromosome-negative MPNs, bone marrow FDG uptake might imply JAK2V617F mutation status and predict prognosis.

EP313

Solitary and multiple metastases in the skeletal muscles on 18F-FDG PET/CT imaging

A. Nocuñ, B. Chrapko; Chair and Department of Nuclear Medicine, Medical University of Lublin, Poland, LUBLIN, POLAND.

Introduction: Skeletal muscle metastases (SMM) are suggested to occur more frequently than it is usually recognized, however, currently available publications on SMM imaging contain a large number of case reports and only few comprehensive studies. The aim of the present study was to retrospectively investigate the features of SMM detected by 18-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) with particular attention to patterns of solitary and multiple intramuscular lesions, their frequency and impact on cancer staging. Materials and Methods: Our database was analyzed for patients with pathologically proven malignancy, who underwent FDG PET/CT in our institution. The subjects with SMM were included into the study group based on the final diagnosis confirmed by follow-up or histopathology. Images were acquired using a PET/CT system Biograph mCT S(64)-4R (Siemens, Germany). CT was performed without contrast enhancement. Image evaluation was performed visually and by means of maximum standardized uptake values (SUVs). Results: The selected group with SMM consisted of 31 patients (1.7% of the database), 18 females and 13 males. A total of 233 lesions were found with SUVmax ranging from 3.2 to 26.8 (average 10.6±6.3). The prevalence of SMM evaluated in specific primary malignancies was the highest in melanoma (6.9%). The most common site of muscle metastases was the torso. Three patterns of skeletal muscle metastatic involvement were observed: 1) multiple SMM associated with extamuscular metastases (20 patients, 64.5%), 2) solitary SMM with other metastatic sites (9 patients, 29%) and 3) isolated SMM without other abnormalities on FDG PET/CT scans (2 patients, 6.5%). In the first and second pattern (93.5% of cases) the presence of SMM did not alter the staging. Conclusions: Solitary SMM are less common than multiple. On FDG PET/CT imaging SMM are usually associated with other metastases and their presence does not affect tumor staging. The cases of isolated SMM, detected as the only abnormality on FDG PET/CT scan, are very rare. Nevertheless, in patients with diagnosis of malignant disease, a solitary, FDG avid intramuscular focus should be suspected to represent metastasis. Biopsy is mandatory in such cases.

EP314

Role of ^{18}F-FDG PET/CT in the Diagnosis and Staging of Rosai Dorfman Disease

S. Karunanithi[1,2], A. Mukherjee[2], R. Kumar[2]; [1]Malabar Institute of Medical Sciences, Calicut, INDIA, [2]All India Institute of Medical Sciences, New Delhi, INDIA.

Aim: To evaluate the role of ^{18}F-Fluorodeoxyglucose (^{18}F-FDG) positron emission tomography/computed tomography (PET/CT) in the diagnosis and staging of Rosai-Dorfman disease (RDD). Materials and Methods: Study was a retrospective data analysis of histopathologically proven RDD who underwent FDG PET/CT in the department of Nuclear Medicine, AIIMS, New Delhi between July 2005 to August 2014. Twenty six patients (mean age-31.5 years, median-33 years, range: 3-48) with clinically suspected and/or histopathologically proven RDD underwent ^{18}F-FDG PET/CT imaging for staging and/or localisation of the disease. The scans were done with a dedicated PET-CT scanner (Biograph 2, Siemens, Germany). All patients fasted for at least 4-hours. Blood glucose was less than 140mg/dl. FDG PET-CT study was evaluated by two experienced Nuclear Medicine physicians. The PET-CT findings were be grouped as nodal, extranodal and both. SUVmax of nodal and extranodal lesions were measured. Results were verified with clinical follow up and histopathology. Histopathological confirmation of the suspected lesion was taken as reference standard. Results: Age of patients ranged from 3-48 years [mean of 31.5 (±1.25) years]. M:F ratio was 1:1. Of the 26 patients with RDD, PET/CT demonstrated pure lymph nodes (LN) involvement in 15 (57.7%), extranodal in 3 (11.5%) and both nodal & extranodal lesions in 8 (30.8%) patients. Pure LN involvement patients presented with generalised LN in 12 and with bilateral cervical LN in 3 patients. Retro-orbital mass was the extarnodal site who presented with pure extranodal involvement. In patients with both nodal and extranodal involement, skeletal and soft tissue lesions were the extranodal sites. The mean SUVmax of nodal and extranodal lesions were 6.8 and 5.7 respectively. PET/CT emerged as excellent imaging modality for assessment the disease burden with 100% sensitivity and PPV for detecting nodal and extranodal lesions. In our study extranodal in total was found in 42.3% of patients. It correlates with the literature which quotes extranodal involvement is seen in 25%-43% cases. We had 12 patients with generalized lymph nodes involvement which mimics lymphoproliferatve disorders. In this scenario, FDG PET/CT findings are nonspecific for RDD, and a biopsy is needed to establish the diagnosis. This study was the first to evaluate the role of FDG PET/CT in RDD in a larger population till date. Conclusion: ^{18}F-FDG PET/CT is a very useful imaging investigation for diagnosing and staging in RDD. PET/CT emerged as excellent imaging modality for assessment the disease burden for detecting nodal and extranodal lesions.

EP315

Alert Management In Oncologic Unenhanced 18F-FDG PET-CT Studies

J. Mucientes, B. Rodríguez, A. Prieto, J. Cardona, M. Mitjavila; Hospital Puerta de Hierro Majadahonda, Madrid, SPAIN.

AIM The aim of this poster is to describe the most common findings in oncologic unenhanced 18F-FDG PET-CT studies which must be immediately or as soon as possible communicated to the referring physician. MATERIAL AND METHODS We revised unenhanced 18F-FDG PET-CT and described the most common findings encountered in oncologic patients which can be life-threatening or require a priority or immediate evaluation. We described these findings with supporting images. RESULTS When a PET-CT study is finished is useful a fast evaluation to assess the image quality and the possible findings which need a immediate or priority clinical evaluation. We divided the findings depending on

the location. Head and Neck Unsuspected brain metastases is one of the most frequent findings which may require a priority evaluation by the referring physician. If there is brain herniation, evaluation should be immediate. Neck airway obstruction or stenosis due a tumour needs to be evaluated clinically. Chest Pneumothorax is other of the most frequent findings in patients referred to a FDG PET-CT scan. Recent pulmonary biopsy is one of its causes. Severe pleural or pericardial effusion needs clinical evaluation and may need thoracentesis or pericardiocentesis.Unsuspected great vessels tumour infiltration may require a priority evaluation.Focal cardiac uptake may require a priority echocardiography. Abdomen Some infrequent findings as pancreatitis, cholecystitis or appendicitis may require clinical evaluation or surgical treatment. Patients should be explored to assess their clinical status. Skeletal Fracture risk assessment and evaluation of soft tissue masses which can produce spinal cord compression should be done in patients with bone metastases. CONCLUSION There are many findings to assess at the end of oncologic PET-CT scans. Some of this findings may require immediate or priority clinical/complementary evaluation even in unenhanced PET-CT studies.

EP316

Can 18F-FAMT replace 18F-FDG for malignancy detection? A meta-analysis of diagnostic accuracy

A. Achmad[1], A. Bhattarai[1], R. Yudistiro[1,2], T. Higuchi[1], Y. Tsushima[1]; [1]Gunma University, Maebashi, JAPAN, [2]Mochtar Riady Comprehensive Cancer Center, Jakarta, INDONESIA.

Aim: This meta-analysis evaluates the diagnostic accuracy of -3-^{18}F-α-methyl tyrosine (^{18}F-FAMT) PET in malignancy detection in comparison with that of ^{18}F-FDG PET. **Material and methods:** Electronic search was performed for diagnostic test accuracy studies directly comparing ^{18}F-FAMT and ^{18}F-FDG PET for detection of malignant tumors from the inception of ^{18}F-FAMT to August 2015. Study quality, the risk of bias and sources of variation among studies were assessed using the QUADAS tool. A separate meta-analysis was performed for diagnostic performance based on visual assessment and based on diagnostic cut-off. The meta-analysis method was applied according to the study availability after systematic review. Whenever possible, a bivariate random-effect model was used for analysis and pooling of diagnostic measures across studies. **Results:** Forty-two peer-reviewed basic science investigations and clinical studies were reviewed, and six eligible studies (272 patients, all were prospective studies) of various type of cancer were meta-analyzed. The diagnostic accuracy of both radiotracers were consistent under either univariate or bivariate meta-analysis. The diagnostic accuracy of ^{18}F-FAMT was higher than ^{18}F-FDG for malignancy based on both visual assessment (diagnostic odd ratio (DOR): 8.90 (95% CI 2.4-32.5) vs 4.63 (95% CI 1.8-12.2, area under curve (AUC): 87.8% vs 86.1%) and diagnostic cut-off (DOR: 13.83 (95% CI 6.3-30.6) vs 7.85 (95% CI 3.7-16.8), AUC: 87.0% vs 87.1%), respectively. Resultant data of accuracy based on visual assessment were only slightly heterogeneous. **Conclusion:** ^{18}F-FAMT PET has a better diagnostic performance for malignancy detection compared to ^{18}F-FDG PET.

EP317

18F-FDG PET-CT Appropriateness According to EANM Guidelines: Analysis of 200 18F-FDG PET-CT Request-Forms from a Single PET-CT Centre

M. Mattoli[1], V. Scolozzi[1], D. Ripani[1], L. Indovina[2], V. Rufini[1], A. Giordano[1], M. Calcagni[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [2]Institute of Physics, Università Cattolica del Sacro Cuore, Rome, ITALY.

Introduction: The appropriateness for oncological ^{18}F-FDG PET-CT is established by EANM guidelines published in 2010 (v.1.0) and updated in 2015 (v.2.0). A pre-requisite for evaluating the appropriateness is to have an evaluable request-form: it should report a clear clinical indication with all information attached. Aims: to assess whether the request-forms for PET-CT were evaluable in order to establish the appropriateness according to EANM guidelines v.1.0 and v.2.0; to analyse the most common clinical indication. Materials and methods: We retrospectively evaluated 200 oncological ^{18}F-FDG PET-CT request-forms. We defined "evaluable" the request-form in which the clinical information was sufficient to evaluate the appropriateness. Otherwise, the nuclear physician retrieved other additional clinical information in the medical record. Results: EANM guidelines v.1.0: 117/200 (58.5%) request-forms were non-evaluable: in 76/117 (65%) the clinical indication was unclear, and in 41/117 (35%) additional information was needed despite a clear clinical indication. EANM guidelines v.2.0: 76/200 (38%) request-forms were non-evaluable because of unclear clinical indication. After retrieving the missing data, all clinical indications were identified. Significant difference (p=0.01, χ^2test) between non-evaluable request-forms according to EANM guidelines v.1.0 and EANM guidelines v.2.0 was found. The clinical indications were: follow-up (n=65), restaging (n=40), staging (n=32), response evaluation (n=35), pulmonary nodule characterization (n=22), guiding biopsy/radiotherapy planning (n=4); unknown primary malignancy (n=1), screening (n=1). Conclusions: Applying the EANM guidelines v.1.0, more than half of the request-forms were not evaluable, while applying the EANM guidelines v.2.0 the rate of non-evaluable request-forms was significantly lower. The main reasons making the request-form non-evaluable were: 1) clinical indication missing or unclear, regardless the guidelines used; 2) missing of specific information (histotype; whether locally advanced; whether the relapse is potentially curable) only required by EANM guidelines v.1.0, that can be considered more restrictive than those of 2015. Finally, the most common clinical indication was "follow-up", the only indication not present in both guidelines. This finding can be attributed to the precautionary attitude of the referring physicians and/or to "defensive medicine" attitude while it is known that PET-CT cannot be used to monitor oncologic patients. The consequences of this "malpractice" are: unnecessary exposure to radiations; longer waiting-list for patients needing an appropriate PET-CT; high healthcare costs; increased number of exams and reduced time for tumour-board discussions and for educational sessions, especially in an Academic centre. On the contrary, a clear clinical indication is mandatory, regardless from the guidelines' version, reflecting the professional competences of referring physicians.

EP318

Improving Patient Accesibility to Nuclear Medicine and Radiation Therapy Services in Argentina: Challenges and Pitfalls Encountered in the Implementation of an Ongoing Nationwide Initiative

D. J. Passadore[1,2], J. C. Furnari[1], V. E. Ugarte[3], L. Rovere[4], V. J. Ugarte[5]; [1]Comisión Nacional de Energía Atómica, Buenos Aires, ARGENTINA, [2]Fundación Centro Diagnóstico Nuclear, Buenos Aires, ARGENTINA, [3]Fundación Escuela Medicina Nuclear, Mendoza, ARGENTINA, [4]Comisión Nacional de Energía Atómica, San Carlos de Bariloche, ARGENTINA, [5]Centro de Medicina Nuclear y Molecular de Entre Ríos, Paraná, ARGENTINA.

Aim. A national strategic plan for improving the availability and utilization of nuclear medicine and radiation oncology in our country is being carried on under the coordination of the Comisión Nacional de Energía Atómica (CNEA, the local National Atomic Energy Commission), in order to mitigate the uneven deployment of these technologies, which affects patients' accessibility and equality in healthcare. The present article describes the challenges and pitfalls faced in implementing the initiative, which is ongoing, named Plan Nacional de Medicina Nuclear

(PNMN, i.e. National Plan of Nuclear Medicine). Materials and Methods. Seven new facilities are being built in different regions all over the wide geography of the country that currently don't have or have limited access to hybrid imaging technologies and the most modern radiation therapy (RT) techniques. Most of the new centers comprise the installation of PET/CT and SPECT/CT cameras as well as Cyclotron and PET Radiopharmacy, together with the RT devices. All new centers are planned to be operational during the biennium 2016-2017, although the different services will be available on a gradual basis, depending mainly on the availability of specialized human resources. The total amount invested in equipment sums up to approximately 90 million USD and another 82 million USD in buildings and service areas. The new centers are receiving on-site as well as remote support for different purposes but basically for training; equipment set-up, acceptance testing and maintenance and advice for achieving compliance with regulatory requirements, from previously existing centers and facilities, in operation for several years. Results. The crucial pitfalls originate from the short period of time assigned to the construction process and the necessary coordination with the specification and installation of the equipment, all of which must comply with the nuclear and pharmaceutical regulatory requirements together with the significant number of new centers to be built. The major challenge is to identify, recruit and establish teams of physicians, technologists, pharmacists and other essential human resources, especially in remote and therefore less populated regions of the country. Conclusions. Being a country with a long history of development of the peaceful applications of nuclear energy, it is considered to be a pending issue the federalization of access to nuclear medicine and radiotherapy. Nevertheless, the scale of the initiative entails such a number of specialized human resources that imposes a major challenge to its success, moreover if a homogeneous level of quality must be provided.

EP319

Intracardiac tumor thromboembolism initially detected by ^{18}F-FDG PET/CT

S. Lee[1,2,3], D. Lee[4], J. Kim[3,2], J. Choe[2,5]; [1]Department of Nuclear Medicine, G Sam Hospital, Hyosan Medical Foundation, Gyeonggi-do, KOREA, REPUBLIC OF, [2]Department of Medicine, Graduate School, Korea University, Seoul, KOREA, REPUBLIC OF, [3]Multimodal Imaging and Theranostic Lab, Cardiovascular Center, Korea University Guro Hospital, Seoul, KOREA, REPUBLIC OF, [4]Department of Medical Oncology, G Sam Hospital, Hyosan Medical Foundation, Gyeonggi-do, KOREA, REPUBLIC OF, [5]Deptment of Nuclear Medicine, Korea University Anam Hospital, Seoul, KOREA, REPUBLIC OF.

Cardiac ^{18}F-fluorodeoxyglucose (^{18}F-FDG) uptake with oncologic purpose FDG positron emission tomography/computed tomography (PET/CT) has been widely reported and accepted as variable. Thus, cardiac FDG uptakes are often not well assessed and evaluated during malignancy work-up. We report two cases of intracardiac tumor thrombi initially detected by FDG PET/CT. Case 1: Initial staging FDG PET/CT scan of a 36-year-old female for pancreatic cancer revealed focal hypermetabolism on left atrium. On the background CT images, there was no definite abnormal finding but PET finding suggested intracardiac tumor thromboembolism. Patient underwent transthoracic echocardiography for clarification of the FDG-avid lesion. The echocardiographic examination revealed a mass lesion in LA around MV annulus. Case 2: Patient underwent FDG PET/CT for malignancy of unknown primary origin (MUO) work-up. This patient suffered recurrent multiple embolic brain infarction without underlying disease. PET scan suggested primary site as lung cancer, with multiple lymph node metastases in meduastinum, and there noted irregular hypermetabolic lesion in the left atrium. Patient had undergone echocardiography 2 month earlier without abnormal finding. According to the PET finding, follow up echocardiography was done and newly developed LA mass lesion was detected.Emergency operation was conducted for resection of LA tumor thrombi and pathologic result was metastatic squamous cell cancer from lung origin. Conclusion: ^{18}F-FDG PET/CT findings led to the diagnosis of unexpected intracardiac tumor thromboembolism in these two cases.

EP320

How Can We Use Digital Programmable LED Lighting in a Nuclear Medicine Environment?

M. M. Knopp[1], J. Milacek[2], M. I. Knopp[2], K. Binzel[2], C. L. Wright[2], M. V. Knopp[2]; [1]Emory University, Atlanta, GA, UNITED STATES, [2]The Ohio State University, Columbus, OH, UNITED STATES.

While dedicated commercial solutions for ambient LED lighting have been available for years and are increasingly used in healthcare environments, broader utilization has been limited due to high costs. Fully digital, IP addressable lights have entered broadly into the consumer market and thus are economical and available in a large variety of LED configurations. We explored, assessed and report on experience of deploying such systems in a nuclear medicine environment. While there are several standards evolving from home automatization to bus based technologies, we focused on the broadly adapted standard of the ZigBee. A major advantage of such a consortium approach is interoperability of LED lights and control. Manufacturers support software development tools and have smart device apps available for local and remote control. Most devices are uniquely IP addressable and enable variation in intensity and hue. We focused on the programmability in hue for creating specific ambience such as a calming setting either in the dose injection rooms, the imaging suites, or the reading rooms, we also looked at the feasibility system interfaces to enable visual feedback for timing or procedure feedback. We utilized replaceable bulbs in recessed housings, lightstrips and standalone fixtures. Patient, subject and staff experiences and visual perception of LED intensity and hue was recorded by interview and questionnaire. The implementation of consumer level, IP addressable LED lighting proved to be simpler than anticipated and economical. While manufacturer software applications are available, complex applications do require customization. This can be achieved by software coding utilizing a large portfolio of developer toolkits which also enable vast flexibility including complex applications to support visual feedback approaches. We implemented several use cases e.g. remaining length of examination feedback and hue guidance for breath holding. Especially for patient instructions / feedback, traditional use of verbal communication can now be supplemented or replaced with visual guidance. The overall perception and acceptance of ambient LED lighting concepts was even more positive than originally anticipated in all areas of patient, imaging, and reading rooms. The deployment of consumer level programmable LED components was found to be feasible, robust, and economical. The feedback and acceptance has been exceptional as the inherent flexibility and customization enables new concepts to improve room ambience, thus patient and staff experience and its IP based programmability facilitate light hue and intensity as a nonverbal guidance and feedback tool.

EP321

Diagnostic performance of PET/CT or PET and CT for detection of peritoneal carcinomatosis: a meta-analysis

H. Zhou; West China Hospital, Chengdu, CHINA.

Purpose: The study aims to perform a meta-analysis to compare the diagnostic performance of 18F-FDG PET/CT and CT for detection of peritoneal carcinomatosis (PC). Methods: Articles of 18F-FDG PET/CT and CT on PC published in English from January 1990 to September 2016 was searched in the PubMed, EMBASE, Cochrane Library, Web of

Science, and EBSCO databases to identify eligible studies on PET/CT or CT of peritoneal metastases. QUADAS was used to evaluate the methodological quality of the included studies. Pooled sensitivity, specificity, and diagnostic odds ratios (DOR) were calculated both on a per-patient basis. Summary receiver operating characteristic (SROC) curves were also drawn to obtain the area under curve (AUC) and Q* value. Results: 27 articles were included in the analysis. On a per-patient basis, the pooled sensitivity of PET/CT (68%) was significantly higher than that of CT (60%), and the pooled specificity of PET/CT (95%) was markedly higher than that for CT (88%). Conclusions: This meta-analysis indicated that FDG PET/CT was better than CT on a per-patient basis for diagnosis of peritoneal carcinomatosis (PC).

EP322

18F-FDG PET-CT Appropriateness: Comparison between EANM Guidelines 2010 (v.1.0) and EANM Guidelines 2015 (v.2.0) in 200 Oncological Patients

M. Mattoli[1], V. Scolozzi[1], D. Ripani[1], L. Indovina[2], V. Rufini[1], A. Giordano[1], M. Calcagni[1]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [2]Institute of Physics, Università Cattolica del Sacro Cuore, Rome, ITALY.

Introduction: The EANM guidelines 2010 (v.1.0) define the clinical indications for oncological ^{18}F-FDG PET-TC as "appropriate" or "promising"; the EANM guidelines 2015 (v.2.0) define them as "appropriate". Aims: to compare the ^{18}F-FDG PET-CT appropriateness between the two EANM guidelines versions; to match the appropriateness with clinical indications. Materials and Methods: We retrospectively compared the appropriateness of 200 consecutive oncological ^{18}F-FDG PET-CT applying EANM guidelines v.1.0 and EANM guidelines v.2.0. Results: For EANM guidelines v.1.0: 61/200 (31%) appropriate PET-CT for restaging (n=37), pulmonary nodule characterization (n=9), staging (n=8), guiding biopsy (n=3), response evaluation (n=3), unknown primary tumor (n=1); 15/200 (7%) promising PET-CT all for treatment response; 124/200 (62%) inappropriate PET-CT for follow-up (n=65), staging (n=24), response evaluation (n=18), pulmonary nodule characterization (n=13), restaging (n=3), and screening (n=1). For EANM guidelines v.2.0: 127/200 (64%) appropriate PET-CT for restaging (n=40), staging (n=32), response evaluation (n=36), pulmonary nodule characterization (n=15), guiding biopsy (n=3), unknown primary tumor (n=1); 73/200 (36%) inappropriate PET-CT for follow-up (n=65), pulmonary nodule characterization (n=7), and screening (n=1). Conclusions: The amount of inappropriate and appropriate PET-CT was specular: higher inappropriate for EANM guidelines v.1.0, and higher appropriate for EANM guidelines v.2.0. The main causes were: 1) clinical indication not present in both EANM guidelines (follow-up); 2) indications of EANM guidelines v.1.0 rather restrictive (few types of primary tumors, locally advanced, ^{18}F-FDG avid). Although the EANM guidelines v.2.0 are less restrictive, we believe that some clinical indications in these guidelines deserve further clarifications: 1) "*differentiation of benign from malignant lesions*": which are the characteristics of the lesions and in which organ? PET-CT performance is different on the basis of these two aspects; 2) "*Staging patients with known malignancies":* how the malignancy was proved? Is it ^{18}F-FDG avid? Several malignancies are not ^{18}F-FDG avid. 3) "*Monitoring the effect of therapy on known malignancies*": which therapy? Which timing? How often the effects have to be monitored? The response evaluation is completely different on the basis of the type and duration of therapy. 4) "*Detecting tumour recurrence, especially in the presence of elevated tumour markers*": which is the proper level of increased markers? At first measure even if the level is borderline high? There are false positive results for tumour markers, as well as false negative results for PET-CT. It is hopeful that the EANM committee provides further information for each of these critical points in order to reduce the number of not-useful PET-CT.

EP323

Extra-pelvic extension of recurrent intra-pelvic tumor in FDG PET/CT : anatomical consideration

H. Munechika, T. Saginoya, Y. Miura, S. Takekawa, Y. Takano, Y. Teranishi, S. Hashimoto, Y. Fukaya, K. Watanabe; Southern Tohoku General Hospital, KORIYAMA, JAPAN.

Purpose ; Intra-pelvic malignancy can be detected easily by FDG PET/CT but an intra-pelvic tumor extending toward extra-pelvic space is not assisted adequately by FDG PET/CT alone in the setting of tumor recurrence. This is an educational exhibit to show extra-pelvic extension of a recurrent intra-pelvic tumor with anatomical consideration. Material and Method ; FDG PET/CT findings are correlated with enhanced-CT and MRI findings in a recurrent tumor after various treatment in cases with a rectum, uterus or bladder carcinoma. Anatomical landmarks are created to see which of the anatomical structures in the pelvic wall and floor can be passed through by a tumor to extent from the intra-pelvic to extra-pelvic space. The anatomical landmarks of the pelvic wall and floor indicate the following structures ; ①paces of the pelvic floor (urogenital triangle and rectal triangle) ②bones (pubic ramus, ischiopubic ramus, ischial ramus, ischial tuberosity, sacrum) ③muscles and ligaments (burbospongiosus muscle, ischiocavernus muscle, transverse perineal muscle, perineal membrane, perineal muscle, obturator internus muscle, levator ani, piriform muscle, sacrospinous ligament) ④foramina and fossa (sciatic foramen, ischiorectal fossa, sacral foramen, obturator foramen) Discussion and Conclusion ; The landmarks of the pelvic wall and floor facilitate to recognize anatomically extra-pelvic extension of a recurrent intra-pelvic tumor in FDG PET/CT and it is convinced by enhanced-CT and MRI because of better delineation of the landmarks.

EP324

Gastric Hernia Mimicking Lung Mass in PET-CT: Case Report

G. Mutevelizade, Y. Parlak, G. Gumuser, D. Goksoy, E. Sayit; Celal Bayar University, Manisa, TURKEY.

Gastric Hernia Mimicking Lung Mass in PET/CT: Case ReportA 54 years old male patient was referred to our clinic for PET/CT scan with the indication of primary esophagus carcinoma pre-treatment staging in November 2013. In 2011, he was treated for lung cancer and had received chemotherapy and radiotherapy in a different clinic. In June 2013 thorax CT showed progresssion in the dimensions of the lung mass and F-18 FDG PET/CT was performed for restaging. PET/CT had been reported as progression of size and metabolic activity of the mass located in the paravertebral area at the left lower lobe (SUV max:6.4). Also, newly formed malignant thickening of the wall at distal esophagus was reported. Primary esophagus adenocarcinoma had come as a result of the endoscopic biopsy. We reported malignant thickening at the lower end of esophagus in PET/CT examination in our clinic (SUV max:19.3). Also, rolling hernia was determined at the paramediastinum localization of the neighborhood of esophagus which had moderately increased FDG uptake at the gastric wall (SUV max:6.4). Thorax and abdominal CT was performed and the same lesion was reported as rolling hernia due to its wall structure similar to the gastric fundus and liquid content inside. Gastric barium X-Ray was done and gastric hernia presence was confirmed. While the evaluation of F-18 FDG PET/CT scan for oncologic patients, some non-oncological conditions may lead to incorrect assessments. It should be considered that this can affect the stage of the disease and management of medication. That's why we have to be very careful while interpreting PET/CT scans and multidisciplinary approach can be useful in case of suspense.

EP325

Role of FDG PET-CT in predicting response to Selective Internal Radiation Therapy (SIRT) in Hepatocellular carcinoma (HCC)

M. Jreige, P. Mitsakis, A. Van-Der-Gucht, M. Nicod Lalonde, M. Silva Monteiro, A. Denys, J. Prior, N. Schaefer; Centre Hospitalier Universitaire Vaudois (CHUV), LAUSANNE, SWITZERLAND.

Aim of the study: To determine different conventional and functional imaging staging variables affecting response to SIRT in HCC patients. Materials and methods: We reviewed retrospectively imaging studies of patients with HCC referred in our institution for SIRT. FDG PET-CT images in the pre-therapeutic setting were analyzed and SUVmax for lesions and SUVmax and SUVmean of normal liver parenchyma were reported. T stage was determined for each case based on initial liver MRI results by analyzing number and size of lesions and vascular invasion. Results of different variables were correlated to progression-free survival (PFS) based on a Kaplan-Meier survival analysis and Log-Rank Test. Results: Sixty patients undergoing SIRT were enrolled retrospectively. All patients received prior FDG - PET and liver MRI. A positive correlation with PFS was shown with SUVmax using a threshold of 8g/ml corresponding to the mean value of the population (p=0.049) using the Log Rank test. However, morphologic criteria measured in MRI as singularity of lesions versus multiple lesion (p = 0.071), lesion size less or more than 3 cm (p=0.274), lesion size less or more than 5cm (p=0.629) or vascular invasion (p=0.541) did not predict PFS in our patient population. SUVmean outside lesions using a threshold of 2.5 g/ml was not predictive for further PFS as well. Conclusion: In our population only SUVmax in HCC lesions with a threshold of 8g/ml in the FDG - PET prior to SIR therapy was predictive for PFS. Morphologic parameters as single vs multiple lesions, lesion size or vascular invasion were not predicting median PFS. . Further studies using bigger sample or prospective approach are needed.

EP-17 – Sunday, October 16, 2016, during Exhibition hours, e-Poster Area
Clinical Oncology: Thyroid & Parathyroid

EP326

Protein expression heterogeneity between primary tumor and distant metastasis in differentiated thyroid cancer

I. LIM, J. Choi, J. Myung, M. Lee, B. Byun, B. Kim, C. Choi, S. Lim; Korea Cancer Center Hospital, Seoul, KOREA, REPUBLIC OF.

Purpose: The aim of this study was to investigate the protein expression heterogeneity between primary tumor and distant metastasis in differentiated thyroid cancer (DTC) patients in terms of glucose metabolism and somatostatin receptor (SSTR). Method: We retrospectively reviewed 18 DTC patients (M : F = 7 : 11, Age; 56 ± 10) with bone or soft tissue metastases. The protein expressions were assessed as negative, weak positive, strong positive by immunohistochemistry in terms of glucose transporter 1 (GLUT-1), hexokinase 2 (HK-2), and somatostatin receptor 2 (SSTR-2) from surgical specimens. The correlations between protein expression and iodine avidity and FDG avidity were evaluated using radioiodine scan and 18F-FDG PET scan. These parameters were analyzed using Chi-squared test, Mann-Whitney test and spearman correlation.Results: Metastatic lesions showed higher GLUT-1 expression (65%, 11/17) than primary lesions (50%, 9/18). HK-2 were expressed highly in both primary (17/18) and metastatic (16/17) sites. Primary lesions revealed similar SSTR-2 expression (9/18) to metastatic lesions (7/17). The GLUT-1 expression tended to show positive correlation between primary and bone metastasis (r=0.46, P=0.06), but the HK-2 and SSTR-2 did not show the correlation between them respectively (HK-2 r=0.21, P=0.42; SSTR-2 r=0.056, P=0.83). Of the 8 patients who underwent surgery and PET imaging within 1 year, GLUT-1 positive group showed higher SUVmax than GLUT-1 negative group (p=0.046), while HK-2 (P=0.74) and SSTR-2 (P=0.65) did not show significant difference. Regarding iodine avidity and SSTR-2 expression, no significant difference was observed in terms of SSTR-2 expression between iodine avid and iodine non avid patients (P=0.32). 1 of 6 patients showed SSTR-2 expression in case of iodine non avid patients.Conclusion: GLUT-1 expressions showed positive correlation between primary tumors and bone metastatic lesions of DTC, which was not observed for HK-2 and SSTR-2. Particularly, SSTR-2 targeted therapy could be applied for some iodide non-avid patients.

EP327

Thyroglobulin Doubling Time as a prognostic indicator in management of differentiated Thyroid cancer

S. Fatima, S. T. Butt, M. Faheem; Nuclear Medicine , Oncology & Radiothearpy Institute (NORI), Islamabad, PAKISTAN.

Serum thyroglobulin (Tg) is most important disease predictor in post thyroidectomy differentiated thyroid cancer(DTC) patients. Raised Thyroglobulin indicates unsuccessful surgery or disease recurrence in post treatment patients. Objective of this study was to evaluate the prognostic value of the serum Thyroglobulin doubling-time in differentiated thyroid cancer patients. **Methods:** We retrospectively analyzed total of 431 patients with DTC presenting to department of Nuclear Medicine between January 2009 to December 2013. Patent having raised anti-Tg antibody were excluded from the study. Total 328 patients' data with 3 or more serum Tg measurements was finally submitted for analysis. The Tg doubling-time was computed using Tg values measured during routine follow-up. Patients were followed for a mean of 26.9 months and a median of 27.2 months. **Results:** Of the 328 patients, 119 patients had 4 or more measurements that revealed detectable serum Tg. The Tg doubling-time (Tg-DT), calculated using all available data, varied widely, and were grouped into those that were less than 1 year (9 patients), those that were 1-3 years (15 patients), and those that were more than 3 years (22 patients), as well as those with a negative value due to decrease in serum Tg (63 patients). There were also 83 patients who had three or fewer serum Tg measurements that showed detectable but stable Tg levels, as well as 177 patients in whom serum Tg measurements were below the lower limit of detection. In the group of patients with a Tg-DT of less than year the cause specific survival at 5 years was 50%, and in the group with a Tg-DT of 1-3 years it was 95%. In all other groups it was 100%. Many classical prognostic factors (age, gender, tumor type, tumor size and stage) as well as the Tg-DT were significant indicators of survival by univariate analysis, but Tg-DT remained the only independent predictor by multivariate analysis. Tg-DT was also the only independent predictor of distant metastases and loco-regional recurrence on multivariate analysis. **Conclusions:** Tg-DT is a very strong prognostic predictor superior to the classical prognostic factors in patients with DTC.

EP328

Is Thyroglobulin at Ablation a Good Predictor for Thyroid Remnant Size in Differentiated Thyroid Cancer?

H. C. Martins[1], G. Costa[1], R. Silva[1,2], P. Gil[1], J. Isidoro[1], J. Pedroso de Lima[1,2]; [1]Centro Hospitalar e Universitário de Coimbra, Cabeceiras de Basto, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde., Coimbra, PORTUGAL.

Aim: Stimulated thyroglobulin (sTg), measured at radioiodine remnant ablation (RRA) in patients with differentiated thyroid cancer (DTC), is an

important predictive factor of persistent disease. However, Tg produced by normal thyroid cells may contribute to the sTg value. We aimed to study the relationship between sTg level in RRA period and the thyroid remnant size (TRs), using post-therapy whole-body scan (131I-ptWBS). **Materials and methods:** We review DTC cases referred to our department for RRA, prepared with recombinant human TSH (rhTSH) and with low-iodine diet in the week preceding the treatment. Anti-thyroglobulin antibodies (TgAb) and sTg were measured on the fifth day after the first rhTSH injection. Patients with positive TgAb, with evidence of 131I-uptake outside the thyroid bed on 131I-ptWBS and suspected to have persistent disease on the first 6-12 month follow-up period (Tg≥1ng/mL and suspicious neck ultrasound) were excluded. A total of 274 patients (225 woman, 49 men; average age±sd:48.7±14.4 years-old) were selected. For each patient, TRs was assessed by 131I-ptWBS, using a fixed-circular region of interest (ROI) placed in thyroid bed. The geometric mean (GM) of the total counts (cts) in the ROI was calculated, corrected for the thigh background and normalized according to the treatment activity (nGM). Based on nGM, remnants were classified into small(S)-nGM≤10cts/MBq; medium(M)-10cts/MBq<nGM≤50cts/MBq and large size (L)-nGM>50cts/MBq. *Spearman's* rank *correlation* coefficient was used to test the association between sTg and the TRs. Statistical analyses were carried out using SPSS version-23. **Results:** 151 patients (55.1%) were included in group-S (average sTg=11.9±41.3ng/mL, range:0-357ng/mL); 93 (33.9%) in group-M (average sTg=48.6±137.3ng/mL, range:0-1161ng/mL) and 30 (11%) in group-L (52.9±95.2ng/mL, range:0-406ng/mL). When all patients were taken into account, a moderate positive correlation between nGM and sTg was found (r_s=0.55,P<0.001). When divided according to remnant size, a moderate positive correlation was found in group-S (r_s=0.57,P<0.001), however, we did not find a significant correlation between nGM and sTg values in group M and L (r_s=0.05,P=0.66 and r_s=0.24,P=0.20 respectively). **Conclusion:** Radioiodine-scintigraphy and sTg are important tools to evaluate the functional status of both normal and neoplasic thyroid tissue. However, in DTC patients, our results suggest that in the absence of clinical/imagiological disease, a moderate correlation between TRs and TG was only found in small remnant size patients. Therefore, we hypothesize that TRs is not a good predictor of sTg values in patients submitted to less extent thyroidectomies.

EP329

Serum thyroglobulin concentration after rhTSH stimulation as a prognostic factor during adjuvant radioiodine treatment of differentiated thyroid cancer

D. Handkiewicz-Junak, A. Ledwon, A. Kropinska, J. Roskosz, E. Paliczka-Cieslik, Z. Puch, T. Gawlik, T. Olczyk, B. Jarzab; Centre of Oncology - MSC Memorial Institue, GLIWICE, POLAND.

Measurement of serum thyroglobulin (Tg) levels is a well established marker for monitoring patients with differentiated thyroid cancer (DTC). Tg concentration during adjuvant radioiodine treatment after thyroid hormone withdrawal is prognostic factor. However, if the adjuvant radioiodine treatment is performed after rhTSH stimulation there are no data when is the most appropriate time to measure Tg concentration. The aim of the work was to compare Tg concentration measured on 3rd and 6th after rhTSH stimulation as a prognostic factor during adjuvant radioiodine treatment. **Patients and Methods.** 279 patients with DTC treated with total/near total thyreoidectomy and adjuvant radioiodine treatment after rhTSH stimulation were included into the study. Most patients were diagnosed with papillary thyroid cancer (91%). 37% had T3/T4 disease and 23% had lymph node metastases. Only patients with negative Tg antibodies were evaluated. Median time of observation in the studied group was 5 years. **Results**. Median Tg concentration during 1st, 3rd and 6th day of rhTSH stimulation was 0,9 ng/ml, 8 ng/ml i 16 ng/ml respectively. During follow-up structural recurrence was diagnosed in 17 (6%) of patients. Tg concentration on 1st, 3rd and 6th day of rhTSh stimulation was higher in patients diagnosed with recurrence during follow-up however the difference was statistically significant only for measurements performed on day 3rd of stimulation (median 15 ng/ml vs 40 ng/ml respectively in patients without and with recurrence). In all measurements Tg concentration was highly related to diameter of thyroid remnants. **Conclusions.** Preliminary results suggests that although during adjuvant rhTSH aided radioiodine treatment the highest Tg concentration is on day 6, results from day 3 of stimulation are more sensitive to predict disease recurrence.

EP330

^{131}I-SPECT/CT usefulness in the follow up of patients thyroidectomized for thyroid papillary microcarcinoma (PTMC)

A. Spanu, I. Gelo, L. Mele, B. Piras, S. Nuvoli, G. Madeddu; University of Sassari, SASSARI, ITALY.

Introduction: PTMC present excellent prognosis in most cases, but it can be multicentric/multifocal and present neck lymph node metastases, local recurrences and also distant metastases. Thus, PTMC lesion identification is mandatory for the most precocious and appropriate treatment. In this study, we evaluated 131-SPECT/CT usefulness, in PTMC patients in follow up post-thyroidectomy. **Methods**: Among 704 follow up patients with differentiated thyroid carcinoma, we retrospectively selected 321 PTMC patients. At surgery, 19 patients were at high risk (H), 76 at low risk (L) and 226 at very low risk (VL); 94 patients had multicentric disease (47 bilateral). In 294 cases, 48 h after diagnostic 185 MBq ^{131}I dose, and in 27 cases, 5 days after radioiodine therapeutic dose, planar WBS (5 cm/min) followed by SPECT/CT over neck/chest and other suspected regions was performed using hybrid dual-head gamma camera with high energy, parallel hole collimators and with low dose x-ray tube, for total 557 exams. **Results**: Both planar and SPECT/CT were negative in 196/321 patients, while planar evidenced 277 iodine fixing foci in 113/321 patients and SPECT/CT 332 in 125 patients confirming all foci evidenced by planar, but correctly characterizing 79 foci in the neck and outside classified as benign or unclear at planar and identifying 55 further occult foci. Globally, SPECT/CT correctly classified 80 malignant lesions in 23 patients (4H, 5L, 14VL), while planar, although evidenced 48 metastases in 11 patients (4H, 4L, 3VL), only characterized 15 in 2 patients (1H, 1L). Seventeen/23 patients (1H, 3L, 13 VL) only had neck lymph node metastases, 9 VL being T1a N0M0 with undetermined Tg, while in the remaining 8/17 Tg was <2.5 to> 10 ng/ml; 2/23 patients (1L, 1VL) only had metastases outside the neck (lung and mediastinum) both of them with Tg <2.5 ng/ml; 4/23 patients (3H, 1L) had metastases in both the neck and outside with Tg levels from <2.5 to> 10 ng/ml. In 6/23 cases PTMC was multifocal. **Conclusion**: This study confirms that PTMC can be aggressive since our follow up patients developed metastases in 7.8% of cases. 131I- SPECT/CT proved higher performance than planar to evidence and characterize malignant lesions, in particular in patients VL, T1aN0M0 and very low Tg levels, obtaining a global incremental value in positive patients of 43.2% than planar and changing planar classification and patient management in 24.8% of cases. SPECT/CT wider use is suggested in PTMC patient follow up.

EP331

The incremental value of ^{131} IODINE SPECT/CT in the management of DTC patients

A. Ezzine[1,2], M. Ben Fredj[1,2], H. Regaîeg[1], R. Sfar[1], S. Melki[1,2], H. Boudriga[1], M. Nouira[1,2], K. Chatti[1], S. Ajmi[1], M. Guezguez[1]; [1]Nuclear medicine department, Sousse, TUNISIA., Sousse, TUNISIA, [2]LR 12Es02, Faculty of Medecine Sousse, University of Sousse, Sousse, Tunisia, TUNISIA.

Aim: The aim of this study is to evaluate the incremental value of single photon emission computed tomography/computed tomography (SPECT/CT) over planar radioiodine whole-body imaging and to assess its clinical impact on the management of patients. Materials and methods: We retrospectively reviewed planar ^{131}I whole-body and ^{131}I-SPECT/CT imaging findings in 27 of differentiated thyroid cancer (DTC) patients (23 women and 4 men) with an average age of 49 years-old, who underwent ^{131}I therapy for thyroid cancer (22 papillary and 5 follicular) approximately 5 days after the therapeutic administration of 3,7 GBq (100 mCi) of ^{131}I. The foci of increased tracer uptake were identified in the neck, thorax and elsewhere. Serum thyroglobulin level, histopathology and other imaging findings served as the reference standard. Results: Planar imaging showed 57 foci of uptake and SPECT/CT showed 67 foci, confirming all foci seen on planar imaging but identifying an additional 10 occult foci in 8 of 27 patients. SPECT/ CT correctly characterized 63 uptake foci unclear on planar imaging. It was a determinant in classifying as neoplasic 49 foci of 67 (73, 13%) and identified 14 foci of 67 as false positive findings. Only in 4 cases, SPECT/CT was insufficient and a complementary exploration was needed. Globally, SPECT/CT modified therapeutic management in 43.33% and avoided unnecessary treatment in 20, 89% of patients with only single benign lesions or physiologic uptake. Conclusion: ^{131}I-SPECT/CT is a valuable addition to standard post-therapy planar imaging. It improved diagnostic confidence and provided crucial clinical information leading to change of management for a significant number of DTC patients.

EP332

131I-SPECT/CT predictive value to the occurrence of radioiodine-positive cervical lymph node metastatic disease a year after ablation in patients with thyroid cancer

I. Iakovou, E. Giannoula, V. Mpalaris, V. Athanasiou, D. Katsaboukas, S. Georga, D. Lo Presti, K. Badiavas, G. Arsos; Academic Nuclear Medicine Department, Aristotle University, Papageorgiou General Hospital, THESSALONIKI, GREECE.

PURPOSE: To investigate the value of 131I-SPECT/CT performed at the first radioablation to predict the occurrence and/or persistence of radioiodine-positive cervical lymph node metastatic disease (CND) after a year. **METHODS:** All 87 consecutive DTC patients (23/64 men/women,47.9+-16.9 yrs, 54/4/29 - papillary/ follicular/ follicular variant of papillary DTC, 47/20/17/3 - T1/ T2/T3/T4, 23 N1, 2 M1 stage) referred to our department for ablation in 2014 enrolled in the study. 131I-WBS and SPECT/ CT just after ablation and 7-12 months later at TSH stimulation was performed. The outcome variable of the study was the detection or exclusion of 131I-positive CND. **RESULTS:** Of 65 patients without a SPECT/CT diagnosis of 131I-positive CND at ablation, 63 had no 131I-positive CND at follow-up (49 no uptake, 14 thyroid remnant persisted). In the 2/65 patients a new radioiodine-positive CND lesion was detected. In 20 of 22 patients with a SPECT/CT 131I-positive CND diagnosis there was no evidence of 131I-positive CND (15 no uptake, 5 thyroid remnant persisted) at the time of follow up. In almost all cases (19/ 20) where CND was treated with radioiodine, lymph nodes were smaller than 1ml. while lymph node size was bigger than 1.2ml in the 2 cases of persistent CND. **CONCLUSION:** 131I-SPECT/ CT at ablation has a high negative predictive value with regard to the occurrence of radioiodine-positive CND a year after initial treatment. Even if the diagnosis of CND at ablation scan may consequence to an early surgical re-intervention, the fact that small size CND responds well to radioiodine treatment motivates for new studies to elucidate the parameters predictive of response to treatment of CND by 131I .

EP333

Clinical Significance of Follow-up I-131 Diagnostic Scintigraphy after Radioactive Iodine Ablation Therapy on Well-differentiated Thyroid Cancer

H. Song; Jeju National University School of Medicine, Jeju-si, KOREA, REPUBLIC OF.

<META NAME="author" CONTENT="송희성">**Purpose** This retrospective study researched for clinical significance of routine follow-up (F/U) I-131 diagnostic scintigraphy (Dx-scan) after radioactive iodine therapy (RI-Tx) on well-differentiated thyroid cancer. **Subjects & Methods** Three hundreds eighteen patients were enrolled. All underwent total thyroidectomy due to well-differentiated thyroid cancer and high dose RI-Tx to ablate remnant thyroid tissue. The definition of complete ablation was below 2.0 of F/U stimulated thyroglobulin (sTg) plus negative finding of F/U Dx-scan after RI-Tx. The rest except complete ablation was regard as incomplete ablation. Re-treatment performed when pathologic results of recurrence or clinical findings of highly suspicious recurrence. **Results** Five of complete ablation patients (n=185) were taken the re-treatment (2.7%). Main diagnostic modalities affecting the re-treatment were Dx-scan (n=2), contrast CT (n=1), ultrasonography (n=1) and sTg (n=2). 29 of incomplete ablation patients (n=133) performed the re-treatment (21.8%). Chief diagnostic tests affecting the re-treatment were FDG PET/CT (n=14), contrast CT (n=5), ultrasonography (n=9), Dx-scan (n=2), and sTg (n=2). Dx-scan influenced in 1.1% of complete ablation patients and 1.5% of incomplete ablation patients for the re-treatment. **Conclusion** F/U Dx-scan after RI-Tx is not useful for detecting recurrence especially in incomplete ablation patients, considering difficulties of the preparation of I-131 diagnostic scan compared to FDG PET/ CT, ultrasonography and contrast CT.

EP334

Are TSH serum levels greater than or equal to 30 mIU/L prior to RAI a predictor of successful treatment of patients with differentiated thyroid carcinoma?

E. Vasilenko[1], D. Fomin[1], I. Guryanov[2]; [1]Russian Scientific Center of Roentgenoradiology, Moscow, RUSSIAN FEDERATION, [2]National Research University Higher School of Economics, Moscow, RUSSIAN FEDERATION.

Aim: Comparative evaluation of combined treatment results in patients with DTC at different levels of TSH-stimulated prior to RAI. Materials and Methods: The study included 197 patients (36 female, 161 male) of the age group 18-75 years with a mean age of 47 years. In all cases DTC was confirmed by histological tests (154 papillary carcinoma cases and 43 follicular thyroid cancer cases, stage T1-T3, N0-N1, M0). 4 weeks prior to RAI all patients were suggested to follow an iodine-free diet with the abolition of L-T4 supplementation. Although recent ETA (2010) and ATA (2015) guidelines recommend that serum TSH levels should be $\geq$ 30 mIU/L for successful treatment, in 50 patients this level has not been achieved due to their severe physical condition or individual characteristics. Nevertheless, radical radioiodine activities from 3.0 to 4.2 GBq and posterior scintigraphy were carried out for all patients. A year after RAI a stimulation test with the abolition of L-T4 supplementation was performed for all patients. Test results were regarded as negative if the Tg level was less than 2 ng/ml and scintigraphy showed no disease. The data was analyzed using several statistical methods: analysis of variance (ANOVA), linear and logistic regression models. Linear regression and ANOVA allowed us to compare serum TSH levels and find significant differences between the two groups of patients (remission/no remission). The dependent variable was serum TSH level and the independent variable was treatment success. Logistic regression allowed us to estimate the impact of serum TSH level change on the success of treatment. Results:

Linear regression and ANOVA showed that mean serum TSH level in the no-remission group was 58.709 mIU/L and in the remission group it was 62.903, but the difference of these means was not statistically significant (t-value = 0.77, p-value = 0.442 at p<0,05). Analysis of variance also confirmed it. Logistic regression showed that there was no impact of serum TSH levels on the treatment success (t-value = 0,771 p-value = 0,44 at p<0,05). Based on this logistic regression model, it has been unable to predict the failure of a single treatment according to serum TSH levels (R^2 (Nagelkerke)=0,005). Conclusion: The resulting data from the analysis showed that there was no statistically significant association between serum TSH levels prior to RAI and DTC remission. If the standardized protocol for patient preparation for RAI is observed, it is not required to reach any fixed TSH threshold.

EP335
Comparison of FLT-PET/CT and FDG-PET/CT in detection of metastases of differentiated thyroid cancer

A. Murai[1], K. Kato[2], S. Iwano[1], S. Ito[1], S. Naganawa[1]; [1]Nagoya University Graduate School of Medicine, nagoya, JAPAN, [2]Nagoya University School of Health Sciences, nagoya, JAPAN.

Purpose: 3′-deoxy-3′-18F-fluorothymidine (FLT) has been recently developed as a PET/CT proliferation tracer. Up to the present, there have been few studies investigating its role in differentiated thyroid carcinoma (DTC). The aim of this study was to assess the efficacy of FLT-PET/CT for the detection of metastases in DTC in comparison with 2-deoxy-2-18F-fluoro-D-glucose (FDG)-PET/CT. **Materials and Methods:** We examined 17 patients (9 women, 8 men; mean age, 59.6±5.2 years) with DTC who had undergone total thyroidectomy and were hospitalized to be given I-131 therapy. All patients were examined by FLT-PET/CT and FDG-PET/CT before the therapy, and they were examined by I-131 scintigraphy after the therapy. Metastases in lymph nodes, bones and lungs were assessed in the 7, 16 and 2 divided segments, respectively. The sites of metastases were identified by I-131 scintigraphy, CT, MRI and clinical information. The positive findings for metastases at FLT-PET/CT and FDG-PET/CT were defined as areas of focally increased uptake, exceeding that of surrounding normal tissue. The sensitivity and specificity were calculated on a segment basis. **Results:** Lymph node metastases of DTC were confirmed in 10 of a total of 119 segments in 6 patients, bone metastases in 28 of a total of 187 segments in 10 patients, and lung metastases in 26 of a total of 34 segments in 13 patients. The sensitivities of FDG-PET/CT and FLT-PET/CT in detecting lymph node metastases were 100% and 20%, respectively (p=0.013), and both their specificities were 98% (p>0.05). Their sensitivities in detecting bone metastases were 39 and 57%, respectively (p>0.05), and their specificities were 100 and 97%, respectively (p>0.05). Their sensitivities in detecting lung metastases were 51 and 8%, respectively (p=0.003), and both their specificities were 100% (p>0.05). **Conclusion:** The sensitivities of FLT-PET/CT in detecting metastases of DTC in lymph nodes and lungs on a segment basis were significantly lower than those of FDG-PET/CT. However, the sensitivity of FLT-PET/CT in detecting bone metastases was higher than that of FDG-PET/CT, although the difference was statistically not significant.

EP336
Prognostic impact of 18F-FDG PET/CT in detecting residual or recurrent medullary carcinoma of thyroid in realtion to rising calcitonin marker velocity

M. Siddique, A. Hasaan, H. Bashir, M. Nawaz; Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore.Pakistan., Lahore, PAKISTAN.

Objective: The aim of this study is to evaluate the efficacy and clinical impact of the ^{18}F-FDG PET/CT in localizing site of recurrence of medullary thyroid cancer(MTC) in patients with rising serum calcitonin level. **Material and Methods:**Retrospective analysis of 77 consecutive patients with histological diagnosis of MTC from 1995 to 2015, registered at a single center. The association of gender, age at diagnosis, pathologic findings, the TNM stage and rising tumor marker levels were correlated with ^{18}F-FDG PET/CT findings and overall survival. Results were confirmed by histopathological analysis in patients who underwent repeat surgery and by clinical followup - mean of 4 years(range: 6 months-8 years). **Results:** Seventy-seven(8.1%) of the total thyroid cancer patients registered at our centre had MTC. Mean age 37 years[range: 17 to 67 years]. Twenty-five females, 52 males. 17(22%) underwent partial thyroidectomy due to irresectable disease, 60(78%) had total thyroidectomy. By TNM staging; 10(13%) had stage II, 8(10.4%) had stage III disease and 47(61%) had stage IV disease. In 12(15.6%) histology was missing. Distant metastasis were present in 27(35%) at baseline. 10 pulmonary, 12 bone, 6 liver and one brain metastases. 12 of 77had MTC associated with MEN syndromes; 10 MEN IIA and two MEN IIB. On multivariant analysis, extrathyroidal extension, age greater than 40 years at diagnosis and distant metastasis were poor prognostic factors for survival (p-value: <0.05). 19 underwent ^{18}F-FDG PET/CT due to elevated post thyroidectomy calcitonin levels at baseline measured at 4 weeks - 6 months. 5, 1, 5 and 7 has post-op serum calcitonin level <50, 50-100, 100-1000, >1000respectively. Post op calcitonin was unavailable in 1 patient. Serum calcitonin levels doubled in 13(62%) over 4 months-5 years. 7(37%) had declining calcitonin levels. Nine of 12 with rising tumor markers, were upstaged by ^{18}F-FDG PET/CT findings. Hypermetabolic lesions were detected in 9/19(47.7%), with confirmation in 5 true positives (TP), 4 false positive(TP). Negative PET with no evidence of disease on follow up in 10/19(52.6%), indicating 10 true negatives (TN). In our series the sensitivity, specificity, PPV and NPV and accuracy was 100%, 71.4%, 56%,100% and 80% respectively. In addition, rate of change of calcitonin level over time showed no correlation with PET positivity. **Conclusion:** ^{18}F-FDG PET/CT scan is a sensitive imaging tool for detection of MTC recurrence. Additional information is gained in nearly 50% of patients with raised calcitonin levels by detecting occult disease or confirming findings of other imaging tools.

EP337
18f-fdg pet/ct accuracy diagnosis in thyroid incidentalomas

F. ZELAYA REINQUET, Jr., A. RENDA ALCALDE, Jr., D. Ruiz Hernandez, M. Castrillon, Jr., C. Castillo Berrio, F. Loira Bamio, J. Nogueiras Alonso, L. Campos Villarino, R. Guitian Iglesias, A. Lopez Lopez; EOXI Vigo Hospital Meioxeiro, Vigo, SPAIN.

Thyroid incidentaloma (TI) in FDG-PET studies, is defined as pathological uptake of 18F-FDG by the thyroid gland in patients without known thyroid disease. According to current literature reports the prevalence of these findings in FDG-PET studies around 1.2% and 4.3%, with a malignancy rate between 25% and 50%. The diffusely increased FDG uptake is attributed to benign autoimmune thyroid disease, while the focal uptake may be associated with primary malignancy and less frequently to metastasis. PURPOSE: 1) Know the percentage of patients who underwent histopathologic thyroid study (HTS) through FNA, by finding TI in FDG-PET study in our Center. 2) Determine the type of thyroid disease (benign vs malignant) study confirmed by HTS and establish relationship with the TI uptake pattern in FDG-PET. MATERIALS AND METHODS: We have performed a retrospective review of 567 reports of HTS of our center during 72 months (Dec/2009-Dec/2015); and cross database and select those patients in which indication of HTS study was based on the TI FDG-PET findings.From 567 HTS reports we selected those that within the following inclusion criteria (IC):1) Uptake pattern of TI describing in the FDG-PET report. 2) Evaluate the HTS findings regarding PET-FDG in a time not exceeding three months from the acquisition of tomography. RESULTS: From 567 HTS, 20 patients reports(PR) had inclusion criteria

(IC).Of the 20 reports:• 8 men and 12 women• Average age 64.65 years. 18F-FDG focal uptake 14 patients: 8 with DTC (differentiated thyroid carcinoma) definitive diagnosis.5 with benign pathology(2 follicular benign nodule and 3 nodular thyroid hyperplasia) .1patient in study.Medium SUV: 8.4g/ml.(range1,2-3,4g /ml) 18F-FDG diffuse uptake 6 patients:• 6/6 (100%) benign pathology (5 multinodular goitre/1chronic thyroiditis).• Medium SUV : 2.18g/ml.(range 2,8-36,6g/ml). CONCLUSION: We determined that in our series, 18F-FDG PET had a high sensitivity to detect thyroid disease in correlation with HTS (100%). In the focal uptake group, the sensitivity for detecting thyroid cancer was 61,53%.We found no relationship between the absolute value of the SUV and the likelihood of malignancy of the lesion. Although the sample is small and there is a selection bias of patients, the results of our study confirm those reported in the literature. It is advisable to enlarge explorations by the discovery of incidental FDG uptake in PET-CT studies especially in cases with focal uptake pattern.

EP338

Evaluation of the Thyroid Incidentelomas of the Patients Detected on F-18 FDG PET/CT

f. s. simsek[1], z. p. koc[2], t. a. balci[3], d. kuslu[1], y. narin[4], e. dönder[3], i. h. ozercan[3]; [1]elazıg training and research hospital, elazig, TURKEY, [2]mersin university, mersin, TURKEY, [3]firat university medicine faculty, elazig, TURKEY, [4]elazıg medical park hospital, elazig, TURKEY.

Background and Aims: The prognosis, meaning and risks of the patients with incidental thyroid nodules with FDG uptake is a challenging subject. There is no consensus about how to manage these kinds of patients. Aim of this study is to compare the lesion size and standardized uptake value (SUV) of the thyroid lesions of the patients with and without lymph node uptake and evaluate the results of the patients in follow up. **Materials and Methods:** 33 patients (14 Male, 19 Female; mean: 56±14,5 years old) who has increased uptake on F-18 FDG PET/CT examination were subjects of this study. In retrospective evaluation: mean size of the thyroid nodules were 1,9±1,2 cm; mean SUVmax value of these lesions were 7 ±4,5 and 11 patients among these 33 had additional lymph node involvement with lesion size of 1,8±0,9 cm and SUVmax of 6,8±3,2. Independent samples T test was performed and $p<0.05$ considered as significant. **Results:** In comparative analysis the age, lesion size and SUVmax value of the lesions of patients with and without lymph node involvement were not significantly different ($p<0,05$). Fine needle aspiration biopsy was performed to 10/33 patients (7/10; negative, 1/10; insufficient, 1/10; suspicious, 1/10; atypical aspirates) and total thyroidectomy/tru cut biopsy was performed to 5 of 33 patients (2/4 papillary thyroid carcinoma; 1/4 multinodular guatr; 1/4 malign mesenchimal tumor; 1/4 follicular adenoma). **Conclusion:** Additional lymph node uptake is not an indicator of higher SUVmax values or increased tumor size according to the results of this investigation. **Key Words:** thyroid, insidenteloma, F-18, FDG, lymph node.

EP339

Pre-ablation rhTSH-stimulated F-18 FDG PET/CT changes patient management in increased-risk thyroid cancer

G. Rendl, L. Rettenbacher, G. Schweighofer-Zwink, K. Hofstetter-Hörl, C. Pirich; Paracelsus Private Medical University Salzburg, SALZBURG, AUSTRIA.

Aim To evaluate the added-value of pre-ablation rhTSH-stimulated F-18 FDG PET/CT in comparison to the posttherapeutic whole body radioiodine scan in patients with advanced thyroid carcinomas. *Material and Methods* 53 sequential patients with moderate-to-high-risk thyroid carcinoma (31 females and 22 males) with a mean age of 58.5 ± 15.8 years were included in this study. 34, 14 (2 Hurthle cell variant) and 5 patients had papillary, follicular and poorly differentiated thyroid carcinoma, respectively. The majority of patients had a pT3 stage (n=40), pT3(m) (4 pts.), T2 (2 patients), pT4a (6 patients) and pTxN0M1 (1 patient), respectively. All patients underwent FDG PET/CT with low dose CT on the day of their first radioiodine ablation (after administration of recombinant human TSH two days before), and a posttherapeutic whole body radioiodine scan (RIS) in planar and SPECT/CT technique. *Results* 12 out of 53 patients had a positive FDG PET/CT but negative RIS, of whom 5 patients had histologically verified metastases in lymph nodes. The treatment plan was changed to surgery in 4 patients while one underwent palliative radiotherapy and tyrosinkinase-inhibitor therapy. One patient refused to undergo surgery and progressed clinically. Posttherapeutic RIS was equivocal to FDG PET/CT in 39 patients and just 2 patients presented with RIS positive but FDG PET negative metastasis of whom one each had cervical lymph node metastases and pulmonary metastases. *Conclusion* About 23 % of patients with advanced thyroid cancer had rhTSH-stimulated FDG PET positive but radioiodine-negative metastases, leading to changes in patient management.

EP340

Role of ^{18}F-Choline PET/CT in high-risk DTC patients. Comparison with ^{18}F-FDG PET/CT

B. Dib, G. Bottoni, L. Foppiani, V. Altrinetti, M. Massollo, M. Massollo, M. Cabria, **A. PICCARDO**; AZIENDA OSPEDALIERA GALLIERA, GENOVA, ITALY.

Aim: to evaluate the sensitivity and clinical impact of ^{18}F-Choline-PET/CT in patients affected by high-risk differentiated thyroid cancer (DTC) with suspected disease relapse during follow-up. We also compared ^{18}F-Choline-PET/CT findings with those of ^{18}F-FDG-PET/CT. **Materials and methods**: we prospectively evaluated 15 high-risk DTC patients who underwent total thyroidectomy and radioactive iodine treatment, and showed high/increasing thyroglobulin levels (median 8.1 ng/ml, range 1.6-340.0) under TSH suppression with L-thyroxine. All patients underwent ^{18}F-FDG-PET/CT and ^{18}F-Choline-PET/CT within 40 days from each other. For both imaging modalities we performed a both patient-based and lesion-based-analysis, and calculated the sensitivity. The standard of reference was based on clinical, imaging and histological data. In particular, histopathological results were available for 9 out of 15 patients. **Results:** the standard of reference confirmed disease relapse in all patients. On patients-based analysis, both ^{18}F-FDG-PET/CT and ^{18}F-Choline-PET/CT were positive in 10 out of 15 patients (sensitivity 67%). ^{18}F-FDG-PET/CT was negative in 5 patients of which 4 affected by a non-virulent DTC subtype. ^{18}F-Choline-PET/CT was negative in 5 patients of which 3 affected by a virulent DTC subtype. Indeed, mismatching findings between the two imaging modalities were shown in 4 patients. The diagnostic association of the two modalities was positive in 12 out of the 15 patients (sensitivity 80%). On lesion-based-analysis, ^{18}F-FDG-PET/CT detected 22 out of 36 metastases (sensitivity 61%), ^{18}F-Choline-PET/CT 17 out of 36 (sensitivity 51%) and the association of the two modalities showed 25 out of 36 (sensitivity 69%). A lesion-based analysis to determine the sensitivity of each modality in detecting lesions according to anatomical locations was also performed; ^{18}F-Choline-PET/CT was more sensitive in detecting lymph-node relapse (13/19, 68 %) than ^{18}F-FDG-PET/CT (11/19, 58%). ^{18}F-FDG-PET/CT was more sensitive in detecting lung metastases (8/14, 57%), than ^{18}F-Choline-PET/CT (1/14, 7%). The 3 bone metastases were correctly identified by both modalities (sensitivity 100%). The association of the two modalities slightly the identification of lung metastases (9/14, sensitivity 64%).When we looked at the therapeutic implications, ^{18}F-Choline-PET/CT influenced treatment management in 3 out of 15 patients (20%). Conclusion: ^{18}F-Choline-PET/CT may add important diagnostic informations during the follow-up of high-risk DTC patients. Although its sensitivity does not seem to be higher than that of ^{18}F-FDG-PET/CT, ^{18}F-Choline-PET/CT may be considered a useful complementary tool especially in patients affected by non-virulent DTC subtypes and/or with suspected lymph-node relapse.

EP341

Role of 18F-FDG PET/CT in the therapeutic management of DTC with cervical lymph nodes metastasis

M. Larg[1,2], **M. Saftencu**[2], C. Pestean[1,2], E. Barbus[1,2], D. Piciu[1,2]; [1]The Oncology Institute "Prof. Dr. Ion Chiricuta", Cluj-Napoca, ROMANIA, [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, ROMANIA.

AIM Differentiated thyroid carcinoma (DTC) is the most frequent endocrine tumor, having a 10-year survival rate over 90%. In some forms of DTC, radioiodine therapy might lose its sensitivity. In these patients, 18-F FDG PET/CT scan might bring additional information about the aggressiveness of the neoplasm. Our aim was to analyze the influence of 18F-FDG PET/CT scans in changing therapeutic approach for DTC patients with clinically and ultrasonographically detected cervical lymphadenopaties. **MATERIALS & METHODS** Our group consisted of 94 patients (n=94) with DTC and cervical lymph nodes metastasis. All patients had positive serum thyroglobulin (TG) levels (>5 ng/mL in stimulated conditions), negative TG-antibodies and negative whole body scan. Clinical and ultrasonographic exams were performed, showing swollen cervical lymph nodes. Data regarding age, gender, stage, TSH, TG and TG antibodies, previous CT scans, surgical treatment, RIT and hormonal substitutive treatment was analyzed. Patients fasted for 6 hours before undergoing 18F-FDG PET/CT examination and blood glucose levels were measured. Whole body scans were acquired 60 minutes after i.v. injection of 10 mCi 18F-FDG. **RESULTS** Out of 94 patients, 31 (31.95%) presented pathological 18F-FDG uptakes on their PET/CT scan in laterocervical lymphnodes, having the SUV (standard uptake value) lbm Max between 3-11.4. A group of 5 patients presented secondary tumors with various localizations (neck, mediastinum, lungs). Follow-up was indicated for the group of patients with normal PET/CT scans, while the patients with laterocervical lymph nodes metastatis had their therapeutic strategy changed. **CONCLUSION** 18F-FDG PET/CT examinations have an important role in patients with DTC and lymphatic metastasis, changing the therapeutic approach in 1/3 of the patients.

EP342

Role of recombinant human TSH in the diagnostic accuracy of 18F-FDG/scan-PET/CT in patients with differentiated thyroid carcinoma suspected of tumor recurrence

J. M. Nogueiras Alonso, F. Zelaya, C. Castillo Berrio, M. Castrillón, A. Renda Alcalde, R. Guitián Iglesias, F. Loira, L. Campos Villarino, D. Ruiz Hernández; Hospital Do Meixoneiro, VIGO, SPAIN.

Introduction: Whole body scan (131INa-WBS) in follow-up and identification of recurrent differentiated thyroid carcinoma (DTC) allows to guide the treatment. But 15-20% of patients with recurrence despite elevated Tg thyroglobulin, do not concentrated 131INa with WBS negative. FDG uptake is linked to neoplastic dedifferentiation, losing the ability to capture and organify iodine, TSH receptor expression, which stimulate cellular uptake and glycolysis persist. It´s postulated that TSH or rhTSH (human recombinant), stimulate cell metabolism accumulating more FDG. For some researchers the FDG-PET-CT sensitivity increases with TSH stimulation compared with suppressed TSH, detecting bigger FDG avidity, for other researchers the clinical impact is poor. Our objective was the prospective evaluation of 18-FDG-PET-CT locating pathological foci in patients with CDT and progressive elevation of Tg, and negative WBS, comparing the diagnostic yield with and without rhTSH in the same patient. Materials and methods: Study of 74 patients with DTC treated with thyroidectomy and 131INa radio-ablation, which showing progressive increase of Tg and negative 131INa-WBS, 16 patients were examined with 18F-FDG-PET/CT(GE Discover ST), with and without rhTSH, separated in 3 to 14 days, 15 patients with positive Tg-antibody only were explored with rhTSH. The standard reference was the histopathology, if it wasn't possible they were followed by Tg, and response to treatment. Results: 90 FDG-PET/CT in 74 patients (24-81 years), 26 men and 48 women. In 16 patients it was acquired with and without rhTSH. With the suppressed TSH we got 5 positive PET and 11 negative (meanTg/PET negative: 7.6ng/ml), SUVav: 2.65g/ml, S:33.33%, Sp:100%, PPV:100% and NPV:9.09 %. With rhTSH was positive in 15 and negative in 1, SUVav: 9.25 g/ml, S: 100%, Sp:100%, PPV and NPV of 100%. In 10/16 (62.5%) detection was possible only with rhTSH. In 74 patients with rhTSH the cut-off of Tg was 15 ng/ml, S: 58%; Sp: 76%; PPV: 75%; NPV: 59%. Accuracy: 66%. significantly higher ($p < 0.05$) than unstimulated Tg with negative PET. The location of foci showed no significant difference in the same patient with or without rhTSH. Conclusion: The use of rhTSH significantly changed the management for 10/16 patients (NF without rhTSH), increasing the sensitivity of 18F-FDG PET/CT, especially in patients with relatively low value of Tg (<10 ng / ml).

EP343

The utility of ^{18}F-FDG-PET/CT in differentiated thyroid cancer patients and elevated thyroglobulin after total thyroidectomy and ^{131}I ablation

K. Mladenov[1], **B. Spassov**[2], D. Vassileva[2]; [1]Clinic of Nuclear Medicine, University Hospital "Alexandrovska", Sofia, BULGARIA, [2]Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, BULGARIA.

Background: Whole-body ^{131}I scintigraphy (WBS) and serial thyroglobulin measurement (Tg) are standard methods for detecting thyroid cancer recurrence after total/near total thyroidectomy and ^{131}I ablation. Some patients with thyroid cancer recurrence have negative WBS scans (WBS-negative) but elevated Tg (Tg-positive). Positron emission computer tomography with ^{18}F-fluorodeoxyglucose (^{18}F-FDG-PET/CT) had been introduced in the clinical practice as an effective modality for detecting various cancer types. However data regarding the utility of ^{18}F-FDG-PET/CT for detecting recurrent thyroid cancer in Tg-positive WBS-neg patients are limited. **Aim:** This study aimed to evaluate the role of ^{18}F-FDG-PET/CT in recurrent differentiated thyroid carcinoma WBS-negative patients that are Tg-positive. **Material and methods**: We retrospectively reviewed 32 patients (8 men and 24 women), aged 31-67 years with histologically demonstrated differentiated thyroid cancer that underwent total/near total thyroidectomy followed by ^{131}I ablation. WBS and ^{18}F-FDG-PET/CT were performed according to standard operative protocols. Patients were WBS-negative but were suspected to have recurrence based on Tg levels. **Results**: ^{18}F-FDG-PET/CT identified negative scans and FDG accumulating lesions in 9 (28%) and 23 (72%) patients, respectively. Reasons for negative scans were insufficient thyroid-stimulating hormone stimulation applied to the low diagnostic dose of ^{131}I, very small tumor deposits to be detected by a gamma camera, a loss of concentration of iodine in the tumor and iodine-resistant metastases. In the positive group, 47.8% (11/23) had loco-regional disease (thyroid and local lymph nodes) while the remaining 52.2% (12/23) had distant metastases in mediastinum and lung. **Conclusion:** ^{18}F-FDG-PET/CT enables detection and precise localization of loco-regional recurrence and distant metastases of differentiated thyroid cancer in patients with elevated serum thyroglobulin but WBS-negative. Patients with positive ^{18}F-FDG-PET/CT accumulating lesions will probably need a change in their clinical management.

EP344

18-FDG-PET-CT the best diagnosis method in TENIS patients with elevated Tg-antibody

J. M. Nogueiras Alonso, **M. Castrillón**, A. Renda Alcalde, C. Castillo Berrio, L. Campos Villarino, F. Loira, D. Ruiz Hernández, R. Guitián Iglesias; Hospital Do Meixoneiro, VIGO, SPAIN.

The differentiated thyroid carcinoma DTC has a good prognosis and high cure rate with survival rate at 10-year of 80-90%, but with a recurrence of 20%, it can be ruled by: negative cervical US, negative 131INa-whole body scan (I-WBS) and undetectable thyroglobulin (Tg). With a negative I-WBS, the positivity of antiTg-Ab interferes and invalidates the proper determination of Tg, knowing that if the tissue is dedifferentiated and decreased iodine uptake ability by con-trast increases glucose metabolism of the tumor cell, in this sense F18-FDG/PET able to locate disease. We analyzed prospectively the use of 18F-FDG-PET/CT in follow up of patients with elevation antiTg-Ab and negative131INa-WBS.Material and methodsFrom 77 patients with DTC, negative I-WBS and detectable Tg followed for 4 years, we found 15 patients with detectable antiTg-Ab. 18F-FDG-PET/CT was made at 3rd day of stimulation with Thyrogen®, analytical (TSH, Tg and an-tiTg-Ab) basal and stimulated (3rd day), reviewed by two nuclear physicians.ResultsPatients: 15, papillary (10), follicular (4), (9♀-5♂) mean age 56,85y (31-79y).Eleven patients had metastatic lymph node involvement at initial diagnosis. After Thyrogen® all patientes showed elevated TSH (25.30 to 173.4 mIU/ml) and detectable antiTg-Ab (61-2530ul/ml), Tg(0.5-391.7ng/ml).31 Pathological hypermetabolism foci were obtained in 15 patients located in cervical region(25), supraclavicular(3), mediastinal(4), bone(1) with SUVmax of 1.5g/ml to 23.3g/ml.In 9 patients were confirmed metastatic DTC with pathological study (TP), one patient died and the result is pending in 5 patients.Conclusions18F-FDG-PET/CT shows high sensitivity (100%), detecting tumor foci susceptible to cleavage with a good diagnostic accuracy it could be considered as a suitable diagnostic method in patients with elevated antiTg-Ab and negative I-WBS. The sample is still very small, and is required a larger sample to correlate the values of antiTg-Ab with sensitivity and specificity PET/CT.

EP345

Cytological and Histopathological Correlation of Follicular Neoplasms of the Thyroid: Fine-Needle Aspiration Biopsy Results of 985 Patients and a Single Center Experience

S. INCE[1], E. ALAGOZ[1], O. EMER[1], **H. SAN**[1], A. AYAN[1], K. OKUYUCU[1], A. O. KARACALIOGLU[1], S. DEVECI[2], B. GUNALP[1], N. ARSLAN[1]; [1]GULHANE MILITARY MEDICAL ACADEMY, DEPARTMENT OF NUCLEAR MEDICINE, ANKARA, TURKEY, [2]GULHANE MILITARY MEDICAL ACADEMY, DEPARTMENT OF PATHOLOGY, ANKARA, TURKEY.

OBJECTIVE: Fine-Needle Aspiration Biopsy (FNAB) is a useful method for evaluation of thyroid nodules. However, it's not sufficient for the diagnosis of malignancy when follicular neoplasm is reported. We aimed to analyze final histopathological results of our follicular neoplasms in order to determine the prognostic value of FNAB. MATERIAL AND METHOD: Data from FNAB results of 985 consecutive patients were retrospectively analyzed. Patients with cytological diagnoses of follicular neoplasm who underwent thyroidectomy were evaluated. RESULTS: From 985 cases, 125 (12.69%) aspirates were non-diagnostic. 665 (67.51%) were benign; 60 (6.09%) were atypia of undetermined significance (AUS), 28 (2.84%) were follicular neoplasms; 4 (0.4%) had suspicion of malignancy; 44 (4.46%) were malignant tumors; 4 (0.4%) were parathyroid neoplasms; and 5 (0.5%) were Hurthle cell neoplasm on FNAB. Besides, 50 (5.07%) patients were underwent lymph node biopsy. Of 28 follicular neoplasms 16 were surgically treated: 10 (62.5%) were benign; 6 (37.5%) were malign. Benign cases included 8 follicular adenomas and 2 goiters; malign cases included 5 papillary carsinomas and 1 follicular carcinoma. The calculated risk of malignancy and positive predictive value in follicular neoplasm group was 37.5%. Of 5 Hurthle cell neoplasms 4 were surgically treated and all of them were benign: 2 were goiters; 2 were Hurthle cell adenomas. CONCLUSION: FNAB is a primary method for preoperative evaluation of thyroid nodules. Although it prevents unnecessary thyroidectomies, false positive ratio is somewhat high in follicular neoplasms. Although our result is a little higher than the malignancy risk in follicular neoplasms reported in the literature (15-30%), it is still close proximity to the upper range. We think this is because all follicular neoplasms were not surgically treated and clinical properties of the study group were not got into account.

EP346

Clinicopathologic features and prognostic factors of tall cell variant of papillary thyroid carcinoma: comparison with classic variant of papillary thyroid carcinoma

K. Okuyucu[1], E. Alagoz[1], N. Arslan[1], O. Emer[1], **S. Ince**[1], S. Deveci[2], A. Ayan[1], A. Taslipinar[3], B. Gunalp[1], O. Azal[3]; [1]Gulhane Military Medical Academy, Department of Nuclear Medicine, Ankara, TURKEY, [2]Gulhane Military Medical Academy, Department of Pathology, Ankara, TURKEY, [3]Gulhane Military Medical Academy, Department of Endocrinology, Ankara, TURKEY.

Objective: Tall cell variant (TCV), an aggressive form of papillary thyroid carcinoma (PTC), frequently presents with extrathyroidal disease and recurrence. The aim of this study was to evaluate the clinicopathologic features and outcomes of patients with TCV by comparing them with a larger group of patients with classic variant of papillary thyroid carcinoma (cPTC). Patients and methods: A total of 2500 patients with differentiated thyroid carcinoma were treated and monitored during a 23-year period (1992-2015). Of them, 2250 (90%) had PTC and 235 (9.5%) had follicular thyroid carcinoma. Of the 2250 patients, 862 (38.3%) and 70 (3.1%) had cPTC and TCV, respectively. Cases of TCV and cPTC of PTC were compared on the basis of risk factors. Results: Patients with TCV were significantly older compared with cPTC patients (P<0.001). Tumor size was significantly bigger (P=0.01) and preablation thyroglobulin level was significantly higher (P<0.001) in TCV patients than in cPTC patients. The incidence of capsule invasion, extrathyroidal extension, and vascular invasion was significantly higher in TCV (P=0.003,<0.001, and 0.011, respectively). The incidence of initial lymph node metastasis was significantly higher in TCV (P<0.001). Patients with TCV were mostly at an advanced stage compared with patients with cPTC (P<0.001). Development of local or distant metastasis during the follow-up was significantly higher in TCV than in cPTC. Sex and multifocality were not statistically significant. Conclusion: TCV has a higher incidence of local or distant metastasis and mortality rate. Thus, it must be treated with the highest possible I-131 ablation doses and followed up carefully.

EP347

Clinical Value of Radioactive Iodine 131 Ablation Therapy in Postoperative Patients with Papillary Thyroid Microcarcinoma

j. Wang, s. Li, l. zhang, x. Yao, r. Liu, f. Wang, z. Wang; Nanjing First Hospital, Nanjing, CHINA.

Objective: To explore the clinical application value and the prognostic evaluation of patients with papillary thyroid microcarcinoma(PTMC) who underwent radioactive iodine 131(I-131) ablation therapy after thyroidectomy. **Material and methods**: we collected 71 cases of patients with PTMC who underwent thyroidectomy, pathological examination, and I-131 ablation therapy in 2015, and analyse their data retrospectively. Measurement data were described with mean±standard deviation($\overline{x}\pm s$), and using logistic regression to describe relation between the risk of PTMC recurrence and age, gender, foci number>1, extrathyroidal invasion , cervical lymph node metastasis >3. **Results**: Mean age of cohort was 41.46 years ±11.47;male/female ratio was 1:3.56;foci number >1 were 35, and others were 36.The mean tumor size was 0.47 cm ±0.39. Extrathyroidal invasion was seen in 14.08% of cases. Cervical lymph node metastasis was seen in 35.07% of cases, among them the metastatic rate of lymph node in neck central area was 52.15%, and other areas was

47.85%. All patients performed I-131 ablation therapy with 100mCi. Cervical lymph node metastasis and pulmonary metastases recurred in 9.86% of cases after I-131 ablation therapy, among them the metastatic rate of cervical lymph node was 7.04%, lung metastases were 2.82%. Univariate analysis showed that PTMC recurrence was associated with extrathyroid invasion and cervical lymph node metastasis number>3($P < 0.05$).Age, gender and foci number were unrelated to PTMC recurrence ($P>0.05$). **Conclusions**: It was revealed that extrathyroidal invasion, cervical lymph node metastasis >3 contribute to PTMC recurrence after I-131 ablation therapy. I-131 ablation therapy, serving as one main tool for targeted therapy of remanent thyroid, can display metastases sites and reduce recurrence rate.

EP348

Management of bone metastasis of differentiated thyroid cancer: Critical role of Iodine 131

S. E. Bouyoucef, D. mouas, A. Amimour, M. Habbeche, A. Talbi, A. Khelifa, s. Rahabi, F. Brahmi; CHU Bab El Oued, Algiers, ALGERIA.

Objective: To determine the role of Iodine 131 in the management of bone metastasis of differentiated thyroid cancer Patients and methods This is a retrospective study including 78 patients with bone metastasis of differentiated thyroid cancer (DTC) with a regular follow up at the department of nuclear medicine of CHU Bab El Oued. Those 18 men and 60 women with an average age of 52 years (range from 20yrs to 70yrs) presented bone metastasis of DTC with the following pathological variants: 60 follicular (pure or variant forms), 11 papillary (9 pure and 2 variants) and 7 indeterminate. From the 78 patients, bone metastasis were the onset of DTC in 31 patients and discovered during the follow up in 47 patients. Bone mets were associated with mets in other parenchymal sites in 41 patients (including 30 in lungs). The most common site of bone mets were spine (56) followed by pelvis (54) then skull (42). All patients were treated with radio iodine, 33 alone and 45 in association with other therapeutic modalities (Surgery, external radiotherapy and targeted chemotherapy). Results 78 patients received at least 11GBq with a global average of 18GBq. For patients who were treated by radio iodine alone average of cumulative dose was inferior than those patients who received additional therapy (16GBq versus 20GBq). Any complication of radio iodine treatment was noted for the 78 patients. Intrinsic stimulation alone was used in 57 patients and associated with recombinant TSH in 21 patients. 53 patients of 78 are well stabilized during 3 years by radio iodine and 40 patients have a survival of more than 5 years among them 13 patients with more than 10 years survival. All 60 patients are still stable and well controlled by radio iodine alone or associated with surgery and external radiotherapy. 8 Refractory cases for radio iodine were noted and moved to oncology to receive targeted or general chemotherapy. However, we have had 17 patients died and for 12 patients the reasons of their death were not linked to direct complications of bone metastasis. Conclusion Radio iodine treatment of bone metastasis under intrinsic alone or associated with external stimulation is an appropriate and safe therapy for bone metastasis of differentiated thyroid cancer. However active surveillance for at least twice a year is recommended for assessing regularly the status of bone mets and decide whether another complementary therapy is needed or not.

EP349

Treatment of malignant struma ovarii: report of 3 cases

A. Oudoux, A. Olivier, E. Leblanc, M. Jafari, J. Beaujot, H. Kolesnikov-Gauthier; CENTRE OSCAR LAMBRET, LILLE Cedex, FRANCE.

Struma ovarii (SO) is a rare tumor, mostly benign, defined as a predominance of thyroid tissue within a mature ovarian teratoma (approximately 3% of all ovarian teratomas). Malignant transformation occurs in less than 5% of all cases. After a local resection of the ovarian tumor, no consensus exists between surveillance alone and adjuvant therapy. We report our institutional experience. **Case report:** 3 patients (49, 67 and 56 years old) presented left ovarian mass (8, 4 and 6 cm respectively). One patient was asymptomatic and 2 patients presented metrorrhagia. They all underwent surgery. Because ovarian malignancies were suspected on imaging, two patients had a total hysterectomy with bilateral salpingo-oophorectomy, omentectomy and pelvic-aortic lymphadenectomy. Unilateral salpingo-oophorectomy was performed in the patient with a localized cystic lesion. On pathological examination, the ovarian mass was a papillary thyroid carcinoma (lesion sizes: 7, 5 and 2.5 cm respectively). One patient had metastatic retrocave lymph node (5 cm) and omental nodules. For adjuvant therapy, they all underwent total thyroidectomy (2-3 months later), with the intention to treat with ^{131}Iodine. The thyroid consisted of normal tissue (2/3 patients) and 0.8 mm papillary micro-carcinoma (1 patient). Radioactive ^{131}I therapy (3.7 GBq) was administered 5 to 8 weeks later. The stimulated serum thyroglobulin level was increased to 3.4 and 19 ng/mL for 2 patients and inferior to 1 ng/mL for the last one. ^{131}I post-therapeutic scintigraphy only showed thyroid remnant uptake, without abnormal uptake for all patients. They were maintained on thyroid hormone suppression with thyroxine. Six months later, stimulated serum thyroglobulin, diagnostic ^{131}I scintigraphy (185 MBq) and neck ultrasonography were normal for all patients. The subsequent follow-up consisted of a clinical examination and thyroglobulin measurements performed every six months for two years and annually thereafter. They remained free of disease respectively 5, 4 and 1 year later. **Conclusion:** If surgery is the first phase treatment of malignant SO, adjuvant therapy is not always proposed. In our institution, complementary ^{131}I ablation is administered in case of lesions over 2 cm, disease outside the ovary or aggressive histological features. Total thyroidectomy is necessary before radioiodine therapy. Post-therapeutic ^{131}I whole-body scintigraphy specifies the extent of the disease. After thyroid remnant ablation, serum thyroglobulin level can be used as a tumor marker. The clinico-biological monitoring of SO must be extended for 20 years, cases of late recurrence having been described.

EP350

Effect of adjuvant Lithium on Thyroxine (T4) concentration after radioactive iodine therapy

E. N. B. Hammond, M. W. H. Vangu; Charlotte Maxeke Johannesburg Academic Hospital, University of Witwatersrand, Johannesburg, SOUTH AFRICA.

Purpose: To study the effect of adjuvant lithium on serum T4 concentration in patients treated with RAI therapy in our environment. Methods: This was a prospective simple randomized comparative, experimental cohort study of hyperthyroid patients referred for radioactive ablation therapy in the two main academic hospitals in Johannesburg between February 2014 and September 2015. Results: Amongst the 163 participants submitted for final analysis, 75 received RAI alone whilst 88 received RAI with Lithium. Difference in mean T4 concentration at 3 months between RAI only (17.67pmol/l) and RAI with Lithium (11.55pmol/l) was significant with a small size effect ($U = 2328.5$, $Z = -2.700$, $p = 0.007$, $r = 0.01$). In participants who received RAI with Lithium, significant decrease in T4 concentrations observed as early as 1 month post RAI ($p= 0.0001$) whilst for those receiving only RAI, significant drop in T4 concentrations were observed only at 3 months post RAI therapy (0.000). Females and participants with Graves' who received RAI with adjuvant lithium also demonstrated significant drop in T4 concentrations at 1 month follow-up ($p = 0.002$ and $p =0.003$ respectively). Also, there was statistically significant difference in mean T4 concentration across the 3 visits ($p = 0.001$) for participants with nodular disease who received adjuvant Lithium with RAI therapy whilst

those treated with only RAI showed no significant difference in T4 concentration (p =0.607). Conclusion: Adjuvant lithium leads to a prompter and better response to RAI therapy with lower T4 concentration at end of study which also is achieved faster. Also prompter response and decrease T4 concentrations associated with Graves' disease, nodular goiter and females who received adjuvant lithium therapy.

EP351

Disease-Related Deaths and its Predicting Factors in Patients with Differentiated Thyroid Carcinoma

J. Mihailovic; Department of Nuclear Medicine, Oncology Institute of Vojvodina, Sremska Kamenica, SERBIA.

The aim of the study was to analyze the mortality rate and predicting factors which influenced the disease-related deaths (DRD) in patients with differentiated thyroid carcinoma (DTC) in a 45-year follow-up study. Patients: From 1968 to 2000 363 DTC patients underwent initial thyroid surgery in different hospitals throughout the country. All of them underwent therapy with I-131 in our institution and were monitored until the end of 2015. Among 363 patients, 52 were lost to follow-up. Predicting factors were calculated by the Kaplan-Meier method and Log-rank test. Results: Out of 311, 96 (31%) patients have died during the course of the disease: 36 (37.5%) man and 60 (62.5%) woman aged from 8 to 74 years (mean, 52.9 years). Out of 311 DTC, there were 63 (20.3%) DRD, while 33 patients died due to other causes of deaths. DRD was significantly influenced by patients'age (p=0.001) and nodal and/or distal metastases (p=0.000), while following factors had no influence to cause of death: type of the initial treatment, gender, histology of the tumor and recurrent disease (p=0.863, p=0.956, p=0.870, and p=0.827, respectively). Conclusions: Disease-related deaths occurred significantly more frequent in patients older than 45 years than in patients younger than 45 years. Presence of nodal and distal metastases has also significant influence on DRD. Patients with DTC should be adequately treated and lifelong monitored.

EP352

Long-term Prognosis of Follicular Variant of Papillary Thyroid Carcinoma: An Asian Single-Centre Retrospective Analysis

H. C. Low[1], Y. H. Kao[2], K. S. H. Loke[1]; [1]Singapore General Hospital, Singapore, SINGAPORE, [2]The Royal Melbourne Hospital, Melbourne, AUSTRALIA.

Background: The follicular variant of papillary thyroid carcinoma (FVPTC) is the most common variant of papillary thyroid carcinoma (PTC). The incidence of FVPTC has been increasing in recent years possibly related to ultrasound screening and earlier diagnosis. Several large multicentre studies had shown that FVPTC has similar or better prognosis than classical PTC. Others had reported excellent prognosis of non-invasive encapsulated FVPTC (EFVPTC). This study sought to compare the recurrence rate and long-term prognosis of patients with FVPTC (overall and different subtypes) at our Asian centre with that published in the medical literature. Methods: A retrospective clinicopathologic study of 110 patients with FVPTC from a single centre was performed. Variables evaluated include age at diagnosis, tumour size, tumour encapsulation, capsular and/or lymphovascular invasion, extrathyroidal extension, nodal and distant metastasis, treatment, recurrent or persistent disease and disease-specific mortality. All patients except six underwent total thyroidectomy; the six patients had subtotal or hemithyroidectomy. All patients except one also received adjuvant radioiodine treatment. The median follow-up duration was 92 months. Results: Our cohort consisted of 17 (15.5%) patients with non-invasive EFVPTC, 35 (31.8%) with EFVPTC with capsular and/or lymphovascular invasion, 52 (47.3%) with non-encapsulated FVPTC, and 6 (5.4%) with unknown capsule status. In the non-invasive EFVPTC group, one patient had nodal metastasis and another had distant metastasis at diagnosis. The latter had persistent metastatic disease. No recurrence or disease-specific mortality occurred in this subgroup. In the invasive EFVPTC group, 10 (28.6%) patients had nodal metastasis and 4 (11.4%) had distant metastasis. Four (11.4%) patients had persistent/recurrent disease and 2 (5.7%) died from disease. In the non-encapsulated FVPTC group, 14 (26.9%) patients had nodal metastasis and 8 (15.4%) had distant metastasis. Six (11.5%) patients had persistent/recurrent disease and 1 (1.9%) died from disease. In the last group, 2 patients had nodal metastasis and 3 had distant metastasis. Two patients had persistent/recurrent disease and 1 died from disease. Overall, 27 (24.5%) patients had nodal metastasis, 16 (14.5%) had distant metastasis, 13 (11.8%) had persistent/recurrent disease and 4 (3.6%) died from disease. Information on the cause of death for 6 patients was unavailable. Conclusions: In our cohort, FVPTC behaved more like follicular thyroid carcinoma with higher rate of distant metastasis than classical PTC. Recurrence and mortality rates are also not significantly lower than classical PTC. However, patients with non-invasive encapsulated FVPTC had no recurrence or mortality on follow-up, in keeping with current evidence in the literature.

EP353

Lymphovascular invasion with metastasis (locoregional lymph node or distant) among adult Filipino patients with papillary thyroid carcinoma: A Case Control Study

E. Linchangco, **I. Bandong**, G. Goco; St. Luke's Medical Center- Quezon City, Quezon City, PHILIPPINES.

Papillary thyroid carcinoma is the most common type of thyroid cancer. Treatment includes surgery and remnant ablation with radioactive iodine therapy while follow-up monitoring includes whole body Iodine-131 scans and thyroglobulin monitoring. Lymphovascular invasion has been used as a predictor of metastasis in different cancers. Lymphovascular invasion therefore, might be useful in predicting metastasis in patients with papillary thyroid carcinoma since metastasis in this type of carcinoma travels via the lymphatic route. **Objective:** The purpose of this study is to determine the association of lymphovascular invasion with metastasis among patients with papillary thyroid carcinoma. Records of patients with papillary thyroid carcinoma (histopathologic reports, thyroglobulin levels and whole body Iodine-131 scans) were reviewed retrospectively. **Results:** A total of 108 subjects were recruited for this study, 47 (43.5%) of which had lymphovascular invasion. There was no association found between lymphovascular invasion and metastasis on baseline (p-value = 0.72) and follow-up scans (p-value =0.07). However, there is an association between metastasis resolution on follow-up scans and high dose radioactive treatment (p-value = 0.02) regardless of presence or absence of lymphovascular invasion. Even though no association was seen between lymphovascular invasion and metastasis, a robust percentage of patients with lymphovascular invasion were positive for metastasis on whole body scans. **Conclusion:** There is significant association between the presence of LVI with elevated thyroglobulin levels (p-value = <0.0001). A significant association is also seen with LVI and dose activity with resolution of thyroid remnant, locoregional lymph node and distant metastasis (p-value = 0.02).

EP354

To ablate or not to ablate? The Question in Patients with Papillary Thyroid Microcarcinoma

M. URHAN[1], S. A. AY[2], A. I. FILIZ[3], F. DENIZ[2], A. YONEM[2], Y. KURT[3]; [1]GATA HAYDARPASA TRAINING HOSPITAL DIVISION

OF NUCLEAR MEDICINE, ISTANBUL, TURKEY, [2]GATA HAYDARPASA TRAINING HOSPITAL DIVISION OF ENDOCRINOLOGY, ISTANBUL, TURKEY, [3]GATA HAYDARPASA TRAINING HOSPITAL DIVISION OF SURGERY, ISTANBUL, TURKEY.

Objective: Some suggest completion thyroidectomy and radioablation for patients with -mostly incidentally detected- papillary thyroid microcarcinomas while some others favor just follow-up. We assessed the prognosis of the disease in a group of patients with hemi-thyroidectomy only and in another with thyrodectomized but not ablated. Findings were compared with those of both thyroidectomized and radioablated patients. Methods: Two-hundred fifty-four patients with a proven diagnosis of thyroid cancer <10 mm among 1720 were enrolled. Any patient with capsular invasion, intrathyroidal spread, lymph node invasion and multicentricity was excluded. In group A (22 patients; 15 female, 7 male; mean age 74), patients were hemi-thyroidectomized only while in group B (56 patients; 37 female, 19 male, mean age 62) all cases had a total or near-total thyroidectomy. The preoperative diagnosis was nodular/multinodular goiter. The remaining 176 patients (118 female, 58 male; mean age; 56) had total/near total thyroidectomy and radioablated. All patients were monitored with serum Tg levels measurements for every 6 months and with ultrasound evaluation of the neck. Any lesion seen on ultrasound and an increase in serum Tg/ATg were noted for a period of 2 to 15 years Results: In group A, no other tumor or lymph node invasion was detected in the surveillance period. In group B, in 32 of 56 patients serum Tg levels were less than 2 ng/dl (range; 0.2 to 3.9 ng/dl). In the remaining 24, inital serum Tg level ranged from 2.0 to 9.8 but decreased to <4.0 ng/dl after 6 months. In 9 patients, pathological lesions were detected with ultrasound and lymph node invasion was confirmed with fine needle aspiration cytology. In 2 of these 9 patients; serum Tg values were less than 2.0 ng/dl. In group C, initial serum Tg levels ranged from 10.1 to 19.8 (mean; 14.8), but after radioablation, mean Tg level decreased to <0.8 ng/dl. In 19 patients, (Tg levels; 0.2- 19.8 ng/dl9, lymph node invasion was detected and 12 of them had neck dissection. Conclusion: Approximately 1/10 of patients (11.5 %) with papillary thyroid microcarcinoma treated with total or hemi-thyroidectomy only presented with recurrent disease whereas 10.8% of patients treated with both total thyroidectomy and radioablation presented with recurrent disease in the surveillance period. As the difference is not significant between radioablated and not ablated groups, we do not recommend radioablation for patients with thyroid microcarcinoma with no unfavorable characteristics and follow-up.

EP355

^{131}I-iodine dose planning in well differentiated thyroid cancer treatment by *K*-Means Clustering

L. Mijatovic[1], M. Selmic[2], D. Teodorovic[3]; [1]University of Kragujevac, Faculty of Medical Sciences, KRAGUJEVAC, SERBIA, [2]University of Belgrade, Faculty of Transport and Traffic Eingngineer, Belgrade, SERBIA, [3]Serbian Academy of Sciences and Arts, Belgrade, SERBIA.

Background: Thyroid cancers are the most frequent endocrine carcinomas. A range of clinical parameters (the patient's diagnosis, the patient's age, the tumor size, the existence of metastases in the lymph nodes and the existence of distant metastases) affect a physician's decision-making in dose planning. The choice of dose recommended by a physician is based on physician's expertise and experience. The physician's decision cannot be, without difficulty, explained by exact rules and/or mathematical algorithms. **Aim**: We developed the model that recommends the dose of I-131 iodine that should be given to the individual patient. **Materials and Methods**: The proposed model is based on the *K*-Means Clustering procedure (learning algorithm that solve clustering problem). By using the *K*-Means Clustering procedure we classify observed group of patients into a certain number of clusters that are fixed a priori. The number of clusters is equal to the number of possible I-131 iodine doses. Every cluster represents one specific I-131 iodine dose. The developed model was tested on a group of 183 patients after total/near total thyreoidectomy. All patients had well differentiated thyroid carcinomas. A patient's hystopathologic diagnosis was one of the following: 1. Microcarcinoma papillare glandulae thyreoideae; 2. Ca-papillare glandulae thyreoideae multifocale; 3. Ca papillare-glandulae thyreoideae; 4. Hurtle cell carcinoma glandulae thyreoideae; 5. Ca folliculare gl. thyreoideae (multifocale); 6. Ca folliculare gl. thyreoideae; 7. Microcarcinoma papillare multicentricum. The dose of I-131 iodine that was given to the patients had the following four possible values: 1.85 GBq, 3.7 GBq, 5.5 GBq and 7.4 GBq. **Results**: The proposed approach was tested on the real data from patients treated in the Department of Nuclear Medicine, Clinical Center Kragujevac, Serbia. By comparing the results achieved through the proposed model with those resulting from the physician's decision, it was found that the proposed model is highly compatible with reality. In other words, the I-131 iodine doses suggested by the developed system are similar to the dose values recommended by the experienced nuclear medicine specialist. **Conclusion**: The developed model could be utilized for educational purposes, and with additional developments, it could help and direct young physicians.

EP356

Ablation with 100 mCi radioiodine and thyrotropin alfa in locally advanced thyroid cancer disease

S. Jeong[1], J. Jeong[1], J. Ha[2], S. Lee[1], B. Ahn[1], J. Lee[1]; [1]Kyungpook National University School of Medicine, Daegu, KOREA, REPUBLIC OF, [2]Chosun University Hospital, Gwangju, KOREA, REPUBLIC OF.

Background: It is unclear whether 100 mCi radioiodine (RI) with recombinant human thyrotropin (thyrotropin alfa) is as effective as 150 mCi RI with thyroid hormone withdrawal (THW) for RI ablation in patients with locally advanced thyroid cancer (DTC) disease underwent total thyroidectomy. We evaluated success rates and clinical outcomes by delayed risk stratification (DRS) treated either using 100 mCi RI with rhTSH or 150 mCi RI with THW. *Methods:* A total of 116 DTC patients with T4 or N1b by the 7th edition of the AJCC/UICC staging system were included. Ninety-six patients were treated using 100 mCi RI with rhTSH (LO group) and 80 patients using 150 mCi RI with THW (HI group). Successful RAI therapy was defined as (i) negative stimulated thyroglobulin (Tg) in the absence of Tg antibodies, and (ii) absence of remnant thyroid tissue and of abnormal cervical LNs on ultrasonography. Response to initial therapy was classified as excellent, indeterminate, or incomplete (biochemical or structural) by DRS. *Results:* RI ablation was succeful in 59.3% in the LO group and 55.6% in the HI group. There was no significant difference in the rate of successful RAI therapy between the LO and HI groups (p=0.55). DRS demonstrated that exellent, acceptable or incomplete response was 58.6%, 24.1% and 17.2% in the LO group and 44.4%, 22.2% and 33.3% in the Hi group, respectively. There was no significant difference in the rate of response to initial therapy between the LO and HI groups (p=0.49). *Conclusion:* Ablation using 100 mCi with rhTSH was as effective as 150 mCi with THW to treat locally advanced DTC patients with T4 or N1b disease.

EP357

Comparable Ablation Efficiency of 30 and 100 mCi of I-131 in Low to Intermediate Risk Thyroid Cancers Using Triple Negative Criteria

M. u. Zaman[1], N. Fa[2], A. Zaman[3], U. Zaman[3], R. Tahseen[3]; [1]AKUH, Karachi, PAKISTAN, [2]Dr Ziauddin Hospital, Karachi, PAKISTAN, [3]Dow University of Health Scineces, Karachi, PAKISTAN.

Background: There is a controversy about ablation efficacy of low or high doses of radioioidne-131 (RAI) in patients with differentiated thyroid

cancers (DTC). Purpose of this prospective study was to find out efficacy of 30 mCiand 100 mCi of RAI to achieve successful ablation in patients with low to intermediate risk DTC. **Materials and Methods:** This was a prospective cross sectional study which was conducted from April 2013 till November 2015. Inclusion criteria were patients of either gender, 18 years or older, having low to intermediate risk papillary and follicular thyroid cancers with T1-3, N0/N1/Nx but no evidence of distant metastasis.Thirty-nine patients were administered 30 mCi of RAI while 61 patients were given 100 mCi of RAI. Informed consents were acquired from all patients and counseling was done by nuclear physicians regarding benefits and possible side effects of RAI. After 06 months (range 6-16 months; after 2-3 weeks thyroxin withdrawal), these patients were followed up with stimulated TSH, thyroglobulin (sTg) and thyroglobulin antibodies, ultrasound neck (U/S) and a diagnostic whole body iodine scan (WBIS) for ablation outcome. Successful ablation was considered if stimulated Tg< 2ng/ml with negative antibodies, negative U/S and a negative diagnostic WBIS (triple negative criteria). ROC curve analysis was used to find diagnostic strength of baseline sTg to predict successful ablation. **Results:** Successful ablation based upon triple negative criteria was 56% in low dose and 57% in high dose groups (non-significant p value).Successful ablation based on single criterion (follow-up sTg<2 ng/ml) was 82% in low dose group than 77% in high dose group (p - non-significant). The ROC curve revealed that baseline sTg level ≤ 7.4 ng/ml has the highest diagnostic strength to predict successful ablation in all patients. **Conclusion:** We conclude that 30 mCi of RAI has similar ablation success to 100 mCi dose in patients with low to intermediate risk DTC. Baseline sTg ≤ 7.4 ng/ml is a strong predictor of successful ablation in all patients. Low dose RAI is safer, more cost effective and more convenient for patients and healthcare providers. **Key words**: Radioiodine ablation; differentiated thyroid cancer; successful ablation; low dose; high dose; stimulated thyroglobulin

EP358

Effectiveness of low radioiodine administered activity in patients with low risk differentiated thyroid cancer

I. YEDDES, Jr.[1,2], T. BEN GHACHEM[1], I. MEDDEB[1], K. LIMAM[1], M. SOMAII[1], I. SLIM[1], M. BEN SLIMENE[1]; [1]SALA AZAIEZ INSTITUTE, tunis, TUNISIA, [2]FACULTY OF MEDECINE OF t; university tunis el manarUNIS, Tunis, TUNISIA.

Background: the differentiated thyroid cancer (DTC) is deemed good prognosis tumors with a low potential for development provided to adapt the specific treatment. The postsurgical therapeutic management is still a controversial subject, but the radioiodine treatment is recommended for most patients. Indeed, there is no consensus on the dose of ^{131}I to be administered, although the current trend towards therapy easing through mini-cures for patients with good prognosis. **Aim:** to confirm the non-inferiority in terms of effectiveness of an ablative mini-cure from 1.11 to 1.85 GBq, over a cure of 3.7 GBq, in patients with DTC operated for low and very low risk. **Methods:** We retrospectively studied 157 patients with very low and low risk DTC, followed in the Nuclear Medicine Department of the Salah Azaiez Institute between 2002 and 2012. These patients had a complementary radioiodine therapy with either low dose (group A) or high dose (group B) with an evaluation at six months post treatment and in long-term. **Results:** The average age was 42.8±13.7 years with a female predominance (86.7%). The DTC papillary represented the most common etiology (95%) with a predominance of pure papillary (68%) on the follicular variant (27%). The first cure evaluation did not shown statistically significant difference between the two approaches in terms of therapeutic ablative efficiency (p=0.13). The overall success rate was 77% (121/157), with 83% (54/65) in group A and 72.8% (67/92) in group B. The likelihood of having a remission from the first cure was 1.83 times greater for patients treated with low doses (OR = 1.83, 95% CI: 0.23-1.29). At the end of follow, we have noted one case of refractory disease. The male gender (adjusted OR = 2.71, 95% CI 0.51-4.23, p=0.03), and the baseline Tg ≥ 10 (ng/ml) (adjusted OR = 3.48, 95% CI 1.25-9.67, p=0.01) were significantly independent predictors of successful first cure ablation. **Conclusion:** The results provide that mini-dose protocol is not less effective for ablation of the thyroid remnant than 3.7GBq activity.These results are consistent with the current strategy in the low risk DTC.

EP359

The Predictive Value of Postoperative Serum Thyroglobulin in the Outcome of Radioactive Iodine-131 Thyroid Ablation in Differentiated Thyroid Carcinoma

S. A. A. Elrasad[1], Y. G. Abdelhafez[2], A. Tawakol[1], A. Nawwar[1], S. M. A. El-Refaei[1]; [1]Cairo university, Cairo, EGYPT, [2]South Egypt Cancer Institute, Assiut University, Assiut, EGYPT.

Background: Thyroglobulin is commonly used to monitor patients with differentiated cancer thyroid. It has also become an excellent biological marker for tumor persistence or recurrence. **Aim of study:** To study the relation between the level of baseline serum thyroglobulin (Tg) and thyroid remnant ablation outcome using radioactive iodine-131 (RAI-131) in patients with differentiated thyroid cancer after surgical treatment. **Methods:** A prospective study involved 98 patients (age 20-70 years) with differentiated thyroid cancer, referred for post-surgical ^{131}I ablation. All patients performed baseline serum Tg, anti-Tg-Ab's under TSH stimulation as well as neck ultrasonography, before receiving RAI-131 ablation dose 1110 - 3700 MBq (30 -100 mCi). Follow-up was performed 6-8 months later. Successful ablation was determined by negative whole body ^{131}I scan, negative neck ultrasonography and stimulated serum thyroglobulin level less than 2 ng/mL. **Results:** Successful ablation was reported in 64 out of 98 cases (65.3 %). Baseline serum thyroglobulin level was significantly predictive of ablation outcome. ROC analysis identified a cutoff value of 3.7 ng/ml in predicting ablation outcome. Patients were divided into high and low baseline Tg groups using this cut-off point. Successful ablation was significantly higher in low Tg group 34 out of 44 patients (77.2 %) versus 30 out of 54 (55.5 %) in the high Tg group; P = 0.025. There was no significant difference between the two groups regarding their clinical and pathological data or the given 131-RAI ablative doses. **Conclusion:** Baseline serum thyroglobulin level is associated with ablation outcome. Serum Tg > 3.7 is linked to significantly higher rates of unsuccessful ablation.

EP360

Role of fluorine-18 fluorodeoxyglucose positron emission tomography/computed tomography in primary thyroid lymphoma

Y. Fan[1], **Y. Zhang**[2], Y. Zhi[1], N. Lin[1], J. Zhu[1], X. Wang[1]; [1]Peking university cancer hospital, Beijing, CHINA, [2]Peking university cancer hospital & Institute, Beijing, CHINA.

Objective: Primary thyroid lymphoma (PTL) is a rare malignancy, and this study aimed to investigate the usefulness of fluorine-18 fluorodeoxyglucose (^{18}F-FDG) positron emission tomography integrated with computed tomography (PET/CT) imaging in PTL. **Methods:** We retrospectively reviewed the data of 1141 patients with lymphoma who had undergone ^{18}F-FDG PET/CT. Of these, 17 patients (1.49%) were diagnosed with PTL via histological examination and Ansell criteria. The clinicopathological data were collected. Characteristic imaging features and metabolic information in baseline and interim ^{18}F-FDG PET/CT scans were assessed and summarized by three experienced nuclear medicine physicians. Metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in the baseline PET/CT were adopted as metabolic parameters. Treatment response was evaluated at the end of the first round of treatment or, in patients with progressive disease, at the time of

progression. Prognosis was estimated via the Kaplan-Meier method using clinical and metabolic parameters. **Results**: The mean age of PTL patients was 56 years (range, 37-74 years), and the female-to-male ratio was 1.83. Based on ^{18}F-FDG PET/CT images, the tumor appearances could be categorized into two types: a diffuse enlarged hypermetabolic thyroid (10 cases) and a solitary hypermetabolic nodule (7 cases). No necrosis or calcifications were found in the lesions. Of the 17 patients, 13 were at a limited stage and four were at an advanced stage. Of the 11 patients who underwent interim PET, eight ones showed complete response, two showed partial response, and one had no response. High whole-body TLG on baseline PET and positive residue on interim PET/CT were related to adverse prognosis ($P < 0.05$). Clinical factors, thyroid TLG, and MTV on baseline PET had no correlation with outcomes ($P > 0.05$). **Conclusions:** Baseline ^{18}F-FDG PET/CT may be helpful for characterizing and accurately staging lesions, evaluating the treatment response, and predicting the outcomes of patients with PTL.

EP361

Survival analysis of patients with locally advanced iodine-131 refractory papillary thyroid carcinoma treated with peptide receptor radionuclide therapy

M. Vlajkovic[1], M. Matovic[2], V. Artiko[3], E. Matovina[4], M. Rajic[1], M. Stevic[1]; [1]Clinical Center Nis, NIS, SERBIA, [2]Clinical Center Kragujevac, Kragujevac, SERBIA, [3]Clinical Center of Serbia, Belgrade, SERBIA, [4]Institute of Oncology, Sremska Kamenica, SERBIA.

Aim of the study: Somatostatin receptors are found over-expressed and broadly distributed in human differentiated thyroid cancer (DTC) cells, which provides a basis for their molecular localization and the selection of patients for peptide receptor radionuclide therapy (PRRT) as a possible treatment for iodine-131 refractory, dedifferentiated DTC (DeDTC). The aim of this paper is to emphasize the importance of combined somatostatin receptor scintigraphy (SRS) imaging using Technetium-99m-HYNIC-[D-Phe1,Tyr3-Octreotide](Tc-99m Tektrotyd), and fluorine-18 fluoro-deoxyglucose positron emission and computerized tomography (F18-FDG-PET/CT) in the detection of recurrent diseases and the selection of patients with DeDTC for the PRRT. The secondary goal is the evaluation of PRRT effectiveness in radioiodine-therapy-refractory thyroid cancer patients by means of analyzing the progression free survival period and overall survival rate. **Material and Methods:** The study enrolled 7 patients with locally advanced radioiodine-negative papillary thyroid carcinoma (4 women and 3 men; mean age 59.1±14.0 years, range: 33-77 years). The inclusion criteria for PRRT were the presence of matched focal accumulation on Tc-99m-Tektrotyd and F18-FDG-PET/CT scan. Two out of seven patients who did not meet the criteria for PRRT were treated using chemotherapy. One out of 5 patients treated with PRRT received a single dose of 3.7GBq Y90-DOTA-Tyr3-octreotide (Y90-DOTA-TOC), while the other four were treated using combined 3.7GBq Y90-DOTA-TOC and 3.7GBq Lu177-DOTA0,Tyr3-octreotate (Lu177-DOTA-TATE) radiopharmaceuticals. Only one of the patients received 2 combined PRRT doses during the 3-month interval. **Results:** Response assessment (using RECIST criteria) was performed in all the patients and showed disease stabilization in 3 (42.8%), and complete remission in one patient. The remaining 3 patients (42.8%) showed progressive disease. Kaplan-Meier analysis revealed a post-PRRT mean progression free survival of 20.7months (95% CI, range 9.1-32.3) and mean overall survival rate of 23.2 months (95% CI, range 11.7-34.7). Overall survival in DeDTC patients after the initial treatment was 8 years (95% CI, range 4.3-11.6). **Conclusions:** Our results have shown that the Tc-99m Tektrotyd scan is a reliable method for detecting recurrent disease in radioiodine-therapy-refractory thyroid cancer patients. Combined with the findings of F18-FDG PET/CT, it can be extremely helpful in selecting patients with DeDTC for PRRT. Our results demonstrated that PRRT is a promising therapeutical option in non-radioiodine-avid dedifferentiated thyroid cancer patients, considering mean progression free survival of 20 months. However, the overall survival rate of 8 years for the patients with locally advanced iodine-refractory disease was lower in comparison to the literature data for DTC.

EP362

Role of 18F DOPA PET CT in recurrence Medullary Thyroid Cancer (MCT)

E. Ignacio Alvarez, Arguelles Pérez David Antonio; Instituto Nacional de Cancerología, Ciudad de México, MEXICO.

Introduction: Medullary thyroid carcinoma (MTC) is a slow-growing neuroendocrine tumor originating from parafollicular C cells. MCT accounts for approximately 5% of thyroid carcinomas, this tumor is associated with a higher incidence of metástasis and poorer progronosis compared with the more frequently encountered well-differentiated papillary and folicular thyroid carcinomas. Most frequent sites of metastatic disease are cervical and mediastinal lymph nodes, lungs, liver, and bone. Early detection of this tumor may significantly improve chances of survival. Imaging plays a critical role in both early detection and accurate staging of MTC, wich dictates surgical management. Several studies have compared the sensitivity of FDG and DOTANOC, FDOPA versus versus FDG PET-CT, with sensitivities of 94 vs 62%, 75.61 vs 63.4, respectively. **Case presentation:** We present 5 patients with a history of medullary thyroid cancer, following surgical resection of the thyroid gland, of which 2 had elevated calcitonin <5000 pg / ml, 1 in values of 590 pg / ml and 2 with values <500 pg / ml. The first two patients underwent PET-CT with 18F-FDOPA and 68Ga-DOTATOC, finding concordant injury and not concordant, between the two studies. The patient ranges calcitonin 590 pg / ml study with 68Ga-DOTATOC was negative, while 18F-FDOPA presented with focal uptake at the cervical level. The last 2 whose values calcitonin patients were less than 100 pg / ml, one both studies were performed whose result was negative and the other one is only performed PET-CT 18F-FDOPA, whose result was negative and decided not to the study of 68Ga-DOTATOC by low levels of calcitonin. **Discussion:** Although the number of patients is minimal, the results were similar to those reported in the world literature. That is, the levels of calcitonin are correlated in the expected results in studies PET-CT, as the sensitivity may be as low as 20% and when calcitonin levels are> 1000 pg / ml with a sensitivity up 90%. **Conclusion:** The 18F-FDOPA and 68Ga-DOTATOC dual studies are being complementary studies in these patients in whom it was found that can identify lesions not concordant between the two, which have greater sensitivity than 18F-FDG (55%).

EP363

Side effects of calcium stimulation test in patients with thyroid nodules: experience with 530 patients

T. Gincu, P. Ubl, A. Gessl, M. Krebs, A. Haug, M. Hacker, **S. Li**; Medical University of Vienna, VIENNA, AUSTRIA.

The aim of this study was to investigate the side effects of the calcium stimulation test in patients with thyroid nodules and increased basal calcitonin concentration. **Patients and Methods:** A total of 530 patients (276 females and 254 males, mean age of 58 ± 31 years) had calcium stimulation tests. All patients filled in a questionnaire regarding the side effects within 30 min after completion of the stimulation tests. The differences of side effects between female and male patients were evaluated. **Results:** Warmth feeling was the most frequent occurring side effect in all patients during the calcium stimulation tests, followed by nausea, altered gustatory sensation, and dizziness. The incidences of urgency to

micturate, warmth feeling and dizziness were significantly higher in the female patients as compared to male patients by calcium stimulation test. **Conclusion:** There is a significant gender-specific difference in side effects induced by calcium stimulation test. Female patients have more side effects as compared with male patients by calcium stimulation test. Therefore, more attention should be paid to female patients during the calcium stimulation test.

EP364

Detection of Papillary Carcinoma in Patients with chronic autoimmune thyroiditis

K. Zaplatnikow[1], V. Y. Sukhov[2]; [1]MÄZ, Department for Nuclear Medicine, NÜRNBERG, GERMANY, [2]ARCEM n/a A.M.Nikiforov of MES Russia, St. Petersburg, RUSSIAN FEDERATION.

OBJECTIVE: Autoimmune thyroiditis (AIT) often associated with thyroid nodules. Unfortunately it is not fully examined at a time and we have no even background understanding. Increased thyroid dysfunction in regions with low iodine supply and additional radiation exposure led to increased incidence of thyroid gland diseases: e.g. AIT, nodular goiter (NG) and carcinoma. This study exploited multimodal approach as combination of nuclear medicine data and laboratory tests of AIT and NG. **MATERIALS AND METHODS:** 411 patients that were relocated to Germany between 2005 and 2015 from previous USSR weapon nuclear test region in North Kazakhstan were examinated. Based on US-diagnosed goiter and thyroid nodules and RIA-evidenced AIT all patients underwent full in-vitro thyroid examination and scintigraphy. AIT patients with coexisting suspicious hypofunctional nodes were histologically verified after FNAB (n=39 pts - Gr. A) and compared with pts without suspicious NG and AIT (Gr.B, n=23 pts) and pts with cold nodes without AIT (group C, n=112) and typical AIT only (Gr. D - n=237 pts). **RESULTS:** From the whole cohort of 411 patients (11/6 F:M ratio; age 43+/-15 yrs) 17 had one type of carcinoma: multifocal papillary carcinoma (MPC) and coexisting AIT, remaining in eu/hypothyreotic state with levels of TSH 1,0-12,00 mIU/l and TU 0,3-3,2%. There were only 6 MPC patients in Gr. B with suppressed TSH (<0.01 mU/L) and typical scintgraphic signs of autonomous nodes. Hyperthyroidism/or subclinical hyperthyroidism signs that not considered as AIT evidence were noticed in 37 pts of Gr. C. There were no histological confirmation of carcinoma in any pts in Grs C and D. In group A there was shift to subclinical hypothyroidism (76 vs. 24%), opposite to group B (56 vs. 44%) (P=0.005). Maximal nodes diameter was down to 8% smaller in group A as compared with group B. A positive correlation between nodule size and age was found only in group B (P=0.015). **RESUME:** MPC is often pathology in regions with registered radioactive contamination and iodine deficiency, with background of thyroiditis and the nodular goiter. Presence of AIT led to inaccurate MPC detection because of very low difference in size of nodules (non-statistic significance between groups A and B) due to chronic thyroid lymphocytic infiltration and may blur the growth tendency of thyroid nodes and their functional activity.

EP365

Role of radioguided occult lesion localization (ROLL) in the management of Differentiated Thyroid Cancer, a single center experience

M. Menga[1], B. Elia[1], A. Codegone[1], G. Mensa[2], R. Pellerito[1]; [1]Nuclear Medicine AO Ordine Mauriziano, Turin, ITALY, [2]General and Oncological Surgery, Thyroid Unit AO Ordine Mauriziano, Turin, ITALY.

Aim: ROLL (Radioguided Occult Lesion Localization) is an established procedure widely used in localizing non palpable breast cancer. It has also been successfully employed in localizing differentiated thyroid cancer (DTC) cervical recurrences, since reoperations in the neck can be affected by many side effects and by low probability of complete disease excision. We analyzed data of patients surgically treated for DTC by means of ROLL in our Institution. **Materials:** Data from 14 (4 M 10 F) consecutive patients from December 2013 to March 2016 were analyzed. All the patients were affected by DTC (11 papillary, 1 follicular, 2 Hurthle cell carcinoma). They had received prior total thyroidectomy and at least one radioiodine treatment. Disease persistence was suspected on the basis of persistent Thyroglobulin or AbTG and the patients showed ultra sonographic (US) features of enlarged lymph node or local recurrence. All them underwent ultrasonographically-guided fine needle aspiration (FNA) and cytology was consistent with DTC. Prior to surgical intervention was performed 99mTc-labeled macroaggregated albumin (MAA) injection in to the lesions (45 MBq in 0,2 ml) under ultrasound guidance. Planar scintigraphic images were also obtained in order to help localization. During surgery an intraoperative gamma probe was used for anatomic localization and to confirm complete excision of the lesions within the surgery field. All patients underwent subsequent radioiodine treatment post-surgery. **Results:** No side effects were observed after 99mTc injection. All the radiolabeled lesions were surgically localized and excised. Post-excision count also confirmed no significant activity within the surgical field and count-ratio was positive in the excised lesions. Pathology confirmed neck lymph nodes DTC metastases in 9 patients, neck soft tissues metastases in 4, and recurrences in both neck lymph nodes and soft tissues in 1 patient. After a median follow-up of 15 months 4/14 patients proved to be disease-free, 3/14 have Thyroglobulin or AbTG persistence without imaging localization (biochemical incomplete response), 3/14 showed persistence of Thyroglobulin or AbTG and US positive imaging (structural incomplete response), finally 4/14 patients are still being evaluated since they had surgery less than 6 months ago. **Conclusions:** Despite the small population presented, we confirm that ROLL in DTC patients is a simple, reliable and safe procedure that helps radical metastatic lymph node excision and correct localization of recurrences in the neck, therefore allowing a better control of persistent DTC.

EP366

Risk of incidental thyroid cancer is not increased in overweight or obese patients

S. Kim[1], K. Pak[2], S. Shin[2]; [1]Pusan National University Yangsan Hospital, Yangsan, KOREA, REPUBLIC OF, [2]Pusan National University Hospital, Busan, KOREA, REPUBLIC OF.

Objectives: The relationship between obesity and several cancers including esophagus, colon, kidney, breast and skin have been reported. However, the role of obesity in thyroid cancer is controversial. We aim to evaluate the relationship between overweight and risk of malignancy in patients with thyroid incidentaloma detected by F18-Flurodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT). ***Methods***: From January 2010 to December 2013, a total of 332 thyroid incidentalomas were detected by F18-FDG PET/CT. Patients with fine needle aspiration within 1 year interval with PET/CT were included. After reviewing the medical records, 246 patients were eligible in this study. Body mass index (BMI) was calculated by dividing the weight (kg) by the square of height (m). BMI less than 23.0 was defined as a normal weight (NW) group and 23.0 and more was defined as an overweight or obese (OVOB) group. Using the Bethesda system for reporting thyroid cytopathology, categories I-III (nondiagnostic, benign, and atypia of undetermined significance) were defined as a non-malignancy and categories V-VI (suspicious for malignancy and malignancy) were defined as a malignancy. ***Results:*** Among 246 patients, 105 (42.7%) patients were in NW group and 141 (57.3%) patients were in the OVOB group. Rate of malignancy in NW and OVOB groups were 29.1% and 20.0%, respectively. However, the difference of malignancy rate was not statistically significant (p=0.1055). When patients were categorized according to primary

malignancy, the difference of malignancy rate between OVOB and NW group in each primary malignancy was not statistically significant. ***Conclusions:*** We demonstrated that overweight and obesity did not increase rate of malignancy in patients with thyroid incidentalomas. Due to limitation of retrospective study, further large prospective study should be performed to validate this result.

EP367

Possibilities of comparative 99mTc-pertechnetate and 99mTc-MIBI scintigraphy in management of thyroid nodule pathology

O. Bessolova, O. Perfileva, Y. Kizhaev, V. Vidioukov, K. Teterin, N. Vyrenkova, S. Kozeev, T. Khalatyan, I. Samarkin; Russian Medical Academy of Postgraduate Education, Moscow, RUSSIAN FEDERATION.

Aim: To evaluate clinical usefulness of comparative 99mTc-pertechnetate and 99mTc-MIBI scintigraphy in assessment of thyroid nodules for malignancy. **Materials and methods**: A total of 50 patients (37 women and 13 men) with mean age of 59±7,4 years with solitary or multiple thyroid nodules were included in our study. All the patients were selected for surgery on the basis of clinical, laboratory, ultrasound and fine-needle aspiration biopsy (FNB) data. The size of nodules ranged from 8 to 40mm. The Bethesda System (BS) for reporting thyroid cytopathology was used. The first anterior neck scintigraphy was performed 20-30 min after intravenous administration of 74 MBq 99mTc-pertechnetate. Uptake of 99mTc-pertechnetate in thyroid nodules was compared with uptake in the surrounding normal thyroid tissue. In cases of cold, decreased and equal uptake 99mTc-MIBI scintigraphy was performed the same day 20-30 min after 555 MBq intravenous (GE Infinia Hawkeye 4, Siemens Symbia E Dual). LEHR collimator was used, acquisition 500 000 counts. Images were graded as "match" in cold, decreased or isointense 99mTc-MIBI uptake corresponding to 99mTc-pertechnetate scans, and "mismatch" - in nodule uptake on 99mTc-MIBI higher than on 99mTc-pertechnetate scan. Histopathology served as a gold standard. **Results**: In 34 patients was found benign and in 16 - malignant histology. "Match" status was meant as benign and "mismatch" - as malignant characteristic. For all patients of our study calculated sensitivity, specificity, PPV, PNV were 68,7%, 56,8%, 44,0%, 80,0% respectively. Majority of false negatives (4 from 5) were BS6 patients with malignant focus less than 10mm in size. Suggesting that the scintigraphy does not change the treatment tactic in BS6 patients we applied statistic evaluation to BS1-5 group (38). Calculated sensitivity, specificity, PPV, PNV for BS1-5 group were 80,0%, 58,8%, 22,2%, 95,2%. It is obvious that sensitivity and PNV data increased in such approach. It is useful for differentiated diagnostics of benign thyroid pathology. But in case of BS3-5 group we didn't get significant data cause of statistically small amount of patients (9). Application of scintigraphy in these patients for further management and treatment tactics still stays open to question. **Conclusion**: Comparative 99mTc-pertechnetate and 99mTc-MIBI scintigraphy is an appropriate diagnostic tool if combined with FNB and is most effective in management of BS1-2 group patients. Excluding malignancy with scintigraphy helps in avoidance of unnecessary radical approach in thyroid pathology management.

EP368

Management of Radio-iodine Refractory Thyroid Cancer with 13-cis retinoic acid

P. K. Pradhan, M. Ravina, G. Sankar, N. K. Yadav, A. Prashanth, A. K. Singh, A. Arya; SGPGIMS, Lucknow, INDIA.

Introduction and Aim: Differentiated thyroid cancer accounts for 95% of all thyroid cancers worldwide. The general management is by surgery, radioiodine and levothyroxine suppression therapy. About 7-23% of these patients manifest metastasis. And out of these 2/3rd become refractory to radioiodine.We have evlautaed the role of 13 cis retinoic acid as a redifferentiation agent in thyroid cancer. **Methods:** We administered 13 cis retinoic acid (RA) in 24 patients which were having persistent disease and were radioiodine negative on follow up I131 scan. The dose prescribed was 1.5 mg/kg for 6-12 weeks. Then a low dose iodine scan was performed post 01 month of levothyroxine withdrawalor recombinant human TSH. The patients who showed good response to the therapy indicated by a positive iodine scan were further continued on the therapy for 03 months. **Results:** We evaluated total 24 patients (12 male and 12 female). Out of these 20 were diagnosed papillary carcinoma thyroid (recurrence, pulmonary or cervical lymph nodal metstasis), 01 follicular carcinoma thyroid and 01 poorly differentiated carcinoma thyroid and 02 were hurthle cell variants. In an evaluation of 04 patients treated with RA showed increased tracer uptake, rest 20 patients were radioiodine negative. The patients which turned positive on iodine scan were treated with 100-150 mCi of radioodine depending on the disease. Post radioiodine fall in serum thyroglobulin level was noted in addition to enhanced radioiodide transport and clinical improvement. **Conclusion:** These data suggest that RA redifferentiation therapy, considering especially its comparatively mild side effects (mucositis), may soon represent an alternative therapeutic approach to otherwise untreatable thyroid tumors. Our findings suggest that 13 cis retinoic acid therapy especially a 06 weeks protocol, may induce radioiodine uptake and reduce serum thyroglobulin levels in some patients with DTC, but whether this results in clinically significant response can only be ascertained on long-term follow-up.

EP369

Thyroid cancer in radiation exposed childhood cancer survivors: The influence of screening strategies on cancer-related morbidity

A. Heinzel[1], D. Müller[2], F. M. Mottaghy[1], F. A. Verburg[1]; [1]UK Aachen, Aachen, GERMANY, [2]UK Köln, Köln, GERMANY.

Aim: Childhood cancer survivors who received radiation therapy to the head or chest are at increased risk of developing thyroid cancer. Currently there is no agreement on which screening strategy is best in terms of reducing thyroid cancer related morbidity. The aim of the present study was to compare four strategies: No screening (NS), screening by ultrasound alone (SUS), screening by ultrasound followed by fine needle biopsy (SUSFNAB) and screening by palpation followed by ultrasound and fine needle biopsy (SPAUSFNAB). **Methods:** We built a decision-tree-model to compare the different strategies. The construction of the decision-tree-model and the sensitivity analyses were performed using TreeAge Pro 2009 software (TreeAge Software, Inc.). The input data for the model regarding diagnostic performance of the different strategies are derived from literature. Data on thyroid cancer related morbidity with regard to lymph node metastases, distant metastases, and local invasion (T4a/b) were extracted from the Würzburg Thyroid Cancer Database. We assumed annual screening until age of 45. Afterwards we would expect a risk comparable to the healthy population that would not require regular screening unless there were pathological findings. The 2.5-97.5% confidence interval surrounding the median morbidity was determined using Monte Carlo simulations. **Results:** Likelihood of lymp node metastases: NS 0.059 (0.13-0.014), SUS 0.01 (0.025-0.002), SUSFNAB 0.016 (0.037-0.003), and SPAUSFNAB 0.045 (0.043-0.016). Likelihood of local invasion (T4a/b): NS 0.055 (0.12-0.014), SUS 0.01 (0.025-0.002), SUSFNAB 0.015 (0.035-0.033), and SPAUSFNAB 0.044 (0.09-0.016). Likelihood of distant metastases NS 0.017 (0.038-0.004), SUS 0.001 (0.005-0.001), SUSFNAB 0.003 (0.008-0.001), and SPAUSFNAB 0.01 (0.02-0.004). **Conclusions:** Although cancer-related survival seems to be unaffected, different screening strategies have an impact on cancer-related morbidity in childhood cancer survivors. However, this has to be balanced against the morbidity induced by false positive results of the different screening strategies e.g. caused by unnecessary thyroidectomy.

EP370

Factors influencing the ablative activities of Iodine 131 in children and adolescents followed up for differentiated thyroid cancer. Experience of the Nuclear Medicine Department of Tunisian Center

S. MELKI[1,2], M. NOUIRA[1,2], H. SAKRI[2], R. SFAR[2], A. EZZINE[1,2], H. BOUDRIGA[2], M. BEN FREDJ[1,2], K. CHATTI[2], S. AJMI[2], M. GUEZGUEZ[2]; [1]Lr12es02, Faculty of Medicine of Sousse, Sousse, TUNISIA, [2]Department of Nuclear Medicine, University Hospital Sahloul, Sousse, TUNISIA.

Introduction: Radioactive iodine therapy has subvert the clinical and therapeutic history of differentiated thyroid cancer (DTC). The remission is indeed possible even at the stage of metastases. It is a cancer that can affect the child and the adolescent. The objective of this work is to determine the factors that influence the cumulative administered activities of Iodine 131 for thyroid remnant ablation in younger patients. **Materials and Methods:** We retrospectively studied 15 patients referred to the Nuclear Medicine Department of Tunisian Center, over a 19-year period from December 1991 until December 2010, presented with DTC. It was a papillary carcinoma in 14 cases and vesicular carcinoma in a one case. After surgery, the 15 patients in our series had received radioiodine therapy. The activity of Iodine 131 in each cure was 3700 MBq. An interval of 6 months has been maintained between the cures. The number of administered cures was conditioned by the results of the post therapeutic whole body scans and dosages of thyroglobulin. **Results:** The number of cure of radioactive iodine for thyroid remnant ablation was variable from one patient to another within our series. On average, the complete thyroid remnant ablation was obtained after 3.2 cures (with extremes from one to 7 cures). A single cure of iodine 131 was sufficient for the ablation of the thyroid remnant in 20 % of cases. In 26.6 % of cases two cures were necessary. In 53.4 % of cases three cures or more were needed. The ablative cumulative activity of the Thyroid remnant was superior to 7400 MBq in 55 % of patients presented with a tumor size equal to or exceeding 3 cm, in 75 % of patients presented with a locoregional invasion and in 60 % of patients having metastatic lymph nodes. **Conclusion:** The tumor size, the locoregional invasion and lymph node metastases seem to influence the cumulative administered activities of Iodine 131 for thyroid remnant ablation in children and adolescents followed up for DTC.

EP371

I-131 differentiated thyroid cancer therapy in pediatric patients based on I-123 pre-therapeutic red marrow dosimetry

M. Pacilio[1,2], C. Orlandi[1], V. Cannatà[1], S. Donatiello[1], M. C. Garganese[3], E. Genovese[1], L. Lorenzon[4], M. Pizzoferro[3], M. F. Villani[3], **M. Longo**[1]; [1]Enterprise Risk Management/Medical Physics, Bambino Gesù Children's Hospital, IRCCS, Rome, ITALY, [2]Department of Medical Physics, Azienda Ospedaliera San Camillo Forlanini, Rome, ITALY, [3]Imaging Department, Nuclear Medicine Unit, Bambino Gesù Children's Hospital, IRCCS, Rome, ITALY, [4]Post Graduate School of Medical Physics, Sapienza University of Rome, Rome, ITALY.

Aim: I-123-NaI radiopharmaceutical has several possible advantages for pre-therapeutic red marrow dosimetry in I-131 differentiated thyroid cancer (DTC) therapy: it reduces both radiation exposure and the possibility of stunning of remnant/metastatic tissue; it provides better image quality, localization and delineation of metastatic lesions for further dosimetric assessments. Unfortunately the brief physical half-time of I-123 (as compared to I-131) could be inadequate for dosimetric accuracy. We investigate the possibility of using I-123 for pre-therapy red marrow (RM) dosimetry of paediatric patients with metastatic or recurrent tumours, for the individual calculation of I-131 Maximum Tolerable Activity (MTA) associated with an absorbed dose to RM of 2 Gy. **Materials and methods**: Five patients with recurrent or metastatic DTC were analysed. The biokinetics was studied with I-123 collecting blood samples and whole body (WB) images at 0.5-h (before micturition), 2-h, 4-h, 24-h, 30-h, 48-h and 54-h. The measurements were corrected for the difference between I-123 and I-131 physical half-time. Activities in blood and WB were determined with calibrated gamma counter and gamma camera, and absorbed dose (AD) to RM calculated according to the EANM guidelines. The individual time-activity curves in blood and WB were analytically fitted, calculating the cumulated activity either by integrating the fitting curve from zero to infinity (tau), or to the last experimental point and with physical decay from the last point to infinity (tau limit). The S factors of OLINDA/EXM were used, rescaling for the individual body mass. After I-131 therapeutic administration (performed with the standard administration regimen), RM dosimetry was achieved analogously, measuring at 2-h, 6-h, 24-h, 30-h, 48-h, 72-h and 144-h, and estimating WB activities using a probe at 2 m from the patient. **Results:** The results of I-123 pre-therapy dosimetry show that MTA calculated using tau limit is systematically less (from 2 to 47%) than that calculated using tau. These differences become negligible for I-131 post-therapy dosimetry because of the wider temporal observation window. With the tau limit method, the AD to RM calculated with I-123 pre-therapy dosimetry is systematically higher (from 16 to 57%) than that calculated with I-131 therapy; the differences obtained using the tau method do not always follow the same trend, but the mean AD was 35% higher. **Conclusion:** The I-123 may provide several advantages that are expected to impact I-131 therapy and, even if suboptimal, it may ensure cautionary quantitative evaluations of the I-131 MTA. Nevertheless, accurate dosimetric assessments require post-therapy evaluations.

EP372

Salivary scan can predict salivary dysfunction gland before high dose radioiodine therapy

J. Park[1], J. Hwang[1], S. Park[2]; [1]Soonchunhyang Univ., Bucheon, KOREA, REPUBLIC OF, [2]Soonchunhyang Univ., Seoul, KOREA, REPUBLIC OF.

Purpose : We investigated whether salivary scan (SS) before I-131 therapy in patients with differentiated thyroid cancer (DTC) could predict radioiodine retention in the salivary gland on post-therapeutic I-131 whole body scan. **Methods :** We evaluated 136 patients with DTC who underwent the SS before high dose I-131 therapy. Quantitative and visual assessments were used to analyze the SS including maximum salivary gland uptake ratio (SUmax) at 20 (SU20) and 40 (SU40) min, residual salivary uptake ratio on the washout image (RSw) in comparison with each golden standard (salivary uptake on the radioiodine therapeutic scan, 75 strong vs. 61 normal; 24 acute sialadenitis). **Results :** In SS, SUmax time showed at 20 min (mean 6.3±1.9, n=52), 40 min (mean 6.9±3.5, n=38) and similar SUmax between 20 and 40 min (mean 6.6±2.9, n=45), weak SUmax group (5.4±1.5) and strong SUmax group (10.7±2.1); complete RSw group (3.3±0.7) and incomplete RSw group (4.4±1.0). Strong SUmax group demonstrated stronger radioiodine retention in the salivary gland compared to that of weak SUmax group (87.1% vs. 45.7%, p<0.0001), incomplete RSw group showed stronger radioiodine retention compared to that of complete RSw group (66.3% vs. 36.0%, p=0.001). There was significantly different mean age between strong SUmax group and weak SUmax group (46.0±11.7 vs. 47.5±9.4, p=0.025). In applying acute sialadenitis for golden standard, strong SUmax group showed positive correlation (13.3% vs. 32.3%, p=0.03) and incomplete washout group showed negative correlation (8.0% vs. 23.3%, p=0.04).**Conclusion :** Radioiodine therapeutic scan is more sensitive than acute sialadenitis symptom for the evaluation of salivary dysfunction. Strong uptake of the salivary gland with incomplete washout on SS significantly is related to strong I-131 retention of salivary gland. The SS can predict salivary dysfunction before high dose radioiodine therapy.

EP373

Factors Predicting Early Release from Isolation Room of Thyroid Cancer Patients After Radioiodine-131 Treatment

M. u. Zaman[1], N. Fatima[2], A. Zaman[3], U. Zaman[3], R. Tahseen[3], W. Shahid[3]; [1]AKUH, Karachi, PAKISTAN, [2]Dr Ziauddin Hospital, Karachi, PAKISTAN, [3]Dow University of Health Scineces, Karachi, PAKISTAN.

Background: Patients with differentiated thyroid cancers (DTC) who receive radioactive iodine-131 (RAI) are released from isolation when their dose rate is below the regulatory requirement. The purpose of this study was to find out predicting factors for early release from isolation facility after RAI administration in patients with DTC. **Material and Methods**: This was a prospective study which included 96 (58 females and 38 males) patients with DTC who had received RAI from April 2013 till August 2015. The study was duly approved by the ethical committee of the institute. Patients who had complete information of primary tumor size (PTS), serum TSH, stimulated thyroglobulin level [sTg] with antibodies (IU/ml) at the time of RAI treatment were included. All patients had normal serum creatinine level. To attain lower effective half-life good hydration and administration of soft laxative were ensured. Dose rate was measured (immediately, 24 h and 36 h) at 1 meter distance from anterior mid trunk and a dose rate <50 μSv/h at 1 meter was considered as releasing criterion. At 24 h 50 patients were released while remaining 46 patients were released at 36 h. A post-ablative whole body scan (PA-WBIS) was performed 5-8 days after RAI ablation in all patients. **Results:** Patients released after 24 h were significantly younger, had smaller lesions with higher proportion of papillary cancer, lower sTg, lower sTg/TSH ratio and had received a lower dose of RAI as comapred to those who were discharged after 36 h. Serum TSH and gender were not found to have any significant correlation between two cohorts. ROC and multivariate analysis have shown age ≤37 years, PTS ≤ 3.8 cm, RAI ≤ 150 mCi, sTg ≤ 145 ng/ml and sTg/TSH ≤ 1.085 as strong indepedent predictors for early release. **Conclusion:** We conclude that younger age (≤37 years), smaller tumor size (≤3.8 cm), lower RAI dose (≤150 mCi), lower sTg (≤145 ng/ml) and a lower sTg/TSH ratio (≤ 1.085) are significant independent predictors for release at 24 h after RAI treatmnet in DTC patients. Effective utilization of these factors could help the treating physicians to use limited number of internment facilities with higher throughput, lower cost and lower psychological stress to patients. **Key words:** Radioactive iodine-131; differentiated thyroid cancer; isolation; early release; dose rate

EP374

Doses to members of the public from patients undergoing radioiodine ablation

F. H. Barrack, J. W. Scuffham, P. J. Hinton; Royal Surrey County Hospital, Guildford, UNITED KINGDOM.

Aim: To minimise doses to members of the public, radioiodine ablations are typically performed on an inpatient basis and discharged patients must avoid close contact with others. Many hospitals discharge patients when their estimated activity is less than 800MBq and give restrictions which last until this decreases to 150MBq and 30MBq for contact with people over and under 5 years old respectively. The aim of this work was to estimate doses if this activity based method was used and investigate the impact moving to a contact pattern based approach would have on inpatient stays. **Material and Methods:** Retrospective analysis was performed for 368 I-131 thyroid carcinoma treatments between 2009 and 2016 (81, 160 and 127 received 1.1GBq, 3.7GBq and 5.5GBq I-131 respectively). Count rate measurements were made using a Geiger counter 2.5m above the bed immediately after administration, then twice daily until the patient was discharged. Exponential clearance was assumed and the time taken to reach 800MBq, 150MBq and 30MBq was calculated. Doses members of the public could receive was calculated from the estimated cumulated activity, dose rate of $1.2\mu Sv.d^{-1}.MBq^{-1}.m^2$. and assumed contact patterns. The assumed contact patterns were: 15mins/day at 0.3m and 8hours/day at 1m during restrictions; 3h/day at 0.3m and 6h/day at 1m for over 5s afterwards; 8h/day at 0.3m and 8h/day at 1m for under 5s afterwards. Inpatient stays which would limit doses to under 5s to 0.3mSv and give patients restrictions that finished 14 days after administration were calculated using these contact patterns. The minimum inpatient stays required to discharge patients with no contact restrictions were also calculated. **Results:** Using the activity based method, 98% of over 5s and 97% of under 5s could receive >0.3mSv, with < 5% receiving >1mSv. The median inpatient stay using the activity method was 0.2d, 1.4d and 1.7d for 1.1GBq, 3.7GBq and 5.5GBq administrations respectively. For the contact pattern method the required inpatient stay was 0.3d, 1.6d and 1.9d for 1.1GBq, 3.7GBq and 5.5GBq administrations respectively with 14 day restrictions, increasing to 1.9d, 3.6d and 3.8d with 1.1GBq, 3.7GBq and 5.5GBq for no restrictions. **Conclusion:** When discharging based on activity, while only 5% could feasibly receive over 1mSv, 98% of over 5s and 97% of under 5s could receive over 0.3mSv. However, considering contact patterns could allow better tailoring of discharge date and restriction lengths so doses for members of the public could be reduced to less than 0.3mSv.

EP375

Therapeutic compliance improvement in patients who undergo ^{131}I radioablation

M. Saftencu[1], C. Pestean[2,1], M. Larg[2,1], E. Barbus[2,1], D. Piciu[2,1]; [1]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, ROMANIA, [2]The Oncology Institute "Prof. Dr. Ion Chiricuta", Cluj-Napoca, ROMANIA.

AIM Therapeutic compliance is defined as the congruence between a patient's behavior and his personalized healthcare recommendations, as indicated by his physician. Radioiodine ablation (RIA) is a form of nuclear therapy for several thyroid conditions such as differentiated thyroid carcinoma or Graves' disease. It is safe and effective, but the patient has to follow strict rules in order to obtain the best therapeutic efficiency with a minimal risk. We wanted to evaluate and develop methods for increasing the therapeutic compliance in patients who undergo RIA. **MATERIALS & METHODS** We analyzed a prospective cohort of 40 patients (n=40) who were scheduled to undergo RIA therapy, out of which 20 patients received access to our website for thyroid-disease support, where they watched custom-made videos with instructions about patient preparation, radioiodine administration, radiation protection measures and also where they had the option to ask us further questions on-line. The access was provided a month before RIA. The other group of patients had access to the same kind of information, but only verbally or printed, in the morning prior to radioiodine administration. 7 days after RIA procedure, we analyzed the compliance and the anxiety levels for each patient through several questionnaires based on validated psychometric tools. Data regarding age, sex, primary diagnostic, surgical treatment, RIT and hormonal substitutive treatment were analyzed. **RESULTS** There was a significant increase of compliance levels in the group who had access to personalized information via internet (p=0.001), especially compliance related to radiation protection measures. Also, these patients had shown lower anxiety and hospital-related stress levels. **CONCLUSION** Well-instructed patients that undergo radioiodine ablation have a better therapeutic compliance, improving their quality of life. This can be achieved by using on-line interactive platforms, being a great step towards personalized medicine.

EP376

Evaluation of life quality in differentiated thyroid cancer patients from The Institute of Oncology, Cluj-Napoca, Romania

E. Barbus[1,2], **M. Saftencu**[2], C. Pestean[1,2], M. Larg[1,2], C. Moisescu-Goia[1], D. Piciu[1,2]; [1]The Oncology Institute "Prof. Dr. Ion Chiricuta", Cluj-Napoca, ROMANIA, [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, ROMANIA.

Aim: We wanted to identify if quality of life (QoL) is altered in patients with differentiated thyroid cancer (DTC) by using a dedicated thyroid cancer questionnaire that evaluates disease-specific and radiation protection data. **Materials & Methods**: We developed a specific questionnaire for DTC patients and we used it for QoL evaluation in several disease-related matters and radiation protection concerns about radioiodine ablation. 52 patients (n=52) with DTC took the questionnaire prior to radioiodine treatment administration. We evaluated the QoL in these patients based on their answers. The study was conducted in The Institute of Oncology "Prof. Dr. Ion Chiricuta" from Cluj-Napoca, Romania. The questionnaire consisted of two parts: the first part contained 30 questions about disease-specific issues (general aspects including surgery-related stress and classical hypothyroidism symptoms), while the second part had 20 questions regarding radioprotection measures for the patient and his family. The questionnaire was based on validated psychometric tools. **Results**: We identified the most important disease- and radioprotection-related factors among DTC patients: the most significant disease-related identified factors were fatigue, weight gain, anxiety, post-surgical voice alterations, edema/myxedema, lability of affect and post-surgical cosmetic appearance changes. Radioprotection-involved factors are mainly represented by anxiety triggered by taking the radioiodine pill and irradiation-linked stress. This can lead to worries related to birth carrying, hair loss and secondary tumors due to irradiation. **Conclusion**: Implementing a specific, thyroid-disease related questionnaire for DTC patients is a helpful tool for the physician, helping him in the improvement of disease management and patients' quality of life.

EP377

Impact of lymphocytic thyroiditis on the outcome of papillary thyroid carcinoma treated with radioactive iodine

M. H. M. Sayed; Clinical Oncology and Nuclear Medicine Department, Faculty of Medicine, Assiut University, Assiut, EGYPT.

OBJECTIVES: A higher incidence of lymphocytic thyroiditis (LT) has been reported in patients with papillary thyroid carcinoma (PTC). However, the Impact of LT on the prognosis of PTC remains controversial. The aim of the current study was to assess the impact of LT on the outcome of radioactive iodine (I-131) treatment for patients with PTC. **METHODS:** 50 consecutive patients with PTC, underwent total or near-total thyroidectomy, followed by I-123 whole body scan (WBS), neck ultrasound (US), serum thyroglobulin (Tg) and serum Tg antibodies (TgAb) asssay, and subsequent I-131 ablation after 40 days without thyroid hormone replacement (TSH > 30 μIU/ml) were retrospectively enrolled in current study. 6 months later follow up I-131 WBS, neck US, serum Tg and serum TgAb were performed following suspension of L-thyroxin for one month (TSH > 30 μIU/ml) in 39 patients and following rhTSH stimulation in 11 patients. Patients were classified into two groups according to the presence or absence of lymphocytic thyroiditis. **RESULTS:** Of the studied 50 PTC patients, 20/50 (40%) had LT. There was no significant difference regarding age, gender, histopathology, extent of surgery, and ablative dose of I-131 between both groups. 19/20, (95%) of patients with evidence of LT and 23/30 (76.7%) of patients without evidence of LT, had negative follow up I-131 WBS. However, one patient of those with evidence of LT, and 4 of those without evidence of LT who had a negative follow up I-131 WBS, had serum Tg > 5 ng/ml, with US findings suggestive of residual disease in the neck. The overall successful ablation rate were 18/20, 90% in patients with evidence of LT compared to 19/30, 63.3% in patients without evidence of LT ($P < 0.05$). **CONCLUSION:** We found a significantly better outcome and higher successful I-131 ablation rate among PTC patients with histopathologic evidence of LT compared to those without evidence of LT.

EP378

Unusual False Positive Iodine Uptakes in Patients with Differentiated Thyroid Carcinoma

A. Oral[1], B. Yazici[1], C. Eraslan[2], Z. Burak[1]; [1]Ege University Medical Faculty, Department of Nuclear Medicine, Izmir, TURKEY, [2]Ege University Medical Faculty, Department of Radiology, Izmir, TURKEY.

Aim: Radioiodine is the most specific radionuclide for differentiated thyroid carcinoma (DTC) imaging. Despite its high specificity and sensitivity false positive I-131 uptakes could be seen on whole body scintigraphy (WBS). Besides physiological sites unusual I-131 uptakes can be seen on I-131 WBS that may cause misdiagnosis and unnecessary radioiodine treatments. In this study, we aimed to present the I-131 WBS and concomitant SPECT/CT images of unusual false positive radioiodine uptakes and the patients' clinical outcomes. **Materials and Methods:** The I-131 WBS's of 1507 patients with DTC who were treated in our clinic between 2012 and 2015 were retrospectively reviewed. Expected false positive I-131 uptakes like in breasts or thymus were excluded from the study. Concomitant SPECT/CT imaging was performed to patients with unexpected I-131 uptakes on I-131 WBS. The unusual I-131 uptakes on WBS were accepted as false positive due to patients' concomitant SPECT/CT images, radiological findings, low serum thyroglobulin levels and negative follow-up scintigraphies. The unusual false positive I-131 uptakes were included in the study. **Results:** 21 patients (1.4%) had 23 unusual false positive I-131 uptakes on I-131 WBS and concomitant SPECT/CT imaging. The vast majority (87%) of the patients' unusual findings were seen on post-therapeutic I-131 WBS, the rest (13%) were seen on diagnostic WBS. The unusual findings were located in cranial, thoracic, abdominal and pelvic regions in 1, 15, 1 and 6 patients respectively. The I-131 uptakes were due to bronchiectasis in 2 patients, lung infection in 1 patient, subcutaneous injection into gluteal fatty tissue in 3 patients, aortic calcification in 2 patients, benign bone cyst in 1 patient, vertebral hemangioma in 1 patient, recent non-thyroidal surgical procedure site in 1 patient, rotator cuff injury in 1 patient, mature cystic teratoma in 1 patient and ovarian follicle cyst in 1 patient according to SPECT/CT, radiological and clinical findings. However the possible reasons of 9 false positive I-131 uptakes couldn't be explained by radiological findings. **Conclusion:** We suggest that the false positive I-131 uptakes and underlying mechanisms (inflammation, trapping, increased perfusion, etc.) must be kept in mind and unexpected findings must be considered together with serum thyroglobulin levels, SPECT/CT and radiological findings to avoid misdiagnosis and unnecessary radioiodine treatments.

EP379

Combination of radioiodine therapy and ultrasound-guided percutaneus radiofrequency ablation in benign thyroid disease

A. Mader, C. Happel, H. Korkusuz, F. Grünwald, W. T. Kranert; University Medical Center, Frankfurt, GERMANY.

Aim: Radioiodine therapy (RIT) and thyroidectomy are standard treatment procedures for nodular goiters. Both are, however, associated with side effects. Especially goiters of large volume cannot be treated sufficiently by RIT in many cases due to increased required amounts of radioidine-131 that may lead to radiation induced thyroiditis and tracheal

stenosis. Unfortunately, just in these cases also thyroidectomy involves high surgical risks especially in elder patients. Therefore a local ablation to reduce target volume prior to RIT may lead to a significantly reduced required therapy dose of radioiodine-131 and makes these patients treatable again. The aim of this study was to evaluate effectiveness of RIT in combination with radiofrequency ablation (RFA). Success criteria were volume reduction of the goiter and the resulting decrease in dose of radioiodine-131. **Material and Methods:** In ten patients (5 f. median age 53a) suffering from nodular goiters, a combined treatment of RFA and RIT was performed. RFA was performed directly prior to RIT under local anesthesia and sterile conditions with the CelonPower System® (Olympus Medical Systems Group) and cooled bipolar applicators. The system generates a variable output power of up to 250 W at a frequency of 470 kHz achieving a target temperature of 60-110°C. A trans-isthmic approach was chosen to position the probe. The patient was placed in a supine position with a hyperextended neck. The tissue destruction was imaged sonographically. The reduced vital volume was used to calculate the potential reduction of the necessary dose of radioiodine-131. **Results:** RFA led to a statistically significant median reduction of vital thyroid volume ($p < 0.01$) of 34% (median: 18 ml; range: 10-59 ml). Therefore the required dose of radioiodine-131 could potentially be reduced significantly ($p < 0.01$) by 438 MBq (range: 414-1,565 MBq). **Conclusion:** The bipolar radiofrequency system is safe to use without neutral electrodes. It provides a current flow and therefore a steady energy disposition between the tips of the applicator probe. Vital thyroid volume and therefore the necessary dose of radioiodine-131 can be significantly reduced by the performance of an RFA prior to RIT. Country-specific caps for discharge values can be met faster and the radiation exposure of healthy organs such as kidneys, bone marrow and bladder can be reduced significantly by the administration of reduced amounts of radioiodine-131. The combined treatment is a safe and effective alternative to surgical intervention in cases of large nodular goiters.

EP380

Radiation risk perception and quality of life in patients with thyroid cancer who receive radioactive iodine therapy

M. Robert[1], G. Fleury-Bahi[1], F. Kraeber-Bodéré[1], C. Rousseau[2], D. Rusu[2], A. Bonnaud-Antignac[1]; [1]Université de Nantes, Nantes, FRANCE, [2]ICO site René Gauducheau, Nantes, FRANCE.

Aim. Little is known about patient's nuclear risk perception during hospitalization, whereas emotional state can influence risk perception and that risk perception can also influence patient's emotional quality of life in return. This study investigates the evolution of patient's nuclear risk perception during the treatment and determine the influence of risk perception on the quality of life and coping with treatment and illness. **Materials.** The sample included 45 thyroid cancer patients who had total thyroidectomy interviewed before, during and after radioiodine therapy. Interviews were focused on nuclear risk perception, iodine 131 experience, anxiety, quality of life, coping with treatment and coping with illness. **Methods.** 135 interviews were audiotaped, transcribed and analyzed according to the categorical thematic analysis and a semiquantitative analysis. **Results.** The patients met had little knowledge about radioactivity, radiation protection measures and associated risks, consequently they developed anxious beliefs concerning the radioprotected environment before their hospitalization. Information about the treatment are fragmented between the different health care professionals and, for the patients, the search for a feeling of controllability before treatment is compromised. That is the reason why, during the hospitalization, patient's nuclear risk perception depends on caregiver's behavior toward radioactivity. Their perception of the seriousness of the risk and vulnerability evolve during the treatment. Foremost, seriousness of risk and vulnerability for those around them are discussed before the treatment and then, loneliness and radio-protection measures confront the patient to his cancer and to nuclear risks. We can notice that, more than the radioactivity, the isolation affects the emotional quality of life of patients during their hospitalization. Results also demonstrate different factors of vulnerability such as the administered radioactivity (3,7 GBq or 1,1 GBq), the thyroid hormone withdrawal, the patients with toddlers, the number of treatments and experiences of previous treatments. **Conclusion.** The findings illustrate the importance of taking into account the development of beliefs and perception of nuclear risk throughout the support. A group information session should be proposed to educate the patient about radiation exposure and health risks, and nuclear medicine department should make caregivers aware of watchfulness toward treated patients.

EP381

Occurrence of papillary thyroid micro-carcinoma in an adolescent with congenital dyshormonogenetic hypothyroidism

W. Amouri, D. Ghorbel, F. Hamza, I. Jardak, F. Kallel, S. Charfeddine, F. Guermazi; Habib Bourguiba hospital, sfax, TUNISIA.

AIM: to describe an unusual case of papillary thyroid micro-carcinoma in a boy with dyshormonogenetic congenital hypothyroidism **MATERIALS AND METHODS:** the patient record was reviewed retrospectively. We analysed clinical outcomes and thyroglobulin rate as well as imaging findings after radio-iodine therapy. **RESULTS:** we report the case of 17-year-old adolescent diagnosed with congenital goitrous hypothyroidism at neonatal age. A familial history of dyshormonogenetic goitre was found. The boy was treated by adequate thyroxine replacement until 17 years of age, when he presented with a large multi-nodular goitre. The patient underwent total thyroidectomy. Pathological examination revealed multifocal papillary thyroid micro-carcinoma. Serum thyroglobulin level after thyroidectomy was 5ng/ml. So, the patient was referred for radio-iodine ablation. The whole body scan post 100 mCi Iodine-131 showed cervical and physiologic thymus uptake. The patient was then maintained under suppressive daily dose of 150 μg of 1-thyroxine. CONCLUSION: Papillary thyroid carcinoma complicating dyshormonogenetic goitre has been rarely reported in the literature. The management of these cases is based on total thyroidectomy because future development of a second malignancy in thyroid tissue remains possible. In our case, ablative radio-iodine therapy was indicated since serum thyroglobulin rate was abnormal.

EP382

Quantitative ^{131}I planar imaging of patients undergoing thyroid cancer treatment

R. Barquero[1], H. Pérez-García[1], A. Cardenas[2]; [1]Hospital Clínico Universitario Valladolid, Valladolid, SPAIN, [2]Hospital Nacional Edgardo Rebagliati Martins, Lima, PERU.

Aim: Patients undergoing differentiated thyroid cancer (DTC) are treated (after ablation) with^{131}I. A post-treatment control acquiring a planar Gammacamera image is done seven-ten days after administration. The present study focused on the quantification of the activity uptake in these images. **Methods:** Ten patients undergoing ^{131}I DCT treatment have been studied with administered activities from 3.7 to 4.44 GBq after a low dose of rhTSH. A static planar local imageof each patient is obtainedwith a Siemens e-cam Gammacamera with HEGP collimator at 15 cm skin-collimator distance and with energy window of 15% centered at 364 keV. Sensitivity (cps/MBq) in each acquisition is calculated as the product of geometric efficiency and intrinsic effiencicy. Geometric efficiency is estimated byMonte Carlo simulation with MCNPX and an accurate simulation of the lesion, collimator and the Gammacamera crystal. Intrinsic efficiency of device is previously obtained from the quantification of an imageof a

reference source of calibrated activity in air. All images are analyzed with the free software ImageJ. A specific low pass filter is applied to eliminate collimator artifacts in each image previously to the quantification. The total counts rate for each patient´s lesion is obtained drawing a ROI encompassingthelesion. In order to retain only the geometric component of events in the photopeak, the ROI size is delimitedwith a diameter as the full with ten maximum (FWTM) of the central profiledefined of the lesion.The attenuation correction is estimated with a simple exponential approximation with 2.5 cm thickness of tissue between lesion and skin of each patient. The method to quantify the activity uptake has been validated with a set of independent measurements using different phantoms and calibrated sources. **Results:** ROI radius from all lesions goes from 12 to 28 mm. The sensitivity value has a mean value of 26.5 cps/MBq with a standard deviation of 6%. The value of the activity uptakes of the patients goes from 0.05 MBq (1.56 μCi) to 1.86 MBq (50.20 μCi). No correlation between administered activities and activity uptakes has been found. **Conclusions:** Activity uptake of each lesion of patients in ^{131}I DTC therapy can be estimated with accuracy by means of an absolute quantification of each lesion. The procedure relies on the Monte Carlo simulation and an independent measurement to determine the intrinsic efficiency of the Gammacamera device. The activity uptake in all analyzed cases is always less than 0.06% of the administered activity.

EP383

Does the time of whole body scan affect to physiological hepatic visualisation after radioiodine remnant ablation?

Z. Hasbek[1], **S. S. Gül**[2], E. Çiftci[1], B. Turgut[1], S. A. Ertürk[3], A. Cakmakcılar[3]; [1]Cumhuriyet University School of Medicine, Department of Nuclear Medicine, SIVAS, TURKEY, [2]Gaziosman Paşa University School of Medicine, Department of Nuclear Medicine, TOKAT, TURKEY, [3]Cumhuriyet University School of Medicine, Department of Nuclear Medicine, Sivas, TURKEY.

Aim: Postoperative radioiodine remnant ablation (RRA) is routinely used at most institutions to destroy residual thyroid tissue and occult foci of neoplastic cells in differentiated thyroid cancer (DTC). Diffuse homogen hepatic uptake in whole body scan (WBS) after RRA suggest that there is occult or visible remnant thyroid tissue and/or tumor tissue in the body. It is thought that the reason of this situation is hepatic metabolisation of radioiodine (^{131}I) marked thyroglobulin fragments which secreted by tumor tissue. Diffuse homogen hepatic uptake after the low dose diagnostic ^{131}I WBS performed 8-12 months after RRA is suspected that the presence of metastatic focus anywhere in the body. The purpose of this study was to investigate whether or not early or late WBS after RRA has an affect on the physiological hepatic uptake. **Materials-Methods:** In this study 58 DTC patients were evaluated (46 female, 12 male, mean age: 48.5 (19-75 years old)) who referred to nuclear medicine department for RRA. The therapeutic ^{131}I dose ranged from 100 mCi to 200 mCi. WBS after RRA was performed earlier (in 1-3th day after RRA) in 24 patients (group 1); and was performed later (in 8-9th day after RRA) in 34 patients (group 2). Diffuse hepatic uptake of radioiodine were evaluated visually by two experienced nuclear medicine physicians. **Results:** 3 of group 1 (8.1 %) have diffuse hepatic uptake whereas all patients of group 2 (%100) have diffuse hepatic radioiodine uptake ($p<0,0001$). There is not a statistically significant relationship between the hepatic uptake and thyroglobulin and TSH level during the WBS ($p>0.05$). Also there is not a statistically significant relationship between the hepatic uptake and given radioiodine dose ($p>0.05$). **Conclusion:** Physiological diffuse hepatic uptake of radioiodine in WBS after RRA may not be seen during the early (1-3 day) WBS. But it does not mean that there is any residual thyroid tissue or metastatic tissue. It is thought that half life of serum thyroglobulin affect this situation.

EP384

Low-Risk Papillary Microcarcinoma (PMC) Post-surgical Thyroablative rhTSH 1.1 GBq Radioiodine Therapy - Fact or Fiction?

P. Solný[1,2], T. Kráčmerová[1,2], L. Jonášová[1], P. Vlček[1]; [1]Department of Nuclear Medicine and Endocrinology, Charles University 2nd Faculty of Medicine, Prague, CZECH REPUBLIC, [2]Department of Dosimetry and Application of Ionizing Radiation, FNSPE; Czech Technical University in Prague, Prague, CZECH REPUBLIC.

Aim: It is discussed whether Papillary microcarcinoma (PMC) patients classified as low- risk based on the presence of lesion that is less than 10 mm in diameter should be even treaded by radioiodine after surgical thyroablation. Moreover; recombinant human TSH (rhTSH) introduction become another option to judge in radioiodine therapy (RAIT) conception world-wide. The question to treat or not to treat is set and, sadly, mostly retrospective studies are given as answer. In case of conservative approach to thyroid carcinoma treatment post-surgical radioiodine therapy is preferred for most of PMC patients. Aim of this study was to investigate whether PMC patients stimulated with rhTSH will obtain a thyroablative (300Gy) absorbed dose when 1.1 GBq of 131I is administered. **Materials and methods:** PMC patients for this study means a) stimulated thyroglobulin (Tg) lower than 6.5 ug/l in the absence of Tg antibodies, and b) absence of larger (more than 0.5 ccm) remnant thyroid tissue and of abnormal cervical lymph nodes on ultrasonography. 17 PMC patient volunteers (15 F, 2 M) assisted to undergone up to 5 post-therapeutic scintigraphy examinations (5, 24,(30) 48, and 72 h after administration) and SPECT; if necessary, using Symbia S gamma camera. Whole body (WB) radioiodine activity was monitored by radiometer SVLD probe (relative measurements referred to data 1.5 h after administration). Gammacamera system was calibrated and quantitative imaging was done. Measured data were fitted and cumulated activity was determined up to 400 h after administration. Mass of the treated tissue was measured by sonography or estimated from SPECT volumetric analysis. Absorbed dose was determined for 200 h cumulated activity extrapolation. **Results:** For 18% of patients no or background similar accumulation was observed. For 24% of volunteers dosimetric evaluation confirmed radioiodine thyroablation (300Gy exceeded within accumulating remnants). For 29 % sufficient absorbed dose was not unequivocally proved regarding the measurement errors. For 29% of patients absorbed dose was classified as insufficient to be named as thyroablative. During ongoing follow up no recurrence was observed for 15 patients one year after therapy. 2 of the patients have not been checked yet. **Conclusions:** Based on the dosimetric measurement 1.1 GBq radioiodine therapy was cancelled as potentially insufficiently thyroablative. PMC patients are now treated using 1.85 GBq according EANM guidelines. Further dosimetry measurements are being done to make evidence-based patient treatment if treated.

EP385

Calculation of Therapeutic Activity of Radioiodine in Graves' Disease by Means of Marinelli's Formula, Using Technetium (^{99m}Tc) Scintigraphy

P. Szumowski, S. Abdelrazek, M. Mojsak, M. Sykala, D. Jurgilewicz, J. Mysliwiec; Medical University, Bialystok, POLAND.

The therapeutic activity of ^{131}I administered to patients with Graves' disease (GD) can be calculated by means of Marinelli's formula. The thyroidal iodine uptake ($^{131}IU_{max}$) needed for the calculation is usually determined with the use of ^{131}I. The purpose of the paper was to estimate $^{131}IU_{max}$ on the basis of technetium uptake in the thyroid at 20 minutes ($^{99m}TcU_{20min}$). **Methods:** Eighty patients suffering from Graves' disease were qualified for radioiodine therapy with measurement of fT_4, fT_3, TSH and TRAb. Prior to the treatment, all the patients were euthyroid.

$^{131}IU_{max}$ for each patient was determined according to the levels of ^{131}I after 24h ($^{131}IU_{24h}$), while effective half-life (T_{eff}) according to the measurements of $^{131}IU_{24h}$ and ^{131}I uptake after 48h ($^{131}IU_{48h}$). Additionally, on the day before measuring $^{131}IU_{24h,}$ $^{99m}TcU_{20min}$ was calculated for each patient. **Results:** It was demonstrated that there existed a correlation, with statistical significance at $p<0.05$, between the following pairs of values: TRAb and $^{131}IU_{24h}$, TRAb and $^{99m}TcU_{20min}$, and $^{99m}TcU_{20min}$ and $^{131}IU_{24h}$. The interdependence between $^{131}IU_{24h}$ and $^{99m}TcU_{20min}$ at the level of significance $p<0.05$ is described by the following algorithms: $^{131}IU_{24h}=17.72x\ln(^{99m}TcU_{20min}.)+ 30.485$, if TRAb<10IU/ml, and $^{131}IU_{24h}=18.03x\ln(^{99m}TcU_{20min}.)+ 38.726$, if TRAb>10IU/ml. **Conclusion:** It is possible to predict thyroid iodine uptake $^{131}IU_{24h}$ in Graves' disease on the basis of measuring the uptake of $^{99m}TcU_{20min}$. This shortens the time necessary for diagnosis, reduces

EP386

Development Of Radiation Protection Recommendations According To The Dose Rate And Social-Family Characteristics, In Hyperthyroidism Patients Treated With Iodine 131

J. OROZCO-CORTÉS[1], R. DÍAZ-EXPÓSITO[1], I. CASÁNS-TORMO[1], V. LÓPEZ-PRIOR[1], A. AMR-REY[1], H. BOWLES-ANTELO[1], N. LUQUERO-LLOPIS[2], C. ALAMAN-SÁNCHEZ[2], S. DÍEZ-DOMINGO[2]; [1]NUCLEAR MEDICINE SERVICE. HOSPITAL CLÍNICO UNIVERSITARIO DE VALENCIA, VALENCIA, SPAIN, [2]RADIOLOGIC PROTECTION SERVICE. HOSPITAL CLÍNICO UNIVERSITARIO DE VALENCIA, VALENCIA, SPAIN.

OBJECTIVE Our objective was to evaluate the usefulness of developing individualized radiation protection recommendations, in patients with hyperthyroidism, based on social and family characteristics of the patient and in the measurement of a dose rate in μSv/h at 3 hours after iodine 131 treatment(DR). **MATERIAL AND METHODS** 95 patients(66 women), mean age (58±16) ,21-88 y/o, 47 with diffuse goiter(DG), 48 multinodular goiter(MG). The administered activity was established by type of goiter, qualitative estimation of glandular size and thyroid uptake with previous scintigraphy, age and weight of the patient. The radiation protection recommendations were developed according to the norms of Spanish Society of Radiologic Protection and International Commission on Radiological Protection(ICRP), establishing the total days of restriction of close contact with children-pregnant(ChP)-R1 and with adults-R2, according to DR and social-family characteristics of the patients (group 1 (45): without ChP, partner age>60 or without partner; group 2 (13): without ChP, partner age<60; group 3 (37): patients with ChP. **RESULTS** Mean administered activity was 11.6±1.6(8-15 mCi) without significant differences(SD) between men(11.4±1.6)-women(11.7±1.6). Mean DR was 23.5±6(11-39) μSv/h, and it was higher in men(26.4±5.4) than women(22.3±5.9, p=0.002), and also R2 was higher in men(8.6±1.7) than women(7.6±2.2, p=0.02). Mean activity administered to patients with MG(12.1±1.6) was higher than DG(11.2±1.4, p=0.008), but without SD in DR, R2. The DR was higher when the administered activity was >10 mCi(N=64) vs ≤10(N=31)(24.4±5.6 vs 21.7±6.5, p=0.042). When DR≥23(N=51), both R1 and R2 were higher than if DR<23 (N=44)(p<0.0001). Both groups 1 and 2 showed higher R2 (p<0.0001) if DR≥23 than if DR<23 (8.5±1.7 vs 6.5±1.2). In group 3, R1 was higher, when DR≥23, than if DR<23(16.3 ±3.3 vs 13.2±2.5, p=0.003). Group 1 showed lower R2 than group 2(7.3 ±1.8 vs 8.6±1.6,p<0.023), although there was not SD in the DR between both groups(23.7±6.5 vs 24.6±6). **CONCLUSIONS** We confirm the usefulness of developing recommendations on radiation protection, according to the DR and the social-family conditions of patients with hyperthyroidism treated with iodine 131. The established days of restriction of close contact are higher in all patients if DR ≥23 μSv/h (mean value in our patients). But these days are also higher in the patients with determined social conditions(group 2 vs 1) independently of DR obtained, thus reinforcing the importance of establishing individualized recommendations.

EP387

Cytotoksyczne supresorowe limfocyty T zaburzenia w chorobie Gravesa-Basedowa po radiojodem 131 I Leczenia

M. Płazinska[1], E. Rosiak[1], R. Matyskiel[1], A. Czarnywojtek[2,3], M. Kobylecka[1], L. Królicki[1]; [1]Department of Nuclear Medicine, Medical University of Warsaw, Warsaw, POLAND, [2]Department of Pharmacology, Poznan University of Medical Sciences, Poznan, POLAND, [3]Department of Endocrinology, Poznan University of Medical Sciences, Poznan, POLAND.

AIM: Activation or failure of apoptotic pathways can contribute to various autoimmune diseases, including Graves' disease (GD) and thyroid-associated ophthalmopathy. Radioiodine (^{131}I) is widely used for the treatment of Graves' hyperthyroidism but can induce alterations in immune response, and the development or worsening of Graves' orbitopathy (GO).The aim was to assess the apoptosis in peripheral blood (PB) lymphocyte subpopulations after 131I treatment of patients with Graves' disease and to examine its association with GO activity. **MATERIALS**: We included prospectively 54 patients (42 females, 12 males ; mean age 37.2 ±10.2 years) with Graves' hyperthyroidisms after 131 I treatment (20 ± 5.0 mCi). Clinical assessment, determination of serum TSH, fT3, fT4, thyroid autoantibodies levels were carried out at the onset and after 1, 3, 6, 9 and 12 months of 131 I treatment. According to the severity and activity of GO all patients before 131 I had NOSPECS score < 3 and CAS score < 3. Up to 4.5 months after 131-I therapy and within one year of post-treatment follow-up all patients were euthyroid. **METHODS**: PB lymphocyte subpopulation were analysed by flow cytometry and FITC, PE-conjugated antibodies have been used: CD3 FITC/Anti-HLA DR, CD4 FITC/CD8 PE for surface phenotyping. The Annexin V/Propidium iodide protocol is was used to assess apoptotic cells. Linear regression models was used to assess the association of CAS score and degree of apoptosis in CD8+ suppressor/cytotoxic T cells **RESULTS**: 6 months after 131I treatment in 34 patients we observed significant increase in CD8+ suppressor/cytotoxic T cells in comparison with the initial evaluation (48% ± 3.90%, 95%, p = 0.01), but most of CD8+ T cells have undergone apoptosis (67% ± 8.15% (95% PU p < 0.05). Decreased levels of functional CD8+ suppressor/cytotoxic T cells resulted in an elevated CD4/CD8 ratio. There was a positively correlation between the increase of the percentages of apoptotic lymphocytes and the exacerbation GO in CAS score (p < 0.05). **CONCLUSION**: Graves' orbitopathy exacerbation after radioactive iodine therapy with may be associated with increased apoptosis of CD8+ suppressor/cytotoxic T cells. This result need further evaluation in larger group of patients.

EP388

The dose to bone marrow in small pool PTS during ^{131}I therapy for Hyperthyroidism

V. Longari, C. Canzi, M. Castellani, F. Buffoni, I. Martina; Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, ITALY.

AIM : A higher iodine (I) uptake at 4 than at 24 h is the hallmark of the so called "small pool" pts with immunogenic hyperthyroidism. The rapid release of I in the blood leads to a decrease of the administered dose to the gland and to an increase of the extrathyroidal tissues irradiation. Aim of this study was to calculate the dose released to the bone marrow of "small pool" pts treated with high activities of ^{131}I necessary to achieve hypothyroidism. **MATERIALS and METHODS :** 7 hyperthyroid females (mean age 59,5; range 38-77y TSH 0.005±0 uIU/ml; FT3 20,3±8,3 pg/ml; FT4 47,5 ± 27,6 pg/ml; TRAb 40,3.± 35.8 UI/L) identified by a previous ^{123} I dosimetric study as "small pool" pts, underwent ^{131}I therapy and a second dosimetric study. All pts had multiple thyroid scans (range 2-671 hrs) and blood samples (range 0,13-670 hrs) at different times; whole body scans were also acquired at the same

times of the thyroid images in 6 pts. The delivered doses to thyroid (DT) and bone marrow (DBM) were derived from ^{131}I uptake calculated on thyroid and whole body images and from ^{131}I levels in blood samples. DMB was calculated by summing the dose derived from the activity in circulating blood (BD) and in the whole body (WBD). The ablative target dose to the thyroid was set to 300 Gy.A mean ^{131}I activity of 604 ± 55 MBq was administered in order to reach the target dose. **RESULTS:** The rapid release of I in all "small pool" pts detected at ^{123} I scintigraphy, was confirmed by the ^{131}I therapetic study (^{131}I uptake mean values at 4 and 24 hrs respectively 74,2%±6,3 and 63,5%±10,7; p=0,01). The mean of DT(mDT), DBM(mDBM), BD(mBD),WBD(mWBD) along with minimum and maximum values are reported in the table. Hypothyroidism occurred in 5 pts within a mean time of 3.7 months, while persistent hyperthyroidism was observed in 1 pt after 1 year. The last patient treated has still an extremely short follow up. **CONCLUSIONS :** In our pts, the dose to the bone marrow is much lower than the limit of 2 Gy and the main contribution is due to the Beta particles in circulating blood. These results show that in "small pool" pts the use of high activity is safe to achieve the clinical endpoint.

EP389

18F-DOPA PET/CT in the diagnosis and localization of cervical lymph node extension of medullary thyroid carcinoma

L. M. VIJA[1,2], A. Hitzel[1,2], M. Bauriaud[1,3], A. Salabert[2], L. O. Dierickx[3], E. Gabiache[3], S. Grunenwald[4], P. Payoux[1,2], P. Caron[1,4], F. Courbon[1,3], S. Zerdoud[3]; [1]Paul Sabatier University, Toulouse, FRANCE, [2]Nuclear Medicine Department, Pierre Paul Riquet Hospital, Toulouse, FRANCE, [3]Nuclear Medicine Department, IUCT-Oncopole, Toulouse, FRANCE, [4]Endocrinology Department, Larrey Hospital, Toulouse, FRANCE.

Background: Medullary thyroid carcinoma (MTC) is a thyroid neuroendocrine tumor with frequent lymph node extension and recurrence. Patients with high initial or persistent calcitonin levels necessitate preoperative lymph node extensive staging for adequate cervical surgical management which systematically comprises cervical ultrasound. Conventional neck imaging (ultrasound, CT) sometimes fails to localise all recurrent or metastatic disease, leading to further functional explorations. 18F-DOPA PET/CT seems to be the best functional imaging examination for detection of present, persistent or recurrent MTC. **Aim:** To assess the impact of 18F-FOPA PET/CT on lymph node MTC staging and surgery. **Material and methods:** Twenty-five MTC patients (15 men, 10 women, median age 53.5 years), with increased calcitonin levels (median 270ng/ml [8-4270]) were prospectively explored with 18F-DOPA PET/CT (n=27 exams), CT (n=15) and neck US (n=24) in University Hospital of Toulouse PET Center (14 patients) and IUCT-Oncopole (11 patients) at diagnosis (n = 2) and in the post-operative follow-up (n = 23). Pathologic neck lesions were surgically removed, when possible (n=62 lesions; 3 patients). 18F-DOPA PET/CT sensitivity for pathologic lymph node detection was assessed comparatively to histopathological findings. **Results:** 18F-DOPA PET/CT presented an excellent concordance with neck ultrasound (K=0.9) and cervical CT (K=1) and higher sensitivity than cervical ultrasound (54% vs 48%) for lymph node detection. 18F-DOPA PET/CT performance for the characterisation of suspect cervical lymph nodes compared to histological findings was superior to cervical ultrasound on lesion analysis (sensitivity: 50% vs 31%). 18F-DOPA PET/CT sensitivity was 55% (5/9 patients) in patients with serum calcitonin levels below 150 pg/mL, detecting lymph nodes with plasma calcitonin levels as low as 28 ng/mL, 90% (9/10 patients) for calcitonin levels between 150-500 pg/mL and 100% for calcitonin levels higher than 500pg/ml (6 patients). ROC curve analysis confirmed an 18F-DOPA PET/CT specificity of 100% for calcitonin values greater than 200 pg/mL. Early (10 minutes post injection) cervical centered acquisitions exclusively detected cervical lymph node uptake in three patients. **Conclusions:** 18F-DOPA PET/CT imaging could represent a useful complementary exam for better detection of cervical lymph nodes and preoperative lymph node classification. Although recent international guidelines do not recommend PET/CT evaluation if calcitonin levels are under 150 pg/mL, it would be interesting to evaluate the role of 18F-DOPA PET/CT for preoperative cervical lymph node detailed staging for both primary or recurrent CMT even for calcitonin levels between 20-150 pg/mL

EP390

Dual phase ^{18}F-DOPA PET/CT in medullary thyroid carcinoma

D. Grigolato, M. Cucca, M. Zuffante, L. Locantore, P. Brazzarola, M. Ferdeghini; Azienda Ospedaliera di Verona, VERONA, ITALY.

Aim: To evaluate the performance of ^{18}F-L-dihydroxyphenylalanine ^{18}F-DOPA PET/CT at 20 and 60 minutes post administration in the detection of medullary thyroid carcinoma (MTC), locoregional and distant MTC metastases. **METHODS:** We retrospectively evaluated 24 MTC patients (9 male, 15 female, age range 25 -82 years) with persistently high serum calcitonin levels. They underwent ^{18}F-DOPA PET/CT between January 2013 and December 2015 and in all of them a dual acquisition PET/CT was performed: early images (at 20 minutes) centered over the neck to half thorax (2 to 3 beds) and late total body images (at 60 minutes). The activity administered was 2,5 Mbq/kg. All scans were carried out on a 16-slice Gemini Big Bore TOF (Philips) with 2 minutes for bed position. Seven patients were studied for staging purpose before initial surgery and 17 patients underwent PET/CT for restaging and therapy control. They were followed up for at least 6 months after the PET/CT assessment. The results were compared with histological data or with complementary imaging modalities during follow-up. **RESULTS:** Early images were positive in 21 of the 24 patients, corresponding to a patient-based sensitivity of 87%, while the late study was positive in 19 patients with a sensitivity of 79%. In the preoperative staging all patients demonstrated high uptake in the known primary tumors at early imaging with decreased uptake from 20 to 80 % in the late acquisition, one patient had cervical pathological nodes. Distant metastatic disease was seen in 12 patients, all showed lymphoadenopathy (laterocervical/subclavear nodes in 5 patients and mediastinal nodes in 11 cases), one liver localization, two patients with pulmonary involvement and three cases with bone metastases. Three patients did not showed any increased of ^{18}DOPA despite the elevation of s-calcitonin and they were also negative at radiological imaging. Four patients received different surgical approaches after ^{18}F-DOPA imaging. In the early acquisition two patients had bone lesions in the sternum and they both showed rapid wash-out. During therapy a patients demonstrated progression disease with an increased number of bone and pulmonary lesions, while the other three patients had stable disease. **CONCLUSION:** Although the limited number of patients in our study the results were promising: ^{18}F-DOPA PET/CT allowed early diagnosis of a noteworthy number of patients with distant metastasis, guiding surgical compartment approach of the neck when judged possible and enabled therapy assessment. The best diagnostic results were obtained with early imaging.

EP391

Qantitative Approach In Dynamic Parathyroid Scintigraphy And FCH PET For Evaluation Of Parathyroid Vs. Thyroid Anomalies

A. Koljevic Markovic, 1964.[1], M. Jankovic[2], J. Talbot[3], M. Gauthe[4], W. Langsteger[5], L. Imamović[6], V. Miler Jerković[7], M. Paskas[8], G. Pupić[1], D. Popović[2], R. Džodić[9]; [1]National Cancer Research Center Serbia, Belgrade, SERBIA, [2]University of Belgrade- School of Electrical Engineering of Serbia, Belgrade, SERBIA, [3]Hospital Tenon, University

P&M Curie, Paris, FRANCE, [4]Hospital Tenon, Paris, FRANCE, [5]St Vincent's Hospital, Universities of Innsbruck | Graz | Vienna, Linz, AUSTRIA, [6]St Vincent's Hospital, Linz, AUSTRIA, [7]University of Belgrade- School of Electrical Engineering, Belgrade, SERBIA, [8]Innovation Center University of Belgrade- School of Electrical Engineering, Belgrade, SERBIA, [9]National Cancer Research Center Serbia,University of Belgrade Medical Faculty, Belgrade, SERBIA.

PURPOSE: Scan data novel processing and statistic analysis of time/activity/curves (TAC) in parathyroid were applied to evaluate hyperfunctional lesions (HL), for differential diagnosis vs thyroid anomalies (TA) by different radiopharmaceuticals: MIBI and FCH as well as modifying time acquisition protocols. **METHOD:** In patients suspected for primary (PHPT) hyperparathyroidisim (median age 58) preoperative 99mTc-MIBI scintigraphy (EANM guidelines 2009) was applied in 53pts and in four patients FCH PET two phase (early dynamic 8 min plus static acquisition) protocol. New designed software deals with region of interest in matrix and automatic preprocessing (linear fitted TAC logarithm, ensamble coupling) plus segmentation (automatic TACs clustering), as well as fractal analysis for TACs in order to analyze lesions and noise artifacts. **RESULTS:** 1.Scintigraphy PHPT histopathology: solitary- 44pts, hyperplasia: 8pts and one carcinoma; median lesion volume up to 1cm^3; concomitant HL and TA in 36/53pts; findings had PPV 81%. PL had typical uptake pattern with late phase peak, independent to PTA volume and/or PTH levels. Ratio of HL-to-normal thyroid uptake was 1.35(±0.21). Parameters of optimal HL curve (associated with correlation matrix) enabled clear visual interpretation in time interval 10.-25.min after i.v. MIBI application. Fractal theory was helpful in matrix 5x5 designing classifier dimension 1.1-1.3 for automatic procedure. A new method raised PPV (97%). 2. FCH PET: autonomy 2pts, hyperplasia 2pts (one patient with concomitant thyroid nodule) median volume 1,1cm^3. FCH had true positive results; following parathyroid time/uptake showed that in dynamic early phase after 5 minutes was maximal PL uptake as well as in thyroid (and thyroid nodule). The acquisition protocol of FCH visualize HL in early static as well as late static acquisitions.For now SUV values determined in static scans showed lower values for TA compared to HL and the pitfalls stay in parathyroid hyperplasia concomitant to thyroid anomalies. **CONCLUSION:** Quantitative approach facilitated the recognition of hyperfunctional parathyroid in the presence of concomitant thyroid anomalies, in scintigraphy but that was not the added value in FCH PET early dynamic acquisition protocol. Still, the benefit of quantification can be applied in modifying acquisition protocols in more efficient way in conventional as well as hybrid molecular imaging.

EP392

18F-fluorocholine PET/CT imaging is useful in localization of hyperfunctioning parathyroid tissue in primary hyperparathyroidism: a comparative study with 99mTc-MIBI SPECT/CT and neck ultrasonography

K. Sönmezoğlu[1], **B. Vatankulu**[1], M. Ocak[2], R. Özcan Tutar[3], H. Pehlivanoğlu[1], E. Karayel[1], A. Karataş[4], S. Teksöz[4], L. Kabasakal[1], Y. Bükey[4]; [1]İstanbul University Cerrahpaşa Medical Faculty Department of Nuclear Medicine, İstanbul, TURKEY, [2]İstanbul University Pharmacy Faculty, İstanbul, TURKEY, [3]İstanbul University Faculty of Sciences, İstanbul, TURKEY, [4]İstanbul University Cerrahpaşa Medical Faculty Department of General Surgery, İstanbul, TURKEY.

Aim: In patients with primary hyperparatiroidism (pHPT), preoperative localization of hyper-functioning parathyroid gland(s) is a very important issue in order to enable less invasive parathyroidectomy as well as to minimize post-surgical morbidity and cost. Several recent studies reported that 18F-fluorocholine (FCH) PET/CT imaging is an effective method to determine hyper-functioning parathyroid tissue. The aim of this study was to evaluate the assessment of the diagnostic value of FCH-PET/CT for preoperative localization of hyper-functioning parathyroid tissue by comparing with ultrasound (US) and Tc-99m-MIBI SPECT/CT imaging. **Materials and methods:** A single-institution prospective study was carried out in series of 28 consecutive patients with a biochemical diagnosis of non-familial pHPT, who undergone a neck US, Tc-99m-MIBI SPECT/CT, and FCH-PET/CT as well. The diagnostic performance of the imaging methods was compared against histology as the gold standard and postoperative serum Ca and PTH values. **Results:** There were 19 (67%) female and 9 (33%) male patients with a mean age of 49 years. Preoperative mean PTH and Ca levels level were 167 ± 28.0 pg/ml (reference 10-55 pg/ml) and 11.4 ± 1.1 mg/dl (reference 9-10.5), respectively. Totally 30 lesions removed at surgery and histopathological examination revealed 21 parathyroid adenomas and 9 hyperplastic parathyroid glands. The sensitivity, specificity and positive predictive value of FCH-PET/CT imaging was 92.0 %, 100 %, and 100 %, respectively and superior comparing to neck US (63.2%, 56.6%, 78.3%) and MIBI SPECT/CT (76.4%, 100%, 91%). FCH-PET/CT was able to localize hyper-functioning parathyroid gland in 7 out of 28 cases with negative results on both neck US and MIBI SPECT/CT imaging. **Conclusion:** We agree that 18F-fluorocholine PET/CT is a promising imaging modality for the detection of hyper-functioning parathyroid tissue, most probably due to its superior spatial resolution. It has also some other advantages including low radiation burden and short scanning time, despite to its high cost. Therefore, it should be considered in cases with negative or discordant results on conventional imaging.

EP393

PARATHYROID SCINTIGRAPHY combining dual-isotope AND dual-phases imaging

K. LIMAM, I. Meddeb, I. Yeddes, M. Somai, A. Mhiri, I. Slim, M. Ben Slimane; salah aziez Institut, tunis, TUNISIA.

Introduction: Parathyroid scintigraphy is a reliable imaging for the diagnosis of parathyroid adenoma causing hyperparathyroidism. This exam can be performed by different procedures depending on the team experience and the available materials. The most common are dual-isotopes subtraction parathyroid scintigraphy and dual-phase imaging. Our purpose is to evaluate the results of combining both techniques on accuracy of the diagnosis. **Materials and methods**: This is a retrospective study in which we studied the cases of 35 patients with retained parathyroid adenoma diagnosis. Surgery, histological confirmation, and postoperative normalization of PTH was the reference standard. A parathyroid scintigraphy including a dual-isotope and a dual-phase imaging was performed. The imaging exploration starts with a thyroid Tc-99m pertechnetate scintigraphy followed by a parathyroid Tc-99m sestamibi scintigraphy with static cervical acquisition at 15 and 150 minutes and a thoracic acquisition at 30 minutes. **Results:** Twenty-seven out of thirty-five explorations (77%) were positive in both procedures and showed no significant difference. In fact, we noticed an increased uptake at the early images of the parathyroid Tc-99m sistamibi scintigraphy compared to the thyroid Tc-99m pertechnetate scintigraphy. These additional foci were still visible on late acquisitions of the parathyroid scintigraphy (late wash out). Seven exams (20%) had positive subtraction scintigraphy with a negative dual-phase imaging (early wash out). Only one exam concluded to a positive dual-phase imaging with a negative dual -isotope imaging. **Conclusion:** With a dual-isotopes subtraction we have nearly ninety-seven percent of positive diagnosis, but when we combine it to a dual-phase imaging we increase the accuracy of our parathyroid scintigraphy to show the parathyroid adenoma. These two methods of exploring the hyperparathyroidism are in fact complementary.

EP394

Radioguided Surgery With 99mTc-Sestamibi Primary Hyperparathyroidism: Experience in our institution

U. Jon, A. Perissinotti, C. Cardenas-Negro, A. Allende-Riera, M. De Sequera-Rahola, E. Martinez-Gimeno, D. Cabello, O. Vilahomat; Hospital Universitario Nuestra señora de la Candelaria, Santa Cruz de Tenerife, SPAIN.

Aim: To report our experience in the use of 99mTc-Sestamibi for radioguided surgery in primary hyperparathyroidism and compare results of planar, SPECT/TC images and ultrasound with surgery, histopathological findings and also pre and post-surgery parathormone (PTH) and calcium blood levels. **Methods:** Radioguided parathyroidectomy surgery was performed in 18 patients with primary hyperparathyroidism. All patients were studied with ultrasound and 99mTc-Sestamibi scintigraphy before surgery. Planar and SPECT/CT 99mTc-Sestamibi scintigraphy images were acquired 15 minutes after radiotracer injection and planar delayed images at 120 minutes. Also pre and post-surgery PTH and calcium blood levels were measured. 185 Mbq of 99mTc-Sestamibi was injected on the day of the surgery for hand-held gamma probe radioguided parathyroid identification. Ultrasound and scintigraphy results were compared with histopathological findings and PTH and calcium blood levels. **Results:** In 16/18 (89%) cases histopathological findings of the radioguided resected tissue was compatible with parathyroid adenoma and serum calcium levels normalized after surgery. 12 out of this 16 patients (75%) showed at least a 50% reduction of their serum PTH levels with (mean reduction 57%). In one case histopathological results showed salivary gland tissue in what was thought to be an ectopic parathyroid adenoma; the patient continued with high serum PTH and calcium levels. Successful hand-held gamma probe radioguided resection of parathyroid adenoma showed an intense ex-vivo count rate with a 29% mean decrease activity of surgical bed activity. Planar 99mTc-Sestamibi scintigraphy imaging correctly identified the parathyroid adenoma in 11/18 (61%) cases and 7/18 (39%) were considered as normal studies. SPECT/TC successfully identified the parathyroid adenoma in 15/18 (83%). In two patients all imaging studies showed no abnormal findings, but in one of them parathyroid adenoma was successfully identified by hand-held gamma probe during surgery. The remaining case was considered a false positive SPECT/TC result as what was depicted as a probable ectopic parathyroid adenoma was histopathological reported as salivary gland tissue. Ultrasound correctly identified the pathologic parathyroid gland in 7/18 (39%) patients and was normal in 10/18 (56%) cases. In one case ultrasound showed incorrect localization the parathyroid adenoma. **Conclusions:** Our experience showed that SPECT/TC 99mTc-Sestamibi scintigraphy in patients with primary hyperparathyroidism supplies crucial information for the successful identification of the hyperfunctioning parathyroid gland and is also of great value for surgery planning purposes. Furthermore, the use of hand held gamma probe during surgery allows to differentiate between the pathologic parathyroid glands and normal tissue.

EP395

Radioiodine kinetic in small pool hyperthyroid patients

C. Canzi, V. Longari, M. Castellani, F. Buffoni, I. Martina, R. Benti; Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milano, milano, ITALY.

Small pool (SP) patients are characterized by a high intrathyroidal iodine turnover. This results in thyroid uptake higher at early times (4-6h) than at 24h and, as a consequence, in an increment of radioiodine bound to protein circulating in blood and accumulating in liver that could increase dose to extrathyroidal tissues during therapy for hyperthyroidism. **Aim:** to study radioiodine kinetic in thyroid, blood, whole body(WB) and liver in SP patients in comparison to non small pool (NSP) patients and to evaluate the contributions of blood self-irradiation and penetrating radiation from WB to mean absorbed dose to blood (D_{blood}) per unit of administered activity (A_0). **M&M:** After a pre-therapy dosimetry 7 hyperthyroid patients were classified as SP. After therapeutic administration blood samples were taken since 0.1h to about 168h and thyroid and WB images were acquired with a gammacamera at 2,5,24,48,96 and 168h to stud iodine kinetic in blood, thyroid, WB and liver. The same study was performed on 3 NSP patients. **RESULTS:** Thyroid: in SP patients mean uptake at 5h was higher than at 24h: 74±6% and 64±11% respectively; in NSP it was the contrary: 34±12% and 49±11% respectively . Blood: up to 5h, there was no difference in radioiodine clearance between SP and NSP patients. After 24h, while in NSP patients there was a continuous decrease of ^{131}I concentration, in SP there was a high increase, in correspondence of thyroid dismission, with a slow clearance. The contribution of blood self-irradiation to D_{blood} per unit of A_0 was 0.39 ±0.20Gy/GBq and 0.06±0.02Gy/GBq for SP and NSP patients respectively (p=0.02). WB: there was no difference between SP and NSP patients in radioiodine clearance rate. The contribution of penetrating radiation from WB to D_{blood} per unit of A_0 was 0.19±0.05Gy/GBq and 0.15 ±0.03Gy/GBq for SP and NSP patients respectively (p=0.31). Liver: in NSP patients liver wasn't visible on WB images at any time. In SP patients liver was clearly visible since 24h. Mean dose to liver per unit of A_0 was 533±298mGy/GBq. **CONCLUSIONS:** Radioiodine kinetic in SP hyperthyroid patients is quite different from NSP ones: in thyroid, uptake is higher at 5h than at 24h; in blood, after an initial fast clearance, there is an increment of concentration at 24h; in WB scans liver is clearly visible since 24h. In these patients the contribution of blood self-irradiation to D_{blood} per unit of A_0 is more important than the contribution of penetrating radiation from WB.

EP396

The interrelation of the blood absorbed dose and ablation success in thyroid cancer patients after ^{131}I radioiodine therapy based on biphasic retention model

F. Tabeie, M. Dayagi, B. Shafiei; Shahid Beheshti university of medical sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Purpose: Radioiodine therapy with ^{131}I is still a standard treatment of differentiated thyroid carcinoma patients post surgery. The required amount of radioiodine to achieve complete ablation is still subject to debate. The administered activity must be chosen with maximum ablation to target organ as well as minimal red marrow toxicity. The aim of this paper is to investigate the interrelation of the blood absorbed dose and ablation success of thyroid carcinoma patients after ^{131}I radioiodine therapy. **Materials & Methods:** Total of 93 patients were arranged into three administered activity groups; 3.7 GBq (37.3 %), 5.55 GBq (56.6 %) and 7.4 GBq (6.0 %). The blood doses were calculated by external dose rate measurements of patients with an ionization chamber 2, 6, 12, 24 and 48 hours post administration of ^{131}I . Ablation success defined as the negative ^{131}I whole body scan and low Tg level after 6 months follow up post therapy. The whole body retention and residence times were determined by integrating biphasic decay curves fitted to the whole-body retention times. **Results**: Total of 70 male and 23 female patients aged 45±16 years had 6% follicular and 94% papillary thyroid carcinoma. Six months of follow up showed 58.0%, 38.3% and 20.0% ablation success in 3.7 GBq , 5.55 GBq and 7.4 GBq administered activity groups respectively. Average of the blood dose in 3.7, 4.62, and 5.55 GBq administered activity groups were 483±15, 491±24 and 502±38 mGy, respectively. Clearly there was no significant correlation between administered activity and ablation success in all groups. The blood dose distribution in 3.7 and 5.55 GBq groups showed significant correlation with ablation rates (r= 0.84, p=0.01) , but did not confirmed in 7.4 GBq group. **Conclusion:** This study clearly showed two important results. Increasing the

administered activity will not necessarily increase the ablation success and in the same administered activity patients the ablation success depends on the blood absorbed dose.

Procedural Errors and Their Impact on PET Quantification

T. Nguyen, C. Baun, P. F. Høilund-Carlsen; Dept. of Nuclear Medicine, Odense University Hospital, Odense, DENMARK.

Aim: In PET quantification, procedural variations and human errors will affect standardised uptake values (SUVs). Scan parameters extracted from DICOM image file metadata or patient records for SUV computation can contain data entry error that often unnoticed would yield faulty results. Practical deviations from protocol prescriptions also add to variability. We systematically assessed such inconsistencies and the impact on SUVs. **Materials and Methods:** Five research projects performed at our department from Jan 2015 to Jan 2016, totalling 201 patients, were retrospectively analysed. This included both FDG-PET/CT studies of various protocols (60 min and dual-time scans) and sodium fluoride (NaF)-PET/CT scans. Typed DICOM file entries of relevant parameters (patient weight, tracer dose, injection and scan time) were compared to corresponding registrations in handwritten records. Variations from protocol prescriptions were also recorded when applicable. Any whole number deviations were listed, from which variance estimates in terms of SUV ratios were calculated. **Results:** About 39% of studies had registration inconsistencies between DICOM and patient record entries. Discordance in patient weight (-1—100 kg) in these entries was seen in ~4% of studies, which would amount to a 0.99—41 factor difference in SUVs. Also, dissimilarity in tracer dose of -12—19 MBq ($p = 0.05$) and uptake time of -59—10 min ($p = 0.3$) would yield -5%—7% and -31%—7% SUV de-/increment, respectively. Deviations from protocol prescripts occurred in ~90% of studies with discrepancies in dose of -106—208 MBq ($p < 0.01$) and uptake time of -54—41 min ($p < 0.01$). These would translate into SUV variations by corresponding factors of 0.4—1.1 and 0.7—1.3. Errors collectively in each study would with DICOM entries give a 0.02—1.3 factor SUV difference and with patient record entries a factor of 0.4—1.3 difference compared to intended protocol parameters. **Conclusion:** Inconsistencies in parameter registrations found in routine PET/CT imaging practices are somewhat frequent. Both mainly small and a few highly discrepant DICOM and patient record entries would result in variable SUVs. Registered practical variations in tracer dose and uptake time compared to protocol prescriptions were most significant. This caused in worst cases SUV changes by more than 50% and variability to only increase significantly further with cumulative deviations. While most are expected practical variations, human errors are, therefore, in some instances not a negligible source of quantification bias.

EP398

A Comparison between Standard and Angular-Response-Function-Modeled GATE Simulations in Molecular SPECT: Focus on Computational Efficiency and Accuracy

M. R. Ay[1], H. Mahani[2], G. Raisali[2], A. Kamali-Asl[3]; [1]Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiation Medicine Engineering Department, Shahid Beheshti University, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: While Monte Carlo modeling plays a crucial role nuclear medicine imaging, its performance is always challenged by a high computational demand, especially in high-resolution molecular SPECT simulations. In the current work, we compared standard GATE simulation with angular-response-function (ARF) modeled one based upon computational efficiency as well as accuracy. **Materials and Methods**: For this purpose, we modeled a dedicated molecular SPECT camera developed in our department, HiReSPECT scanner, in GATE. MC simulations were performed for low- (technetium-99m) as well as high-energy (iodine-131) collimators. The collimators were both high-resolution. The ARF allows the GATE to get rid of cumbersome photon transportation in the collimator by pre-calculating collimator-detector response. The ARF tables were extracted by a built-in function using a set of MC simulations at different energy-windows, and then implemented for simulation of NEMA image quality (IQ) phantom. To assess the performance of the ARF modeling, two NEMA IQ phantom simulation datasets (with and without the ARF incorporation) were acquired. Subsequently, each was iteratively reconstructed using a dedicated OSEM algorithm. There were 4 subsets and 3 full-iterations. **Results**: The ARF modeling results in an energy-dependent acceleration factor. The speed-up factor was 7.26 for the low-energy collimator and 12.82 for the high-energy one, considering the same noise-level of 5% for uniform part of the NEMA IQ phantom. Normalized mean square error (NMSE), as an index reflecting accuracy of the ARF modeling, between OSEM reconstructed images of hot-rods part of the NEMA IQ phantom (with and without ARF modeling) was 0.07 and 0.09 for the low- and high-energy collimator, respectively. System sensitivity was 1.32 cps/μCi for the low-energy collimator without ARF modeling, and a sensitivity of 1.24 cps/μCi was obtained when the ARF was modeled. In addition, the simulated system sensitivity (without ARF modeling) is consistent with that of experimental measurement, a 7.5% difference. **Conclusion**: The ARF modeling offered by the GATE makes it possible to dramatically shorten MC simulations of SPECT camera (by a factor between 7 and 13) without compromising accuracy of the data. The acceleration is substantial, especially when a high-energy molecular SPECT simulation is desired.

EP399

Improvement of the distortion effect in dual head PET scanner for breast imaging using an add-on Compton camera

H. Lin[1,2], C. Chiang[1], K. Lue[1], Y. Ni[3], K. Chuang[1]; [1]Department of Biomedical Engineering and Environmental Sciences, National Tsing Hua University, Hsin Chu, TAIWAN, [2]Medical Physics Research Center, Institute for Radiological Research, Chang Gung University/ Chang Gung Memorial Hospital, Taoyuan, TAIWAN, [3]Health Physics Division, Institute of Nuclear Energy Research, Atomic Energy Council, Taoyuan, TAIWAN.

Aim Development of dedicated breast PET scanners is an active research area. Due to the limited angular coverage, fully 3D tomographic images without generation of distortion and artifact is very difficult without rotation of the detectors. In this work, we proposed a novel approach to improve the distortion effect by combing the PET and Compton imaging to achieve the 3D tomographic images without detector rotation. **Materials and methods** Stochastic origin ensembles (SOE) approach based on Markov chains is a good candidate for hybrid PET and Compton imaging since it's universal with any camera geometry. For each measured events (PET events or Compton events), the origins are randomly assigned on a conical surface or a line depending on the event type. During the reconstruction course, origins of the events are randomly moved at a condition of acceptance probability and finally those origins converges to the quasi-stationary state which can be voxelized in a reconstructed image. Monte Carlo simulation for the breast scanner design with a ring diameter and axial length of 15 cm is performed. The scanner comprises a dual head LSO PET detector and a Compton camera in

orthogonal directions. The Compton camera is composed of two double-sided silicon strip detectors as scatterers and LaBr3 scintillation detector as an absorber. A breast phantom embedded with several lesions of different sizes was used to evaluate the proposed system and reconstruction method. **Results** Preliminary simulation results suggest that the distortion and artifact is improved with the incorporation of Compton imaging, especially at the direction orthogonal to the dual head PET. The value for contrast recovery coefficient for small hot lesions of breast phantom can achieve similar performance with rotating dual head PET (full angular coverage). Furthermore, the addition of Compton camera can provide a ~10% gain in sensitivity compared to the dual head breast PET-only. **Conclusion** We conclude that the proposed method can reduce the artifact from the missing projections and improve the image quality of breast PET imaging.

EP400

Comparisation of GE® Discovery IQ 5 rings vs Discovery IQ 4 rings physical performance of according to NEMA NU 2-2012

A. Loi[1], C. Ghetti[2], D. De Vittor[1], G. Serreli[2], M. Carta[1], O. Ortenzia[2], M. Sireus[3], S. Massa[4], S. Loi[4], G. Baldari[5], G. Melis[6], L. Ruffini[5], M. Scarlattei[5], S. Zucca[4]; [1]Alliance Medical, Cagliari, ITALY, [2]Fisica Sanitaria AUO Parma, Parma, ITALY, [3]Scuola di Specializzazione in Fisica Sanitaria, Università degli Studi di Cagliari, Cagliari, ITALY, [4]Fisica Sanitaria AOB Cagliari, Cagliari, ITALY, [5]Medicina Nucleare AUO Parma, Parma, ITALY, [6]Medicina Nucleare AOB Cagliari, Cagliari, ITALY.

Aim: The purpose of the study was to compare the physical performance of two configuration (4 rings-*IQ4R* - and 5 rings-*IQ5R*) of the new integrated PET/CT system Discovery IQ (*DIQ* -GE Medical Systems). Measurements has been performed following the NEMA NU 2-2012 (*NU12*). **Materials and methods:** The *DIQ* combines a sixteen multi-slice helical CT scanner with a scalable PET tomograph which is available in configuration from 2 to 5 rings. Each ring consist of 18 double block of 8x8 BGO crystals. The crystal dimensions are 6.3x6.3x30 mm^3. The *IQ4R* consists of 32 (4x8) rings of crystals allowing the acquisition of 63 images with an axial field of view coverage of 208 mm (63x3.27 mm). The *IQ5R* consists of 40 (5x8) rings of crystals allowing the acquisition of 79 images with an axial field of view covarege of 260 mm (79x3.27 mm). The low- and high-energy thresholds are set to 425 keV and 650 keV, respectively for *IQ4R* and *IQ5R*. The coincidence time window is set to 9.5 ns. **Results**: Spatial resolution was measured at different radial position (@1, 10, 20 cm) and along three main directions (radial -*rpr*, tangential- *tsr*- and axial-*asr*). The *rsr*,were 4.73, 5.22 and 7.94 mm @1, 10, 20 cm respectively (IQ4R); 3.80, 4.70 and 8.23 mm @ 1,10.20 cm respectively (IQ5R).The *tsr* were 4.92, 4.89 and 4.91 mm @1, 10, 20 cm respectively (IQ4R); 4.70, 4.74 and 5.19 mm @1, 10, 20 cm respectively (*IQ5R*). The *asr* were 4.90, 6.07 and 5.19 mm @1, 10, 20 cm respectively (*IQ4R*); 4.81, 5.79 and 6.50 mm @ 1, 10, 20 cm respectively (*IQ5R*).The sensitivity increased from 14.5 cps/kBq (IQ4R) to 22.4 cps/kBq (*IQ5R*) at radial position r=0 cm and from 13.4 cps/kBq to 20.1 cps/kBq at radial position r=10 cm. The scatter fraction was 39.93% (*IQ4R*) and 37.48% (*IQ5R*). The NECR peak was 75.9 kcps at 9.1 kBq/cc in *IQ4R* and increased to 128.4 kcps at 9.3 kBq/cc for *IQ5R*. Losses and random counts accuracy corrections were 3.22% for *IQ4R* and 4,34% for IQ5R. Also image quality, accuracy of the attenuation and scatter correction were evaluated for both systems. **Conclusion**: The new integrated PET-CT system Discovery IQ has excellent performances in both 4 and 5 rings with high sensitivity and a very good NECR response. Which configuration is better for own PET center depends mainly on the numbers of patients/year and the availability of a cyclotron in site.

EP401

Development of 18F-FDG doped alginate phantoms for advanced applications in Nuclear Medicine

J. Cortes-Rodicio, M. Hernandez-Garcia, M. Garcia-Fidalgo; Osakidetza, Vitoria-Gasteiz, SPAIN.

INTRODUCTION AND OBJECTIVES: The purpose of this work is to develop PET phantoms that simulate realistic geometrically situations we found in our nuclear medicine department. In particular, we developed phantoms for applications of true PET guided biopsies, for PET contour delineation verification, and in-body resolution measurements. **METHODS AND MATERIALS:** For all situations, we used a fast drying alginate powder dissolved in 18F-FDG doped water, with the FDG activity concentration of the phantom bulk similar to the clinical practice (2.5MBq/kg). According with the final usage, three different inserts were introduced inside the phantoms before the alginate was settled: (1) First, for testing purposes of a novel device for true-PET guiding biopsies, several spheres with diameters between 5 and 10mm and an activity concentration of 4:1 with respect the background were introduced inside the volume. In this case, the accuracy of the position of the biopsy needle tip with respect to the centre of the spheres can be measured after a PET guided biopsy procedure.(2) Second, a tumour phantom was built to verify the tumour delineation based on metabolic PET imaging for radiotherapy planning. In this case, the size of the 4:1 inserts was at least 4ml, with different shapes according with realistic tumour plaster moulds. The manual drawing contours of the inserts based on PET imaging were then compared with the real shape obtained from a previous CT scan of the phantom.(3) In the third case, we introduced FDG doped zeolites (diameter<1mm) with different activity concentrations (range 2:1 - 12:1) inside the phantom body. By this way, we can measure the resolution of our equipment in real clinical situations. RESULTS: All the alginate phantoms built were successfully used. First, the improvement of the precision and accuracy of the PET guided biopsies using the novel guiding device could be measured. Second, we provide a reliable training phantom for manual tumour delineation based on metabolic PET imaging. Finally, the real clinical resolution of our PET/CT equipment was characterized. CONCLUSIONS: Emerging nuclear medicine necessities require precise assessment and characterization prior the clinical implementation. In this context, we have successfully built different PET phantoms to meet the new challenges of our department. Anyway, the process of phantom elaboration has to be improved and the fields of application broaden.

EP402

Gated reconstruction in 18F-FDG PET-CT quantitative imaging: impact on SUV estimation of tumor motion inside the lung with dynamic thorax phantom

M. Zuffante[1], E. Zivelonghi[1], F. Sciumè[1], F. Dusi[2], P. Polloniato[1], D. Grigolato[1], M. Cucca[1], L. Pavanello[1], C. Cavedon[1], M. Ferdeghini[1]; [1]AOUI Verona, Verona, ITALY, [2]Scuola Specializzazione in Fisica Medica, Università degli Studi di Milano, Milano, ITALY.

Introduction and purpose The methods based on SUV maps suffer from poor SUV and volume quantification due to respiratory motion. The aim of this study was to assess the impact of respiratory-gated PET-CT (4D-PET-CT) on SUV and SUV-based volume quantification in lung tumors using the respiratory track of patient and a dynamic thorax phantom. **Materials and Methods** 4D-PET-CT was performed by means of a Philips Gemini BigBore TOF scanner, using the Varian RPM gating system and a Dynamic Thorax Phantom. Administration and acquisition parameters were 5000 Bq/ml 18F-FDG in a sphere of 8 ml and 2 ml, 2 min/bed, retrospective-mode for both PET and CT modalities. The phantom was scanned at different motion amplitude ranging between 1.0 and 2.5 cm using the respiratory track of patient and cos4. Data were reconstructed in 1 (no sorting), 4, 5, 6, 7, 8, 9 and 10 phases. SUVmax values

within the lesion in max expiration (ph0) were studied as a function of the number of phases into which the breathing cycle was split. Lesion volumes were also obtained by three different methods: a) fixed SUV=2.2 threshold, b) 40% of SUVmax isocontour and c) gradient-based method. The volumes were also studied as a function of the number of phases in ph0. **Results** Comparison between the gated and the non-gated PET images showed a maximum 25% reduction in the total lesion volume calculated as 40% of SUVmax isocontour. Measurements of the maximum standardized uptake values in the gated mode showed an increase of up to 22% compared with that of the nongated measurements. Furthermore SUVmax value increases with the number of phase bins. The smaller sphere showed a greater drop in SUVmax than the larger sphere for the same motion amplitude. For the same sphere volume, the greater drop in SUVmax was obtained for the larger motion amplitude. **Conclusion** 4D-PET-CT offers a clear advantage in 18F-FDG SUV estimation for tumors that move with respiration. The effect of gating should depend on the lesion's size and lesion motion amplitude. A balance between acquisition time, SNR and SUV estimation accuracy seems to be achievable by using 4-6 phases, depending on lesion size and location. 4D-PET-CT might improve volume quantification as well; however, further research is needed in order to find the optimum segmentation method independently from tumor motion, as residual inconsistencies are observed after motion correction.

EP403

AniMate - An open source software for absolute PET quantification

C. Malbert; INRA, Saint-Gilles, FRANCE.

Image derived insulin sensitivity and glucose metabolic rate (MRglu) are essential to investigate whole body insulin resistance in type II diabetes and in obese individuals. PET imaging coupled with arterial input function measurement once correctly analyzed with compartmental kinetic modeling has been used to evaluate MRglu for the heart, liver, skeletal muscle, brain and more recently duodenum (Iozzo, 2015). While the workflow has been simplified by dedicated software such as Pmod (Switzerland), the calculation of the input arterial function is difficult, time consuming and prone to errors. Furthermore, calibration procedure is complex and the actual experiment requires exact timing with intermingled sampling. The aim of this work is to present an integrated open source software solution to streamline the workflow from the cross calibration down to the delivery of an arterial input function correctly formatted for data modeling. AniMate is a set of software modules written in Labview 2015 (National instruments, USA) that interact between each other to minimize user interaction to create a flexible automated workflow. All software modules have a comprehensive english user interface and are multiplateform aware. AniMate comprises four modules. One module aims at getting in line arterial counts and is directly interfaced with a Canberra 2007 photomultiplier tube and a WPI peristaltic pump. Another module is dedicated to get blood sample volume using a precision connected scale and plasma activity using a desktop gamma counter (2470 Wizard, PerkinElmer). These two modules have provision for cross calibration using PET as source calibrator. A third module serves as master timer. It extracts time frames from the PET machine and convert them into sampling time to automatically create a logbook of the experiment. A fourth module is dedicated to data integration for creation of the composite arterial input curve from inline data together with plasma samples. This module was also capable to build complex arterial input curves required when several organs are scanned sequentially. Finally, it extracts the endogenous glucose production from FDG fate. An additional module is mastering the automatic euglycemic clamp using an algorithm derived from Furler et al (1986). AniMate has been used successfully in more than 30 preclinical studies with miniature pigs and has been proved to be effective in reducing the work burden required for MRglu calculation both during the actual experiment and in analyzing the numerous pieces of informations that eventually will be used in data modeling.

EP404

Evaluation of auto-segmentation methods for the determination of skeletal tumor burden on F18-NaF PET/CT bone scans

A. Swallen, S. Chung, **A. Nelson**; MIM Software, Inc, Cleveland, OH, UNITED STATES.

Purpose/Objectives: Interpretation of F18-NaF PET/CT bone scans can be challenging due to the large number of lesions that can be present. Our goal is to evaluate different methods to automatically segment areas of high fluoride uptake for the determination of skeletal tumor burden on NaF PET/CT. **Methods/Materials:**Nine NaF PET/CT scans were processed using two auto-segmentation methods to identify areas of abnormal NaF uptake defined as > 10 SUV. Method 1 used an automated body segmentation method to outline the whole body. Method 2 identified bones by first outlining the whole body like Method 1, then thresholded the body to CT bone HU range, and used contour post-processing to finalize the bone contours. Areas > 10 SUV were then identified within the final region generated by each method. Comparison was made to a region created by applying a cutoff of 10 SUV to the manually created bone VOIs for each subject. Total lesion fluoride uptake (TLF10) and fluoride tumor volume (FTV10) were compared for each method. **Results:**The average TLF10 from the manual contours was 4648 SUV*mL with a range of 370-16436 SUV*mL. The average FTV10 from the manual contours was 292.67 mL with a range of 28.48-1167.37 mL. The percent difference in TLF10 and FTV10 for each method compared to the manual method were: Method 1 (137.18%, 90.10%), Method 2 (2.94%, 3.40%). Conclusions: The second method of auto-segmentation was found to produce the most accurate measurements of skeletal tumor burden as defined by areas within manually defined bone VOIs with >10 SUV.

EP405

Evaluation of quantitative parameter of Q.Clear, a new image reconstruction algorithm for PET, compared with conventional iterative reconstruction

T. Ishimori, Y. Nakamoto, K. Togashi; Kyoto University, Kyoto, JAPAN.

(Objectives) Quantitative analysis using standardized uptake value (SUV) is commonly used in oncological FDG-PET imaging. Recently, a new Bayesian penalized-likelihood reconstruction algorithm Q.Clear has been developed to generate images with lower noise compared to conventional OSEM. However, it is not clear how Q.Clear reconstruction affects quantification of clinical FDG-PET. We evaluated quantitative characteristics of Q.Clear reconstruction in terms of comparison of SUV on clinical images between Q.Clear and conventional OSEM. **(Methods)** Images of 40 FDG-PET/CT whole body scans with known or suspected malignancies were reconstructed by Q.Clear (β=300) and conventional OSEM (iteration 4, subsets 12) methods. SUVmax by Q.Clear (QSUV) and that by conventional OSEM (CSUV) were measured on the same region of interest placed on the liver, heart, brain. In 29 PET/CT scans, QSUV and CSUV of 40 malignant tumors (lung, colon, liver, lymph nodes, bone and soft tissue, etc.) with a diameter of 38.0 ±36.6mm were measured and compared with each other. In 5 scans, QSUV using various reconstruction conditions (β=300, 400, 500 and 600) were compared with one another. **(Results)** QSUV of the tumor (8.9±6.3) was significantly greater than CSUV (8.3±6.4)($p<0.01$). As for the brain and the heart, QSUV was significantly greater than CSUV (brain: QSUV=13.7±3.3, CSUV=12.8±2.9; $p<0.01$, heart: QSUV=5.9 ±3.4, CSUV=5.8±3.3; $p=0.02$), while the difference of QSUV and CSUV of the liver (QSUV; 3.2±0.2, CSUV; 3.2±0.3) was not significant. Increasing β values reduced QSUV in the liver, heart, brain and tumor significantly. **(Conclusions)** Significant differences between QSUV and CSUV of the tumor and the normal organs should be noted in quantitative evaluation of PET images, while SUVmax of the liver is relatively

consistent regardless of reconstruction algorithms. When using Q.Clear reconstruction, appropriate β value should be selected in terms of not only image noise reduction but also SUVmax.

EP406

Amyloid Burden Clusters: An Exploratory Study

J. S. Oh[1], H. Moon[1,2], M. Oh[1], S. Oh[1], J. Roh[3], J. Lee[3], J. Kim[1]; [1]Department of Nuclear Medicine, Asan Medical Center, University of Ulsan College Medicine, Seoul, KOREA, REPUBLIC OF, [2]Department of Medical Science, University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF, [3]Department of Neurology, Asan Medical Center, University of Ulsan College Medicine, Seoul, KOREA, REPUBLIC OF.

Aim The brain amyloid PET became one of representative imaging biomarkers for the investigation of amyloid-β associated cognitive and movement disorders. To the best of our knowledge there have been less literature that addressed the amyloid burden as clusters or networks in brain as compared to other brain imaging modality (e.g. anatomical/functional or metabolic connectome) studies. Therefore, we performed an exploratory investigation of the amyloid burden clusters using 60 visually diagnosed amyloid-positive patients among patients with Alzheimer's disease or mild cognitive impairment patients in our Neurology Clinics. **Materials and methods** All patients underwent 20min PET-CT scan on GE Discovery 690(Elite)/710 PET cameras 60 min after 185MBq i.v. of F-18 Florbetaben (FBB). 3D volumetric MRIs were also acquired for each subject for the anatomical precision of volume of interest (VOI) definition. Freesurfer-based parcellation of brain was conducted using these 3D MRIs resulting in sulcul/gyral parcellation of brain. Reference region was defined by cerebellar cortex for the purpose of uptake count normalization forming uptake ratio (also equivalent to standard uptake value ratio; SUVR). Seed regions were picked from representative VOIs of amyloid burden - PC square (posterior cingulate cortex and precuneus), bilateral middle frontal cortices (MFC)/ lateral temporal cortices (LTC). For an exploratory purpose, bilateral VOIs were used as different seed regions. Since global (nonspecific) mean uptake cause seemingly global high correlation, we corrected for all regional amyloid uptake by subtracting global mean uptake. Interregional correlation analysis was conducted using aforementioned seed regions and sulcul/gyral level parcellation of brain. **Results** Each seed region correlated with different regions of brain, forming many different clusters. All seed regions exhibited correlation with contralateral (mirrored) regions with lower correlation than in the ipsilateral ones. All seed regions but PC square exhibited correlation with themselves and their mirrored contralateral regions. PC square exhibited high correlation with itself and partial correlation with superior frontal cortex. **Conclusion** All representative amyloid burden-susceptible regions formed different clusters in terms of inter-regional correlation. Therefore, we suggest whole brain amyloid burden may be better described by a global (composite) VOI or a well-designed weighted sum of these subregions.

EP407

Radiomics of 18F-choline fusion PET/MRI for prostate cancer detection prior to targeted prostate biopsy

M. R. Piert, M. S. Davenport, J. Montgomery, L. P. Kunju, J. Siddiqui, V. Rogers, X. Shao, I. El Naqa; University of Michigan, ANN ARBOR, MI, UNITED STATES.

Objectives: MRI-guided (targeted) prostate biopsies are rapidly adapted to improve the diagnostic performance of prostate biopsies. We tested the value of texture analysis on 18F-choline PET/CT in conjunction with apparent diffusion coefficient (ADC) maps from diffusion-weighted MRI to improve the detection of significant prostate cancer (Gleason ≥ 3+4) over that from multi-parameter (mp) MRI alone. **Methods:** 18F-choline PET/CT (Siemens mCT PET/CT, HiRez, time-of-flight) and 3 Tesla mpMRI (Philips Achieva) of the pelvis were performed in 23 subjects with rising prostate specific antigen levels (PSA mean 7.9 ± 3.5 ng/mL) for known (n=17) or suspected (n=20) prostate cancer prior to a scheduled prostate biopsy procedure. PET and T2-weighted (T2w) MR volumes of the prostate were spatially co-registered (MIM software). Biopsy targets were selected based on visual appearance on MRI and graded as low, intermediate or high risk. Volumes-of-interest were defined to obtain 18F-choline SUV and ADC values. For texture analysis, a regularization and variable selection method (called elastic net) with 80% Lasso (L1 norm) to 20% ridge (L2 norm) penalty (binomial logistic model). Regularization parameter selection was done with 10-fold cross-validation and classification assessment using AUC with performance generalization using 1000 bootstrap re-sampling. Sampled image texture features (including global, GLCM, NGTDM, GLRLM, GLSZM) from 18F-choline PET, ADC and fused PET/MRI (normalized by peak signal) were applied. ROC analysis was performed for individual parameters (18F-choline maximum SUV, minimum ADC), and texture analysis from 18F-choline, ADC, and fusion PET/MRI. The biopsy procedure was performed after registration of real-time transrectal ultrasound (TRUS) with a 3D T2w MR sequence with embedded target information. Histology (Gleason scores) from image-guided (targeted) plus standard (systematic 12-core) biopsy cores, as well as from prostatectomy specimen (n=6) was used as reference. **Results:** A total of 37 lesions were identified by mpMRI (19 low; 10 intermediate; 8 high risk), and mpMRI-assigned risk was a good predictor of final pathology. Twelve subjects were ultimately identified with Gleason ≥ 3+4 prostate cancer. The 18F-choline maximum SUV (AUC=0.79) and minimum ADC (AUC=0.68) as sole measurements were inferior to their respective texture analysis (AUC=0.82 and 0.86). Texture analysis of the combined PET/MRI classifier performed slightly better at AUC=0.88. **Conclusions:** Texture analysis of PET/MRI classifiers warrants further investigation for the identification of significant primary prostate cancer. Beth Israel Plugin for FIJI: A free and open source software tool for PET/CT processing in research

S. Kanoun[1,2,3], I. Tal[4], J. Vrigneaud[2], A. Cochet[1,2,3]; [1]LE2I, UMR CNRS 6306, Dijon, FRANCE, [2]Centre Georges Francois Leclerc, Dijon, FRANCE, [3]CHU Dijon, Dijon, FRANCE, [4]Beth Israel Deaconess Medical Center, Boston, MA, UNITED STATES.

Aim: To develop a new collaborative free and open source software tool, provide image processing capabilities and facilitate data collection on PET/CT. **Presentation:** The software is developed by Beth Israel Deaconess Medical Center (Boston) in collaboration with other institutions. Based on FIJI (ImageJ distribution) and distributed with the General Public License (GPL), the software can be used with any operating system (Windows, Mac OSX, GNU/Linux). The project is open for any collaboration to provide a free software support for processing and data collection on PET/CT images. Software quantifications has been validated using a PET/CT phantom and with a clinical dataset and has shown identical results than commercial workstations. Functionalities: - DICOM compatibility: parsing and reading. - PET/CT display: PET and CT display, image fusion, LUTs availability, MPR and MIP reconstruction, image annotation, secondary capture. - Quantification: SUV (max, mean, peak, SD), SUL, MTV (absolute or relative threshold), TLG. Regular or irregular ROI drawing. - Results export in CSV files (global results and for each ROI), ROI coordinate saving. - Possibility to develop dedicated tool for specific research topics: data organization in local or remote database, advanced image processing, multi reader collaborative studies.... - Other: MRI registration, additional image processing using ImageJ/Fiji functions, automatic updates… **Conclusion:** Beth Israel Plugin for FIJI provides

free image processing and data collection services with personalized features capabilities. This free software solves usual software cost and availability issues. Based on a collaborative project, each researcher is welcome to suggest new image processing topics and participate in building an open source multipurpose software tool for scientific applications.

Method for accurate registration of PET and MRI to histopathology of the prostate

M. R. Piert, J. Siddiqui, V. Rogers, J. Montgomery, M. S. Davenport, L. P. Kunju; University of Michigan, ANN ARBOR, MI, UNITED STATES.

An exact co-localization of image data with pathology is needed to establish the accuracy of imaging to distinguish low risk (indolent) from intermediate/high risk (significant) primary prostate cancer and to determine tumor boundaries to guide focal prostate cancer treatments. Due to poor correlation of slice thickness and orientation between imaging and histology, verification of medical imaging results of smaller prostate lesions by pathology is challenging. Here we demonstrate an objective methodology using ex-vivo prostate specimen MRI and patient-specific 3D printed molds to facilitate registration. **Methods and results:** The registration process involves multiple steps. First, *in-vivo* PET is registered to a high resolution (0.75 mm^3) 3D T2-weighted (T2w) MR sequence at 3 Tesla using commercially available software. The most difficult, second registration step is the mapping of pathology onto MRI, aided by *ex-vivo* prostate specimen MRI. Following prostatectomy, an *ex-vivo* T2w 3D specimen MRI is performed with the prostate immersed in perfluorocarbon solution to reduce susceptibility artifacts. Segmentation of the prostate then serves as mold design template. The scan also facilitates image registration utilizing embedded intra-prostatic imaging features. Mold sleds spaced 3 mm apart simplify later accurate gross sectioning of the specimen within the mold. Following complete fixation of the prostate, a second specimen MRI is performed; then the prostate is gross sectioned without repositioning in the mold. Volumetric 3 mm stacks of histology sections are then registered onto *ex-vivo* high resolution specimen MRI, providing a consistent registration of the *ex-vivo* MRI to pathology. All prostate cancer foci are outlined by the pathologist on whole-mount HE slices and lesion boundaries are transferred into the *ex-vivo* MRI. **Results:** The methodology allows the retrospective verification whether in-vivo imaging correctly identified and classified all tumor lesions identified at final pathology. Also, it is possible to determine the true tumor extension on *in-vivo* PET and MRI, thereby determining boundary errors based on visual image inspection as well as mathematical thresholding techniques. Furthermore, this methodology permits retrospective genomic and immunohistochemical analyses of specific imaging features. **Conclusion:** Additional expenses related to advanced registration techniques as described here are small in comparison to the overall costs of clinical trials. Employing such techniques improves the impact of imaging research, which is particularly true for prostate cancer, which often presents with multi-focal disease of varying clinical significance. Optimization of Filter Thickness in Filtering Technique for DISA Crosstalk Compensation

K. S. Chuang[1], H. H. Lin[1,2], Z. J. Wei[1], C. C. Chiang[1], Y. H. Lee[1], Y. F. Wang[1], C. S. Lin[1]; [1]National Tsing-Hua University, Hsin-Chu, TAIWAN, [2]Medical Physics Research Center, Institute for Radiological Research, Chang Gung University/Chang Gung Memorial Hospital, Taoyuan, TAIWAN.

Aim: Dual isotopes simultaneous acquisition (DISA) permits the imaging of two radiotracers in the same physiological state with perfect registration. However, crosstalk exists when the photopeak of the two photons from the dual isotopes are close. Artificial neural network (ANN) is the most used technique to toggle the crosstalk. However, it requires up to 26 energy windows which are not available in most SPECT. Recently, we used a filter on the collimator to alter the energy spectrum of the detected photons. It is possible to separate the two isotopes based on the attenuation differences in data from the two scans with and without the filter. In this study, we explore the effect of filter thickness on the decontamination and determine the optimal thickness. **Materials and methods:** A large filter thickness generated a larger attenuation difference between two photopeak windows and enabled a better separation between isotopes. A thicker filter absorbed more photons and caused an increase in image noise. The determination of filter thickness is a tradeoff between the noise and degree of decontamination. A figure of merit (FOM) was defined as the ratio between the attenuation difference in photopeaks of the two isotopes caused by the filter and Poisson noise in the projection data. We plotted FOM as a function of filter thickness and the one with largest FOM was regarded as optimal. **Results:** A thickness of 0.2 mm gold was found to be optimal for $^{123}I/^{99m}Tc$ DISA. The gold was selected for its high Z and excellent ductile property. The gold film is attached to the one of the two collimators of an E.CAM (Siemens, German) for DISA simulation. Preliminary results demonstrate that the proposed method improves image contrast and removes the artifacts caused by the energy crosstalk. The results show that quantitative recovery from mixed ^{99m}Tc and ^{123}I sources is comparable to that from matched single-isotope sources. **Conclusion:** In this study, a DISA SPECT technique to tackle the crosstalk using filter is proposed and the optimized thickness of the filter is determined. Projection data with and without filter are used to separate the energy spectrum. This method is simple to perform and yet generates promising results.

EP411

Improved Quantification of Preclinical 68Ga PET studies with a CT-based Positron Range Correction

J. Cal-Gonzalez; Medical University of Vienna, Vienna, AUSTRIA.

Aim. Image quality of PET tracers that emits high-energy positrons, such as ^{68}Ga, ^{82}Rb or ^{124}I, is significantly affected by the "positron range" (PR) effect. PR effects are especially important in small animal PET studies, as they limit the spatial resolution and quantitative accuracy of the images. The aim of this study is to show how the quantitative results of ^{68}Ga-DOTATOC PET/CT imaging of neuroendocrine tumors in mice can be improved using a novel tissue-dependent and spatially-variant positron range correction (TDSV-PRC). **Materials and methods**. Monte Carlo simulations of the positron propagation in biological tissues were used to obtain the PR distributions for the most common radionuclides used in PET. These results were used to define voxel-dependent kernels which take into account the different materials that a positron may travel through until it annihilates. These kernels are computed before the PET reconstruction based on the associated CT scan, and they are incorporated in the forward-projection step of the iterative reconstruction. The performance assessment of the method has been carries out using two acquisitions of mice with xenografted neuroendocrine tumors injected with ^{68}Ga-DOTATOC and scanned in the Argus PET/CT system. Scan time was 60 minutes after 30 minutes of uptake, using an energy window of 100-700 keV. Image reconstruction was done using a 3D-OSEM algorithm with and without the proposed correction. Quality of the mice images was based on signal-to-noise ratio, measured by mean activity within the tumors and the standard deviation in a uniform region located within the liver. Activity profiles through the tumor and residual activity in the lungs and air surrounding the mice bodies were also evaluated. **Results**. We observed an activity recovery within the tumor of 106% (mouse 1) and 150% (mouse 2), from images at the same

noise level (12% in a uniform region). This level of noise was achieved after 250 (without PRC) and 100 (with PRC) image updates. A significant reduction of apparent tumor size was observed when PRC is applied, giving similar tumor delineations than the ones obtained from the CT images. Significant reduction of activity in lungs (27% for mouse 1 and 40% for mouse 2) was observed in the PRC images. **Conclusions and future work**. The proposed TDSV-PRC produces artifact-free images for large PR radionuclides such as ^{68}Ga. Further evaluations in a larger cohort of mice with neuroendocrine tumors are being performed and will be presented at the conference.

EP412

Clinical Impact of Anti-Thyroglobulin Antibodies & Hashimoto's thyroiditis In The Follow-up Of Differentiated Thyroid Cancer Patients

A. Zakir Ali, R. P, P. B; Basavatarakam Indo-American Cancer Hospital & Research Institute, Hyderabad, INDIA.

AIM To predict the prognosis of DTC patients from their anti-thyroglobulin trend & the status of Hashimoto's thyroiditis. **MATERIAL & METHODS** We evaluated about 102 patients retrospectively having only locoregional disease. A first follow-up(FFU) WBI scan alongwith serum thyrogloblulin(Tg1) and serum anti-thyroglobulin antibody(TgA1) was performed after 6 months of radioiodine therapy(RIT). A second follow-up(SFU) WBI scan or whole body tumor scintigraphy was performed after 1.5 years post RIT alongwith serum thyroglobulin(Tg2) & serum anti-thyroglobulin antibody(Tg A2). The status of Hashimoto's thyroiditis(HT) were also noted. The patients having high serum TgA1 levels(> 18 IU/ml) were divided into two groups: Group A having negative FFU WBI scan(ablated or TENIS). Group B having a positive FFU WBI scan(residual or recurrence). The Group A were further divided into 2 subgroups based on the presence or absence of elevated Thyroglobulin levels:[a] Non-TENIS(Tg1 < 10 ng/ml) and [b] TENIS patients(Tg1 > 10 ng/ml). The group B patients underwent RIT +/- surgery. The subsequent serum anti-thyroglobulin antibody levels after 6 months were taken as TgA2 levels. **RESULTS** 24 out of 102 patients are positive for Hashimoto's thyroiditis(HT). 16 out of 102 patients have elevated TgA1. Only 6/16 TgA1 positive patients have HT. Out of the 16 patients who had elevated serum TgA1, 12 patients belonged to Group A and 4 patients belonged to Group B. Out of the 12 patients belonging to Group A, 10 belonged to Non-TENIS category & 2 to TENIS category. Out of 10 pts belonging to Non-TENIS category, 9 had a decreasing trend and 1 had an increasing trend of TgA2 as compared to TgA1. Out of the 9 having a decreasing trend, 5 had > 50% decrease(4 positive for HT) and 4 had <50% decrease(1 positive for HT). The single patient with increasing trend of TgA2 had negative HT(diagnosed to have liver metastasis). Out of the 2 TENIS category patients(both negative for HT), one had a decreasing trend(<50%) of TgA2 and the other an increasing trend. Out of the 4 patients belonging to Group B, all had a decreasing trend of TgA2 with one having >50% decrease(negative for HT) and 3 having <50% decrease(one positive for HT). **CONCLUSION** The trend of the serum TgA levels(increasing and < 50% decrease) alongwith a negative HT status predicts a poorer prognosis whereas a decreasing trend of >50% with HT positivity suggests a good prognosis. It is especially useful in identifying occult TENIS syndrome patients.

EP413

Synthetic PET Image Modeling

C. HUERGA[1], P. CASTRO[2], L. ALEJO[1], R. PLAZA[1], E. GUIBELALDE[3]; [1]Medical Physics Department, Hospital Universitario La Paz, MADRID, SPAIN, [2]Medical Physics Departament, Hospital Universitario La Princesa, MADRID, SPAIN, [3]Department of Radiology, Faculty of Medicine, Complutense University, MADRID, SPAIN.

Aim: To evaluate techniques of image processing is quite common to use synthetic images for its validation. In this work we show a model to generate synthetic PET images. The proposed model includes fundamental aspects for description of PET image: effect partial volume (EPV), noise (covariance) texture, and dependence with noise magnitude (variance). To compare synthetic PET images with real FDG-images, we apply a non-linear filtering based on wavelets. M**aterial and methods:** Synthetic images were produced simulating NEMA IEC Body Phantom which includes "hot" spheres. A dataset of 128 x 128 images with voxel size 3,906mm x 3,906mm x 4.25mm was performed where an ellipsoid simulates phantom section and a set of six spheres are embedded with the same diameter as the real ones. Image resolutions characteristics are obtained experimentally from recovery coefficient (RC) following the method proposed by Prieto [Prieto,2010]. RC is defined as the ratio of the activity concentration presented in the image and the real (introduced) activity. The mathematically images generated were convoluted varying SD kernel value until coincidence RC with experimental values. The noise texture is performed by random phase shift of noise power spectrum (NPS)[Fredenberg, 2010]. The NPS is obtained via Fourier transform of uniform phantom acquisition. The model also introduces the correlation intensity. Then, the expression for noise's model we propose is: $I_{noise}(x,y)=I_0(x,y)+f(I_0(x,y) * noise(x,y)$. Where I_0 is the synthetic image without noise and convoluted with the PSF. Function f represents dependence of variance with magnitude, we used expression proposed by Geng [Geng, 2003], the symbol * indicates a pixel by pixel product, and *noise(x,y)* is the noise texture image defined above. Real images were acquired using PET /CT Discovery LS (GE Healthcare), with CT based attenuation correction using OSEM reconstruction. Images dataset using 18FDG and NEMA phantom was acquired. To compare real 18FDG-images (A) with synthetic (B) SURE wavelet filter with appropriate performance for PET images [Turkheimer,1999] was used. **Results:** Both A and B exhibit the same behavior. Global gain in SNR is about 30% in both A and B. Signal decrease in smallest spheres. With different sphere-background ratio (SBR): SBR=5-1 (low-contrast) -9% in A and -6.5% in B, decreasing when SBR is larger: SBR=20-1 (high-contrast) -2.8% in A and -2.2% in B. We show noise texture, real and synthetic phantom in order to evaluation. **Conclusions:** We show a model to generate synthetic PET image. It's a valid alternative to MC models.

EP414

Validation of an Automatic Segmentation Algorithm for SPECT/CT Based Tumour Dosimetry

M. Gray, I. Murray, G. Flux; Joint Department of Physics, Royal Marsden NHS Foundation Trust, London, UNITED KINGDOM.

Aims: To assess the performance of a novel user-independent automatic segmentation algorithm for SPECT/CT applications. The algorithm had been previously developed for PET/CT applications in external beam radiotherapy. **Method:** The Fuzzy Logic Automatic Bayesian (FLAB) segmentation algorithm developed by Hatt et al was initially coded and tested using experimental 2D PET data. A NEMA image quality phantom with fillable inserts of varying diameter from 37 mm to 10 mm was filled with 350 MBq of Tc-99m giving a target:background ratio of approximately 10:1. SPECT/CT acquisitions with varying projection time per view from 240 to 30 seconds were performed on a Philips Brightview XCT gamma camera. 128 x 128 and 256 x 256 acquisitions were set up to assess the impact on FLAB accuracy as a function of noise. All data sets were reconstructed using OSEM and with the Philips resolution recovery algorithm. FLAB code was generated and incorporated into a workflow set up on the Siemens Symbia.net. All inserts were segmented using this workflow. Accuracy of FLAB using OSEM was compared against FLAB with resolution recovery. Assessment of using smaller voxels was assessed. The addition of a low pass filter on pre-segmented data was also tested to determine its impact on FLAB accuracy.

Results: Preliminary results indicate FLAB is strongly dependent on the reconstruction algorithm and voxel size. Segmentation errors e(OSEM), and e(AST)) ranged from 13% (37 mm sphere) to 245% (10 mm sphere) and 25% to 300% respectively. In terms of voxel size; segmentation with OSEM ranged from an accuracy of between 2 to 3 voxels difference for the 10 mm sphere and from less than 1 to 2 voxels for the 17mm and 37 mm spheres. Low pass filtering showed small changes in performance for all spheres for cut off frequencies between 0.4 and 1 cycles/cm. **Conclusion:** A systematic difference in segmentation performance was apparent between OSEM and resolution recovery. Smaller volumes could be delineated with better precision using resolution recovery. There was no significant difference between the segmentation accuracy using a 128 or 256 matrix indicating FLAB is robust to increasing statistical noise with SPECT. A degree of filtering with a low pass filter may improve delineation accuracy.

EP415

Automated segmentation of the skeleton in PET/CT scans

M. Sadik[1], R. Kaboteh[1], N. Hasani[1], M. Landgren[2], L. Svärm[2], O. Enqvist[3], F. Kahl[3], L. Edenbrandt[4]; [1]Department of Clinical Physiology, Göteborg, SWEDEN, [2]Centre for Mathematical Sciences, Lund, SWEDEN, [3]Dept of Signals and Systems Chalmers University of Technology, Göteborg, SWEDEN, [4]Department of Clinical Physiology, Göteborg and Malmö, SWEDEN.

Aim: Hitherto there is no imaging biomarker included in the risk-stratification of prostate cancer patients even though it is well known that for example the extent of bone metastases assessed with diagnostic imaging methods is closely associated with survival. An automated method to calculate Bone Scan Index has recently been established as a first imaging biomarker in this field. The aim of this work is to develop new imaging biomarkers for the assessment of tumour burden to the skeleton from PET/CT images. The first step is to segment the skeleton in the CT images. **Materials and Methods:** The automated method was designed to specifically detect and segment the different bones of the thoracic and lumbar spine, pelvis, ribs, sternum, clavicle and scapula. For the classification of uptake as metastasis or benign, for example in fluoride-PET images, the exact localisation will be important. The first step of the automated method aims at approximate bone localization. A convolutional neural network is used to detect a set of anatomical landmarks. These landmarks together with a shape model are used to align an atlas to the query image. The atlas together with the image is input to a second convolutional neural network that performs the actual segmentation. CT images from 50 patients who had undergone FDG-PET/CT scans were used to develop and evaluate the segmentation method. Experienced image readers performed manual segmentations of the skeleton in the CT images. The PET/CT images were obtained with a Biograph 64/True V PET/CT (Siemens) using a low dose radiation CT. The Sørensen-Dice index was used to quantitatively evaluate the similarity between the automated and the manual segmentations as well as the similarity between two separate manual segmentations. For the purpose to compare the performance of the automated segmentation method, intra and inter observer variability in manual segmentations of the L1 vertebrae was studied. **Results:** The mean Sørensen-Dice index for comparison automated-manual methods were in these selected bones: Vertabra Th11=0.86, L1=0.87, L4=0.89, Sacrum-coccyx=0.91 Pelvic bone=0.95. The corresponding index comparing two manual L1 segmentations were 0.87 (same observer) and 0.86 (different obserservers). **Conclusion:** A completely automated method for 3D segmentation of the skeleton in CT images is proposed. The performance of the automated segmentation method is similar to that of experienced image readers. In future work we will use this segmentation method for the analysis of PET images based on for example sodium fluoride or choline.

EP416

Q.Freeze for Respiratory Motion Correction in PET/CT: Assessment and Optimisation with a 4D PET/CT phantom and patient data

G. Havariyoun, E. Kalogianni, D. Ruiz, B. Corcoran, N. Mulholland, G. Vivian; King's College Hospital NHS Trust, London, UNITED KINGDOM.

Background: PET/CT imaging of the lung and abdominal region is often affected by patient respiratory motion. This can lead to an apparent increase in tumour volume, an underestimation of tracer concentration and mismatched PET-CT images. **Purpose:** This study aimed to assess the efficacy and any optimisation requirements of a commercially available respiratory motion correction system in a clinical setting. **Materials and Methods:** The data of n=17 patients who had undergone standard 3D-PET/CT and 4D-PET/CT (n=15) or 4D-PET/4D-CT (n=2) acquisitions was retrospectively analysed. Overall n=33 lesions were considered for analysis. Furthermore, gated and un-gated acquisitions were performed with a dynamic phantom, and an in-house designed PET/CT insert, driven by patient specific respiratory traces to simulate liver and lung lesions in motion (in homogenous and heterogeneous environments). Reconstruction and acquisition parameters were varied to assess impact on image quality. Signal to Noise Ratio (SNR), Noise Equivalent Counts (NEC), maximum and peak Standardised Uptake Values (SUV) and lesion volume were assessed for gated and un-gated acquisitions. For the phantom acquisitions, results were compared to ground truth values obtained with the phantom motionless. **Results:** Patient Data: There was a significant ($p<0.05$) decrease in SUV_{max} (0.35±0.70) and SUV_{peak} (0.20 ±0.50) of the n=33 patient lesions with 4D-PET/CT (58% phase). Rejection of counts, due to non-periodic respiration, led to a significant ($p=0.006$) decrease in NEC (0.49±0.64 Mcounts/m). There was a significant ($p<0.05$) decrease in SNR (2.30±1.28) with 4D-PET/CT. Use of 9 or 12 subsets in the reconstruction of patient gated acquisitions increased SNR by 40% and 25% respectively. Phantom Data: Lung lesion: SUV_{max} increase of 2.0±6.5% (4D-PET/CT) and 1.8±6.3% (4D-PET/4D-CT). Volume decrease of 2.2±6.7% (4D-PET/CT) and 3.1±6.4%. No significant difference between the SUV_{max} ($p=0.9$) and lesion volume ($p=0.06$) results obtained with 4D-PET/CT and 4D-PET/4D-CT. Liver lesion (lung-liver boundary): A statistically significant ($p=0.008$) difference in SUV_{max} obtained with 4D-PET/CT and 4D-PET/4D-CT. Excessive number of subsets used for reconstruction led to overestimation of SUV_{max} when compared to ground truth. Use of 9 or 12 subsets led to improved SUV_{max} results and decrease in background variability. **Conclusions:** The impact of respiratory motion in PET/CT is highly dependent on motion amplitude and lesion location. Results do not justify the extra radiation exposure implicated with the use of 4D-PET/4D-CT. Q.Freeze has indicated the ability to correct for respiratory motion in PET/CT imaging. However, appropriate setup and reconstruction settings are required in order to achieve this.

EP417

Performance characterization of a preclinical SPECT/MR scanner

M. Segbers, J. de Swart, M. Bernsen, J. Haeck, M. de Jong; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: The Mediso nanoScan (Mediso, Budapest Hungary) SPECT/MRI integrates both modalities for the first time in a single imaging platform. In this study the performance of the SPECT subsystem has been characterized and the accuracy of MRI based attenuation correction was investigated. **Material and Methods:** For all scans 99mTc-pertechnetate was used. Resolution was measured using a micro Jaszczak phantom (rod sizes 0.7 - 1.5mm) at 12 different concentration levels (0.05 - 75 MBq/ml) for two sets of apertures: Standard-Whole-Body (SWB) and High-Sensitivity-Whole-Body (HSWB) apertures. We assessed system

linearity by scanning a 50-mL syringe at 24 different levels of radioactivity (between 0.03 and 50 MBq/ml) with both apertures, and the activity concentration range for which the system was linear (5% error margin). In addition, Signal-to-Noise Ratio's (SNR) were obtained for all scans by Region Of Interest (ROI) analysis. Five different syringes with varying diameters (between 1-ml and 20-ml) were scanned with the HSWB aperture using similar amounts of radioactivity (2.2 ± 0.4MBq/ml). The Monte Carlo based reconstruction used a 3D Gradient Echo (TE/TR = 2.33/20) MRI as an attenuation map by segmenting air and water. A cylindrical ROI measurement was performed in the center of the reconstructed images, with and without attenuation correction. The ROI results were compared to the true concentration determined by a dose calibrator. **Results:** For activity levels higher than 3.2 MBq/ml in the Jaszczak phantom both apertures resolved the 0.9 mm rods, between 1.6 and 3.2 MBq/ml the SWB apertures still resolved the 0.9mm rods. Below 1.6 MBq/ml both apertures resolved the 1.0mm rods, but at 0.2 MBq/ml both collimators did not resolve any rods. The system was linear in the range between 0.07 - 54 MBq/ml and 0.2 - 64 MBq/ml for the HSWB and SWB apertures, respecively. For the HSWB apertures SNR was twice as high over almost the entire activity range (0.03 - 50 MBq/ml). Without MR attenuation correction the activity in the syringes was underestimated by on average 5%; the highest underestimation was found to be 13% for the 20-ml syringe. With attenuation correction, an overestimation of the activity concentration of on average 7% was found. **Conclusion:** The HSWB aperture showed only a small trade-off in resolution, while SNR improved by a factor of 2 . The HSWB was capable of quantitative imaging for activity concentrations as low as 0.2 MBq/ml. MR-based attenuation correction led to a 7% overestimation of the activity concentration.

EP418

Evaluation of the use of 40% threshold contours for texture features computation on PET image

M. CARLES[1,2], I. TORRES-ESPALLARDO[1], U. NESTLE[2], L. MARTÍ-BONMATÍ[1]; [1]Hospital Universitario y Politécnico La Fe, Valencia, SPAIN, [2]University Hospital Freiburg, Freiburg, GERMANY.

Lesion heterogeneity has an impact on threshold-based segmentation on PET images. Frequently, PET studies used texture features (TF) for lesion heterogeneity characterization derived from threshold contours of 40% of tumor maximum intensity. We evaluated the use of 40%-contours for TF computation as bias in quantification of lesion heterogeneity. TF derived from 40%-contours, $TF_{40\%}$ for twenty-eight heterogeneous experimental phantoms, were compared with respect to TF derived from the ideal contour of the whole lesion, TF_{Ideal}. Heterogeneous phantoms were developed by a mixture of alginate and ^{18}F-FDG. Imaging was performed with a PET/CT system using acquisition times of 15 min (PET) and 3.7 s (CT). Direct correspondence between alginate and FDG distribution permitted approaching VOI_{Ideal} by applying the growing region algorithm on CT image with a threshold interval of 65-135 HU. The comparisons of 8 TF (4 first order and 4 second order) were performed in terms of linear correlation (LC) and standard deviation (SD) of the relative deviation (δ40%-Ideal=100(TF40%-TFIdeal)/(TF40%+TFIdeal)/2). SD(δ40%-Ideal) for conventional indexes, mean activity concentration (C_{mean}) and volume (V), was considered the criteria for reasonable stability. Results from the comparison showed that SD(δ40%-Ideal) for 5/8 TF were lower than for C_{mean} and for 6/8 TF were lower than for V. In addition, significant LCs ($p<=0.001$) were obtained for all TF under study, V and C_{mean}. In summary, this work presented the first evaluation of $TF_{40\%}$ with heterogeneous experimental phantoms. From the low deviation and high linear correlation obtained with respect to TF_{Ideal}, the current use of 40%-contours for heterogeneity quantification by TF could be concluded as a reasonable approach.

EP419

Optimized PET-CT acquisition and reconstruction based on patient morphology

D. Vallot[1,2], F. Courbon[1], L. Dierickx[1,2], E. Gabiache[1], S. Zerdoud[1], S. Brillouet[1], M. Bauriaud[1], O. Caselles[1,2]; [1]Institut Claudius Regaud - IUCT Oncopole, Toulouse, FRANCE, [2]SIMAD, Toulouse, FRANCE.

Aim: The aim of this study was to optimize image quality based on patient morphology and position using the new penalized-likelihood image reconstruction algorithm (Q.Clear). **Materials and methods:** In order to improve image resolution, the reconstruction field of view (FOV) was adapted to patient morphology during acquisition, based on the CT scout views (50, 60 and 70 cm). The β noise reduction factor of the Q.Clear algorithm was thus adapted to maintain homogeneous image quality for each FOV (in the range 250 to 450). First analysis was based on images acquired on a Discovery IQ PET/CT using a NEMA PET image quality phantom filled with 18F-FDG. Recovery coefficient (RC) and background variability (BV) were measured for the different reconstructions. 30 18F-FDG oncological patients exams were then analyzed. Acquisition and reconstruction protocols were as described above. Average injected activity was 159 MBq. Overall image quality comparison between optimized versus non-optimized reconstruction was evaluated by 3 experienced physicians in a blind way. **Results: Phantom study** The ratio of RC (or BV) measured for two different β values is nearly the same whatever the FOV. This result is observed for each of the six spheres.Taking into account the smaller sphere (10 mm in diameter), the statistical analysis clearly showed that both RC and BV were better adapting the β value to the FOV, confirming that spatial resolution is improved by this optimization. When comparing the different reconstructions, the higher RC for each sphere were obtained with the smaller FOV and β values, with BV values remaining in the lower specifications limits . **Clinical study** 64 % of the patients were scanned with a FOV of 60 cm. During the blinded comparison between optimized and non-optimized reconstruction, the nuclear medicine physicians always preferred the optimized one. **Conclusion:** Global image quality and image resolution have been improved adapting acquisitions and reconstructions protocols to patient specificities. Optimized settings are now implemented in clinical routine in our facility. This optimization will be evaluated in the near future for head and neck exams.

EP420

Investigation of possibilities for gamma camera imaging of patients injected with Targeted Thorium Conjugate TTC (^{227}Th-labelled mAb)

E. Larsson[1], O. Lindén[2], T. Ohlsson[1], A. Cleton[3], C. Hindorf[1]; [1]Department of Radiation Physics, Skåne university hospital, Lund, SWEDEN, [2]Department of Oncology, Skåne university hospital, Lund, SWEDEN, [3]Clinical Science, Bayer Pharma AG, Berlin, GERMANY

.

Introduction Imaging of ^{227}Th (T½=18.7 d) is challenging as: 1) the injected activity will be low (from 1.4MBq), 2) the emitted photons have a relatively low yield (80-94keV, 7%), (236keV, 12%), (256keV, 7%) and 3) the daughter ^{223}Ra is also radioactive (T½=11.4 d). The most predominant photon energies emitted from ^{223}Ra and its short-lived daughters are: ^{223}Ra: (81-98keV, 52%), (154keV, 5.6%), (269keV, 13.7%) and ^{219}Rn: (271keV, 10.8%). The aim of this study was to investigate the possibility to separate between ^{227}Th and ^{223}Ra, and to determine acquisition settings to allow imaging of patients injected with ^{227}Th labelled antibody-chelator conjugate. **Materials&Methods:** All acquisitions were performed on a GE Discovery 670 NM/CT gamma camera equipped with MEGP and HEGP collimators. All images were acquired in list-mode, which allows for optimization of energy windows after acquisition. Due to the low count rate, only planar imaging was evaluated. Two spheres were filled with 250 kBq/

L ^{227}Th and ^{223}Ra, respectively. Imaging was performed with the spheres placed in a Jaszczak phantom filled with air, water and with ^{227}Th (50 kBq/L) added to the water. A background image with no radioactive sources present was also acquired. **Results&Discussion:** As the signal-to-natural background is low, background subtraction has to be performed. Analyses of line profiles indicate that the HEGP collimator reduces scattered photons in the images. Four separate energy windows are identified for quantitative imaging: 1) 75-100keV; 2) 135-165keV; 3) 215-260keV; 4) 260-285keV. However, a summation of window 1 - 4 is desirable for qualitative imaging in order to improve count statistics. The phantom experiments demonstrate that ^{227}Th and ^{223}Ra can be distinguished from each other in images acquired in energy windows 3) and 4) when the sources do not overlap. The separation will improve if scatter correction is performed. In the First-in-Man trial of BAY 1862864, planar static patient images were acquired for 40 minutes at different points in time after a single injection of the TTC (1.4MBq). An X-ray scout image was acquired for fusion with the NM-image to facilitate anatomic localization. **Conclusion:** It is possible to image ^{227}Th in patients and to distinguish ^{227}Th from ^{223}Ra. Acquisition settings recommended for planar images are: HEGP collimator, 40 min acquisition time, energy windows: 1) 75-100keV; 2) 135-165keV; 3) 215-260keV; 4) 260-285keV and 5) the sum of windows 1-4. Background subtraction and filtration of the image is needed to reduce noise.

EP421

Compensation of Missing Data in Sinograms of a PET Scanner with Partial Geometry for Robust Image Reconstruction

S. Shojaeilangari, M. Ay; Research Centre for Molecular and Cellular Imaging, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Purpose: Positron emission tomography (PET) is a noninvasive functional imaging technique to observe metabolic processes in the body with various clinical and preclinical applications such as cancer diagnosis, disease staging, therapeutic evaluation, and drug discovery. The partial geometry of scanners (less number of detectors for developing low cost systems) results projection incompleteness of data which leads to degraded image reconstructions. To preserve the quality of the reconstructed images, we applied an inpainting technique to projection data as a preprocessing stage before reconstruction. **Method:** The applied inpainting method is based on a penalized least squares approach using the discrete cosine transform to fill the missing data appeared in sinograms and suppress the artifacts as well. Then, various reconstruction approaches including FBP, MLEM, RAMLA, and OSEM were used to compare the quality of reconstructed images. We evaluated the method using both synthetic phantom images with simulated gap mask and real phantoms scanned in two scenarios: once with all detectors operational (baseline), and once with some detector blocks. Quantitative evaluations were performed by computing the root mean squared error and difference between the reconstructed images of non gapped and gapped sinograms, as well as computation time. **Results:** The simulation results demonstrate that the applied gap compensation approach prior to reconstruction is able to effectively control gap artifacts, as well as Poisson random noise. In particular, OSEM reconstruction after gap filling preprocessing showed promising robust results to different noise levels and gap structures. For the simulation study, the root mean squared error of recovered images for FBP, MLEM, RAMLA, and OSEM were 26.24% , 25.74%, 25.85%, and 10.56% respectively, when compared to the baseline. After adding Poisson noise and synthetic gapped structure to data without inpainting stage, these results changed to 85.11%, 35.08%, 34.95%, and 69.60% respectively. After applying the preprocessing stage, the results improved considerably which were 27.65%, 25.61%, 26.69%, and 13.53% respectively for the mentioned reconstruction algorithms. **Conclusion:** Sinogram inpainting approach prior to commonly used PET reconstruction algorithms was effective to decrease the occurrence of artifacts due to gaps between detector modules in a partial geometry PET scanner.

EP422

Detectability of small objects using digital PET

D. Koopman[1], M. L. Groot Koerkamp[2], H. Arkies[1], P. L. Jager[1], S. Knollema[1], C. H. Slump[2], P. G. Sanchez[3], J. A. van Dalen[4]; [1]Isala, Department of Nuclear Medicine, Zwolle, NETHERLANDS, [2]MIRA Institute for Biomedical Technology and Technical Medicine, Enschede, NETHERLANDS, [3]Philips Healthcare, Eindhoven, NETHERLANDS, [4]Isala, Department of Medical Physics, Zwolle, NETHERLANDS.

Background: Small lesion detection with FDG-PET/CT imaging is limited by the low spatial resolution of PET and the use of relatively large voxels. Recently, a prototype digital PET system (Philips Healthcare) was installed with an improved spatial resolution and faster time-of-flight performance, compared with analog PET systems. Based on the system acceptance data, we evaluated the small-object detectability of this system and compared it with a state-of-the-art analog system. **Method:** We performed a phantom study using a NEMA Image Quality phantom and a micro phantom, with sphere diameters 4-37 mm. Phantoms were filled with FDG with sphere-to-background ratio 10:1. PET/CT scans with 20 minutes scan duration were acquired on both digital PET prototype and analog PET (Ingenuity TF, Philips Healthcare). We reconstructed PET data using default reconstruction settings, with multiple voxel sizes: 4x4x4 mm^3 and 2x2x2 mm^3 voxels for both systems and additionally 1x1x1 mm^3 voxels for digital PET. Mean and maximum contrast recovery coefficients (CRC_{mean} and CRC_{max}) were measured for all phantom spheres and percentage changes between analog and digital PET CRCs were calculated. **Results:** With digital PET, we found higher CRC_{mean} and CRC_{max} values for all spheres and all voxel sizes, in comparison with analog PET. CRCs increased more in smaller spheres and with smaller voxels. With 4x4x4 mm^3 voxels, CRC_{mean} and CRC_{max} values increased with 5% and 7% respectively for spheres $\geq$ 13 mm while for spheres < 13 mm, these values increased with 11% and 35%, respectively. Furthermore, using 2x2x2 mm^3 voxels, CRC values additionally increased up to 32% for the smallest spheres. Comparing digital PET using 1x1x1 mm^3 voxels with analog PET using 2x2x2 mm^3 voxels, we found CRC_{mean} and CRC_{max} increases up to 56% and 74% respectively for the smallest spheres. **Conclusion:** Digital PET produces higher CRCs as compared to analog PET, especially for small phantom spheres and with small voxel reconstructions. This suggests that the detection of small lesions may improve with digital PET. Clinical studies are needed to see the actual impact of digital PET imaging on lesion detectability.

EP423

Evaluation Of Surgically Excised Non-Functioning Pan-Creatic Endocrine Tumours Followed By Radiopeptide Treatment; To Optimise PRRT, Aiming To A Longer Term Survival

G. S. Limouris[1], G. P. Fragulidis[1], I. Karfis[1], M. Paphiti[2], D. Voros[1], L. E. Moulopoulou[1], R. V. McCready[2]; [1]National and Kapodistrian University of Athens, Athens, GREECE, [2]Royal Sussex County Hosp, Brighton, UNITED KINGDOM.

Aim: We first report on adjuvant peptide receptor radionuclide therapy (PRRT) in 18 non-functional pancreatic neuroendocrine tumours (NF-PNETs) followed surgical lesion excision as an adopted technique in our Institution, aiming to optimize PRRT for a longer term survival. **Materials and methods:** Eighteen NF-PNETs received adjuvant PRRT i.a., after transhepatic infusions; 6 of them received ^{111}In-Octreotide, in a dosage of 4.0 -7.0 GBq, (12 cycles with treatment intervals of 5-8 weeks) and 12

n.c.a.^{177}Lu-DOTATATE in a dosage of 7.4 GBq (6 cycles with treatment intervals also of 5-8 weeks), following their surgical excision as first-line treatment.Twelve patients underwent pancreato-duodenectomy and 6 distal pancreatectomy and splenectomy. Intraoperative Liver Ultrasonography was performed to enhance missed lesion detection. Liver metastases were present in 7 patients[3 bilobar, 4 unilobar]. The latter underwent hemihepatectomy or segmentectomy; in bilobar patients, concomitant major hepatectomy was planned and were subjected to pre-operative evaluation of the future liver remnant by Indocyanine Green clearance test. Prophylactic cholocystectomy was planned to obviate adverse events due to the use of somatostatin analogues. Response assessment was classified according to the RECIST criteria. Absorbed doses delivered to metastases, kidneys and red marrow were calculated according to OLINDA 1.0 program. CT/MRI were performed before and after the end of treatment and monthly US images for follow up. **Results:** In all 18 cases immediately resulted in a significant down slowing of the tumour aggressiveness clinically and biochemically confirmed, accelerating the therapeutic efficacy, prolonging the survival rate assessed by Kaplan-Mayer curves. Follow-up for 34 months compared to an other 17 patients cohort without surgical exeresis, the disease stabilisation was significantly lower in a 13% ($p < 0.05$) in favour to the partial remission. **Conclusion:** In pts with metastatic liver-lesions, scheduled for surgical exeresis complementary, adjuvant radiopeptide therapy slows down the tumour aggressiveness, accelerates the therapeutic efficacy and improves the patients RECIST score assessment in favour to the partial remission scoring. The drawback of the concept is that surgical lesion debulking lurks the danger of tumour dissemination. The latter drives us to the skepsis that P R R T should precede the scheduled surgical excision by a therapeutic scheme of 2-3 cycles of n.c.a. Lu-177 DOTATATE for tumour ablation.

EP424

^{117m}Sn colloid as a potential candidate to replace ^{169}Er colloids in radiosynovectomy of small joints

K. Liepe[1], J. Lattimer[2], K. Selting[2], A. Bendele[3], J. Simon[4]; [1]Klinikum Frankfurt, Frankfurt (Oder), GERMANY, [2]University of Missouri, Columbia, MO, UNITED STATES, [3]Bolder BioPath Inc, Boulder, CO, UNITED STATES, [4]IsoTherapeutics Group, LLC, Angleton, TX, UNITED STATES.

Abstract: Radiosynovectomy or radiosynoviorthesis (RSO) is a common therapeutic treatment of arthritis in Germany and in many other countries. In this regard, ^{169}Er is universally used for the therapy of small joints but its availability is limited particularly outside of Europe. The dosimetry characteristics of ^{117m}Sn and ^{169}Er are very similar therefore making ^{117m}Sn is an ideal replacement for this application. **Methods:** In a safety trial 5 dogs were injected the left elbow using 93 ± 2 MBq of ^{117m}Sn colloid. The animals were sacrificed after 49 ± 1 day's ($>3 * t^{1}/_{2\ phys}$) and the amount of activity in the dissected tissue was measured. **Results:** 99.19 ± 0.36% of administered activity (%ID) was determined in to be in the synovia of the treated joints despite multiple prior synovial punctures. The majority of the radiocolloid that was found outside the treated joint was in the liver (0.70 ± 0.36%ID), significant lower are the %ID in local lymph node at treated site (0.07 ± 0.03%ID) and spleen (0.01 ± 0.07%ID). Over the follow-up period 0.06 ± 0.02%ID was found in blood, faces and urine within the first 14 days; 0.75 ± 0.38%ID in organs outside the joint after 45 days. In postmortem autoradiographic studies most of activity was found in the macrophages of sub-synovial tissue and less commonly in a few other locations (synovial lining cells, macrophage-like cells and macrophages). **Summary:** ^{117m}Sn colloid is useful in RSO of small joints with a high target dose and very limited dose outside the joint. Autoradiographic studies documented a fixed uptake in macrophages by phagocytosis. These macrophages were found in all layers of the synovium, which showed transportation of ^{117m}Sn colloid from the surface to varying depths. This opens up the possibility of treating larger joints.

EP425

Effectiveness of radiosynovectomy with Re-186 and P-32 colloid in a single study for chronic hemophilic synovitis : A Preliminary result

M. Amoui[1], R. Naghshine[1], P. Eshghi[2], S. Akhlaghpoor[3], M. Hakiminezhad[4], M. Hakiminezhad[1]; [1]Shohada-e Tajrish Hospital-Shahid Beheshti University of medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Pediatric congenital hematologic disorders Research Center - Mofid hospital- Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Pardis-e Noor Medical Imaging center, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Students' Scientific Research Center-Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Bleeding in joint is a common complication of hemophilia. Repeated bleeding could lead to chronic synovitis followed by irreversible damage and severe loss of joint function within first or 2nddecades of life. Radiosynovectomy (RSV) is a non-surgical procedure to deactivate synovium and preserve joint function by beta emitting radiopharmaceuticals. The common radiotracers are P-32 and Y-90 in United States and Canada and Re-186, Y-90 and Er-169 in Europe. These agents are selected by accessibility, physical properties of radiocolloids and joint size. This ongoing study evaluates the efficacy of locally produced P-32 and Re-186 radiocolloids in chronic hemophilic arthritis. In addition, this is the first experience of RSV with Re-186 colloids in Iran and to our knowledge, the first analysis of these two radiocolloids in a single study. **M & M**-Hemophilic patients were referred for RSV with poor response to clothing factor prophylaxis. It has been performed with 10-37 MBq P-32 or 37-74 MBq Re-186 radiocolloids. Episodes of joint bleeding was assessed after one year (mean : 22 months). Appropriate response was defined as non-target joint. Clotting factor consumption and physical activity were evaluated, as well. **Results**-Thirty-seven patients (mean age: 14. yrs. - Range: 2-36 yrs.) with 51 joints were enrolled. Sonography-guided RSV was carried out with P-32 in 28 cases (knee:14, ankle:4, elbow:9, Shoulder:1) and Re-186 in 23 cases (ankle:15, elbow:8). Six cases were excluded (2 cases due to patient's decease secondary to intracranial hemorrhage and 4 others due to patient's unavailability). Appropriate response was seen in 29 cases (65%) and target joint remained in 16 cases (35%). This response rate doesn't correlate with joint type (P value=0.155), grade of synovitis (P value=0.068) or serum anti-factor (P value=0.959). No statistically difference was noted between two radiocolloids (P value=0.669 for identical joints) .Presence of DJD correlated with poor response to therapy (P value=0.02).RSV was repeated in 7 cases which showed appropriate response in 4 cases (57%). More than 50% of factor reduction was noted in 84% of cases with complete stop in 25% of all cases. Physical activity was improved in 73% of cases. **Conclusion**: RSV is an effective method to stop or reduce episodes of bleeding, achieved with a single injection of radiotracer in an out-patient setting. It could be performed with Re-186 or P-32 radicolloids depending on availability with similar results. Keywords: joints, orthopedics, radiation, phosphorus, radioisotopes

EP426

The Evaluation of Patients with Diffuse Pigmented Villonodular Synovitis of Knee with Functional Scoring Systems After Surgery and Radiosynovectomy

H. I. ATILGAN[1], **M. SADIC**[2], M. H. OZSOY[3], M. KORKMAZ[2], O. FAKIOGLU[4], A. A. BASKIN[2], K. DEMIREL[2], R. ORAK[5], G. KOCA[2]; [1]Kahramanmaras Necip Fazil City Hospital, Kahramanmaras, TURKEY, [2]Ministry of Health Ankara Training and Research Hospital, ANKARA, TURKEY, [3]Memorial Ankara Hospital, ANKARA, TURKEY, [4]Hatay Dortyol State Hospital, Hatay, TURKEY, [5]Istanbul Haydarpasa Numune Training and Research Hospital, Istanbul, TURKEY.

Aim: To evaluate the symptoms and functional status of patients with pigmented villonodular synovitis (PVNS) of the knee using the modified Marshall scoring system and musculoskeletal tumor society (MSTS) rating scale before therapy and six months after radiosynovectomy (RS). **Materials and methods:** Evaluation was made of 29 knee joints of 29 patients with DPVNS. Arthroscopic synovectomy was applied to all patients and additional posterior open synovectomy to five. Yittrium-90 (Y-90) citrate colloid was used in the RS procedure. RS was performed 11.8±13.3 weeks after the operation. In the six months after RS, patients were evaluated with the modified Marshall scoring system and MSTS rating scale. **Results:** The patients were 17 females and 12 males with a mean age of 31.8±12.9 years years (range: 13-54 years). The preoperative modified Marshall score was poor in 24 patients and fair in five patients. In the follow-up period, the scores were excellent in 17 patients, good in 10 patients and fair in two patients. The mean modified Marshall scores increased after the operation and RS from 12.93±2.93 to 25.52±2.90 ($p<0.001$).The mean MSTS scores increased from 17.52±4.82 to 26.86 ±2.46 ($p<0.001$). In one of four patients with a score of 22 and three patients with a score of 24, maximum scores were obtained in the follow-up period with the effect of surgery and RS. **Conclusion:** RS with Y-90 citrate colloid after surgical excision in the treatment of PVNS is a reliable and efficient treatment method for the increase of functional capacity and decrease of symptoms.

EP427

Biological Therapy and Radiosynoviorthesis in Patients with Rheumatoid Arthritis and Psoriatic Arthritis

M. Szentesi, III, P. Géher, III; Semmelweis Univ., Budapest, HUNGARY.

Objectives: During biological therapy sometimes 1 or 2 joints could be affected by inflammation. In this cases always the question is how to solve the problem. Change of the biological or basic therapy, use surgical synovectomy or radiosynovectomy (RSO)?**Patients and Methods:** In our reumatological department 2100 patients with RA and PA were treated with biological therapy between 2002 and 2015. In 100 patients we applied RSO because of the inflammation of the knee joint during biological therapy. We made a long term follow-up in 72 patient. All participants provided written informed consent. 62 participants inflammatory knee joint disease was diagnosed on the basis of the American College of Rheumatology. 55 of 62 patients with rheumatoid arthritis were seropositive, 7 seronegative. Steinbrocker functional stadium II was observed in 52, stadium III in 10. 10 patients were psoriatic arthritis. Mean age of 13 male and 61 female patients was 51.4 years (range 24-79) years. In 38 patients the right knee, in 34 the left knee was treated by radiosynovectomy. Mean duration of disease was 7.3 years (range 0.5-25), of synovitis (6.3month (range 3-8) Mean number of punctions of the treated joint prior to radiosynovectomy was 4,2 per patient and of steroid administrations prior to radiosynovectomy 3,0. In 12 patients a systemic steroid therapy has been performed. **Results:** During the study period, inflammation decreased. In the first two years excellent and good results were recorded in 82,2%. Two years after radiosynoviorthesis 83.3% of patients did not need another punction. Before the knee inflammation patients were in complete remission which status has been achieved after RSO as well. DAS: 2,4+-0,4. **Conclusions:** 1. RSO is an effective method to treat the inflammation of the knes. 2. The RSO performed during biological tehrapy is as effective as in the case of patients without biological therapy. 3. In case of a succesful RSO there is no need for biological or basic therapy neither for surgical synovectomy. 4. However an intraarticular injection has a low risk for infection it is recomended to avoid the biological therapy during the RSO.

EP428

^{223}Ra-dichloride SPECT and planar quantitative images for targeted alpha-emitting therapy of bone metastases

N. Benabdallah[1], M. Bernardini[2], C. de Labriolle-Vaylet[3], D. Franck[1], **A. Desbrée**[1]; [1]Institut de Radioprotection et de Sûreté nucléaire, Fontenay-aux-Roses, FRANCE, [2]Nuclear Medicine Department, Hôpital Européen Georges Pompidou, Paris, FRANCE, [3]UPMC, Univ Paris 06 Biophysics - Nuclear Medicine Department, Hôpital Trousseau, Paris, FRANCE.

Purpose: ^{223}Ra-dichloride (Xofigo®, Bayer HealthCare) is the first alpha-emitter radiopharmaceutical that has received approval for the treatment of patients with castration-resistant prostate cancer metastasized to bones. This radiopharmaceutical mimics calcium and forms complexes with the bone mineral hydroxyapatite at areas of increased bone turnover such as bone metastases. To better determine the dose-limiting toxicities to bone marrow due to this new therapy and correlate absorbed dose to therapeutic response, patient-specific dosimetric studies are required. To that aim, it is necessary to compare ^{223}Ra-dichloride uptake to bone lesion locations and its quantitative biodistribution into the bone by ^{223}Ra emission images. The purpose of this study was to investigate the possibility of quantitative SPECT imaging of ^{223}Ra to enable accurate activity quantification. **Methods:** The gamma camera imaging parameters were determined by measuring sensibility, spatial resolution and energy spectrum, with a syringe containing 240 kBq of ^{223}Ra. SPECT/CT images of a NEMA Phantom (60 projections, 360° rotation and 30s per view) were realized to determine the best reconstruction parameters available on clinical software. Finally, the accuracy of quantitative SPECT imaging was investigated using an anthropomorphic TORSO phantom containing a cylindrical insert and 3 spherical spheres. **Results:** The results from the basic imaging parameters showed that the 85 keV ± 20%, 154 keV ± 20% and 270 keV ± 10% energy windows are the more suitable for ^{223}Ra imaging. The sensitivity of the gamma camera in the 3 combined windows was 155.4 cps/MBq. The parameters giving the optimal volumetric and the optimal quantitative reconstructions were determined. The phantoms study showed that activity could be quantified to within 36 % for a 3.7 cm diameter sphere without background activity and the lowest ratio (ratio of 6 between spheres and background) could be quantified to within 39%. **Conclusion:** Absolute quantitative ^{223}Ra SPECT imaging is achievable with careful attention to the scatter and attenuation correction and system calibration. With this study, a clinical protocol has been established. Further studies on patient images will now be performed to confirm these findings, which will open the door for patient-specific ^{223}Ra treatment planning.

EP429

Baseline ^{99m}Tc-DPD Distribution Can Predict Bone Marrow Toxicity in Patients Undergoing ^{223}Ra-Dichloride Therapy

F. Fiz[1], S. Sahbai[1], C. Campi[2], M. Piana[2], G. Sambuceti[3], C. la Fougère[1]; [1]Nuclear Medicine Unit, Department of Radiology, University of Tübingen, Tübingen, GERMANY, [2]Department of Mathematics, University of Genoa, Genoa, ITALY, [3]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY.

Rationale: ^{223}Ra-Dichloride, owing to its prevalent alpha-emission, allows treating skeletal localizations from castration-resistant prostate cancer (CRPC), with limited bone marrow radiation exposure. However, given the impaired bone marrow (BM) reserve in patients with multiple CRPC bone metastases, hematologic toxicity is possible and relatively frequent. Predicting the occurrence of BM dysfunction would allow a better tailoring of treatment protocols. In order to do so, we applied a computational analysis application to ^{99m}Tc-DPD SPECT/CT images, to compare tracer distribution to trabecular bone to subsequent hematological parameters variation. **Patients and Methods:** Images from forty-two ^{99m}Tc-DPD SPECT/CT scans of CRPC patients before ^{223}Ra-Dichloride

therapy were analyzed with a dedicated software application, which automatically separated trabecular bone from the remaining osseous components (including the external cortical compact bone and osteoblastic areas). It then extracted the blood-pool corrected counts (target-to-background ratio, TBR) from trabecular bone in the co-registered SPECT images. Axial and appendicular bones were considered separately. Thereafter, percent decrease of leukocytes and platelets was assessed after three/six ^{223}Ra-Dichloride cycles (%WBC3 and %WBC6; %PLT3 and %PLT6, respectively). These indexes were related to TBR within trabecular volume and to presence of appendicular disseminated disease (>5 foci at visual analysis). **Results:** Axial TBR was positively correlated with both %WBC3 and %WBC6 (R=0,54 and R=0,53, respectively, p<0,01); the same behavior was observed for appendicular TBR (R=0,46 and R=0,42, p<0,05). Correlation between TBR and %PLT3 was looser (R= 0,34 and 0,37, for axial/appendicular bones p<0,05); yet, it became more evident at the %PLT6 time-point (R=0,4 and R=0,5; p<0,05 and p<0,01). Presence disseminated appendicular metastases purported a greater leukocytes decrease (p<0,001 and p<0,01 for %WBC3 and %WBC6, respectively). Moreover, standard deviation of TBR values in appendicular bones correlated with %PLT6 (R=0,57, p<0,01) and with %PLT3-6 (R=0,49 and 0,46, p<0,05). **Conclusions:** Radiotracer uptake detected in correspondence of axial trabecular skeleton, where active BM is normally housed, correlates with occurrence of hematopoietic toxicity, especially in the long term. Tracer distribution to the appendicular trabecular bone seems to play a somewhat less important role in hindering hematopoietic turnover. Conversely, presence of active disease in the appendicular skeleton strongly predicted a worsened BM function after therapy, emphasizing the role of appendicular BM reactivation in patients with massive axial skeleton osteoblastic reaction. These data support the use of computational techniques in predicting the possible occurrence of BM toxicity and in dose tailoring.

EP430

Dosimetric evaluation of ^{177}Lu-exendin: feasibility for therapy of insulinomas

I. van der Kroon[1], T. Jansen[1], W. Wietske[1], M. Brom[1], L. Joosten[1], C. Frielink[1], M. W. Konijnenberg[2], D. Wild[3], M. Gotthardt[1], **E. P. Visser**[1]; [1]Radboudumc, Nijmegen, NETHERLANDS, [2]Erasmus Medical Centre, Rotterdam, NETHERLANDS, [3]University Hospital Basel, Basel, SWITZERLAND.

Aim: Although diagnosis of insulinomas is relatively easy, surgical removal is more difficult and is associated with a morbidity of 35%. The glucagon-like peptide-1 receptor, which is highly expressed on most insulinomas, is a promising target for non-invasive treatment. In this study, the potential of ^{177}Lu-exendin as a therapeutic radionuclide to treat insulinomas was investigated. To calculate the absorbed dose to the organs and to the islets of Langerhans, a combined organ scale and small scale dosimetry model was used. ***Materials and Methods:*** Time-integrated activity coefficients for whole body and kidneys were determined from time series of planar ^{111}In-exendin scintigraphy images acquired in a previous study of 5 healthy subjects and 5 type 1 diabetes patients. Tumor time-integrated activity coefficients were obtained from serial ^{111}In exendin SPECT/CT images (n=2). Finally, pancreas and islet time-integrated activity coefficients were obtained from a preclinical study in rats. Organ and tumor absorbed doses were calculated using OLINDA/EXM, whereas for islet doses Monte Carlo (MC) simulations were performed. To predict the doses delivered by ^{177}Lu-labelled exendin from the ^{111}In-exendin data, the biological behavior (biodistribution, clearance) for both radiopharmaceuticals was assumed to be equal. The differences in half lives, particles emitted with corresponding energies and relative yields between ^{111}In and ^{177}Lu were accounted for by adaptation of the time-integrated activity coefficients, by changing the S-values, and by using the results of ^{177}Lu-based MC calculations for the islets. ***Results:*** The insulinoma absorbed dose per unit administered activity of ^{177}Lu varied between 3.9 and 9.3 mGy/MBq. For the kidneys, this range was 12.9 - 20.5 mGy/MBq. The ranges for the pancreas and the islets were 0.09 - 0.22 mGy/MBq, and 0.62 - 2.27 mGy/MBq, respectively. In case the kidneys are considered as the dose limiting organ with a maximum absorbed dose of 27 Gy [1], the maximum dose that could be delivered to the insulinomas would be about 19 Gy, obtained by administering 2.1 GBq of ^{177}Lu-exendin. The maximum islet absorbed dose would then approximately be 4.6 Gy, which is below the value of 10 Gy, as reported in ref[2] as the threshold above which 16% of the patients developed diabetes after >20 years due to beta cell damage. ***Conclusion:*** A maximum insulinoma dose of about 19 Gy could be reached using ^{177}Lu-labelled exendin, which could be sufficient for a treatment effect. EP431

Patient-Specific Dose Estimation of ^{99m}Tc-Hynic-Tyr^3-Octreotide in Children

X. Hou[1], B. Birkenfeld[2], H. Piwowarska-Bilska[2], A. Celler[1]; [1]Department of Radiology, University of British Columbia, Vancouver, BC, CANADA, [2]Nuclear Medicine Department, Pomeranian Medical University, Szczecin, POLAND.

Aim: Technetium-99m-hydrazinonicotinamide-Tyr^3-octreotide (^{99m}Tc-Hynic-TOC) is recognized as a promising alternative to ^{111}In-diethylenetriaminepentaacetic acid (DTPA)-octreotide for diagnosing neuroendocrine tumors (NETs). However, its radiation dosimetry information is limited and only concerns adults. As importance of pediatric radionuclide diagnostic procedures and therapies increases, similar dosimetric studies for children need to be performed. Thus, in this study we report the patient-specific 3-dimensional biodistribution and radiation dosimetry for children using ^{99m}Tc-Hynic-TOC. **Materials and Methods:** Eight children/teenage patients (ages 3-17 years) with suspected or diagnosed NETs were enrolled in this study. Patients imaging included a series of 2-3 whole-body planar scans and SPECT/CT performed using GE Hawkeye camera over 2-24 hours after the injections of ^{99m}Tc-Hynic-TOC. Additionally, one patient had a 30min dynamic scan. Patient and organ-specific time-activity curves for kidneys, liver, spleen and tumors (4 patients, 5 lesions) were determined from the series of whole-body scans. Our iterative adaptive threshold method was used to determine organs' volumes and absolute activities from images reconstructed using SPECT/CT data with quantitative corrections. Subsequently, the time-integrated activity coefficients (TIACs) were obtained by rescaling the time-activity curves based on the absolute activity values. Individual organ doses were calculated based on the Voxel-S value approach. All image analysis and dose calculations were performed using our dosimetry software, JADA. A hybrid planar/SPECT option was used to estimate TIAC for organs/tumors and to perform dosimetry analysis. Estimated children doses were compared with adults' dosimetry (Grimes et al JNM2011). **Results:** The average values of children's TIAC were 0.18±0.08 (0.08-0.35), 0.33±0.12 (0.17-0.53), 0.78±0.26 (0.42-1.19) Bq·h/Bq for the kidneys, spleen and liver, respectively. The uptake time-activity curves, as determined by a 30-min dynamic planar scan, showed maximum uptake at 1 min to 1.5 min for spleen and liver, respectively, and slower, about 7min, for kidneys. The average doses per injected activity were 0.033 ±0.010 (0.020-0.050), 0.024±0.012 (0.011-0.048) and 0.016 ±0.008 (0.004-0.027) mGy/MBq for kidneys, spleen and liver, and 0.008±0.003 (0.006-0.012) mGy/MBq for tumors. In general, no statistical differences were noted between children of different

ages; however, significant dose differences were found between different patients. The children doses were very similar to those for adults. **Conclusion:** In this study, we report biodistribution and dosimetry information for children injected with ^{99m}Tc-Hynic-TOC for diagnosis of neuroendocrine tumors. No significant differences were found between children doses and those previously reported for adults. However, substantial disparity between different patients emphasizes the importance and necessity for patient-specific dosimetry.

EP432

Comparative Investigation of Internal Dose Calculation Methodologies

W. Lehnert, K. Schmidt, S. Kimiaei, M. Bronzel, A. Kluge; ABX - CRO advanced pharmaceutical services GmbH, Dresden, GERMANY.

Objectives The need for individual patient dosimetry is increasingly perceived as relevant for patient care in radionuclide therapy (2013/59/EURATOM). Different methodologies for dose calculation exist and their accuracy is an important factor in dosimetry. In this work we aimed (1) to compare two phantom-based safety dosimetry dose calculation tools, the ICRP-endorsed IDAC 1.0 package, and OLINDA/EXM 1.1, and (2) to investigate Voxel S dose calculation. All evaluations were performed using QDOSE, a comprehensive software solution allowing for direct comparison of different methodologies. **Methods** For safety dosimetry, the software tools IDAC 1.0 and OLINDA/EXM 1.1, which are both based on the stylized Cristy-Eckerman phantom series, were compared for patient data acquired with ^{177}Lu-Dotatoc (mean of large patient collective) and ^{177}Lu-Dotatate (3 patients with 4 therapy cycles each). For ^{177}Lu-Dotatate the absorbed doses to kidneys were also compared to Voxel S. **Results** Comparing IDAC 1.0 to OLINDA/EXM 1.1, the differences in absorbed doses to all organs for ^{177}Lu-Dotatoc were within 2%, except for the remainder body (4.8%) and red marrow (31.6%) when kidneys, spleen and remainder body were included as source organs. If red marrow was included as a source organ, the dose to red marrow calculated with IDAC was lower than with OLINDA/EXM, with a maximum difference of -27.5%. Absorbed doses to the kidneys for ^{177}Lu-Dotatate varied from -0.83% to 1.35% between IDAC and OLINDA/EXM. Differences of -24.2% to 27.1% were observed between OLINDA/EXM without and with individual kidneys mass adaption. Voxel S doses were -8.17% to -13.7% lower than doses calculated with OLINDA/EXM using kidneys mass adaption. **Conclusions** In general, the differences between IDAC 1.0 and OLINDA/EXM 1.1 are small, but in either case using individual target organ masses for dose calculation is advisable. The observed larger differences are related to a red marrow correction implemented in OLINDA/EXM while IDAC follows MIRD and assumes only self-absorption for electrons. The successor IDAC 2.0 uses the ICRP reference phantom and will incorporate measured absorbed fractions for electrons and therefore surpass the previous limitations. The differences in absorbed dose for Voxel S compared to OLINDA/EXM and IDAC could be partly related to differences in geometry between individual patients and the stylized reference phantom. However, similar differences were previously seen for spherical objects between Voxel S and the spherical model (OLINDA/EXM) indicating Voxel S to be more accurate due to improvements in the Monte Carlo code EGSnrc (DOSXYZnrc) used for the Voxel S Generation.

EP433

Patient dose comparison between GATE Monte Carlo voxelized dosimetry and MIRD method

J. Kim[1], M. Lee[2], K. Kim[2], J. Lee[2], C. Yi[1]; [1]Korea Research Institute of Standards and Science, Daejeon, KOREA, REPUBLIC OF, [2]Seoul National University, Seoul, KOREA, REPUBLIC OF.

The aim of this study was estimation of radiation dose using GATE voxelized dosimetry and compare the simulated dose results with dose from the MIRD method estimated by Olinda software. Three patient data (60.7 ±10.7 kg, 53.7±13.5 years old, 1F:2M) were retrospectively analyzed in this study. For all patient, PET/CT scans were performed after IV injection of 166.5±14.0 MBq of ^{68}Ga- RGD. Eight serial PET emission scans (30, 30, 30, 45, 60, 180, 180 and 300 sec/bed; 5 beds) were performed during 90 min. Gate Monte Carlo (MC)-based voxelized dosimetry simulations were performed using CT images (attenuation information) and PET images (radio-pharmaceuticals distribution). Eight serial PET scans yield eight serial radiation dose map. Finally, we obtained patient dose distribution using dose maps and time information. For comparison, radiation dose from MIRD method were also accessed. Regions of interest (ROIs) were drawn for 5~7 organs, i.e. gall bladder, kidney, liver, lungs, pancreas, spleen and stomach. Radiation dose for each organs were evaluated by injected dose normalized cumulated activity (residence time) and OLINDA software. For the patient who have heavier weight than standard MIRD phantom (63 vs. 57 kg, female), the estimated dose from MIRD method were over-estimated by 7.6% than MC simulation. For the other two patients who have righter weight than standard MIRD phantom (49 vs. 57 kg, female; 70 vs. 73 kg, male), the estimated dose from MIRD method were severely under-estimated by 47.5% and 40.5% than MC simulation Estimated radiation dose from MIRD method were significantly under-estimated for righter patient than MIRD model. Fixed weight of standard MIRD phantom causes large estimation error. For the patient specific dosimetry for each individual, MC- based estimation is strongly recommended.

EP434

Biokinetcs and Dosimetry of ^{99m}Tc-MAG3 scans in infants

J. Soares Machado, J. Tran-Gia, S. Schlögl, M. Lassmann; University of Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY.

AIM: Renal scans are among the most frequent exams performed on infants. This patient group is classified as “high risk group” with a high probability for developing stochastic radiation effects. As there are only limited data on the biokinetics and dosimetry in this patient group, the aim of this study was to reassess the dosimetry for infants undergoing ^{99m}Tc-MAG3 renal scans based on a retrospective analysis of existing patient data. **METHODS:** Two physical kidney phantoms based on the data of MIRD pamphlet 19 (Bouchet et al., JNM 2003) (newborn: 8.6ml, 1-year-old: 23.4ml) were designed and fabricated with a 3D printer (Renkforce RF1000) for retrospectively calibrating planar gamma camera images (Siemens E-Cam Signature). The kidney phantoms were filled with ^{99m}Tc (newborn: 9.5MBq, 1-year-old: 22.9MBq) and placed inside a water-filled torso phantom (IEC 61675-1). For each acquisition, bed and detector were set to the same position whereas the kidney-depth inside the torso was varied between 8.2cm, 11.7cm and 15.2cm for determining a depth- and size-dependent calibration function. Were retrospectively analyzed data of 10 patients (8 males and 2 females; age: 1.6 to 13.2 months) with normal kidney function who had undergone renal scans (mean activity: 17.4MBq ^{99m}Tc). All scans were planar, dynamic, centered at the patients’ kidneys and started at the bolus injection with durations of up to 35 minutes. The activity in the planar images was quantified by inserting the counts obtained in a ROI analysis of the kidneys, the bladder and the whole-body (including adequate background ROIs) in the calibration function. The patient-specific organ sizes and depths were obtained from ultrasound data. The organ-specific time-activity curves were integrated to obtain the time-integrated activity coefficients (TIACs). Based on these data, absorbed-dose and effective-dose coefficients were assessed with OLINDA/EXM for the newborn and the 1-year-old phantoms. **RESULTS**: The mean TIAC values for kidneys, bladder and WB were 0.11±0.08h, 1.29±1.07h, and 0.75±0.48h. The mean absorbed-dose coefficients of kidney and bladder were 0.06mGy/MBq and 0.36mGy/

MBq (newborn), and 0.03mGy/MBq and 0.24mGy/MBq (1-year-old), respectively. Compared to ICRP publication 128 (Ann. ICRP 44, 2015), the kidney absorbed-dose coefficients for the 1-year-old were 43.3% higher whereas the bladder absorbed-dose coefficients were 35% lower (no data is available for newborns). Related to the effective-dose coefficients, the mean value was 14.5% lower. **CONCLUSION:** By introducing a novel approach of quantitative planar imaging, this retrospective analysis provides new data on biokinetics and dose assessments to infants after renal scans with ^{99m}Tc-MAG3.

EP435

Evaluation of response of ^{90}Y citrate radiation synovectomy in hemophilic joint arthropathy

A. KAMRA, S. PAWAR, J. KALE, C. S, M. DESAI, S. MOHANTY; SETH GS MEDICAL COLLEGE AND KEM HOSPITAL, MUMBAI, INDIA.

Aim- Arthropathy is a frequent complication of repeated intra-articular bleeding in patients with hemophilia; causing pain, deformity, and disability. The purpose of study was to assess the response of intra articular ^{90}Yittrium (^{90}Y) citrate therapy in hemophilic joint arthropathy and evaluate the reduction in the reaction of proliferated synovium and subsequently repeated bleeding episodes. **Materials and Methods**-20 joints (17 knees, 2 elbows and 1 ankle) were selected for radiation-synovectomy with repeated (>3) intra-articular bleeds over six months causing disability and restriction of movement. They were injected intra-articularly with ^{90}Y-citrate (185MBq in knee joint and 111MBq in elbow and ankle joints). The intra-articular localization of ^{90}Y-citrate was confirmed using Bremsstrahlung radiation; planar and SPECT-CT images. The joints were immobilised for 72 hours in static splints using adequate compression and regular ice packs application. The patients were given cover of relevant and proportionate factor before and after the intra-articular injection. All patients were followed up for period of 6 to 18 months for response evaluation in terms of number of bleeding episodes, pain and movement pre and post therapy. **Results**- Out of 17 knees, in10 knees number of bleeding episodes reduced from an average of 21 times per six month to 2 times in 6 months and in 7 knees number of bleeding episodes reduced from an average of 18.84 times per 6 months to no bleeding till date. Out of 2 elbows, bleeding reduced from an average of 12 times in 6 months to 2 times per 6 months. The single ankle joint treated, showed reduction in bleeding episodes from 12 times in 6 months to no bleeding. All joints show reduction in pain from 4-10 to 0-8 on the Visual Analogue Scale. Out of 17 knees, 8 knees showed improvement in mobility due to reduced frequency of bleeds, 9 knees showed no improvement in movements due to development of advanced stage of arthritis. Out of 2 elbows, one showed improvement and other showed no improvement in movement. The single ankle joint treated showed significant reduction in bleeds, also had significant improvement in the joint range. The two tailed test showed statistically significant results ($P<0.0001$) for reduction in number of bleeding episodes post radiation-synovectomy. **Conclusion**- ^{90}Y-citrate therapy is an efficient treatment in the hemophilic joints in reducing the number of bleeds, reduction in pain and improvement in the mobility of the joint treated.

EP436

Sn-117m colloid distribution and autoradiography in the normal canine elbow

G. R. Gonzales[1], J. Simon[2], S. Gonzales[2], A. Bendele[3], C. Doerr[1], **N. R. Stevenson**[1]; [1]R-NAV, LLC, The Woodlands, TX, UNITED STATES, [2]IsoTherapeutics, LLC, Angleton, TX, UNITED STATES, [3]Bolder BioPATH, Boulder, CO, UNITED STATES.

OBJECTIVES: To determine the physical distribution and autoradiographic cellular distribution of a homogeneous Sn-117m colloid (HTC) injected into normal canine elbow joints. **METHODS:** Sn-117m (t1/2=14d) is considered to be a small sized joint radiosynoviorthesis (RSO) therapeutic with a conversion electron energy of ~140 keV and a tissue range of 300μm. A HTC was injected into the elbows of 5 normal dogs at the University of Missouri School of Veterinary Medicine. The joints were then collected after ~3 half-lives for sectioning and microscopic evaluation. Elbows from the 5 dogs were decalcified for 14 days and processed for paraffin embedding and sectioning. Half of the sections were stained with Toluidine Blue. The remaining paired sections were dipped into KODAK Autoradiography (AR) Emulsion, air dried and placed into a light-tight box. Slides were then sequentially prepared and submerged in KODAK Developer D-19, distilled water, KODAK fixer and again in distilled water. Toluidine Blue stained slides were then paired with their adjacent AR slides and examined. **RESULTS:** Two of 5 elbow sections had mild and one of 5 had minimal, focal synovial and/or subsynovial macrophage infiltration in the anterior surface of the distal humerus opposite to the olecranon. The remainder of the synovium and subsynovial tissues were generally unremarkable and without inflammation, although a few small foci of macrophage accumulations were observed. There were no microscopic changes in articular cartilage or bone associated with the treatment. Based on AR results, the Sn-117m was most intense in macrophages that had migrated beneath the synovial lining in the subsynovial tissues mainly adjacent to the humerus in 3 of 5 elbows. It was also present within the normal type A (macrophage like) synovial lining cells in normal synovium in all elbows and occasionally noted in single cells (presumably macrophages) that were in the deeper connective tissues under the synovial lining. A few blood vessels contained AR positive cells. Sn-117m containing cells were generally absent in the cartilage, bone, and connective tissue. **CONCLUSION:** After ~3 half-lives the Sn-117m colloid was localized in synoviocytes throughout the joint in all 5 elbows. Macrophages were distributed in variable density in all layers of the synovium, and macrophages and synoviocytes contained the Sn-117m colloid. Retention of the HTC for ~3 half-lives and throughout the synovial layers in the elbow of the hounds suggests that Sn-117m is an appropriate RSO therapeutic isotope for small joints and possibly for intermediate and large joints.

EP437

Post I131-therapy planar scintigraphy. Is it sufficient for neck lymph node staging? Comparison to SPECT/low dose CT imaging

T. Pipikos[1], J. Koutsikos[2], F. Vlachou[1], A. Nikaki[1], K. Dalianis[3], V. Papoutsis[1], E. Tsiakas[1], V. Prassopoulos[1]; [1]Nuclear Mecine & PET/CT Department, Hygeia SA, Athens, Marousi, GREECE, [2]Nuclear Medicine Department, NIMITS Hospital, Athens, GREECE, [3]Medical Physics Department, Hygeia SA, Athens, Marousi, GREECE.

Aim: Post radioiodine therapy scan is of great importance in the staging and therapy decision making of DTC patients. Image resolution though and anatomical information provided is poor, reducing sensitivity and specificity. We evaluated the performance of planar post therapy scan in neck lymph node staging in patients with DTC, compared to SPECT/low dose CT hybrid imaging. **METHODS**: Twenty-eight patients with DTC and total thyroidectomy were studied after administration of 2775-3700 MBq of ^{131}I for thyroid remnants radioablation. A week after radioiodine administration a planar ^{131}I whole-body scintigraphy (WBS) was performed, followed by a^{131}I SPECT/ low dose CT imaging the day after. Planar and SPECT/CT data were compared and correlated with ultrasound imaging (U/S), which was considered as gold standard for evaluation of thyroid or thyroglossal cyst remnants, or for pathological lymph nodes. The patients were under clinical surveillance in the next 16 months. **RESULTS:** WBS was false positive in 8/28 (28,5%) patients regarding neck lymph node involvement and also false negative in one

patient. False positive neck lymph node represented either thyroglossal duct cyst(2/8) or residual thyroid gland (5/8) or normal bio distribution(esophagus) (1/8), as it was confirmed from the SPECT/CT and U/S. SPECT/CT imaging identified correctly all above cases and moreover revealed a small pathologic lymph node in the lower neck, missed in planar imaging. Over all ^{131}I SPECT/CT in our study altered nodal stage from N1 to N0 in 8 from 28 patients and ustaged one patient. **CONCLUSION:** ^{131}I Planar imaging does not seem sufficient for neck lymph node staging in patients with DTC. SPECT/CT should be performed, since it is clearly superior , based on our results.

EP438

Head and neck pahntom for targeted radionuclide therapy calibrations and verifications

T. Kráčmerová, L. Jonášová, Z. Wolf, **P. Solný**; Department of Nuclear Medicine and Endocrinology Charles University 2nd Faculty of Medicine, Prague, CZECH REPUBLIC.

Aim Commercially available phantoms for nuclear medicine are quite expensive and many of them are only bespoke ones. Moreover; these phantoms are not usually very variable, though they are well reproducible. Aim of this work was to propose, develop and test an anthropomorphic (head, neck and shoulders), variable, reproducible and clinically achievable phantom for thyroid remnants simulations and gamma camera calibrations. Basic requirements were: water or tissue equivalence, safety during handling (robust, waterless, easily filled and source position system). **Materials and methods** Several materials available for phantoms were tested, however these materials were considered as unsuitable. A phantom contenting water may be split, leak through caps and cause damage to gamma camera. Radionuclide sources have to be adapted to the phantom and fastened well. Solid phantoms (PMMA etc.) are not so variable (limited variable positions for sources). The material is not easily accessible and not cheap. Our phantom consists of silhouette made of thermoplastic mask used in external beam radiotherapy and sonography gel which is basically water with organic supplement. The mask is fully filled with the gel. Other phantom components simulate cervical spine bones (adapted wild boar bones), a pharynx, a larynx, an esophagus, and blood vessels in the neck region. **Results and discussion** The homemade phantom was prepared and is tissue equivalent (CT checked). It is safe for handling and enable inserting the sources easily. The position system is also available which allows gamma camera system calibration in required settings. The phantom also enables individual patient source positioning simulations what may make dosimetry measurements more precise.

EP439

Is the asymmetrical mix of yttrium lutetium treatment more efficient than single radionuclide treatment of neuroendocrine tumours? - preliminary study

A. Mazurek[1], S. Piszczek[1], S. Osiecki[1], A. Gizewska[1], E. Witkowska-Patena[1], G. Kaminski[2], M. Dziuk[1]; [1]Military Institute of Medicine, Department of Nuclear Medicine, Warsaw, POLAND, [2]Military Institute of Medicine, Department of Endocrinology and Radioisotope Therapy, Warsaw, POLAND.

Background: Radionuclide therapy using yttrium (^{90}Y) or lutetium (^{177}Lu) labeled somatostatin analogues is one of the option for treatment of neuroendocrine tumors. There are no strict recommendations regarding which of the isotopes should be used. Yttrium is usually used for greater neoplastic lesions than lutetium but most patients have tumors of mixed sizes. **Aim** The goal of the study was to compare the treatment efficiency in neuroendocrine tumours with radionuclide labeled somatostatin analogues in different combinations of radioisotopes. **Methods** The 35 patients were subjected to radionuclide therapy (19 female pts, mean age 65.4 years, mean therapeutic doses 4.1). The tumours were well (G1) and moderately (G2) differentiated according to WHO histopathologic classification. The primary tumour locations were as follows: of unknown location - 11, large bowel - 7, small bowel - 6, pancreas - 5, lung - 4, ovary - 2. The patients were subjected to intravenous administration of somatostatin analogues labeled with β-emitters. The mix composed of 150 mCi (5.55 GBq) ^{177}Lu and 50 mCi (1.85 GBq) ^{90}Y was administered to 23 patients. ^{177}Lu only of activity 200 mCi (7,4 GBq) was given to 10 patients. The two patients treated with 100 mCi yttrium only (3.7 GBq) labeled somatostatin analogues were excluded from analysis. The response to treatment was evaluated 6 months post radionuclide therapy by means of PET/CT with ^{68}Gallium-labeled somatostatin analogues, *contrast*-enhanced CT and clinical assessment. **Results** The results of treatment in group of patients with mixed radionuclide treatment were as follows: stable disease (N= 9), partial response (N=10), progression (N=4). In a group of patients treated with lutetium only the results were: stable disease (N= 6), partial response (N=2), progression (N=2). The mixed yttrium/lutetium treatment resulted in greater number of patients with partial response (43%) comparing to lutetium only treatment (20%). **Conclusion** This comparison may indicate that 150/50 mCi mix of lutetium/yttrium is likely to result in better response than 200 mCi lutetium alone.

EP440

Standardized biodistribution template for nuclear medicine dosimetry collection and reporting

A. Kesner[1], G. Poli[2], S. Beykan[3], **M. Lassmann**[3]; [1]University of Colorado, Anschutz Medical Campus, Department of Radiology, Aurora, CO, UNITED STATES, [2]International Atomic Energy Agency, Vienna, AUSTRIA, [3]University of Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY.

Purpose: As the field of Nuclear Medicine moves forward with efforts to integrate radiation dosimetry into clinical practice we can identify the challenge posed by the lack of standardized dose calculation methods and protocols. All personalized internal dosimetry is derived by projecting biodistribution measurements into dosimetry calculations. In an effort to standardize organization of data and its reporting, we have developed, as a sequel to the EANM Dosimetry Committee guidance document of "good practice of clinical dosimetry reporting" (Lassmann M et al., EJNMMI 2011), a freely available biodistribution template, which can be used to create a common point of reference for dosimetry data. It can be disseminated, interpreted, and used for method development widely across the field. **Methods:** A generalized biodistribution template was built in a comma delineated format (.csv) to be completed by users performing biodistribution measurements. The template will be available for free download at http://bitly.com/IAEA-BDT. The download site includes instructions and other usage details on the template. The .csv-format was chosen as it can be easily edited by commercial spreadsheet software, while it can also be parsed easily by researchers or other developers interested in creating software tools to handle data. Examples of completed spreadsheets (I-131 radioiodine therapy, Lu-177 DOTATATE) are also available on the download site. **Results:** This is a new resource developed for the community. It is our hope that users will consider integrating it into their dosimetry operations. Having biodistribution data available and easily accessible for all patients processed is a strategy for organizing large amounts of information. It may enable users to create their own databases that can be analyzed for multiple aspects of dosimetry operations. Furthermore it enables population data to easily be reprocessed using different dosimetry methodologies. With respect to dosimetry-related research and publications, the biodistribution template can be included as supplementary material, and will allow others in the community to better compare calculations and results achieved.

Conclusion: As dosimetry in nuclear medicine becomes more routinely applied in clinical applications, we need to develop the infrastructure for handling large amounts of these data. Our organ level biodistribution template can be used as a standard format for data collection, organization, as well as to support dosimetry research and software development.

Dosimetry Evaluation Of Direct Radionuclide Cystography In Pediatric Patients

I. SIME LOAYZA, R. Moreno Cano, R. Reyes Marles, R. Padilla Muelas, M. Ibáñez Ibáñez, M. Godoy Bravo, J. Buades Former, L. Mohamed Salem, L. Frutos Esteban, M. Castellón Sánchez, J. Navarro Fernández, F. Nicolás Ruiz, G. Martinez Gomez, M. Claver Valderas; HOSPITAL VIRGEN DE LA ARRIXACA, MURCIA, SPAIN.

Aim: To evaluate the dosimetry of direct radionuclide cystography in pediatric patients and compare with the results obtained with the established recommended ranges in the literature.Material and methods We analyzed 44 patients with ages between 1 and 15 years, divided in 4 groups of age, who underwent direct radionuclide cystography for evaluation and monitoring vesicoureteral reflux, the results were analyzed according to the protocol recommended by the EAMN guidelines. All patients were given a dose of 20 MBq Tc-99m pertechnetate by direct bladder catheterization. The effective dose was calculated by multiplying the equivalent dose (HT) by a tissue weighting factor) by the duration of the test. Anova test was used to analyse the dose difference between different ages. **Results:** We found statistically significant differences between age groups, for the same administered dose. The average dose of all the patients in our study was 0,062 mSv. **Conclusions:** According to effective dose levels recommended by European Guidelines in this technique, our results are in the superior limit, although these differences are very insignificant and similar to those reported in recent publications we intend to try to reduce our radiation levels decreasing the duration of the test without losing diagnostic accuracy.

EP442

Dismal Awareness About Radiation Hazards Among Healthcare Radiation Workers: Point to Ponder?

N. Fatima[1], M. u. Zaman[2]; [1]Department of Nuclear Medicine, Dr Ziauddin Medical University, Karachi, PAKISTAN, [2]Department of Radiology, Aga Khan University Hospital, Karachi, PAKISTAN.

Objectives: To find out core knowledge of healthcare radiation workers including physicians and technical staff as technologists, physicists and nurses and to measure knowledge-gained after attending a one day targeted symposium **Material and Methods:** Fifty-five participants (21 physicians, 25 technologists, 5 physicists and 4 nurses) attended a one day symposium on ionizing radiation and its hazards for healthcare workers at a tertiary care hospital. The participants were registered from 18 different healthcare facilities having radiology, nuclear medicine and radiation oncology services. Participants were solicited to fill a questionnaire comprised of 15 questions focused upon basic of ionizing radiation, their interaction, biological effects and radiation protection methods before and after the completion of session. **Results:** Mean scores of all participants in pre-session assessment was 45.472% which improved to 60.472% after attending session with a mean difference of 14.527% ($p < 0.0001$). Physicians scored significantly better (pre: 54.238%, post: 67.333%) than technical staff (pre: 39.471%, post: 55.088%). Importantly the knowledge-gained after attending session was greater in staff (15.617%) than physicians (13.095%) but not statistically significant (p 0.1183). **Conclusion:** The level of knowledge about ionizing radiation hazards and radiation protection was not satisfactory in healthcare radiation workers. Physicians had significantly better pre and post session scores than technical staff but knowledge-gained after attending session was not significantly different. Lack of knowledge among radiation workers is a global issue and this is the time to revamp their training programs in a meaningful strategy and International Atomic Energy Agency (IAEA) must take the lead.

EP443

Realistic single-cell geometry model: Cellular S-value calculations with Geant4, Geant4-DNA and PENELOPE

N. Falzone[1], R. Freudenberg[2], J. M. Fernández-Varea[3], J. Malcolm[1], S. Able[1], K. A. Vallis[1]; [1]University of Oxford, Oxford, UNITED KINGDOM, [2]Universitätsklinikum Carl Gustav Carus an der Technischen Universität Dresden, Dresden, GERMANY, [3]Universitat de Barcelona, Barcelona, SPAIN.

AIM: The MIRD monograph[1] provides *S*-values for a spherical concentric single-cell model, however cells in culture assume a different morphology when plated that cannot realistically be described by a sphere model. The aim of this study is to compare single-cell S-values derived from Monte Carlo (MC) simulations for a realistic cell-in-culture geometry to the MIRD data. **MATERIALS AND METHODS:** The MC codes PENELOPE[2] and Geant4-DNA[3] were used to transport the full electron spectra of ^{90}Y, ^{99m}Tc, ^{111}In, ^{123}I and ^{131}I in liquid water (mass density $\rho = 1$ gcm^{-3}), by means of event-by-event simulations. Cellular S-values were calculated for a cell model with cell and nucleus radii R_C = 5 μm and R_N = 4 μm assuming both spherical and cell-in-culture geometries. The effects of cell eccentricity on *S*-values were evaluated for eccentric cell/nucleus arrangements in both geometries. Additionally, we compared the results to the standard Geant4 code (Livermore physics list). **RESULTS:** PENELOPE determined *S*-values for the spherical cell were generally within 10% of MIRD values for all radionuclides considered, when the source and target regions strongly overlap i.e. *S*(N←N) configurations, but greater differences were noted for *S*(N←Cy) and *S*(N←CS) configurations. However, Geant4-DNA cellular *S*-values for the realistic cell-in-culture geometry differed significantly from MIRD and PENELOPE derived *S*-values for all cell-nucleus targeting configurations. Furthermore, cell eccentricity greatly affected *S*-values in both models when the radiation sources are located on the surface of the cell (i.e. N←CS configurations). The comparison of Geant4-DNA to Geant4 (Livermore physics list) revealed differences up to 80% depending on the radionuclide and the source and target regions. **CONCLUSION:** Cellular geometry greatly affected calculated *S*-values. When micro-dosimetry is required to evaluate the effect of targeted radionuclides on cancer cells in culture, realistic cellular geometry models are required as well as detailed MC simulations. EP444

The radiobiological effect of fractionation on molecular radiotherapy for bone metastases

A. M. Denis-Bacelar[1], S. Court[1], S. J. Chittenden[2], G. D. Flux[2]; [1]The Institute of Cancer Research, London, UNITED KINGDOM, [2]The Royal Marsden Hospital NHS Foundation Trust, London, UNITED KINGDOM.

Aim: Repeated treatments of bone metastases with radiopharmaceuticals have been shown to improve survival. The optimisation of number and time-interval between administrations could potentially lead to improved treatment outcomes. The aim of this study was to investigate the effect of the number and time-interval between administrations on molecular

radiotherapy with ^{223}Ra-dichloride, ^{188}Re-HEDP and ^{177}Lu-PSMA-HBED-CC for prostate cancer metastatic to bone. **Materials and methods**: The linear quadratic model and the biological effective dose (BED) with the Lea-Catcheside factor were used to compare treatment schemes accounting for the repair of sub-lethal damage between administrations. The maximum tolerated administered activity was determined for a 2 Gy absorbed dose limit to the bone marrow as a function of the time-interval for 1-6 administrations. The bone lesion BED_{lesion} was subsequently calculated from the maximum tolerated activity for every scheme. Patient-specific clinical bone lesion and bone marrow absorbed doses from available literature in ^{223}Ra-dichloride (Pacilio *et al*, EJNMMI 2015), ^{188}Re-HEDP (Liepe *et al*, JNM 2003) and ^{177}Lu-PSMA-HBED-CC (Baum *et al* JNM 2016) treatments were used in the calculations. Typical radiobiological parameters for prostate cancer and bone marrow cells were used. Uniform uptake distribution of the radiopharmaceuticals and a relative biological effectiveness of 5 for ^{223}Ra were assumed. **Results**: For a given total absorbed dose, the BED for repeated administrations increases as the time between fraction decreases, approaching the single fraction situation, indicating the effect of the dose rate overlap between administrations. The maximum BED_{lesion} for ^{188}Re-HEDP and ^{177}Lu-PSMA-HBED-CC was obtained for a single administration of 3.28 GBq (13 Gy) and 128.9 GBq (837 Gy) respectively. For ^{223}Ra-dichloride, a maximum BED_{lesion} of 921 Gy was obtained for 6 fractions of 167 MBq each, administered at 13 hour intervals. The relative differences between the minimum and maximum $BEDl_{esion}$ for all the different fractionation schemes were 1.1%, 4.7% and 57% for ^{223}Ra-dichloride, ^{188}Re-HEDP and ^{177}Lu-PSMA-HBED-CC respectively. The BED_{lesion} for ^{177}Lu-PSMA-HBED-CC administered at 50 hour intervals was on average 17% higher than for well separated administrations. **Conclusion**: From the radiobiological perspective, optimisation of ^{223}Ra treatments according to an absorbed dose limit to the bone marrow showed that the number and time-interval between administrations have a limited effect on the bone lesion biological effective dose. This result would justify a large number of administrations over a long time period to prolong pain palliation. Future work will include the effect of repopulation, in particular for long-lived radiopharmaceuticals and low dose rates.

EP446

Radioprotective Effect of Zinc on Major Salivary Glands

H. I. Atilgan[1], N. Yumusak[2], M. Sadic[3], M. Korkmaz[3], G. Koca[3]; [1]Kahramanmaras Necip Fazil City Hospital, Department of Nuclear Medicine, Kahramanmaras, TURKEY, [2]Harran University, Faculty of Veterinary Medicine, Sanliurfa, TURKEY, [3]Ankara Training and Research Hospital, Clinic of Nuclear Medicine, Ankara, TURKEY.

Aim: To evaluate the radioprotective effect of zinc on the major salivary glands with histopathological examination after high dose of radioiodine (^{131}I). **Methods:** Sixteen Wistar albino rats were divided into two groups consist of eight animals in each group. The first group was the control group that was administrated ^{131}I and the second group was the zinc group that was administrated ^{131}I and zinc by gastric gavage. Zinc was started two days before ^{131}I and continued for five days after ^{131}I therapy. Twenty four hours after the last dosage of zinc animals were sacrified and parotid, submandibular, and sublingual glands were removed bilaterally for histopathological examination. The slices were evaluated for oedema, vacuolization, panacinar inflammation, necrosis and atrophy in acinar epithelial cells; periductal fibrosis, periductal infiltration and periductal leakage in interstitial space; duct ectasia and squamous metaplasia in ductal system; sclerosis and stenosis (fibrin thrombi) in vascular system. **Results:** Oedema, vacualization, panacinar inflammation, necrosis, atrophy, periductal fibrosis, periductal inflammation, periductal leakage, ductal ectasy, squamous metaplasia, sclerosis and stenosis were seen less in zinc group in all glands, except periductal inflammation in submandibular gland. But these data was not statistically significance, except atrophy in sublingual gland. Atrophy is significantly less seen in zinc group when compared with the control group in submandibular gland. **Conclusion:** All of the parameters were less seen in the zinc group in all of the glands except periductal inflammation in submandibular gland that may show the beneficial effect of zinc on early damage of ^{131}I.

EP447

Preclinical assessment by Single Photon Emission Computed Tomography of various combinations of preparative measures on radioiodide thyroid uptake

C. Zwarthoed[1,2], K. Chatti[2], J. Guglielmi[2], M. Hichri[2], C. Compin[2], J. Darcourt[2,1], G. Vassaux[2], D. Benisvy[1], T. Pourcher[2], B. Cambien[2]; [1]Service de médecine nucléaire, Centre Antoine Lacassagne, Nice, FRANCE, [2]Equipe TIRO – UMRE 4320, Université Nice-Sophia-Antipolis, Nice, FRANCE.

Aim: MicroSPECT/CT imaging was used to evaluate quantitatively the influence of the route of iodine administration, of the injection of recombinant human TSH (rhTSH), and of low iodide diet in euthyroid and T3-treated mice. ***Materials and Methods:*** $^{99m}TcO_4^-$ and ^{123}I thyroid uptake on euthyroid and T3-treated animals, fed either on a normal-iodine diet (NID) or on a low iodide diet (LID), treated or not with rhTSH and administered either intravenously, subcutaneously, intraperitoneally or by gavage with the radiotracer were assessed using microSPECT/CT imaging. Western blot was performed to measure Na/I symporter expression levels in the thyroid. ***Results:*** Systemic administration of radioiodide resulted in a higher accumulation in the thyroid than the oral route (x2.35 in NID mice). LID further increased thyroid activity by 2-fold, thus resulting in a 5-fold increase compared to the standard NID/oral route. rhTSH injections stimulated thyroid activity both in euthyroid and T3-treated mice on NID regime, but in this later group uptake levels remained dramatically low compared to those of euthyroid mice. However, combining LID and rhTSH in T3-treated mice resulted in a 2.8 higher uptake compared to NID/T3/rhTSH mice and helped restoring a thyroid activity equivalent to that of euthyroid animals. ***Conclusions:*** Our data demonstrate the potential of SPECT/CT imaging in the study of thyroid physiology as well as to answer clinically-relevant questions. We show that systemic administration of radioiodide favors its accumulation in the thyroid compared to the oral route. These data highlight the importance of LID either in euthyroid- or in T3-treated-, rhTSH-injected-mice. Extrapolated to the human situation and in the context of the clinical guidelines for preparation of patients with differentiated thyroid cancer, our data emphasize the importance of LID to potentiate the efficacy of rhTSH treatment in T3-treated patients.

EP448

^{68}Ga-OPS202 and ^{177}Lu-OPS201 Dosimetry Assessment

S. Beykan[1], U. Eberlein[1], S. B. Jensen[2], J. Kaufmann[3], R. Bejot[3], B. Hakim[3], M. Lassmann[1]; [1]University of Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY, [2]Aalborg University, Department of Chemistry and Biochemistry and Department of Chemistry and Biochemistry, Aalborg University, DK-9000 Aalborg, Denmark, Aalborg, DENMARK, [3]OctreoPharm Sciences GmbH, Ipsen Group, Berlin, Germany, Berlin, GERMANY.

Aim: ^{68}Ga-OPS202 and ^{177}Lu-OPS201 are the newest somatostatin receptor antagonists for diagnostics and therapy in patients with neuroendocrine tumor with the highest affinity towards the somatostatin receptor subtype sst2. In this study we present the results of two dosimetry studies in a pig animal model with the purpose of comparing biodistribution data of ^{68}Ga-OPS202 with ^{177}Lu-OPS201. **Materials and Methods:** In vivo biodistribution and dosimetry studies with approximately 175 MBq of ^{68}Ga-OPS202 (peptide mass: 27μg) and 105 MBq of ^{177}Lu-OPS201

(peptide mass: 8μg) were performed in 5 pigs for both tracers (3 female and 2 male). A series of whole-body PET/CT and SPECT/CT scans were conducted up to 6 hours for ^{68}Ga pigs and 10-12 days for ^{177}Lu pigs, respectively, after the intravenous injection. Blood samples were taken to determine the time-activity curves (TACs) in blood. Organ-specific and blood-based time-integrated activity coefficients (TIACs) were calculated by using NUKFIT (1) for the selected organs and the bone marrow. The ratios of the organ/tissue TIACs between the two groups of pigs (^{68}Ga-OPS202/^{177}Lu-OPS201) were assessed to show differences in the pharmacokinetics. Based on a two-compartment model, the biological elimination rates of the activity from the blood pool by kidney uptake (k_t, unit: d^{-1}) and the biological excretion rate from the kidney (k_h, unit: d^{-1}) were calculated and compared for both groups to distinguish differences in the pharmacokinetics of ^{68}Ga-OPS202 and ^{177}Lu-OPS201. **Results:** TIAC ratios of ^{68}Ga-OPS202 and ^{177}Lu-OPS201 for the kidney and bone marrow were similar (0.015 and 0.016). The higher TIAC ratio for the liver (0.029) denotes a difference in the biological behavior compared to kidney and bone marrow. In all pigs with both tracers unlike humans no spleen uptake was observed. The k_t value of the ^{68}Ga-OPS202 pigs (0.22 d^{-1}) was significantly higher (t-test, $p<0.05$) compared to the ^{177}Lu-OPS201 pigs (0.08 d^{-1}), this is most likely caused by the amino acid kidney protection given iv. to the ^{177}Lu-OPS201 pigs. Although, a higher excretion rate k_h was observed for ^{68}Ga-OPS202 (0.55 d^{-1} vs. 0.002 d^{-1}) no statistical significance was reached (t-test, $p>0.05$). **Conclusion:** The retentions of ^{68}Ga-OPS202 compound were higher in liver compared to kidney and bone marrow. Related to kidney kinetics, the kidney uptake rate in pigs administered ^{68}Ga-OPS202 was much higher than ^{177}Lu-OPS201 pigs which may be associated with differences of in-vivo pharmacokinetics due to the effectiveness of the amino acid kidney protection agent.

EP449

Metrology for clinical implementation of dosimetry in molecular radiotherapy: a new EURAMET project

V. Smyth[1], C. Bobin[2], M. Lassmann[3], L. Struelens[4], J. Tipping[5], S. Judge[1]; [1]National Physical Laboratory, Teddington, Middlesex, UNITED KINGDOM, [2]Commissariat a l'Energie Atomique, Saclay, FRANCE, [3]University of Würzburg, Würzburg, GERMANY, [4]SCK•CEN, Mol, BELGIUM, [5]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM.

It is now widely accepted that routine nuclear medicine therapy (molecular radiotherapy - MRT) would be more effective if treatments were planned on the basis of individual normal and target tissue dosimetry (Strigari et al, 2014). The EURAMET funded project MetroMRT (http://projects.npl.co.uk/metromrt/), which ran from June 2012 to May 2015, demonstrated that it is both possible and practicable to measure the absorbed dose delivered by therapeutic radiopharmaceuticals in individual patients with the same rigorous traceability to primary standards as is required by dosimetry protocols for all other modalities of radiotherapy (eg. IAEA TRS 398, 2000). MetroMRT was the first large-scale European collaboration between clinical medical physicists and radiation metrologists. In June 2016 a new project, MRTDosimetry, was started as follow-on to MetroMRT, to continue the development of practical procedures for implementation of routine patient dosimetry in MRT clinics. The new project consortium is made up of 6 metrology institutes and 13 leading clinical MRT research centres. The project will include the following tasks: Development of a transfer instrument for calibration of clinical activity meters to enable measurement of therapeutic agents with greater accuracy; Development of a protocol for calibration and quality assurance of SPECT-CT and PET-CT based quantitative imaging (QI) systems; Development of radioactive test sources and 3D-printed quasi-anthropomorphic phantoms for validation of QI systems and absorbed dose measurements; Production of an open-access database of test images that can be used for commissioning dosimetry systems; the images will cover a range of cases, and the contained activity and dose distributions will be made available; Development of a method for determining the optimum timing to take a sequence of QI measurements in order to maximise the accuracy of the activity-time integral; Development of a protocol for commissioning an absorbed dose measurement system. Each of the methods and protocols will be trialled extensively by the clinical partners in the consortium, as well as any other centres wishing to collaborate with the project. Details will be presented of the planned outputs, as well as opportunities to join the project as a collaborator. Strigari, L., et al. The evidence base for the use of internal dosimetry in the clinical practice of molecular radiotherapy Eur J Nucl Med Mol Imaging DOI 10.1007/s00259-014-2824-5 (2014) IAEA TRS 398, Absorbed Dose Determination in External Beam Radiotherapy: An International Code of Practice for Dosimetry Based on Standards of Absorbed Dose to Water, Technical Reports Series No. 398, Vienna (2000).

EP450

Energy Spectrum of Electrons Released in the Interaction of ^{60}Co Photons in Water; Comparison with Selected Beta Emitting Radioisotopes

P. Taheri, H. Rajabi, A. Rajabi; Tarbiat Modares University, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: Recent advances in radioimmunotherapy (RIT) have led to a significant increase in medical applications of radioisotopes. However, absence of standard treatment planning procedure hindered application of the technique to the desired level. One of the most important reasons, is the lack of radiobiological information to predict the response of a given cell population to radiation dose from internal source of radionuclides. The major part of radiobiological information were derived from external source of radiation forming the bases of external beam radiotherapy. In recent years, efforts have been made to extrapolate external beam radiobiological information to internal radiation. However, considerable differences have been reported in biological response of equal macroscopic dose of radiation from external and internal sources. In the present work, physical bases of the two types of radiation in terms of electron density, electron energy distribution at the microscopic level were investigated and the results were compared. **Materials and Methods:** Assuming uniform distribution of the radionuclide in water, microscopic dose distributions as well as the energy spectrum of emitted electrons of four radioisotopes (^{131}I, ^{177}Lu, ^{111}In, and ^{90}Y) were determined using Monte Carlo simulation. Similar quantities were calculated for external source of ^{60}Co photons in water. We determined the differences between the microscopic dose distributions of Cobalt-60 and each one of the four isotopes when their macroscopic doses in water were equal. GATE/GEANT4 dedicated nuclear medicine package was used for Monte Carlo simulation **Results:** The results showed that electron energy distributions of four aforementioned sources were significantly different ($P<0.01$) even though they generated almost the same number of electrons per unit volume of medium. The average energy of Cobalt-60 electron electrons was close to the average energy of Yttrium-90 electron spectrum. Normalizing the average dose transferred by Cobalt-60 and radioisotopes, the microscopic dose absorbed at various layers of the target volume were significantly different ($P<0.01$) except for Yttrium-90 that dose variation with depth was not significantly different from Cobalt-60 ($P>0.05$). **Conclusion:** The total number of events (ionisation/excitation) needed to achieve 1 mGy absorbed dose into target volume is almost equal. However, the average electron energy produced on water depends weakly on the type and energy of radiation, energy distribution of electrons and dose distribution for various radiation (^{60}Co photons and four radio-isotopes) are significantly different. ***Keywords:*** *Radionuclide therapy, external radiotherapy, dosimetry, Monte-Carlo simulation.*

EP451

Radiopharmaceutical dosimetry based on serial SPECT or PET images: comparison between the commercial software STRATOS and the Monte-Carlo-based OEDIPE software

N. Benabdallah[1], M. Bernardini[2], T. Guitton[1], K. Ea[1], C. de Labriolle-Vaylet[3], D. Franck[1], **A. Desbrée**[1]; [1]Institut de Radioprotection et de Sûreté nucléaire, Fontenay-aux-Roses, FRANCE, [2]Nuclear Medicine Department, Hôpital Européen Georges Pompidou, Paris, FRANCE, [3]UPMC, Univ Paris 06 Biophysics - Nuclear Medicine Department, Hôpital Trousseau, Paris, FRANCE.

To determine dose-response relationship, either for preclinical and clinical purposes, there is a need to calculate personalized absorbed doses. Even for diagnostic radiopharmaceuticals, performing accurate specific dosimetry is of interest to assess the differences with respect to a standard dosimetry. With the availability of SPECT and PET images also dedicated to small animals, it is now possible to directly estimate the biokinetic of a radiopharmaceutical. For instance, the only commercially available software allowing dosimetric calculations based on the analysis of serial SPECT and PET images is STRATOS by Philips. Although the dose voxel kernel approach allows fast calculations, a most accurate dosimetry can be performed using Monte Carlo codes. In this context, we developed a new biokinetic module to the OEDIPE software that allows the determination of the cumulated activity at the voxel level based on SPECT or PET images. Serial PET ^{18}F-FDG images of mice and ^{18}F-choline images of human patients were used for this study. Standard dosimetry was realized using the OLINDA/EXM software. Personalized absorbed doses and dose-volume histograms were determined with the kernel approach using the STRATOS software and using with the MCNPX Monte Carlo code using the OEDIPE software. The differences in absorbed doses for the preclinical and clinical dataset will be discussed in terms of (i) standard versus personalized dosimetry, (ii) kernel versus Monte Carlo calculations and (iii) organ versus voxel level dosimetry and according to the biokinetic models used.

EP452

Dosage optimization in cadmium-zinc-telluride SPECT gamma camera gated tomographic radionuclide angiography

J. Rydberg, T. Nguyen, B. Zerahn; Herlev Hospital, Herlev, DENMARK.

Purpose: To determine the influence of age, height, and weight on count rate on cadmium-zinc-telluride (CZT) SPECT gamma camera gated tomographic radionuclide angiography. **Methods:** From August to December 2015 a total of 549 patients referred for routine assessment of left ventricular ejection fraction (LVEF) were registered regarding age, height, weight, and count rate in addition to the standard variables: Left ventricular end systolic and end diastolic volumes (LVESV and LVEDV respectively) and LVEF. All radionuclide angiographies were performed on a dedicated cardiac CZT SPECT gamma camera, GE Discovery 530c (GE Healthcare, Milwaukee, WI, USA). A dose of 550MBq 99mTc-labeled human serum albumin was administered intravenously to each patient. An acquisition protocol for multigated acquisition, using 16 frames per R-R interval and requesting 600 accepted beats, was adapted and a 20% energy window centered on 140 keV was performed in all cases. Xeleris 3 Imaging workstation software (version no. 3.0562) was used for reorientation of the heart after applying a generic reconstruction algorithm and filtering. Assessment of standard variables was performed with Cedars-Sinai QBS processing software (revision 2009.0). Each acquisition was analysed by two experienced technologists. Four patients (0.7%) were excluded from the study. Three patients because it was impossible to focus their heart within the field of view due to a high thoracic circumference and one patient because of paravenously administered radionuclide. **Results:** Count rate varied from 1.25 to 8.39 kcounts per second. Registered test variables, except age, were significantly correlated with count rate: age (adjusted R^2: 0.003, P = 0.282) height (adjusted R^2: 0.046, P < 0.0001) weight (adjusted R^2: 0.628, P < 0.0001). A log-transformation was performed on count rate and weight to increase the linear relation. The influence of age in a linear multivariable regression model was negligible and this variable was subsequently excluded from the final model: $log(CountRate) = \beta_0 + \beta_1 \cdot Height + \beta_2 \cdot log(Weight)$ Thus our model explains just below 70% of the variance (adjusted R^2: 0.69) in log(count rate) with coefficients $\beta_0 = 6.075$, $\beta_1 = 0.012$ and $\beta_2 = -1.558$. **Conclusion:** Patient height and weight can be used to predict count rate when performing CZT radionuclide angiography and subsequently used for planning of tracer dosage. This provides the possibility to give a more patient specific dosage in radionuclide angiography.

EP453

SPECT/CT Quantification of Lu-177 Activity Using Phantom Images to Develop a Quantitative 3D Dosimetry for Molecular Radionuclide Therapy

S. Wiessalla, C. Schuchardt, R. P. Baum; Zentralklinik Bad Berka GmbH, Bad Berka, GERMANY.

Aim: Scientifically developed or commercially available 3D dosimetry approaches are based on quantitative SPECT/CT images. The aim of this study was to determine the possibilities and limitations of SPECT/CT quantification of Lu-177 to develop a quantitative 3D dosimetry for molecular radionuclide therapy. **Methods:** Various phantom studies were acquired, which mainly served to optimize the recording protocol and reconstruction parameters. Herewith the existing Siemens Symbia T2 SPECT/CT was calibrated and recovery of activity under different geometric conditions was analyzed. Possibilities and limitations of the current technology were identified and compared. **Results:** The Phantom studies showed, that under ideal conditions, the activities can be obtained from target regions. The result largely depends on the manner of determining the volume-of-interest. When defining the contours with "expert knowledge" and exclusion of overlapping targets, a deviation of the detected activity of +/- 10% compared to the real activity was achieved. Contours obtained by anatomical demarcation of targets defined by CT, and subsequent calibration, demonstrated a deviation of 80% from the actual target activity. The long-term stability of the SPECT/CT system could also be determined, which remained consistent. **Conclusion:** Under certain conditions and constraints a quantified Lu-177 SPECT / CT scan can be used to supplement the planar dosimetry. A statement on the activity per voxel - and thus a voxel-based dosimetry - is not yet possible at the moment due to the variations in the use of CT volume. However, further studies are being performed to improve this concept of hybrid-dosimetry using SPECT/CT to overcome the shortcomings of 2D dosimetry.

EP454

Evaluation of Triple Energy Window scatter correction method in ^{131}I imaging with Monte Carlo

R. Barquero[1], H. Pérez-García[1], A. Cardenas[2]; [1]Hospital Clínico Universitario Valladolid, Valladolid, SPAIN, [2]Hospital Nacional EdgardoRebagliati Martins, Lima, PERU.

Aim: In ^{131}I Imaging high fractions of collimator scatter (s) and penetration events (p) appear that have to be corrected to retain only the geometric component in the photopeak. The currently used correction method in the clinic is the Triple-Energy Window (TEW) based in spectral analysis technics. This study presents an evaluation of TEW method using Monte Carlo simulation (MC) with MCNPX code. **Methods:** The

Gammacamera simulated in this study is a Siemens e-cam with HEGP collimator. The two geometries analyzed are point source ^{131}I in air, and 14 cm diameter Petri dish in air filled with radioactive water of ^{131}I. In both cases, the sources are centered with respect the crystal and are at 10 cm from the collimator face. Both simulations with MCNPX carry on with an accurate description of the source, crystal and collimator. The three main energy emission of ^{131}I 634, 637 and 723 keV are included as source terms. The hexagonal net of the HEGP collimator is realistically simulated with the repeated structure capability of MCNP using the FILL, U and LAT cards. Different energy bins, 308, 327, 400, and 424 keV for each source are conducted in the simulation such as the three TEW windows were covered: MAIN) a 20% energy window centered at 364 keV, LOWER) 6% energy window centered at 318 keV and UPPER) 6% energy window centered in 413 keV. The mean photon fluence per source particle is determined using *F4* tally (mean track length) in the entire field of View (FOV). Total component of the counts is estimated from the simulation results for MAIN window. Counts for (s+p) component are estimated with the trapezoidal approximation: c(s+p)=(c(lower)/w(lower)+c(upper)/w(upper))*w(main)/2, where c(lower) and c(upper) are the counts in the LOWER and UPPER windows, respectively, and w(main), w(lower) and w(upper) are the widths of the MAIN, LOWER and UPPER windows, 73, 22 and 23 keV. **Results**: The component of (s+p) counts is 24% of the total events for both sources, punctual and 14 cm diameter Petri dish. 73% has been estimated by others authors as a true value in the punctual source case. **Conclusions:** The TEW method can underestimate the s+p components in ^{131}I imaging because the trapezoidal approach doesn´t fit well the shape for the background in the energy spectra. Other (s+p) correction methods could be investigated.

EP455

A dose radiation reduction strategy to patients in a Nuclear Medicine Department

R. Jover-Diaz, D. Martin-Rios, A. Martinez-Lorca, G. Salazar-Andia, C. Gonzalez-Roiz, J. Jimenez; Hospital Universitario Rey Juan Carlos, Madrid, SPAIN.

Objective: To reduce radiation rate exposure received by patients in a Nuclear Medicine Department, ensuring performance of proper quality of diagnostic tests. **Method:** We have calculated estimated effective dose per patient on each activity and technique employed. These are included in the Quality Assurance Nuclear Medicine Department Program which are based on the following Nuclear Security publications: ORISE (Oak Ridge Institute for Science and Education) and ICRP (International Comission of Radiologic Protection). **Results:** - Cardiology Department joint action protocol of patients submitted to a cardiac SPECT. Cardiac SPECT at rest was only obtained for those patients with perfusion abnormalities in stress test, after joint assessment with Cardiologist. Thus, a second part of the test has been avoided in approximately 29 % of patients who have undergone stress cardiac SPECT. Taking this into account, effective dose for each patient undergoing cardiac SPECT at rest with an administered activity of 23 mCi (851 MBq) of 99mTc-MIBI has been reduced by Nuclear Medicine in ~ 7.66 mSv (effective dose). Effective dose for each patient undergoing cardiac CT-SPECT at rest with a dose of 130 kVp and intensity modulation (DLP average of 30 mGy.cm), has been reduced by ~ 0,44 mSv (effective dose). This is a dose reduction of 53% - Dose reduction in patients who have undergone body scintigraphy with ^{111}In-Pentetreotide. Since June 2015 only 24-hour SPECT- CT acquisition is performed. This is a dose reduction of 24% - Dose calculation of ^{131}I metabolic therapy in patients with hyperthyroidism. Usually ^{131}I fixed dose are employed of these patients, but since our department activity began, we calculate doses based on the data obtained from thyroid scintigraphy (weight, volume and degree of uptake radiopharmaceutical) - Safer practices using radiopharmaceuticals in Nuclear Medicine department has been pursued, titration to lower posible exposure radiation. However, quality of images obtained should be ensure, acording to ALARA criteria. Dose adjustment for pediatric population is mandatory following scientific societies recommendations. - It has sought to reduce patient dosimetry levels attending to appropiate medical indications of diagnostic and therapeutic nuclear medicine tests when performed. Example, assessment of the clinical record for justification by the specialist in Nuclear Medicine and validation of acquisition protocols for each patient at least twenty-four hours before according to Quality Royal Decree. **Conclusions:** We have achieved a significant dose reduction using different strategies for reducing dose administration without affecting quality diagnostic tests.

EP456

Radiation self-monitoring at home of patients receiving ^{177}Lu-DOTATATE peptide receptor radio-therapy for dosimetry informed radiation protection

L. Livieratos, T. Brothwood, D. Aniceto, R. Fernandez, C. Sibley-Allen, K. Adamson, S. Allen, V. Lewington; Guy's and St Thomas Hospitals, LONDON, UNITED KINGDOM.

Background: Targeted radionuclide therapy with ^{177}Lu-DOTATATE is increasingly used to treat inoperable, metastatic neuroendocrine tumours. Written radiation protection advice is provided for patients post-treatment based on 24 hour whole-body retention measurements. Measurement of external dose rates from patients beyond 24 hours would provide the evidence to review current radiation safety practice and generate more accurate data about whole-body retention and absorbed dose on an individual patient basis. This study aims to assess feasibility of self-monitoring at home for a cohort of non-local patients treated in our hospital over a period of minimum two weeks post-therapy. **Methods:** After a short demonstration of the monitoring procedure during their treatment visit (administration of 7400±10% MBq), patients were issued with a portable energy-compensated GM monitor, simple instructions and a form to record twice-daily external dose rates at arm's length as point of reference for fixed measurement geometry. Cross-calibration for each patient was performed against retention measurements acquired while in hospital at a distance of 2m. Data were analysed on the basis of retention curves and external dose rate in order to calculate personalised whole-body dosimetry and collect a body of data of external radiation exposure for appraisal of radiation safety advice to patients, family members and the public. **Results:** Data were collected for a pilot cohort of 6 patients living up to 517km from our treatment centre. Compliance was excellent with each patient acquiring at least two measurements per day for 14-28 days post-therapy. Effective half-life of the slow component varied from 56 to 103 hours (2.3-4.3 days) non-corrected for isotope decay. Radiation exposure at arm's length from patient 14 days post-administration varied from 0.9 - 11.0 μSv/hr while the maximum exposure recorded 20 days post-therapy was 3.1 μSv/hr. Whole-body retention at 14 days varied from 2.3 to <1 % of injected dose. MIRD-based calculation of whole-body absorbed dose was within range of values (0.2-0.4Gy) calculated by whole-body imaging in a similar cohort of patients. **Conclusion:** Self-performed dose rate measurement at home is a feasible and realistic approach for data collection across centres for radiation protection, personalised whole-body retention and dosimetry purposes. For the first time, this initiative allows dose rate monitoring with patient participation beyond current limitations of geography and availability of fixed-site equipment. We feel this could have a significant impact upon both patient care and the safety advice given to patients and their families after Lu-177 radiopeptide treatment.

EP457

PET Imaging for Y-90 SIRT: Effect of Liver Motion on Dosimetry

M. D. Walker[1], C. A. Porter[1], D. R. McGowan[1,2]; [1]Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM, [2]University of Oxford, Oxford, UNITED KINGDOM.

Purpose: Selective internal radiation therapy (SIRT) using Y-90 microspheres is increasingly used in the treatment of metastatic liver disease. Accurate verification of the dose to tumour and healthy tissue is crucial to allow treatments to be appropriately evaluated on a per-patient basis, and to enable treatment optimisation. We have performed phantom studies to assess the extent to which respiratory motion correction improves PET-derived dosimetry. **Materials and Methods:** A NEMA IQ and The Abdo-Man™ phantom (a 3D-printed liver phantom with fillable inserts) were imaged on a GE Discovery 710 PET scanner using our clinical protocols. Separate tests were performed using F-18 and Y-90. The phantoms were placed on a respiratory motion platform (QUASAR™; Modus QA) using realistic motion waveform and amplitudes. Respiratory gating signals were acquired using an infrared system (RPM; Varian Medical Systems). PET data were reconstructed using the manufacturer's Bayesian penalized likelihood reconstruction algorithm. Various motion correction methods were explored (quiescent period gating, phase-matched gating, phase matched gating combined with deformable image registration, and data driven gating). The resulting images were converted to dose maps (HERMES Hybrid Internal Radionuclide Dosimetry, HIRD™; HERMES Medical Solutions AB). Volumes of interest were placed over the hot spheres and used to generate dose-volume histograms. These DVH's were compared against the reference DVH found without motion. Dosimetry data were scaled such that the maximum dose in the reference DVH corresponded to 107% of the prescribed dose. The volume of the sphere receiving >95% (V_{95}), >80% (V_{80}) and >67% (V_{67}) of this prescribed dose was then calculated and compared for different motion amplitudes and correction strategies. **Results:** Results from the torso phantom using F-18 demonstrate large differences in the volume of the spheres that received "treatment doses" for the different motion amplitudes. For motion amplitudes of 10mm and reconstruction using quiescent period gating for motion compensation, the volume ratio $V_{67}/V_{67\text{-ref}}$ for a 30 mm diameter sphere was unity indicating motion compensation was acceptable; $V_{67}/V_{67\text{-ref}}$ was 1.08 without the use of motion compensation. The calculated ratios $V_{95}/V_{95\text{-ref}}$ and $V_{80}/V_{80\text{-ref}}$ for 10 mm motion amplitudes were however reduced to 0.84 and 0.94 respectively for quiescent period gating. These ratios were further reduced for motion amplitudes of 15 mm, to less than 0.5 in the case of $V_{95}/V_{95\text{-ref}}$ (irrespective of the application of motion correction by quiescent gating). **Conclusions:** In this phantom study designed to represent post-SIRT PET imaging, motion correction improved the accuracy of DVHs.

EP458

Discrepancy between ^{99m}Tc-MAA SPECT and ^{90}Y glass microspheres PET lung dosimetry in radioembolization of hepatocarcinoma

C. Chiesa[1], M. Mira[2], M. De Nile[2], M. Maccauro[1], C. Spreafico[1], C. Zanette[1], G. Aliberti[1], T. Cascella[1], R. Romito[1], C. Sposito[1], E. Seregni[1], A. Marchiano'[1], F. Crippa[1], V. Mazzaferro[1]; [1]Foundation IRCCS Istituto Nazionale Tumori, MILAN, ITALY, [2]Medical Physics School - University of Milan, MILAN, ITALY.

Aim: we quantitatively compared 99mTc-MAA predicted and 90Y-PET absorbed dose to liver lesions, parenchyma, and lung. **Methods:** Two sequential groups (1 and 2) of 35 and 39 hepatocarcinoma patients were treated with 90Y glass microspheres after planning based on attenuation and scatter corrected 99mTc-MAA SPECT images. Group 1 (2) was treated on Thursday (Monday of the 2nd week), i.e. 3.75 (7.75) days after the reference date, with 1 (2.8) million of particles per GBq respectively. We repeated the identical dosimetric method on peri-therapy 90Y-PET images acquired with a PHILIPS GEMINI 64 TOF scanner. We applied the patient relative calibration method in both analysis. PET images were automatically coregistered to SPECT in order to apply identical VOIs. 4 (10) patients showing lung shunt fraction (LSF)>5% were studied as a separate group. Predicted and 90Y-PET absorbed doses to 31 (29) parenchyma and 38 (46) lesions were compared. **Results:** A dual phantom 90Y-PET test followed by direct gammacounter measurement verified that the relative liver to lung concentration ratio was preserved in PET images. In the group 1, the ratio between the 90Y-PET and the predicted parenchyma absorbed dose was median=1.02, range (0.69, 2.04), while for lesions we had median=0.99, range (0.42, 1.91); paired t-test was non significant. In the group 2, ratio for parenchyma was median=1.07, range (0.18, 3.83), and for lesions median=0.81, range (0.29, 2.32); t-test was significant (parenchyma p=0.015, lesions p=0.004). Preliminary liver toxicity data did not show any incidence increase in group 2. In 7 angiogram comparisons, noticeable absorbed dose discrepancy could not be attributed to differences between the two angiographic procedures. About lung, no matter the number of spheres, 90Y-PET LSF was absolutely zero in 9/14 cases, and strongly reduced in 4/14. LSF was confirmed by 90Y-PET only in one patient, who had a thromb in a sovrahepatic vein. **Discussion:** MAA overestimation of LSF is due to 10 micron MAA fraction, more penetrating in capillaries than 25 micron 90Y microspheres, as found by Elshot et al with 30 micron 166Ho microspheres. For the same reason we found an 90Y-PET lesion absorbed dose reduction in group 2 (larger number of 90Y microspheres), with a consequent increased 90Y-PET parenchyma absorbed dose. **Conclusion:** MAA treatment planning for glass microspheres is safe, despite the presence of simulation-therapy discrepancies. However, an improved simulator should be developed, especially, but not only, to avoid unjustified activity reduction in cases with substantial MAA lung shunt.

EP459

A voxel-based correction method to allow quantitative dosimetry comparisons of pre- and post-therapy imaging in ^{90}Y-microsphere treatments

A. J. Craig[1], I. Murray[1], A. Denis-Bacelar[2], N. Khan[3], A. Maenhout[3], B. Rojas-Fisher[4], L. Hossen[4], G. Flux[1]; [1]Royal Marsden Hospital, London, UNITED KINGDOM, [2]Institute of Cancer Research, London, UNITED KINGDOM, [3]Chelsea & Westminster Hospital, London, UNITED KINGDOM, [4]Royal Brompton Hospital, London, UNITED KINGDOM.

Introduction Pre-therapy ^{99m}Tc-MAA SPECT scans are used to plan ^{90}Y-microsphere treatment of liver tumours based on calculations of absorbed dose to normal liver and tumour. Comparison of dosimetric values is limited by the different scan resolutions. Segmentation of normal liver and tumour should not be performed using SPECT due to the non-physiological microsphere uptake. Application of a delineated diagnostic CT to SPECT images for absorbed dose calculation result in inaccuracies due to the partial volume effect (PVE). The aim of this work is to develop a methodology to overcome PVEs allowing calculation and quantitative comparison of absorbed dose to normal liver for pre- and post-therapy imaging. **Methods** Simulation of SPECT scans of known activities for tumour burdens of 3-27% were performed based on delineated patient CT scans. Point spread functions (PSF) of ^{99m}Tc and ^{90}Y were measured and used to simulate different SPECT resolutions. Poisson noise was applied to the SPECT simulated images. An adaption of the modified Müller-Gärtner method was used to resolve SPECT scans into separate maps for normal liver and tumour values. This method is based on an assumption of uniform tumour uptake for the derivation of the normal liver map, and vice-versa. Errors were assessed by comparing total activity in each region to the known ground truth for this method and standard CT delineation. Normal liver absorbed dose maps from simulated pre- and post-therapy SPECT scans were obtained and mean absorbed dose and biological effective dose (BED) were compared. **Results** Calculations of total activity using CT delineation gave errors of 22% and 5% assigned to tumour and normal liver respectively for the ^{99m}Tc SPECT, and 35% and 13% for the ^{90}Y SPECT. This is compared to < 0.2% based on the derived maps. Comparison of livers with different tumour burden led to errors in the mean absorbed dose to normal liver of

4.7-39.9% from CT delineation compared to 0.007-1.1% from the normal liver map. Comparisons of pre- and post-therapy absorbed dose maps resulted in differences of 1.5-4.3% and 0.007-0.004% for CT outlines and the normal liver map respectively. Similarly for mean BED differences were 0.8-7.0% compared to 1.3-1.6%. **Conclusions** The methodology allows an accurate mean absorbed dose to be calculated for a normal liver distribution. Given knowledge of the tumour/normal liver segmentation and the PSF of both ^{99m}Tc and ^{90}Y SPECT, quantitative comparison of pre- and post-therapy dosimetry can be achieved.

EP460

The impact of missing attenuation or scatter correction on 99mTc MAA SPECT based dosimetry for 90Y microsphere liver radioembolization

F. Botta[1], M. De Nile[2], S. Vitali[3], M. Mira[3], L. Lorenzon[4], M. Ferrari[1], M. Pacilio[5], C. Chiesa[6], M. Cremonesi[1]; [1]European Institute of Oncology, Milan, ITALY, [2]Postgraduate School of Medical Physics, University of Milan, Milan, ITALY, [3]Postgraduate school of Medical Physics, University of Milan, Milan, ITALY, [4]Postgraduate school of Medical Physics, Sapienza University, Rome, ITALY, [5]San Camillo Forlanini Hospital, Rome, ITALY, [6]Istituto Nazionale per lo Studio e la Cura dei Tumori, Milan, ITALY.

Aim This study investigates the impact of missing SPECT attenuation and scatter corrections on dosimetric estimates for radioembolization. **Materials and Methods** ^{99m}Tc-MAA SPECT of 63 patients undergoing radioembolization in 2 institutions (IEO and INT) were reconstructed with different combinations of attenuation (AC) and scatter (SC, Double Energy window subtraction) corrections: AC_SC, AC_NoSC, NoAC_SC, NoAC_NoSC (IEO:25 patients, metastasis, selective/lobar treatments; INT:38 patients, hepatocarcinoma, lobar treatments). "Total liver" (TL) and "lesion" (L) were drawn on CT aligned with SPECT. "Healthy liver" (HL) was TL-L. "Irradiated liver" (IL) included voxels perfused by ^{99m}Tc-MAA. "Irradiated healthy liver" (IHL) was IL-L. Relative calibration was adopted. Absorbed dose was calculated at voxel level. Average absorbed dose (D_m) and Equivalent Uniform Dose (EUD) were calculated for L; D_m for HL and IHL. Datasets obtained with different reconstructions were compared with Wilcoxon paired test. The difference D% was calculated between each dataset from AC_NoSC, NoAC_SC, NoAC_NoSC and the reference AC_SC. At IEO, comparison with AC_SC was performed at voxel and differential Dose Volume Histogram level calculating the Normalized Mean Square Difference ($NMSD_{voxel}$, $NMSD_{DVH}$). **Results** For all parameters of L, HL, IHL, differences between AC_NoSC and AC_SC were statistically significant. Difference between NoAC_SC and AC_SC was not statistically significant for HL (IEO and INT patients), while it was significant for L only for INT patients. For L: smallest range of D% (D_m) with AC_NoSC: [-20%,0]. With NoAC_SC: [-40%,+30%]. For HL: smallest range with NoAC_SC: [-5%,+7%] at IEO, [-13%,+11%] at INT. With AC_NoSC: [0,+30%] at IEO, [-21%,+34%] at INT. For IHL: smallest range with NoAC_SC: [-9%, +6%] at IEO, [-30%, +10%] at INT. With AC_NoSC: [-40%,0] at IEO, [-24%,+29%] at INT. NoAC_NoSC always yielded worst results. For HL and IHL, $NMSD_{voxel}$ was sistematically lower for AC_NoSC, $NMSD_{DVH}$ for NoAC_SC instead. No trend was observed for L. **Conclusion** Scatter correction significantly affects macroscopic dosimetric estimates and DVH, especially for HL. L: despite AC_NoSC parameters significantly differ from AC_SC, difference range is smaller with AC_NoSC, (systematic underestimation within -20%). HL: despite AC_NoSC parameters significantly differ from AC_SC, at voxel level AC_NoSC map is closer to AC_SC, while with NoAC_SC differences can be higher than noise fluctuations. With patient relative calibration, centers without Attenuation Correction can plan a safe treatment with HL dose difference - compared to AC_SC - within [-13%,+11%].

EP461

Efficacy of Yttrium-90 Time-of-Flight PET/CT in Post Radioembolization Imaging of Microsphere Biodistribution in Radiosynovectomy

M. Masoomi[1], H. Aldousari[2], S. Alenezi[2], N. Alnafisi[2], Q. Siraj[3], I. Alshammeri[1]; [1]Department of Nuclear Medicine, Adan Hospital, MOH, Kuwait City, KUWAIT, [2]1.Jaber Al Ahmed Nuclear Medicine and Molecular Imaging Center, Kuwait City, KUWAIT, [3]Department of Nuclear Medicine, Farwaniya Hospital, MOH, Kuwait City, KUWAIT.

Introduction & Purpose: 90Y bremsstrahlung scintigraphy suffers from a low spatial resolution, ranging between 11 to 15 mm depending on the choice of energy window, collimator, and image processing. 90Y bremsstrahlung activity on SPECT/CT often appears smooth and diffuse, with ill-defined margins, which are difficult to distinguish from closely adjacent activity foci. As a result, assessment of activity within sub centimetre tumours or tumour vascular thrombosis are often suboptimal on 90Y bremsstrahlung SPECT/CT. Quantitatively, 90Y bremsstrahlung scintigraphy is largely inaccurate, despite compensation techniques for attenuation, scatter, and collimator- detector response, making it unsuitable for dose-response analysis. PET/CT represents a technological leap from 90Y bremsstrahlung SPECT/CT, both qualitatively and quantitatively, allowing direct imaging of 90Y microspheres. The study is aiming to investigate feasibility of 90Y PET-CT imaging as a proposed technique to improve overall detection accuracy of 90Y distribution and leakage post radiation synovectomy. **Methods:** The radionuclide 90Y liquid microspheres are used to perform all the phantom tests. A single dose of 185 MBq of 90Y is used in a discrete and expanded ROI within the Knee phantom to imitate the clinical situation as much as possible. 90Y PET/CT phantom test was performed on a conventional time of flight lutetium yttrium oxyorthosilicate scanner and on a state of art SPECT/CT. Images of the knee phantom with the embedded 90Y will be acquired based on predefined acquisition and reconstruction parameters that are specific to the imaging modalities. Specific findings on 90Y PET/CT will be corroborated by 90Y bremsstrahlung SPECT/CT. PET/CT scans will be performed at zero and 60 minutes and 24 hours post injection. The CT scan will be used to map and delineate the ROI. **Results:** It is expected that the outcome of the pilot study establishes further a scientific platform for embarking more specially on the application of 90Y in synovectomy. Equally, the investigators expected the specific phantom study utilizing new technology, namely TOF PET/CT provides an accurate overall detection setup and approach towards radiation synovectomy in relation to leakage and treatment efficacy. **Conclusion:** The study is ongoing and expected to provide a conclusive information about quantitative and qualitative assessment of 90Y radionuclide imaging and establishes a platform for the follow up patient imaging utilizing the state of art TOF PET/CT at the molecular level. The outcome can be used to provide patient specific treatment planning for successive therapies and potentially improving response and therefore the quality patient care.

EP462

Comparison of ^{99m}Tc-MAA Planar Scintigraphy and SPECT/CT for treatment planning with ^{90}Y-labeled Microspheres

I. Torres-Espallardo, B. Ibáñez, M. Carles, M. Falgás, P. Olivan, C. Olivas, D. Pérez-Enguix, P. Bello; Hospital Universitario y Politécnico La Fe, Valencia, SPAIN.

Radioembolization using glass microspheres labeled with yttrium-90 (Therasphere®, MDS Nordion, Canada) is a locoregional treatment stablished in our center on March 2009. The treatment planning has been performed based on ^{99m}Tc-MAA planar scintigraphy since no SPECT/CT was available at that time in our center. After the acquisition of a SPECT/CT (Bright View XCT) system and provided that the European guidelines

recommend the use of attenuation-corrected SPECT scan for tumor-to-liver ratio (TLR) assessment, we intend to perform the treatment planning using SPECT/CT images. The aim of this work is to present a comparison study between the TLR obtained with both type of images. 22 patients with HCC treated with ^{90}Y glass microspheres were considered. Planar and SPECT acquisitions were performed in all the patients included in this study. The SPECT images were reconstructed using OSEM with attenuation, scatter and decay corrections applied. The TLR for the planar was calculated using manually-drawn regions of interest (ROIs) in the target and tumor areas. For the SPECT images a ROI was generated using a 40%-isocontour of the maximum value observed within the liver. Tumor (TuV) and target (TaV) volumes from SPECT were also compared with the ones obtained from CT. In addition, phantom acquisitions were performed to evaluate the best method for TLR estimation. We have employed alginate in order to reproduce different shapes, sizes and TLRs. Spheres from 11 to 27 cm^3 and cylinders of 250 cm^3 were used to mimic lesions. The inserted activities and TLRs (from 2.5 to 7) were selected to simulate clinical situations. From the analysis of the patient data we have observed that TLR^{SPECT} is higher than TLR^{Planar} in 64% of the cases. In 82% of the cases the TaV^{SPECT} was larger than the one obtained based on CT. On the contrary, TuV^{SPECT} were smaller in 68% cases in comparison with CT. When evaluating the phantom data, as expected, TLR^{SPECT} were always closer to the reference value than TLR^{Planar}. In all the cases the TLR was underestimated. For the cylinders, it was observed that the relative error of the discrepancy was only 2.5% in the case of SPECT-images, whereas it was 33% for the planar-images. As suggested from the European guidelines and according to these initial results, attenuation-corrected SPECT images must be employed in TLR estimation. But, in order to reproduce the reference TLR, a better method to determine the tumor and target volume should be defined.

EP463

Late liver toxicity: a bad known complication of radioembolization

M. Mitjavila Casanovas, L. Gutierrez, S. Mendez, R. González, A. Prieto, J. Cardona, R. de Teresa, A. Ruiz; Hospital Puerta de Hierro Majadahonda, MADRID, SPAIN.

Introduction: selective internal radiation therapy (SIRT) allows the local treatment of colorectal cancer liver metastases (CRCLM) with Yttrium-90 microspheres. Although its use as salvage therapy in chemo-refractory liver disease is established, the progressive use in earlier stages (1st and 2nd line), could lead to poorly identified late toxicities. Radiation-induced liver disease (RIELD) is a sinusoidal obstruction syndrome which typically manifests 4-8 weeks post SIRT. Portal hypertension (PHT) is not considered an expected adverse event with SIRT. **Patients and methods**: A retrospective review of 20 cases followed in our hospital after SIRT of CRCLM is performed. Clinical variables, previous and post- SIRT treatments received are collected. A radiological assessment of the cases expressly seeking signs of HTP is made. **Results**: four/ 20 otherwise healthy patients with synchronous liver only CRC metastasis treated with SIRT in first to fourth line, developed late PHT . Two cases were extensively studied with transjugular liver biopsy and hepatic venopressure gradient. Hepatic failure was the final cause of death in three patients, two of them with demonstrated high figures of bilirubin (more than 20 mg/dl) with no bile duct obstruction. This hepatic failure occurred in later stages of the disease with long-term survivals after SIRT. **Conclusions**: Late hepatotoxicity after SIRT could be more common than described up to now. The use of oxaliplatin and SIRT could have additive effects regarding liver toxicity. It is important that radiologists pay attention to the signs of PHT (varices, splenomegaly, decreased liver volume) monitoring images, as it can be key to identifying this adverse effect.

EP464

Comparison of dosimetric methods in ^{90}Y microspheres hepatic radioembolization related to dose-response evaluation

E. Richetta, M. Manfredi, M. Pasquino, C. Cutaia, S. Valzano, L. Radici, M. Tabone, P. Carbonatto, R. Pellerito, M. Stasi; AO Ordine Mauriziano, Turin, ITALY.

AIM ^{90}Y microspheres radioembolization is considered an effective treatment for hepatocellular carcinoma. Even if the importance of a personalized dosimetry is known, which is the most useful dose parameter is still under debate. The aim of this work is to compare doses to tumor calculated with different methods in order to find the dosimetric parameter that best correlates with the patient-response finalized to address patients to surgery. **MATERIALS AND METHODS** 15 intermediate to advanced HCC patients were treated with ^{90}Y resin-microspheres: no dosimetric approach was used to determine the activity to be administered (BSA method). Dosimetry was performed retrospectively on pre-treatment SPECT ^{99m}Tc-MAA images: mean dose to tumor was calculated using both MIRD (D_{mird}) and Voxel method (D_{voxel} and D_{90}). Following EASL criterion, the response to therapy was evaluated after 1 and 6 months to investigate if some patients could be staged down to surgery. The statistical difference between groups was investigated using Mann-Whitney test; ROC analysis was also performed and significance of difference between AUC was tested (Hanley and McNeil). The same analysis was performed for the administered activity and Tumor-Non Tumor ratio (TNT). **RESULTS** After one month, 10 patients (67%) showed a preliminary complete or partial response (median dose D_{mird}=418 Gy, D_{voxel}=454 Gy, D_{90}=195 Gy), while 5 patients were stable or in progression (median dose D_{mird} = 121 Gy, D_{voxel} = 106 Gy, D_{90} = 68 Gy). No patient was staged down to surgery. After 6 months, 5 of the 10 responding patients staged down to surgery (median D_{mird}=880 Gy, D_{voxel}=570 Gy , D_{90}=310 Gy), while the others 10 patients (D_{mird}=152 Gy, D_{voxel}=125 Gy, D_{90}=98 Gy) remained inoperable. Mann-Whitney test showed a statistical difference between groups (*p*-value: D_{mird} 0.0127, D_{voxel} 0.028 and D_{90} 0.024). AUC calculated on D_{mird}, D_{voxel} and D_{90} were 0.900, 0.860 and 0.870 respectively and when compared no statistical difference were observed among dose calculation methods. The best dose values to separate groups were D_{mird}=418 Gy, D_{voxel}=213 Gy and D_{90}=160 Gy. AUC calculated with the administered activity showed a lower value (0.710) and the p-value (0.198) showed no correlation to response, as well as TNT analysis, confirming the need of a personalized dosimetry. **CONCLUSION** Dosimetry can be useful to identify patients eligible for surgery and can be predictive of patient response. The results show that the investigated dosimetric methods are equivalent in calculating the activity to be administered to the patient.

EP465

Quality assurance of activity administration in Selective Internal Radiation Therapy (SIRT)

H. Levillain, G. Marin, B. Vanderlinden, T. Guiot, M. Vouche, P. Flamen; Jules Bordet Institut, Brussels, BELGIUM.

Abstract: SIRT dosimetry needs accurate and precise determination of administered ^{90}Y microspheres activity. With the assessment of ^{90}Y PET/CT, it is possible to quantify the administered activity. Our aim was to evaluate the difference between the computed administered ^{90}Y microspheres activity and the activity measured on PET/CT images. **Methods:** The study was based on 54 patients treated by liver ^{90}Y radioembolisation. Predictive treatment dosimetry was performed on ^{99m}Tc-MAA SPECT/CT, including the definition of ^{99m}Tc-MAA distribution volume and ^{90}Y microspheres activity prescription. Selected patients had no quantifiable ^{99m}Tc-MAA shunt to non-target organs. The activity to be injected was prepared in accordance with the prescription and measured with the radionuclide

calibrator CRC-15R, Capintec. Pre- and post-injection dose rates of injection box were measured to evaluate the residual activity and compute administered activity. PET/CT images were acquired on a Discovery 690 PET/CT (GE-Healthcare) with two bed positions of 30 minutes and voxels size: 2.7×2.7×3.3mm. The images were reconstructed with 3D OSEM algorithm (18 iterations, 3 subsets, 13.7mm FWHM Gaussian post-filtering) with all available corrections according to the Quantitative Uptake Evaluation in SIR-Spheres Therapy (QUEST) study recommendations. Image processing was performed with Pmod software v3.6. PET/CT was anatomically registered to SPECT/CT and ^{99m}Tc-MAA distribution volume contours were projected on PET. Registration was corrected in case of matching errors assessed by visual inspection. ^{90}Y microspheres activity was then quantified. Student test was performed and relative difference between computed injected activity and activity quantified on PET/CT was calculated. Mean ± SD of errors were computed. Plots of the errors as a function of treated volume size and as a function of the amount of injected activity were performed in order to study their correlations. **Results:** The mean relative difference was 4.7±13.9%. The differences between measured and quantified activities were not statistically significant, p=0.51. No correlation could be demonstrated between relative difference and either the treated volume or the amount of activity. **Conclusion:** Our study has shown that, despite known errors in radionuclide calibrator measurement and PET/CT quantification, the relative difference between them is relatively low. It demonstrates the feasibility of a quality assurance process to improve precision and accuracy of dosimetry.

EP466

Safety And Efficacy Of Radiation Segmentectomy

A. Ozgen[1], N. Alan Selcuk[2], T. Toklu[2], H. O. Ozdemir[1], L. Kabasakal[3]; [1]Yeditepe University Hospital, Dept. of Radiology, Istanbul, TURKEY, [2]Yeditepe University Hospital, Dept. of Nuclear Medicine, Istanbul, TURKEY, [3]Istanbul University, Cerrahpasa Medical School, Dept. of Nuclear Medicine, Istanbul, TURKEY.

Aim; To determine safety and efficacy of high dose superselective radioembolization in patients with primary or secondary tumors who were not suitable for surgery or percutaneous ablation. Materials-methods; 10 patients underwent radioembolization with ^{90}Y loaded microspheres with superselective catheterization. Three patients had cholangiocarcinoma, 3 patients had metastasis of colorectal carcinoma and 4 patients had metastatic breast carcinoma. Mean tumor diameter was 59 mm (range 32-87 mm). Four of the patients had liver only disease while rest had liver dominant disease. Radioembolization was the first choice of treatment in patients with cholangocarcinoma while rest of the patients had systemic chemotherapy also. ^{99m}Tc macroalbumine aggregate injections were made for dose calculation and to explore extrahepatic activity. Mean tumor dose was calculated as 267 Gy (range, 210-450 Gy) and mean tumor free liver parenchyma dose was calculated as 82 Gy (range, 43-110 Gy) using Medical Internal Radiation Dosimetry (MIRD) formulation. Eight patients had single injection of ^{90}Y loaded microspheres while 1 had double injections and 1 had triple injections in the same session. Mean time of follow-up was 10 months (range 5-14 months). Results; Complete response were noted in 8 of 10 patients while partial response were noted in 2 which took 210 Gy of calculated tumor dose. In the follow-up period no recurrence was noted in enpatients with complete response. Progression was noted in non-responding areas in patients with partial response. No major complication was noted during or after the procedures. Liver function tests remained within normal ranges. Leukopenia and thrombocytopenia noted in second week disappeared in forth week in 3 patients. Conclusion; Considering our small group of patients, high dose superselective radioembolization might be a safe and effective method in the treatment of primary and metastatic malignancies of the liver. We also concluded that area of injection might have not covered the whole tumor in patients with partial response.

EP468

Comparison of Standard and Superselective Transarterial Radioembolization

N. Alan Selcuk[1], A. Ozgen[2], I. Karaaslan[3], T. Toklu[1], O. Sonmez[4], O. Eren[4]; [1]Yeditepe University Hospital, Dept. of Nuclear Medicine, Istanbul, TURKEY, [2]Yeditepe University Hospital, Dept. of Radiology, Istanbul, TURKEY, [3]Yeditepe University, Dept. of Physics, Istanbul, TURKEY, [4]Yeditepe University Hospital, Dept. of Oncology, Istanbul, TURKEY.

Aim: To compare standard and superselective transarterial radioembolization (TARE) using microspheres loaded with Yttrium-90 in the treatment of primary and metastatic tumors of the liver in terms of safety, efficacy and technique. **Methods:** A retrospective analysis were performed on 39 adult patients with primary (4 patients) and secondary (35 patients) tumors of the liver who underwent standard TARE (28 patients) and superselective TARE (11 patients). Mean treatment doses, application techniques, complications and response to treatment in the second and sixth months were compared. Treatment doses were calculated using medical internal radiation dosimetry. Treatment results were categorized as total response, partial response, and no response or progression of disease in the targeted area. Follow-up of the patients were made by using PET-CT with contrast enhanced magnetic resonance imaging and/or computed tomography. **Results:** Total or partial response to treatment were observed in all patients in superselective group and 22 (79%) patients in standard group in the first and second follow-up. Mean tumor dose and mean healthy irradiated liver dose were significantly higher in superselective group while whole liver dose was sigfinicantly lower. Mean time for each treatment session for superselective group were signicantly longer than standard group. Multiple injections were needed in two patients in superselective group. Mild angiographic complications were seen in 5 (45%) patients in superselective group and 3 (11%) patients in standard group. Mild to moderate liver toxicity was not seen in superselective group. Post-radiombolization syndrome were observed in 4 (36%) patients in superselective group and in 10 (36%) patients in standard group. Hospitalization was not required in any patient. **Conclusion:** Superselective TARE seems superior in comparison to standard TARE in terms of efficacy and safety and therefore might be prefered in suitable patients in the treatment of primary and metastatic malign tumors of the liver.

EP469

Calculation And Measurement Of Absorbed Doses For Non Uniform Activity Distributions In Liver Radioembolization Using 90Y-PET Imaging

M. D'Arienzo[1], M. Pimpinella[1], M. Capogni[1], M. Tapner[2], E. Spezi[3], N. Patterson[4], P. Chiaramida[5], L. Filippi[6], A. Fischer[7], T. Paulus[7], F. Mariotti[8], P. Ferrari[8], O. Bagni[6]; [1]ENEA, National Institute of Ionizing Radiation Metrology, Via Anguillarese 301, 00123, Rome, ITALY, [2]SIRTEX, North Sydney 2060, NSW, AUSTRALIA, [3]Cardiff University, Cardiff, UNITED KINGDOM, [4]Department of Medical Physics, Velindre Cancer Centre, Cardiff, UNITED KINGDOM, [5]GE Healthcare Medical Systems, Milano, ITALY, [6]Nuclear Medicine Department, Santa Maria Goretti Hospital, Latina, ITALY, [7]Philips Technologie GmbH Innovative Technologies, Research Laboratories Pauwelsstr. 17, 52074, Aachen, GERMANY, [8]ENEA, Institute of Radiation Protection, Bologna, ITALY.

Introduction. Since the introduction of liver radioembolization with ^{90}Y-microspheres there has been an increasing interest in the assessment of absorbed doses. The recent availability of high-resolution ^{90}Y-PET images further stimulated research on this topic. The aim of the present phantom study is to investigate the accuracy of absorbed dose

calculations comparing various dose algorithms with experimental measurements. First we calculated the absorbed dose to the hepatic lesion of an anthropomorphic phantom using a number of well-established dose algorithms using ^{90}Y-PET images. Then we measured the absorbed dose to the tumour using LiF:Mg,Cu,P TLDs inside a cylindrical phantom filled with a homogenous $^{90}YCl_3$ solution. A comparison between calculated and measured absorbed dose was finally carried out. **Materials and methods**. Acquisitions were performed with a GE Discovery ST PET/CT scanner using an anthropomorphic phantom provided with a lesion insert. The first scan was performed with an activity concentration of 5.5 MBq/mL for the lesion and 0.89 MBq/mL for the liver background. The phantom was then acquired at days 4, 5, 6 and 12. Absorbed doses were calculated using different algorithms: I) Direct Monte Carlo (MC) using Raydose II) Kernel convolution using Philips Stratos III) Local-deposition (LD) IV) MC technique considering a uniform activity distribution V) MIRD approach. Measurements of absorbed dose to the tumour region were performed using six home-made liver lesions each filled with an activity concentration of about 6.7 MBq/mL $^{90}YCl_3$. Three TLDs encapsulated by a waterproof envelope were placed into each simulated liver tumour. **Results**. Investigated dose algorithms provided dose estimates with deviations below 9%, except for dose calculations performed on day 1, where the standard deviation over the average absorbed doses was 20%. LD, MIRD approach and Kernel-convolution methods provided comparable absorbed doses with average deviations below 6%. The measurement of absorbed dose to water from ^{90}Y using TLDs turned out to be a viable technique, providing a relative combined standard uncertainty on each absorbed dose measurement below 4% Measured doses were consistent with absorbed doses calculated using full MC techniques with an agreement within 3%, well within the stated uncertainty. **Conclusions**. All dose algorithms provided comparable dose estimates within standard deviations. Due to its immediate use and ease of implementation LD dose algorithm may result practical in a clinical environment where resource-intensive computational systems are not always available. For the first time dose calculations performed on ^{90}Y-PET images were successfully compared with dose mesurements performed with TLDs.

EP470

Personalized Dosimetry planning in Radioembolization with ^{90}Y-microspheres: Methodological Considerations

V. Moran, E. Prieto, A. Zubiria, L. Sancho, M. Rodriguez-Fraile, B. Barbés, L. Ramos, J. M. Martí-Climent; clinica universidad de navarra, pamplona, SPAIN.

Aim: Treatment planning based on proper dosimetry plays an important role in radioembolization outcomes. The aim of this study was to compare different currently available dosimetry methods based on ^{99m}Tc-MAA SPECT/CT and to evaluate the impact of the calibration factor of the SPECT scanner. **Materials and methods**: Retrospective dose quantification was performed on 14 patients with liver malignancy that had undergone ^{99m}Tc-MAA scan for planning radioembolization with ^{90}Y resin microspheres. Different dosimetry approaches were investigated, applying different calibration factors (CF) and calculation methods. The patient specific CF was extracted from the total counts in the SPECT planes containing liver tissue. Those counts were supposed to be proportional to the administered activity corrected by the lung shunt fraction, previously determined by planar scintigraphy. The experimental CF for the SPECT tomograph was obtained from total counts measured in a series of 10 phantom SPECT studies filled with ^{99m}Tc (183±29MBq). Two voxel-based dosimetry approaches were considered: Dose Point-Kernel (DPK) convolution with the kernels of Lanconelli database and Local Deposition Method (LDM) with a self-radiation factor of 1.35 mGy/(GBq.s). Differences between LDM and DPK methods were assessed by voxel based subtraction. CT scan was used to contour the whole liver. The mean absorbed doses in the liver were calculated for each method. Statistical analysis was performed. **Results:** Experimental CF was estimated to be 4.07±0.13 Bq/counts. Patient specific calibration factor was 5.48 ±1.85 Bq/counts (U-Mann-Whitney-test $p<0.01$). The mean deviation in absorbed dose due to the SPECT calibration method was 34±44 %. Due to the uncertainty in the determination of the actual activity in the liver, experimental calibration should be more suitable. For LDM and DPK methods, mean absorbed dose in liver tissue (based on experimental CF) was 16.1 ±10.8 Gy and 15.2±10.6 Gy, respectively (paired t-test $p<0.01$). Although global differences in the whole liver are small, important voxel-by-voxel differences have been observed. In fact, differences greater than 10 Gy were found in a maximum of 3.6 % (mean 1.1 %) of the whole liver volume. DPK tends to provide higher absorbed doses than LDM in outer edge of the uptake region and lower doses in the central area. **Conclusion:** The use of a proper calibration factor is more critical than the use of different dose deposition methods. Different 3D-dosimetry approaches yield important differences in final absorbed doses that can have a substantial impact in treatment planning.

EP471

Yttrium90 synovectomy in the management of chronic knee arthritis: results after 6 months

J. Navarro Fernandez[1], R. Asensio Sanchez[2], L. Frutos Esteban[1], L. Mohamed Salem[1], M. Ibañez Ibañez[1], V. Godoy Bravo[1], R. Reyes Marles[1], I. Sime Loayza[1], M. Castellon Sanchez[1], F. Nicolas Ruiz[1], M. Alcaraz Baños[2], M. Claver Valderas[1]; [1]HCU VIRGEN DE LA ARRIXACA, 30120, SPAIN, [2]Universidad de Murcia, 30120, SPAIN.

AIM: Radiation synovectomy has been used to treat chronically inflamed joints refractory to treatment using conventional agents. Aim to evaluate the effectiveness of radiosynovectomy with yttrium^{90} in patients with rheumatic diseases, villonodular synovitis and other arthropathies. Materials and methods: We performed a retrospective study in which we reviewed the medical records of 20 patients who have been subjected to one radiosynovectomy radioactive yttrium90 for a period of three years. Doses of 185 MBq were used in the all patients. **Results:** Altogether, 50% of the treated patients showed response: **10%** of treated patients were more than 6 months without recurrence of the disease; **15%** of patients were without inflammation or pain for a period of 3-6 months; and, **25%** of patients had a local recurrence of the disease within three months after the application of treatment with radioactive isotope. **Conclusion:** Radiosynovectomy is a safe treatment for the patient can decrease the inflammatory joint pain patient for extended periods.

EP472

Development of ^{188}Re-Functionalized Microspheres as a Second Generation Radioembolization Agent for Hepatocellular Carcinoma Treatment

J. C. De La Vega[1], K. Saatchi[1], C. Rodríguez-Rodríguez[1,2], P. L. Esquinas[2], M. Bokharaei[1], I. Moskalev[3], A. S. Thakor[4], D. Liu[4], A. Celler[5], U. O. Häfeli[1]; [1]Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, CANADA, [2]Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, CANADA, [3]Vancouver Prostate Cancer Centre and Department of Urologic Sciences, University of British Columbia, Vancouver, BC, CANADA, [4]Department of Interventional Radiology, Vancouver General Hospital, University of British Columbia, Vancouver, BC, CANADA, [5]Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.

AIM: This study aims to develop and evaluate the efficacy and safety of monosized, biodegradable microspheres (MS) with ^{188}Re for radioembolization of hepatocellular carcinoma (HCC).

Radioembolization is the administration of MS labeled with a β^--emitting radionuclide into the hepatic artery, which provides 80-90% blood supply to liver tumors. First generation radioembolization agents, TheraSpheres® and SIR-Spheres®, consist of non-uniformly sized MS with ^{90}Y, which can only be produced in nuclear reactors. Additionally, biodistribution studies are challenging due to the difficulty of imaging ^{90}Y's bremsstrahlung emissions. **MATERIALS AND METHODS:** A microfluidic technology was used to produce MS made of a PLA-PEG copolymer functionalized with a customized chelator ("chelomer") for ^{188}Re binding. The effect of the chelomer concentration, PEG content, and reaction conditions on the labeling efficiency was evaluated. An orthotopic HCC animal model was developed in male Sprague Dawley rats. N1-S1 cells (ATCC® CRL-1604), a Novikoff HCC cell line, were injected below the capsule of the left lobe of liver. All injections were performed under ultrasound guidance using an ultra-high frequency transducer (32-56 MHz). A customized catheter for ^{188}Re-MS administration via hepatic intra-arterial catheterization was fabricated. A two-compartment partition model was used to determine a clinically relevant absorbed dose to conduct the study. **RESULTS:** Scanning electron microscopy (SEM) showed that our MS have a narrow size distribution (D = 40.9 +/- 1.4 μm, CV = 3.4%). Thin layer chromatography (TLC) indicated >80% $^{188}Re(CO)_3^+$ binding specificity and good stability (>95% over 24 h). A minimally invasive technique to induce HCC was developed via ultrasound-guided injections. The location, depth, and angle of the injections can be controlled reproducibly. We are currently growing 0.5 cm^3 tumors for treatment with up to 1.7 mCi of ^{188}Re-MS. Biodistribution of the MS and changes in tumor size will be monitored with a pre-clinical SPECT/CT imager (VECTor/CT, MILabs). Levels of hepatic enzymes and proteins will be measured at two different points to evaluate the short- and intermediate-term toxicity. **CONCLUSION:** A second generation radioembolization agent was developed and it is currently being evaluated in an animal model. As ^{188}Re decays by emission of γ photons in addition to β^- particles, ^{188}Re-MS can also be imaged. Hence, it is also feasible to conduct biodistribution studies. Future work revolves around evaluating the theranostic potential of ^{188}Re-MS, conducting MS degradation studies, and evaluating the outcome of using MS with different sizes. For this, we have already produced 20, 30, and 50 μm MS.

EP473

Monte Carlo Comparison between four beta-emitting Radionuclides of Interest for Targeted Radionuclide Therapy of Small Tumors: ^{177}Lu, ^{67}Cu, ^{47}Sc and ^{161}Tb

C. Champion[1], C. Morgat[2], M. A. Quinto[1], P. Zanotti-Fregonara[2], **E. Hindié**[2]; [1]CENBG-CNRS-IN2P3, Gradignan, FRANCE, [2]Hopital Haut-Lévêque, Pessac, FRANCE.

PURPOSE: Radionuclide therapy is increasingly seen as a promising option to target micrometastases or minimal residual disease. Copper-67, scandium-47 and terbium-161 have a medium-energy beta-emission which is similar to that of lutetium-177. They offer the advantage of having diagnostic partner isotopes suitable for pretreatment imaging. The aim of this study was to compare the effectiveness of these isotopes at irradiating small tumor volumes. **METHODS:** Electron dose from uniform isotope distributions was assessed with the Monte Carlo code CELLDOSE in spheres of various sizes (from 5 mm down to 10 μm diameter). All electron emissions, including beta spectra, Auger and conversion electrons were included. As ^{177}Lu, ^{67}Cu, ^{47}Sc and ^{161}Tb differ in electron energy per decay, doses were compared assuming 1 MeV released per μm^3, which would result in 160 Gy if totally absorbed. **RESULTS:** In a 5 mm sphere, the four isotopes yielded similar dose deposits per MeV/μm^3 (145 - 149 Gy). The absorbed doses decreased with decreasing sphere size, thus underscoring the difficulty of irradiating micrometastases. ^{161}Tb, however, delivered a higher dose compared to the other isotopes. For instance, in a 100-μm metastasis, dose deposits were 24.5 Gy with ^{177}Lu, 24.1 Gy with ^{67}Cu, 14.8 Gy with ^{47}Sc and 44.5 Gy with ^{161}Tb. Auger and conversion electrons accounted for 71% of ^{161}Tb dose in this 100-μm metastasis. The differences between radionuclides further increased in cell-sized spheres. In a 10-μm cell, the dose delivered by ^{161}Tb was 3.6 times higher than that from ^{177}Lu, 4.1 times that from ^{67}Cu and 8.1 times that from ^{47}Sc. **CONCLUSION:** Terbium-161 can effectively target micrometastases and single tumor cells thanks to its decay spectrum that combines medium-energy beta emission and low-energy conversion and Auger electrons. These results are in agreement with some recent studies on cell cultures and tumor xenografts.

EP474

The development of materials for a practical use in additive technologies with specified Hounsfield indexes for the creation of individual radiotherapy phantoms

S. Stuchebrov[1], I. Miloychikova[1], V. Kudrina[2], A. Melnikov[1], M. Pereverzeva[1]; [1]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [2]Siberian State Medical University, Tomsk, RUSSIAN FEDERATION.

Currently, the planning of radiotherapy procedures is mainly carried out by computational methods based on the use of the Monte Carlo method. Modern dosimetric planning systems allow to model the character of the interaction of radiation and tissue. However, these methods are limited in accuracy as long as they allow to estimate the distribution of isodose curves in human tissues only approximately. The experimental planning of radiotherapy procedures with the use of individual anatomically precise phantoms will eliminate the inaccuracies of calculation methods. The purpose of this work is to develop a method which allows to create materials with specified HU suitable for rapid prototyping devices by Fused deposition modeling. The ability to carry out a rapid prototyping of organs of particular patients including simulated pathologies will allow to conduct the most accurate planning of gamma-radiation therapy procedures, which will reduce their negative consequences. The use of additive technologies allows to decrease the period of manufacturing of individual phantoms. It is necessary to develop a method which allows to manufacture consumables with specified HU in order to apply this technology. This problem can be solved by manufacturing a mixture of base material founded on ABS plastic and metal additives with different concentrations. The value of HU ranges from -900 to +1000 in human body. However for soft tissues it ranges from -150 HU to +100 HU. Thus it is enough to create filaments with specified Hounsfield units within at least 10 HU in the range of not less than -150 to +150. The mathematical model was created. It allows to calculate the interaction of radiation in plastics which have different impurity concentrations. The experimental samples of materials with different density have been prepared. The filaments for rapid prototyping were produced from these materials. The test samples were printed from these filaments. The values of HU of manufactured materials and printed samples were determined. The developed method allows to obtain materials with specified HU. The obtained filaments are suitable for 3D-printers. Tomography studies have shown that the material filling density is not 100% during the printing of test samples. This problem can be solved by adjustment the printing process. The further work will be aimed for the creation of phantom by the use of the FDM. The phantom will simulate human tissue of a real patient based on his tomogram.

EP475

Virtual CT for Improved Targeted Radionuclide Therapy Dosimetry

G. S. Mok, T. Li; University of Macau, Macao, CHINA.

Aim: Previously we showed that non-rigid registration on sequential CT images is superior to sequential SPECT in 3D targeted radionuclide therapy (TRT) dosimetry. However, sequential CT is not a common clinical

protocol due to the radiation concern. This study proposed a virtual CT (vCT) method for potential improved dose estimation with minimal increase of radiation dose. **Materials and methods:** We modeled 3 anatomical variations each with 3 In-111 Zevalin activity distributions, i.e., a population of 9 phantoms, using the digital 4D XCAT phantom with models of random local organ deformation, whole-body movement, normal respiratory and cardiac motion. We simulated SPECT acquisitions of 128 projections over 360° at 1, 12, 24, 72 and 144 hrs post-injection using an analytical MEGP projector. Attenuation, scatter and collimator-detector response were modeled in the realistic noisy projections which were then reconstructed using OS-EM with 128 updates incorporating full compensations. The corresponding attenuation maps of the phantoms served as the "real" CT (rCT) images. We generated vCT images by registering the whole-body 24-hr CT with the SPECT reconstructed images at other time points using the affine+b-spline method. Organ-by-organ non-rigid registrations for sequential SPECT, rCT and vCT images were performed after segmenting the organs-of-interest on the respective images. For CT-based registration, the acquired motion vectors were later applied to register the SPECT images. Voxel-by-voxel integration was applied on registered images over 5 time points, followed by convolution with a Y-90 dose kernel to generate dose images. Organ dose, differential and cumulative dose volume histograms (DDVH & CDVH) were generated for liver, spleen, kidneys and lungs. **Results:** For the organ dose, the results of vCT were superior to SPECT and were similar to those of rCT registrations with slightly larger SD, i.e., -5.08±2.63% vs. -8.66±2.83% vs. -6.4±2.26% for liver and -6.02±4.28% vs. -14.81±4.91% vs. -6.28 ±3.29% for spleen respectively. For kidneys and lungs where SPECT registration was not feasible due to low organ uptake, vCT registration also approached to rCT, i.e., 1.90±2.98% vs. 1.33±2.81% and -2.61 ±2.66% vs. -2.21±1.16% respectively. Results of DDVH and CDVH were consistent with the organ dose. **Conclusion:** The vCT eased the organ definition problem on the SPECT images especially for low uptake organs and its results were comparable with the rCT registration. It can effectively improve the TRT dosimetric results if there is only 1 CT available in the sequential imaging protocol, reducing the substantial increase of radiation burden from repeated CT scans.

EP476

Image-based internal dosimetry of Cu-64 and Tc-99m labeled radiopharmaceuticals in mice using Monte Carlo method

S. Woo[1], Y. Park[1], K. Kim[1], Y. Lee[1], B. Moon[2], B. Lee[2], J. Kang[1], S. Lim[1]; [1]Korea Institute of Raiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF, [2]Seoul National University Bundang Hospital, Seoul, KOREA, REPUBLIC OF.

The aim of this study was to evaluate the image-based internal dose of radiopharmaceuticals in mice. We performed characteristics of radiopharmaceuticals in the mice organs and tumors using Monte Carlo simulation. The images of Cu-64 and Tc-99m labeled radiopharmaceuticals were acquired using a dedicated small animal PET/CT/SPECT scanner (Inveon, Siemens Healthcare, Malvern, PA). The tumor bearing mouse was injected with 3.7 MBq of Cu-64 labeled radiopharmaceuticals and the other mouse was injected with 18.5 MBq of Tc-99m labeled radiopharmaceuticals. Mice images were acquired at 6 time points after the radiotracer administration (Cu-64: 1, 2, 6, 24, 48, and 70 h, Tc-99m: 0.5, 1, 2, 3, 6, and 24 h). The image of tumor and lung were segmented by mean-based region growing 3D segmentation method and manually. Residence times were computed via time activity curves of the acquired region segmented PET and SPECT series data. The absorbed fractions were calculated using segmented CT images density information. S-values were calculated using Geant4 Monte Carlo method. Internal doses were calculated by residence times of PET and SPECT images and Monte Carlo-calculated S-values. In the case of Cu-64 labeled radiopharmaceuticals, representative residence time of the lung was 1.51 MBq-h/MBq and tumor was 4.72 MBq-h/MBq. Monte Carlo simulated S-value of the lung and tumor were 1.31E-01 and 3.28E-01 mGy/MBq, respectively. An Estimated absorbed dose of the lung was 2.03E-01 and tumor was 1.56E-01 mGy/MBq. In the case of Tc-99m labeled radiopharmaceuticals, representative residence time of the lung was 1.10E-04 MBq-h/MBq and tumor was 4.72E-02 MBq-h/MBq. Monte Carlo simulated S-value of the lung and tumor were 3.88E-01 and 6.15E-02 mGy/MBq, respectively. An Estimated absorbed dose of the lung was 1.56E-01 and tumor was 9.10E-02 mGy/MBq. We performed the internal dose calculation of Cu-64 and Tm-99m labeled radiopharmaceuticals. Image-based Monte Carlo method will become available to calculate the object specific dose of theragnostics radiopharmaceutical in the total body.

EP477

Simulation of radioactive sources in a bone cavity to evaluated the activity quantification in bone marrow dosimetry

M. Salas, S. Schlögl, J. Tran-Gia, C. Kesenheimer, H. Hänscheid, M. Lassmann; University Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY.

AIM: In diagnostic and therapeutic nuclear medicine, the determination of absorbed doses in the bone marrow is of great importance. Due to the tissue composition, the activity distribution in bone marrow can be highly inhomogeneous. Therefore, the aim of this study was to examine the general feasibility of an activity quantification of radioactive sources in a bone cavity using SPECT/CT and PET/CT imaging. **MATERIALS AND METHODS:** An in vitro phantom was built from a small fillable vial (volume: 0.32 ml) surrounded by a bovine femur segment. This setup was mounted in a 3D-printed (Renkforce RF1000) attachment system for a body phantom (IEC 61675-1). Activity distributions inside a human vertebra were simulated by filling the vial with different isotopes (SPECT: Tc-99m, Lu-177, I-131. PET: F-18, I-124) and filling the rest of the bone cavity with different fat/water ratios (100/0, 50/50, 0/100). SPECT/CT (Siemens Symbia T2) and PET/CT (Siemens Biograph mCT) imaging was performed with each of these combinations and the source activity for different VOIs (centered in the maximum of the activity distribution) was quantified. In addition, deviations between the image quantified activities and the activities measured in a dose calibrator (Venstra instruments VIK-202) or in a high purity Germanium Detector (Canberra, Germany) was performed. **RESULTS AND DISCUSSION:** A strong dependence of the quantification on the size and position of the VOIs was observed, which can be explained by partial volume effects caused by the small source volume. For 100% water inside the bone cavity, the Tc-99m quantification showed a deviation of -3.1% in a VOI of 3 ml, Lu-177 a deviation of -2.4% in a VOI of 15.9 ml, and I-131 a deviation of -4.2% for a VOI of 24.8 ml (the minus sign represents an underestimation of the activity). The increase in VOI is related with the sources size and the image resolution for each collimator. For the PET isotopes, fixed VOIs of 16.4 ml including the whole source and centered in the bone cavity were used. Deviations of 8.9% and 8.6% were registered for F-18 and I-124, respectively. No dependency of the activity quantification with respect to the fat/water concentration inside of the bone was found (p=0.972). **CONCLUSION:** This phantom study demonstrates the general feasibility of a quantification of radioactive sources in bone marrow dosimetry using SPECT/CT and PET/CT imaging. Furthermore, no dependency of the quantification on the fat/water ratio in the bone marrow was observed.

Normal distribution of salivary gland tissue on ^{68}Ga-PSMA PET-CT

T. Klein Nulent[1], M. Valstar[2], B. de Keizer[1], A. Al-Mamgani[2], L. Smeele[2], R. van Es[1], W. Vogel[2]; [1]University Medical Center Utrecht,

Utrecht, NETHERLANDS, [2]The Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Background: Functional imaging of prostate-specific membrane antigen (PSMA) with radiolabeled PSMA ligands with PET-CT is increasingly used for detection and (re)staging of prostate cancer. Remarkably, the PSMA epitope is also highly expressed in normal lacrimal and major salivary gland tissue. This results clearly in high tracer uptake in the major salivary glands (parotid, submandibular and sublingual glands) and lacrimal glands on PSMA-PET. In addition, the presence of minor mucosal salivary glands may be visualised, for example in the palate, the nasal cavity and the mucous glands of the supraglottic larynx. This study aimed to describe the distribution and characteristics of normal salivary gland tissue on PSMA-PET in order to facilitate interpretation of the head and neck area. **Methods**: The normal distribution of salivary gland tissue was analysed in 30 consecutive patients who underwent total body PSMA-PET for evaluation of disseminated prostate cancer. These patients did not have any known disorder of the salivary glands or history of irradiation in the head and neck area. Tracer uptake in the major and minor salivary glands and lacrimal glands was recorded by calculating the maximum standardized uptake value (SUV_{max}) on PET images reconstructed according to research guidelines of the European Association of Nuclear Medicine using the Lean Body Mass formula. **Results**: The PSMA-PET scan clearly depicts anatomical areas of salivary gland cell concentration by visualising high tracer uptake. The mean SUV_{max} for the major salivary gland locations were as follows: parotid gland 12,2 g/ml (range 5,2-22,9); submandibular gland 11,6 g/ml (6,0-19,3); sublingual gland 4,4 g/ml (1,4-9,6). PSMA uptake was also seen in the lacrimal glands: SUV_{max} 6,1 g/ml (range 2,5-13,6) and in oropharyngeal mucosal gland locations: Waldeyer's ring 4,3 g/ml (2,2-7,7); nasal cavity 3,4 g/ml (2,2-5,5); palate 2,3 g/ml (1,4-3,6) and the mucous glands of the supraglottic larynx 2,6 g/ml (1,7-3,8). The mean distribution in liver and kidneys were 3,7 g/ml (2,4-5,0) and 29,2 g/ml (16,9-44,5) respectively. **Conclusion**: PSMA-PET provides a very sensitive detection of salivary gland tissue including mucosal localisations. Familiarity with the normal distribution pattern outlined in this study can contribute to adequate interpretation of PSMA-PET imaging. Potential applications may also include: better analysis of salivary gland-sparing techniques in radiotherapy of the head and neck; quantification of salivary gland function; targeted therapy in salivary gland neoplasms; the visualisation of presumed ectopic or heterotopic salivary gland tissue and the detection of residual salivary gland tissue in recurrent plunging ranulas.

EP479

The 68Ga/177Lu-Theragnostic Concept in PSMA-Targeting of Prostate Cancer: A Long(er) Way to Go?

L. Scarpa, S. Buxbaum, D. Kendler, J. Bektic, C. Decristoforo, L. Gruber, L. Geraldo-Roig, B. Nilica, C. Uprimny, K. Fink, P. Lukas, W. Horninger, I. Virgolini; Department of Nuclear Medicine, Innsbruck, AUSTRIA.

Aim Progression to androgen independence is the first cause of mortality in castration resistant (cr) prostate cancer (PC) patients. For this reason a targeted theragnostic approach based on increased expression of prostate-specific membrane antigen (PSMA) on PC cells is an attractive treatment option. **Methods** Ten consecutive patients with progressive crPC were selected for ^{177}Lu-PSMA617-ligand therapy on the basis of PSMA-targeted ^{68}Ga-PSMA-HBED-CC-ligand PET/CT diagnosis showing extensive and progressive tumour load. Following dosimetry along with the 1st therapy cycle restaging (^{68}Ga-PSMA-HBED-CC ligand, ^{18}F-NaF-PET) was performed after 2 cycles (each 6 GBq given via an intravenous infusion pump, 8 to 10 weeks apart). Further re-stagings were performed at 8 to 10 weeks after 3 to 4 additional cycles (each 6 GBq, 8 to 10 weeks apart). PET/CT scans were compared to ^{177}Lu-PSMA617-ligand 24-hour whole body scans and contrast-enhanced dual phase CT. **Results** Dosimetry indicated high tumour accumulation of ^{177}Lu-PSMA617 (4.8±3.5 Gy/GBq; range 1.2-11.5 Gy/GBq) whereas the dose to all organs was acceptable in all patients for a calculated accumulated activity of 24 GBq. In 3/10 patients who had a partial remission ^{177}Lu-PSMA617-ligand therapy led to a significant decrease of PSA values (up to <50% of baseline) combined with decreased SUV_{max}-values obtained by ^{68}Ga-PSMA-HBED-CC-ligand PET/CT after 3 to 4 therapy cycles. Three other patients showed a mixed response and in 2 patients therapy was terminated after 2 cycles due to progression. ^{68}Ga-PSMA-HPED-CC-PET/CT-Response was well correlating to decline of ^{177}Lu-PSMA617-ligand uptake but not to follow-up with ^{18}F-NaF PET/CT which in all patients suggested a flair phenomenon and had no relevance in clinical follow-up. The cumulated activity caused in 4/10 patients only a transient haematotoxicity (Grade less than or equal 2) but led to a 25% volume reduction of salivary glands. **Conclusion** Our data suggest that the ^{68}Ga / ^{177}Lu-PSMA-targeted theragnostic concept could evolve into an importance treatment option of metastasised crPC. We conclude that ^{177}Lu-PSMA617-ligand therapy in patients with crPC is clinically safe and can be effective in patients with progressive crPC. A prospective study is needed to better address the multitude of questions arising with this new treatment modality, especially to timing, dosing and response Evaluation.

EP480

Is Lu-177 PSMA radioligand therapy of prostate cancer safe for patients with single functioning kidney?

A. SINGH, C. Schuchardt, H. Kulkarni, R. P. Baum; ZENTRALKLINK BAD BERKA GMBH, BAD BERKA, GERMANY.

Aim: Lu-177 PSMA radioligand therapy (PRLT) is a promising therapy option for the management of patients with metastatic castration-resistant prostate cancer (mCRPC). High post-therapy uptake in kidneys has been reported as a concern for nephrotoxicity, and a recent study has reported cases of grade 1-2 deterioration of renal function following Lu-177 PRLT. Hence, we aim to assess the safety of Lu-177 PRLT in patients with mCRPC possessing a single functioning kidney. **Methods:** Since April 2013, 119 patients with mCRPC have undergone 300 cycles of Lu-177 PRLT at our center. Two of 119 (1.68%) patients (P1, P2) had a single functioning kidney. Pre-therapy renal function test (RFT): urea, creatinine, eGFR, and MAG3-scintigraphy based tubular-extraction rate (TER) were performed within 1-2 days prior to PRLT, and follow-up RFT performed 2 weeks later. Dosimetry (MIRD scheme, OLINDA/EXM) was performed in 30 patients to assess renal kinetics of Lu-177 PSMA. **Results:** P1 received 3 cycles of Lu-177 PRLT with cumulative radioactivity of 20.1 GBq (mean 6.7 GBq) in 4 months. Baseline RFT: urea 7.3 mmol/L, creatinine 111.8 micromol/L; post-PRLT: urea 6.3 mmol/L; creatinine 102.7 micromol/L. TER reduced from baseline 140 to 129 ml/min (5%), and was clinically insignificant. P2 received 4 cycles of Lu-177 PRLT with cumulative radioactivity of 22.8 GBq (mean 5.7 GBq) in 6 months. Baseline RFT: urea 11.9 mmol/L, creatinine 82.7 micromol/L; post-PRLT, urea 9.1 mmol/L and creatinine 94.1 micromol/L. TER reduced from baseline 199 to 132 ml/min (26%). eGFR remained >60 for both patients persistently. Renal dosimetry revealed an effective half-life of 39 hours, mean absorbed dose of 1 mGy/MBq (mean 0.4-2.0 mGy/MBq), and mean absorbed dose of 6 Gy/cycle. **Conclusion:** In this small number of patients with a single functioning kidney each, no clinically significant acute

nephrotoxicity was observed. Despite a reduction of TER in one patient assessed prior to the fourth treatment, the renal function tests remained within normal limits. The dosimetry performed revealed favourable tracer kinetics. Long term follow-up of these and other similar patients is warranted to validate these findings.

EP481

Dose absorption estimates of the lower gastrointestinal tract during Lu-177 DKFZ-PSMA-617 therapy in patients suffering from mCRPC

I. Schatka, C. Bartel, U. Heimann, F. Wedel, V. Prasad, C. Furth, H. Amthauer, W. Brenner; Charité, Berlin, GERMANY.

Aim - Internal radiation therapy with lutetium (Lu) -177 labeled prostate-specific membrane antigen (PSMA) is a new therapeutic option in patients with metastatic castration-resistant prostate cancer (mCRPC). Of the organs at risk with high tracer accumulation, reliable dose estimations for the lower gastrointestinal tract (LGT) have not been presented so far. The objective of this study was to perform absorbed dose calculations of the LGT and kidneys during Lu-177- DKFZ-PSMA-617 therapy. **Methods -** Nine patients with mCRPC were treated by at least two cycles of Lu-177 DKFZ-PSMA-617 therapy and underwent a thorough clinical follow-up.Out of this cohort, a whole body dosimetry via a stationary dose rate monitor (LB 112 Micro Gamma, Berthold, Germany) has been conducted in three patients (mean age 67 yrs [range 61 - 72]) so far. Additional SPECT/CT images from the skull base to the pelvis were acquired at approximately 1, 4, 24, 48 and 72 h after administration of 3.6 GBq [range 3.5 - 3.7] Lu-177 DKFZ-PSMA-617. Time-dependent activities for the small, upper large and lower large intestines as well as the kidneys were determined by drawing volumes of interest in SPECT/CT images. Curve fitting, residence time calculation and absorbed dose calculation per organ were conducted using OLINDA/EXM. **Results -** The calculated mean absorbed dose for the kidneys was 0.5 Gy/GBq [range 0.4 - 0.6], 0.13 Gy/GBq [range 0.12 - 0.15] for the small intestine, 0.44 Gy/GBq [range 0.42 - 0.45] for the upper large and 0.04 Gy/GBq [range 0.02 - 0.06] for the lower large intestine, respectively. Accordingly, there was no severe bowel obstruction, diarrhea, ulceration or perforation during the cause of therapy or follow-up (6 ± 1 month) within the nine patients. Likewise, there was no evidence of nephrotoxicity, as determined by serum creatinine levels and dynamic renal scintigraphy. One patient complained about mild, self-limiting constipation within three days after therapy. **Conclusion -** Based on the biodistribution and dose calculations, this preliminary data can be used as a first approximation for gastrointestinal risk assessment. Absorbed organ doses of the lower gastrointestinal tract appeared to be uncritical in Lu-177- DKFZ-PSMA-617 therapy.

EP482

Assessment of response, clinical evaluation and toxicity of radioligand therapy (RLT) with 177-Lutetium-DKFZ-617-labelled Prostate specific membrane antigen (177-Lu-DKFZ-617-PSMA) for metastatic castrate resistant prostate cancer (mCRPC): An initial experience in Jaslok

H. RATHORE, H. SHAH, P. ALAND, P. CHAUDHURI, T. BHARADWAJ, C. KALE, C. SHEKAR, A. PARAB, S. PALTRO, P. KOREPU, V. M. JAMES, V. LELE; JASLOK HOSPITAL, MUMBAI, INDIA.

OBJECTIVE: RLT with 177-Lu-DKFZ-617-PSMA is a novel targeted therapy for mCRPC. To assess the efficacy of single infusion of 177-Lu-DKFZ-617-PSMA RLT by prostate specific antigen (PSA) decline, clinical improvement, and early side effects. We present the first clinical experience of treating mCRPC using 177-Lu-DKFZ-617-PSMA. **METHODS:** RLT with 177-Lu-DKFZ-617-PSMA was performed in 8 mCRPC patients, refractory to conventional treatment including hormonal, chemo and radiotherapy. 68Ga-HBED-CC PET-CT was performed in all patients prior to one cycle 177-Lu-DKFZ-617-PSMA RLT (Mean administered activity 7.03 GBq and range 6.67 - 7.4 GBq). In addition, early response was evaluated by serum PSA levels, complete blood counts, liver and renal function tests (LFT and RFT), serum electrolytes, lactate dehydrogenase (LDH) and ionised calcium prior to therapy and followed by 2, 4, and 6 weeks post therapy. All patients were contacted by telephone every week regarding the side effects and any positive or negative change. Study was approved by institutional board and informed consent was taken prior to therapy. **RESULT:** All lesions detected by 68Ga-HBED-CC PET-CT exhibited high 177-Lu-DKFZ-617-PSMA uptake on post therapy planar and SPECT images. Six weeks after therapy 5 patients (62.5%) experienced PSA decline of whom 2 patients (25%) experienced more than 50% PSA decline, 1 patient (12.5%) more than 30% PSA decline, and 2 patients (25%) any PSA decline. Three patients experienced rise in PSA out of which 2 patients (25%) experienced more than 25% raise in PSA with progressive disease, 1 patient (12.5%) experienced clinical improvement. Relevant hematotoxicity (ECOG common toxicity criteria) i.e. grade II/III anaemia and thrombocytopenia is showed by 2 patients (25%) with progressive disease, and the same 1 patient (12.5%) has experienced leucopenia in addition. 1 patient (12.5%) with more than 25% raise in PSA and 5 patients with decline of PSA did not experience any hematotoxicity. 1 patient (12.5%) with progressive disease experienced deranged LFT, RFT and serum electrolytes. Xerostomia was experienced by 3 patients (37.5%), which started within a week and resolved in about 6 weeks post therapy. **CONCLUSION:** 177-Lu-DKFZ-617-PSMA is a novel and promising RLT for mCRPC. Our initial results indicate that radioligand therapy with 177-Lu-DKFZ-617-PSMA is safe, effective and have low early side effect profile. A relevant PSA decline was detected in 62.5% of patients.

EP483

Radiation dosimetry of organs and tissues at risk from ^{177}Lu-DKFZ-PSMA-617 for prostate cancer therapy

M. Hohberg, W. Eschner, M. Schmidt, M. Dietlein, C. Kobe, T. Fischer, A. Drzezga, M. Wild; University Hospital of Cologne, Cologne, GERMANY.

Purpose: The calculation of the absorbed dose is crucial for the evaluation of possible risks against the therapeutic benefits of a new targeted radionuclide therapy. The absorbed dose for possible critical organs was calculated during in the first cycle of a peptide radioligand therapy with ^{177}Lu-DKFZ-PSMA-617 for patients with metastatic prostate cancer. **Methods:** Nine patients with castration-resistant prostate cancer and advanced metastases underwent radioligand therapy with 5.5 ± 0.16 GBq of ^{177}Lu-DKFZ-PSMA-617 therapy. Serial whole body scintigraphies acquired at 0.5/24/48/72 and 168 hours after application were analyzed by regions of interest and time-activity curves were generated for various organs. The cumulative activities and residence times were calculated by integrating a bi-exponential fits over the time-activity curves. Mean absorbed doses were finally estimated using OLINDA /EXM1.1^{TM}. Additionally the mean absorbed doses for each organ were determined when omitting the last measurement (168 hours p.i.) and compared with the results based on data from all measurement points. In a sub-study, the whole body uptake was supplementary measured by a probe counter. These measurements were used as additional monitoring of the absorbed whole-body doses and were compared to the ones obtained by planar scintigraphy. **Results:** The following mean absorbed doses were calculated: 2.82 mGy/MBq (SD= 0.76 mGy/MBq) for the lacrimal glands, 0.72 mGy/MBq (SD= 0.14 mGy/

MBq) for the salivary glands, 0.53 mGy/MBq (SD= 0.17 mGy/MBq) for the kidneys, 0.42 mGy/MBq (SD= 0.12 mGy/MBq) for the nasal mucous membrane and 63.0 μGy/MBq (SD= 22.9 μGy/MBq) for the whole body. Non-specific intestinal retention of activity was lower in patients with extended bone metastases. Omitting the last measurement resulted in a mean deviation of 10% to 30% for absorbed doses as compared to the ones received by analyzing all measurements. The whole body doses by probe counter measurements were in accordance with the ones obtained by planar scintigraphy. The mean deviation between the two methods was 2.36 %. **Conclusions:** After three therapy cycles absorbed doses are not likely to be critical for the kidneys, salivary glands and the nasal mucous membrane except for the lacrimal glands. The lacrimal glands may represent the dose-limiting organs, because critical exposure may result. Whole body scintigraphy appears sufficient for dose estimation but late measurements (168 hours p.i.) are mandatory, if accurate dose calculation is required. Further clinical studies based on a larger number of patients are necessary to validate these results.

EP484

Investigation of a hybrid image approach and a reduction in the number of blood samples for a decreased clinical workload for patient-specific bone marrow dosimetry in Lu-177-DKFZ-PSMA-617 therapy

A. Gosewisch, A. Delker, S. Tattenberg, L. Vomacka, F. J. Gildehaus, A. Brunegraf, P. Bartenstein, G. Böning; University Hospital Munich, Munich, GERMANY.

AIM: Bone marrow (BM) is a critical organ in radionuclide therapy, particularly in Lu-177-PSMA therapy, in which patients typically exhibit high burdens of bone metastases. However, while reliable organ and tumour dosimetry ideally requires sequential SPECT-imaging, BM dosimetry adds a series of planar acquisitions to the imaging protocol for dose estimation of the remainder of the body (ROB). This work aims at investigating a BM dosimetry protocol using a hybrid image approach based on a combination of a single planar image with sequential SPECT images, which still offers acceptable BM dosimetry estimates. Additionally, a possible reduction in the number of blood samples was studied for further minimization of clinical workload. **METHODS:** BM dosimetry was performed on four patients (eight cycles of 3.7GBq Lu-177-PSMA-DKFZ-617), using a full (FP) and a reduced (RP) dosimetry protocol (p.i. each: FP: SPECT/planar whole-body: 24/48/72h, blood: 20/30/40/60/80min and at each acquisition time-point; RP: SPECT: 24/48/72h, whole-body: 24h, blood: 20/60min and at each acquisition time-point). Images were acquired on a SPECT/CT-System (Siemens-Symbia-T2). Quantification included voxel-wise scatter and attenuation correction in case of planar and SPECT images and distance-dependent detector blur for SPECT. Calibration of planar images was done via known net-activity for the FP and via the quantitative 24h-SPECT for the RP. A monoexponential kinetic was assumed for all organs, tumours and the ROB and a biexponential for blood. Subsequent dosimetry was performed according to EANM guidelines. Determination of the ROB-to-BM dose for the RP was done by combining the effective half-life of the sequential SPECT with the planar image 24h to obtain a description of the ROB-time-activity-curve. **RESULTS:** Calibration factors derived from 24h-SPECT and net-activity showed strong correlation and similar means (Pearson's r=0.74, 24h-SPECT: 174 kBq/cps, net-activity: 175 kBq/cps). Results of both protocols showed very strong correlation and similar means concerning the total BM dose and the individual contributions: total BM dose: r=0.91, FP: 39.3+/-15.5mGy, RP: 40.8+/-17.2mGy; ROB-to-BM: r=0.94, FP: 26.3+/-14.4mGy, RP: 29.8+/-16.3mGy; blood-to-BM: r=0.92, FP: 13.0+/-8.7mGy, RP: 11.0+/-8.9mGy. **CONCLUSIONS:** Exploiting the information from sequential SPECT for reduction of planar images and clinical workload seems to be a promising approach. Thereby SPECT calibration of planar images offers a practical alternative to net-activity counting. The number of blood samples could be reduced from eight to five without a drastic change in the derived dose estimates.

EP485

The First Experience on Lutetium (lu)-177 Prostate Specific Antigen (PSMA) Treatment in Castration Resistant Prostate Cancer Patients

C. Soydal, E. Ozkan, D. Nak, O. N. Kucuk; Ankara University Medical Faculty Nuclear Medicine Department, Ankara, TURKEY.

Aim: To report our first safety and efficacy data on Lu-177 PSMA treatment in castration resistant metastatic prostate cancer patients. **Material and Methods:** Totally 14 (mean age: 66.35±3.1) patients received Lu-177 PSMA treatment for castration resistant prostate cancer between the dates April 2015 and April 2016 in our department. Performance status and life expectancy was considered during pretreatment evaluation. Blood count, renal function tests, serum PSA measurement and pretreatment Gallium (Ga)-68 PSMA Positron Emission Tomography (PET)/Computed Tomography (CT) imaging was performed all the patients. Renal function tests and blood counts were repeated after each cycle to follow-up possible hematological and renal toxicity. All the patients who completed all cycles underwent posttreatment Ga-68 PSMA PET/CT for evalution of treatment response. A scoring system based on number (1=no lesion, 2= 1 to 3, 3=4 to 10, 4>10) and SUV was used to evaluate pre and posttreatment Ga-68 PSMA images. **Results:** Gleason Scores of patients ranged 7-9. All the patients were received taxan based chemotheraphy regiments. In pretreatment Ga-68 PMSA PET/CT images while 13 patients had multiple bone metastases, 7 patients had lymph nodes, 3 patients had liver and 2 patients had lung metastases. Mean pretreatment serum PSA level was calculated as 460.97 (min-max: 2.83-2044) ng/mL. Six patients completed 4 cycles of treatment. Treatment of 2 patients was discontinued after 2 cycles due to thrombocytopenia and neurological symptoms, respectively. While grade 2 anemia and grade 1 thrombocytopenia was observed in 1 patient, grade 1 anemia and grade 2 thrombocytopenia was seen in 1 and 1 patient. Significant renal toxicity was not developed in any patient. Complete remission was seen in one patient after 3 cycles. Finally 1 patient died after 3th cycle. Rest of the patients is still under treatment. According to Ga-68 PSMA PET/CT imaging, 4 patients responded to treatment. Additionally, PSA response was seen in 8 patients. Figure 1: Change of serum PSA levels. Conclusion: Based on our first experience, Lu-177 PSMA treatment seems to be safe and efficient in castration resistant metastatic prostate cancer patients.

EP486

Radiation Dosimetry of 177Lu-PSMA; Results from a prospective clinical trial utilising automated voxelized dosimetry and comparison with PSMA PET/CT

J. A. Violet, P. A. Jackson, M. Scalzo, S. Sandhu, P. Eu, R. J. Hicks, M. S. Hofman; Peter MacCallum Cancer Institute, Melbourne, AUSTRALIA .

Introduction: Retrospective series administering radiolabelled small molecules binding to prostate specific membrane antigen (PSMA) demonstrate a favourable therapeutic ratio in men with metastatic castration resistant prostate cancer (mCRPC). Toxicity and efficacy in radionuclide therapy is determined by absorbed dose in normal tissues and tumour and is controlled by adjustment of administered activity. We present regional dosimetry for men with mCRPC treated with ^{177}Lu-PSMA-617 and correlate with pre-therapy PSMA PET/CT. **Materials and methods:** The first ten men recruited in a single-arm prospective study (ACTRN12615000912583) were analysed following the first cycle of ^{177}Lu-PSMA-617 therapy. Administered activities for each cycle were adjusted according to tumour burden, body weight and renal function using a pre-defined method, and administered following oral hydration alone. Following cycle one of four planned therapies, quantitative SPECT/CT imaging was performed at 4, 24 and 96 hours. Series were deformably registered and voxel-specific time activity curves used to

derive three-dimensional absorbed dose maps based on Monte Carlo-determined voxel S-values at a combination of long and short ranges. Parotid gland and tumour dosimetry were correlated to pre-therapy ^{68}Ga-PSMA PET/CT SUVmax. **Results:** Dosimetry estimates to normal tissues following cycle 1 (median administered activity 8000 MBq, range 7300-8500) expressed as mGy/MBq +/- SD were kidney 0.43 +/- 0.11, parotid 0.52 +/- 0.25, submandibular 0.41+/- 0.25, liver 0.08+/-0.01, spleen 0.08 +/- 0.03, spinal marrow 0.2 +/- 0.19, left ventricle 0.09+/- 0.01. Lacrimal gland doses were excluded from the analysis due to limitation by partial volume effects but are qualitatively higher than those observed in parotids. Assuming mean biodistribution the estimated renal and parotid doses following 4 cycles of 800MBq would be 13.76 Gy and 16.64 Gy respectively. The mean dose to tumours with the highest uptake per patient was 37 Gy. The mean tumour absorbed dose he two most intense sites in bone, node and visceral tissue were 28.1 Gy (range 9.6-71.1), 29.2 Gy (range 10.6-53.1) and 38.3 Gy (range 4.2-68.3) respectively. Correlating SUVmax on pre-therapy PET/CT with parotid and tumour absorbed dose yielded squared Pearson correlation of 0.29 and 0.09, respectively. **Conclusions:** Absorbed dose was highest in salivary glands and kidneys. Assuming average biodistribution in this cohort administration of 4 cycles of therapy would not exceed conventional external beam tolerance doses. Tumour absorbed doses in index lesions are high. Pre-therapy PSMA PET/CT demonstrates high variability in correlation with parotid and tumour dosimetry indicating limited potential of using short half-life ^{68}Ga PET for prospective dosimetry.

Concrete walls activation and scrap material in the decommissioning of a PET Cyclotron: preliminary results of Monte Carlo study

S. Vichi[1], A. Infantino[1], G. Cicoria[2], F. Zagni[2], A. Corazza[2], D. Mostacci[1], M. Marengo[2]; [1]Montecuccolino Nuclear Engineering Laboratory, Department of Industrial Engineering, University of Bologna, Bologna, ITALY, [2]Medical Physics Department, "S. OrsolaMalpighi" Hospital, Bologna, ITALY.

Introduction: During the operational life of a PET Cyclotron, the concrete walls of the cyclotron vault are activated by the secondary neutron flux interacting with rare earth's and metals present in the concrete or in the reinforcement bars. For this reason when considering dismantling of such accelerators, a considerable amount of low level solid radioactive waste has to be taken into account. The aim of this work is to define a Monte Carlo approach for the assessment of activation levels of a cyclotron bunker. **Material and methods:** In this work The MC code FLUKA was used to simulate a GE PETtrace cyclotron (16.5 MeV) routinely used in the production of positron emitting radionuclides. The model of the cyclotron includes the magnet and magnet poles, the vacuum chamber, the coils and the target filling station panel (LTF). The target system modeled is the standard GE assembly including a Niobium chamber filled with O-18-water to produce Fluorine-18 by a (p,n) reaction. A detailed MC model of the cyclotron vault was implemented on the basis of the bunker's original construction drawings; the model includes the ducts through the vault walls and the reinforcement rods. Experimental measurements inside the bunker were performed using a compact, portable CZT detector. A Monte Carlo model of the detector and of measurement geometry was developed in order to calibrate the detector for field measurements. **Results and conclusions:** Activation of the cyclotron vault walls and reinforcement rods was scored at different positions, depth and for different workload and life expectancy of the cyclotron. The principal long-lived radionuclides found in concrete were ^{152}Eu, ^{54}Mn, ^{60}Co, ^{154}Eu, ^{134}Cs, ^{3}H while in reinforced rods ^{55}Fe, ^{54}Mn, ^{60}Co were found. After twenty years of cyclotron operation the expected activity concentration of this radionuclides in the concrete ranges from 0.001 Bq/g to 4 Bq/g. For short-lived radionuclides, it was possible to perform experimental measurements and to compare them with simulations. The results obtained are in agreement within uncertainties (e.g. ^{56}Mn standard deviation in activity concentration < 10%). In conclusion, provided a detailed model is developed, Monte Carlo approach to the study of bunker activation level allows to characterize with satisfactory accuracy the radioactive waste from the decommissioning of a cyclotron facility. A preliminary evaluation of radioactive waste allows to identify any critical issue and possible countermeasures to be taken in order to decrease future dismantling costs.

EP488

Calibration of radiation detectors for air exhaust systems: an approach with Monte Carlo simulations

F. Zagni[1], S. Vichi[2], L. Pompignoli[3], G. Cicoria[1], A. Corazza[1], D. Pancaldi[1], M. Marengo[1]; [1]Medical Physics Department, University Hospital "S.Orsola – Malpighi", Bologna, ITALY, [2]Department of Industrial Engineering, Montecuccolino Laboratory, University of Bologna, Bologna, ITALY, [3]Research and Development Coordinator, Tema Sinergie S.p.A, Faenza, ITALY.

Introduction. Air exhaust systems in cyclotron and radiopharmacy facilities involve the use of radiation detectors in order to monitor air contamination and comply with the concentration limits set by the regulations. The calibration of these devices is not straightforward; in this work we used Monte Carlo (MC) simulations in order to evaluate calibration factors for different detectors, in particular for a single-channel NaI scintillator probe. **Materials and methods**. We compared MC results with experimental measurements performed using the probe and a known activity. To do this, a cylindrical tube (1-meter long), similar to a real ventilation duct, was filled with water with a known, uniform, activity concentration of ^{18}F (assessed with a calibrated activity meter) and count-rate was recorded with the probe supported to the external wall surface. The same geometrical setup was modeled using MC simulations. The ratio between simulated and experimental results was used as a scaling factor for the subsequent calibration factors evaluated through simulations, in order to take into account the different count-rate between real and modeled probe, due to the intrinsic efficiency of the scintillation material, light and charge collection by the PMT. Calibration factors for different radionuclides, in particular positron emitters, were evaluated by simulating real measurement conditions, i.e. a duct filled with a uniform activity concentration in air. The difference between results obtained in air and water was analyzed, in particular the positron annihilation distribution in space. Factors for non-PET radionuclides were also estimated. Simulations were performed with both Geant4 and FLUKA toolkits and for each run statistical uncertainty was about 1%. **Results**. For the modeled NaI probe, the ratio between calibration factors for activity distributions in air and water gave 1.25+/-0.02. Simulations show that the difference is not explained only by the different material density, but also by the distribution of annihilation events, which changes significantly when positron are emitted in air. Factor for F-18 was 231±9 cps/(Bq/cm3). Other PET isotopes gave compatible results (thus different positron range was irrelevant for our setup). Geant4 and FLUKA gave compatible results within statistical uncertainties. **Conclusion**. MC simulations provide a feasible and accurate approach to the assessment of correction factors for a variety of radiation detection systems and geometrical setups. This work shows that both the MC toolkits used are able to properly support the calibration procedure of detectors dedicated to the monitoring of air exhaust systems.

EP489

FANC-survey of Administered Activity and Determination of Belgian Diagnostic Reference Levels for Radiopharmaceuticals in Daily Practice

T. Vanaudenhove[1], **M. Vandecapelle**[1], K. Muylle[2], F. Jamar[3], G. Moulin-Romsee[4], B. Dehaes[5], K. Bacher[6], A. Fremout[1]; [1]Health and Environment, Federal Agency for Nuclear Control, Brussels, BELGIUM, [2]Department of Nuclear Medicine, UZ Brussel, Brussels, BELGIUM, [3]Division of Nuclear Medicine, Cliniques universitaires Saint Luc, Université catholique de Louvain, Brussels, BELGIUM, [4]Department of Nuclear Medicine, Sint-Andries ziekenhuis, Tielt, BELGIUM, [5]Department of Nuclear Medicine, Ziekenhuis Oost-Limburg, Genk, BELGIUM, [6]Division of Medical Physics, Ghent University, Ghent, BELGIUM.

Aim: To analyze the distribution of activity administered to patients in Belgian nuclear medicine (NM) departments and deduce national diagnostic reference levels (DRLs) for several types of scintigraphy procedures. **Materials and methods:** Since the 1st of January 2015, all NM departments in Belgium have to register their values of administered activity for one specific diagnostic procedure either during 3 months or for 30 patients. These data are collected by the Federal Agency for Nuclear Control (FANC) and used to determine the national DRL for that specific diagnostic procedure. This value is then compared to values from national and international recommendations. If adequate, the DRL is also calculated in function of the patient weight. First and third quartiles (Q1 and Q3) are computed and used to determine the relative position of an individual department. Belgian DRLs are determined as mean activity for an adult of 70 kg. So far distributions of the administered activity and DRLs were determined for five diagnostic procedures concerning adult imaging : bone scintigraphy (^{99m}Tc-phosphates), myocardial perfusion scintigraphy (^{99m}Tc-radiopharmaceuticals - single injection, one-day and two-day protocols - and ^{201}Tl-chloride), thyroid scintigraphy (^{99m}Tc-pertechnetate and ^{123}I-NaI), pulmonary perfusion scintigraphy (^{99m}Tc-MAA) and PET-scan (^{18}F-FDG, based on incomplete data). **Results:** The Belgian DRL for bone scintigraphy was determined to be 750 MBq. For myocardial perfusion scintigraphy it was determined to be 740 MBq for single injections or two-day protocols and 380/980 MBq for one-day protocols (first/second injection) with ^{99m}Tc-radiopharmaceuticals and 110 MBq for single injections with ^{201}Tl-chloride. For thyroid scintigraphy it was determined to be 165 MBq with ^{99m}Tc-pertechnetate and 12 MBq with ^{123}I-NaI. For pulmonary perfusion scintigraphy it was determined to be 200 MBq. For PET imaging it was determined to be 265 MBq (based on incomplete data, can be reviewed). Approximately linear increase of the statistical quantities (average and quartiles) was observed in function of the patient weight for the bone, myocardial and PET procedures with no weight dependency for the thyroid and pulmonary procedures. **Conclusion:** Due to the large participation (close to 100% for the first four procedures), the determined DRLs are representative for Belgian NM departments. In order to optimize the administered activities in daily practice, every single NM department in Belgium was informed on how their administered activities were situated compared to the national DRLs to enable them, where needed, to take corrective actions and adapt their administered activities conform to the national and international guidelines.

EP490

Survey and decontamination of radium-223 dichloride for alpha-particle radionuclide therapy in clinical facilities

M. Hosono[1], S. Hohara[2], M. Inagaki[2], H. Yamanishi[2], G. Wakabayashi[2], T. Matsuda[2], K. Sakaguchi[1], K. Hanaoka[1], T. Ito[2]; [1]Kindai University, Faculty of Medicine, Osaka-Sayama, JAPAN, [2]Kindai University, Atomic Energy Research Institute, Higashi-Osaka, JAPAN.

Aim: Radium-223 dichloride (Ra-223), a bone-seeking α-emitting radiopharmaceutical for radionuclide therapy, was developed and already incorporated in the management of castration-resistant prostate cancer with multiple bone metastases (mCRPC). Considering the impact of Ra-223 for mCRPC and potentially other bone metastatic diseases, issues concerning radiation control for Ra-223 still require investigation including monitoring using conventional detectors and radioactive decontamination in nuclear medicine facilities. We therefore conducted experiments on monitoring and decontamination of Ra-223, and constructed procedures and standards for handling Ra-223 in clinical facilities. **Methods:** A property of Ra-223 and its daughters of Rn-219, Po-215, At-215, Pb-211, Bi-211, Po-211, Tl-207, and stable Pb-207 is that, in addition to emission of α and β particles, they emit photons of γ-rays and characteristic X-rays that are detected by conventional GM detectors and NaI(Tl) scintillator detectors. Our studies consisted of 2 parts, 1) Monitoring with survey meters for Ra-223, and 2) Swab decontamination. 1) We made a mock contamination source, and conducted spectrum analysis of Ra-223 emission using High Purity Germanium detectors (HP-Ge), and then clarified characteristics of conventional GM detectors and NaI(Tl) scintillator detectors as well as a dedicated α detector for measuring Ra-223 by considering parameters of time constant, distance, and speed. 2) Swab decontamination rates were measured by dropping Ra-223 on materials including linoleum and pig skin, and decontaminating by swab technique with parameters as follows; with or without drying of materials, swab paper soaked with cleaners such as EDTA and commercially available cleaners, and swabbing pressure. **Results:** Regarding monitoring of Ra-223, photon spectrum was analyzed with HP-Ge, and then conventional GM detectors and NaI(Tl) scintillator detectors were more efficient than a dedicated α detector which showed remarkably decreasing counting rates with increasing source to detector distance. In decontamination of materials, drying of materials diminished decontamination rates, which suggested necessity of rapid coping in case of contamination. Swab paper soaked with cleaners provided good decontamination rates of more than 90% for linoleum material. **Conclusions:** An α-emitter Ra-223 should be handled in nuclear medicine facilities according to standard procedures for radiation protection. Characterizing survey detectors for responses to α particles is critical for optimization of measurements. Rapid decontamination of materials before getting dried and use of appropriate cleaners were recommended in case of contamination.

EP491

Radiation safety of intraoperative ^{18}F-FDG Cerenkov Luminescence Imaging in breast cancer surgery

C. Sibley-Allen[1], M. Grootendorst[2], P. Croasdale[1], A. Jones[1], S. Gould[1], E. Lee[1], S. Allen[1], A. Purushotham[1,2]; [1]Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM, [2]King's College London, London, UNITED KINGDOM.

Aim: Breast-conserving surgery (BCS) with or without sentinel lymph node biopsy (SLNB) is the primary treatment for early-stage breast cancer. A key problem in BCS is that in the UK up to 25% of patients require a repeat operation due to positive or close tumour margins on postoperative histopathological analysis. ^{18}F-FDG Cerenkov luminescence imaging (CLI) has the potential to assess tumour margins intraoperatively, with a view to reducing the re-excision rate. Good control of radiation safety is required for the successful implementation of this technique in an intraoperative setting. This study provides occupational radiation safety data from a first-in-human clinical trial assessing feasibility of ^{18}F-FDG CLI-guided surgery in BCS. **Materials and Methods**: Research ethics committee approval and written informed consent were obtained (REC 12-EE-0493). Detailed written procedures and staff training for control of radiation dose were implemented. 150MBq ^{99m}Tc nano-colloid was administered for SLNB. 5 MBq per kg up to a maximum activity of 300MBq ^{18}F-FDG was administered for CLI between 1-3 hours prior

to surgery. Staff performing injections in nuclear medicine, support staff accompanying the patient to theatre, theatre staff and recovery nursing staff were monitored for radiation exposure and contamination. Personal dose equivalent was recorded using calibrated electronic personal dosimeters. Extremity doses were measured with thermo-luminescent finger dosimeters. **Results**: Data from 24 patients provided the following mean and standard deviation radiation doses per procedure: surgeon, 33(15) μSv; anaesthetist 11(5) μSv; nursing 6(3) μSv and support staff 9(4) μSv. The maximum dose to the surgeon from one procedure was 74 μSv. The maximum extremity doses per procedure were 250μSv and 150μSv for the left and right hands respectively. A conservative estimate based upon the maximum procedural dose suggests surgeons could perform 270 procedures before exceeding the 20mSv UK classified radiation worker annual dose limit. No personnel were found to be contaminated with radioactivity after the procedure. Two to three clinical waste bags were generated per procedure with detectable radioactivity levels. Surgical equipment was found to have low levels of radioactive contamination and was stored between 1-3 days until contamination was no longer detectable. **Conclusion**: Radiation safety data shows that ^{18}F-FDG CLI is a low-risk procedure but there is a need for careful control of radiation safety. Radiation expertise in planning, training and procedure supervision ensures safe execution of this novel intraoperative technique.

Pre-Dosing with Cold Antibody (HH1) Reduces Red Bone Marrow Absorbed Doses in Patients Treated with the Novel Antibody-Radionuclide-Conjugate 177-Lu-DOTA-HH1

J. Blakkisrud[1], A. Løndalen[2], J. Dahle[3], H. Holte[4], A. Kolstad[4], C. Stokke[1,5]; [1]The Intervention Centre, Oslo University Hospital, Oslo, NORWAY, [2]Department of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [3]Nordic Nanovector ASA, Oslo, NORWAY, [4]Department of Oncology, The Norwegian Radium Hospital, Oslo University Hospital, Oslo, NORWAY, [5]Oslo and Akershus University College of Applied Sciences, Oslo, NORWAY.

Aim: Red bone marrow is an organ that is often at risk in radioimmunotherapy, possibly leading to undesired haematological effects. ^{177}Lu-DOTA-HH1 is a novel anti-CD37 antibody-radionuclide-conjugate currently in a phase 1/2 study. Two pre-dosing regimens have been investigated, one with 50 mg unlabelled HH1 (Arm 1) and one without (Arm 2). The aim of this work was to compare red marrow absorbed doses for the two arms and to correlate absorbed doses with haematological toxicity. **Materials and Methods:** 8 patients with relapsed CD37+ indolent B-cell non-Hodgkins lymphoma were included for red marrow dosimetry. Four patients received pre-dosing with naked HH1 (Arm 1) four hours before a single injection of ^{177}Lu-DOTA-HH1, and four did not (Arm 2). Two patients in each arm received 10 MBq/kg of ^{177}Lu-DOTA-HH1 and two 15 MBq/kg. Adverse events were graded according to CTCAE v4. Uptake of ^{177}Lu-DOTA-HH1 in the red marrow was visible on SPECT/CT for both arms. SPECT/CT images from multiple time points were used to estimate activity concentration in the red marrow of lumbar L2-L4. Patient specific total marrow mass and cumulative activity were found by assuming that 6.7 % of total marrow is located in L2-L4. The absorbed doses, including both marrow self-dose and cross dose from remainder body, were calculated with OLINDA/EXM. **Results:** The mean absorbed doses to red marrow were 0.95 mGy/MBq for Arm 1 (with HH1 pre-dosing) and 1.52 mGy/MBq for Arm 2 (without HH1 pre-dosing). There was a statistically significant difference between Arm 1 and 2 (student t-test, p = 0.02). Total absorbed marrow doses ranged from 0.67 - 1.29 Gy in Arm 1 and from 1.55 - 2.06 Gy in Arm 2. Patients with Grade 3/4 thrombocytopenia received significantly higher radiation doses to bone marrow than patients with Grade 1/2 thrombocytopenia (p = 0.02). A weaker and non-significant difference between Grade 3/4 and Grade 1/2 neutropenia was found (p = 0.27). **Conclusion:** Pre-dosing with unlabelled HH1 reduces the absorbed red bone marrow dose for ^{177}Lu-DOTA-HH1 patients. Haematological toxicity was more severe for patients receiving higher absorbed radiation doses, indicating that adverse events possibly can be predicted by the calculation of absorbed dose to red marrow.

EP494

Therapeutic efficacy of brief intraperitoneal radioimmunotherapy of ovarian cancer using 213Bi-anti MISRII antibodies

R. LADJOHOUNLOU, Jr.[1], A. PICHARD[1], E. DEHAYES[1], V. Boudousq[1], F. Bruchertseifer[2], A. Morgenstern[3], I. Navarro-Teulon[1], J. POUGET[1]; [1]Inserm U1194, MONTPELLIER, FRANCE, [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY, [3]6 European Commission, Joint Research Centre, Institute for Transuranium Elements,, Karlsruhe, GERMANY.

Hypothesis: *W*e assessed in *in vitro* and *in vivo* models of ovarian cancer the therapeutic efficacy of 16F12 mAbs directed against Mullerian Inhibiting Substance type II receptor (MISRII) radiolabeled with ^{213}Bi **Methods:** *In vitro, b*oth direct and bystander cytotoxic effects were measured using clonogenic assay and standard medium transfer protocol. Typically, Clonogenic survival was assessed in SK-OV-3 donor cells expressing MISRII and exposed for 90 min to 0.06-0.5MBq/mL of 16F12 ^{213}Bi-mAbs. Bystander cytotoxicity was measured in recipient cells grown in non-radioactive culture medium preconditioned for 2 hours in the presence of donor cells. DNA double strand breaks (DSBs) were measured in both donor and recipients cells using immunofluorescent detection of gamma-H2AX and of 53BP1. *In vivo* we explored in athymic nude mice bearing intraperitoneal (IP) MISRII-expressing AN3CA tumor the therapeutic efficacy of brief-intraperitoneal radioimmunotherapy (BIP-RIT, 12.95 - 37 MBq; 37MBq/mg) or of intraperitoneal RIT (IP-RIT; 2.96-12.95 MBq; 37MBq/mg) using ^{213}Bi-16F12. BIP-RIT mimics hyperthermic intraperitoneal chemotherapy as used in clinic. It consists of intraperitoneal injection of high activities of radiolabeled mAbs followed 30 min later by wash of the peritoneal cavity with saline solution to remove unbound radioactivity. The biodistribution of radiolabeled antibodies following IP-RIT (12.95 MBq; 37MBq/mg) or BIP-RIT (37 MBq; 37MBq/mg) was assessed. **Results:** *In vitro* we showed in donor cells a strong direct cytotoxicity of 16F12 ^{213}Bi-mAbs. A significant bystander cytotoxicity was also measured in recipient cells. Genotoxic effects were also demonstrated as measured by the formation of DNA DSBs in both donor and recipient cells. *In vivo*, results of biodistribution indicated that tumour uptake of ^{213}Bi-16F12 during BIP RIT was higher than after IP RIT. The tumour-to-blood uptake ratio was 9 versus 3, respectively, one hour post RIT while it decreased down to 3 and 1, respectively, three hours post-RIT. Finally, a similar delay in tumor growth was observed in mice treated with 12.95 MBq of ^{213}Bi-16F12 following IP-RIT or treated with 37MBq using BIP-RIT. **Conclusions:** We confirmed *in vitro* the therapeutic efficacy of newly developed 16F12 ^{213}Bi-mAbs. *in vivo* results indicate that similar therapeutic efficacy and lower toxicity could be obtained with BIP-RIT compared with IP-RIT. BIP-RIT could be a new tool in the therapy of peritoneal carcinomatosis.

US DOE Tri-Lab (ORNL, BNL, LANL) Research Effort to Provide Accelerator-Produced ^{225}Ac for Radiotherapy

K. D. John; Los Alamos National Laboratory, Los Alamos, NM, UNITED STATES.

A general overview of the US Department of Energy Isotope Program's Tri-Lab (ORNL, BNL, LANL) Research Effort to Provide Accelerator-Produced ^{225}Ac for Radiotherapy will be presented with focus on accelerator-production and final product isolation methodologies. In addition, associated impacts on the quality of the accelerator-produced ^{225}Ac product quality as well as the quality of the associated ^{225}Ac /^{213}Bi generator will be presented. Specifics regarding ongoing evaluations of the accelerator-produced ^{225}Ac by independent end-users related to pre-clinical dosimetry and toxicity studies and broad logistical challenges associated with the accelerator-based production approach will also be discussed.

131I-mIBG treatment dosimetry: dependence on the fitting expression and the role of biodosimetry

I. Torres-Espallardo, J. Balaguer, A. Montoro, N. Sebastián, J. Loaiza, C. Olivas, J. Bautista, M. Adrià, B. Ibáñez, V. Pascual, J. Campayo, J. Villaescusa, A. Cañete, V. Castel, P. Bello; Hospital Universitario y Politécnico La Fe, Valencia, SPAIN.

^{131}I-metaiodobenzylguanidine (^{131}I-mIBG) is a targeted radiopharmaceutical mostly used for patients with refractory or relapsed neuroblastoma. Recent studies indicate a better response using multiple infusions of high dose ^{131}I-mIBG. Our treatment protocol consists of a two infusions separated within 3-4 weeks. The goal is to provide a whole-body (WB) dose of 4 Gy. WB-dosimetry was perfomed according to MIRD schema, where the time-activity curve follows a multi-exponential expression. The aim of this work is to study the variability of the total dose according to the fitting expression and the role of the biodosimetry in supporting the physical dosimetry. **METHODS:** Three patients undergoing 2 administrations each were considered. The WB absorbed doses were calculated for all the patients and administrations. WB-dosimetry was based on external measurements of dose rate. Several fitting expressions were used for each case: bi-, tri-, and penta-exponential curves. For one of the patients of this study cytogenetic procedures were performed to carry out the dicentric chromosome (DC) assay. Blood samples were obtained the day before ^{131}I-mIBG administration (d0) and 7 days after (d7). Also, in vitro irradiation of blood samples was conducted to set-up a dose-effect curve. The frequency of dicentrics was obtained from the analysis of 100 first-division metaphases. WB-dose estimation was carried out taking into account the frequency of dicentric and the Chromosomal Aberration Calculation Software (CABAS) using the dose-effect calibration curve from Montoro et al. (2005). **RESULTS AND DISCUSSION:** The variability of the estimated WB-dose ranges from 4% to 15% when comparing the different fitting curves and it is lower for the second administration for all the patients. The frequency of dicentrics for d0 and d7 were 0.03 ±0.017 and 0.44±0.066, respectively. Giving WB-doses of 0.47 ±0.44 Gy for d0 and 2.71±0.46 Gy for d7. The absorbed dose after fitting the dose rate measurements to a 3-phases exponential was 1.44±0.15 Gy for d7. We do not expect the same value obtained from both methods, but there is a good agreement. **CONCLUSION:** The biodosimetry tool DC-assay could help in estimating the second dose in case of sequential treatment since it takes into account the interindividual variability to radiation exposure and thus individual susceptibility to this type of treatment. Further studies with larger populations should be performed to evaluate the correlation between both methods and to elucidate whether biological dosimetry can be considered a tool for WB-dose assessment and predicting individual response following therapy with ^{131}I-mIBG.

EP497

A shared experience in the treatment of neuroendocrine tumors (NET) with 177 Lu dotatate

G. LOBO[1], M. VERAS[2], G. GOMES[1], C. TINOCO MESQUITA[2], J. MAGALHÃES[1], P. HUNGRIA[1], R. RAMOS[1], A. BARLETE[2], T. SANTOS[2], G. SADECK[2], W. KER[2], N. LAVATORI[2], A. COTRADO[2]; [1]NUCLEOS, BRASILIA, BRAZIL, [2]PROCARDIACO, RIO DE JANEIRO, BRAZIL.

Therapy with 177 Lu-dotatate has shown improvement in the outcome of patients with neuroendocrine tumors, especially for toxicity and progression free survival.To report a casuistry of two different nuclear medicine services in Brazil regarding the treatment of patients with NET and to evaluate the safety and progression free survival.We included patients with NET treated with 177Lu-dotatate in two distinct brazilian services from January 2008 until December 2015. Both services used the same protocol and were studied clinical, epidemiological, scintigraphic and progression free survival variables. In 48 patients (174 cycles), the average age was 58 years, 27 (56%) were women. Thirty-five (72%) completed 4 cycles. There was clinical deterioration in 1 patient, 6 died or had progression of the disease, and 5 lost follow-up (12 discontinued the treatment). Deaths were seen in 21 (43%) patients and progression free survival ranged from 1 to 129 months (mean 32 months). Progressive disease occurred in 4 cases. There was no interruption of the treatment with side effects. The most common ones were: alopecia, mild abdominal pain, nausea and vomiting and mild thrombocytopenia and leucopenia.In this studied population we found that treatment with 177 Lu-dotatate was safe and showed important benefit on progression free survival.

EP498

Relapse therapy with 177Lu-octreotate: safety assesment of multiple repeated cycles peptide receptor radionuclide therapy

A. Yordanova[1], K. Mayer[2], M. A. Gonzales-Caramona[2], M. Essler[1], H. Ahmadzadehfar[1]; [1]Nuclear Medical Department of the University Hospital of Bonn, Bonn, GERMANY, [2]Center for Integrated Oncology (CIO), University Medical Center Bonn, Bonn, GERMANY.

Peptide receptor radionuclide therapy (PRRT) is proved to be an effective therapy in patients with somatostatin receptor positive neuroendocrine tumors. Unclear is yet how many cycles of ^{177}Lu-octreotate can be repeated achieving an acceptable toxocity profile. The purpose of this study was to assess the safety of multiple repeated cycles PRRT with ^{177}Lu-octreotate in patients with recurrent neuroendocrine tumors. ***Methods:*** We summarized retrospective data from 15 patients treated with multiple repeated cycles of ^{177}Lu-octreotate between 2004 and 2015. The median of administrated activity was 63.8 GBq (53.9 - 96.6 GBq) in a median of 9 cycles with a range of 8 to 13 cycles. Nonhaematological and haematological toxicities were assessed by clinical reports and laboratory data. The occurrence of adverse events was then compared in three therapy groups.

The first group included side effects registered from cycle 1 to 4, the second: from cycle 5 to 8, and the third: cycle 9 to 13. We also compared the baseline laboratory assessments with data at the end of treatment. ***Results:*** We observed no life threatening adverse events (grade 4) during the treatment with ^{177}Lu-octreotate. Reversible haematological toxicity grade 3 occurred in 2 patients (13 %). No severe nephrotoxicity (grade 3/4) was registered. Surprisingly more grade 3 adverse events were recorded in the first therapy group (cycle 1-4) as in the other two groups (cycle 5-8 and cycle 9-13). Furthermore there was no significant change in the mean value of thrombocytes, leucocytes and plasma creatinine before and after the therapy. However, the mean haemoglobin fell from 14 g/dl to 11 g/dl. ***Conclusion:*** Relapse therapies with more than 8 cycles of ^{177}Lu-octreotate are well tolerated in patients with recurrent neuroendocrine tumors. ***Keywords:*** PRRT · ^{177}Lu-octreotate · neuroendocrine tumors · relapse therapy.

EP499

The effect of wrong organ volumes on the calculation of TIACs using a PBPK model in PRRT

D. Hardiansyah[1,2], N. J. Begum[1,3], P. Kletting[4], F. M. Mottaghy[5,6], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Radiation Oncology, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Digitale Signalverarbeitung, Information Technology Faculty, Hochschule Mannheim, Mannheim, GERMANY, [4]Department of Nuclear Medicine, University Hospital Ulm, Ulm, GERMANY, [5]Klinik für Nuklearmedizin, University Hospital, RWTH Aachen University, Aachen, GERMANY, [6]Department of Nuclear Medicine, Maastricht University Medical Center (MUMC+), Maastricht, NETHERLANDS.

Aim: The aim of this study was to investigate the effect of erroneously chosen wrong organ volumes as fixed parameters in the physiologically pharmacokinetic (PBPK) model for peptide-receptor radionuclide therapy (PRRT) on the accuracy of the predicted time-integrated activity coefficients (TIACs). **Material and Methods:** The reference *(R)* settings from the literature were used for the estimation of unknown parameters of a PBPK model from the biokinetic data of 15 patients (152±15 MBq of ^{111}In-DTPAOC). In this reference setting the organ volumes of liver and spleen were fixed individually to the calculated true volumes, while the kidneys volumes were set to the reference man values, i.e. male $V_{kidneys}$=0.31 l and female $V_{kidneys}$=0.27 l. The fittings were repeated with the following wrong organ volumes: mean values of the 15 patients (*W1*), twice of the mean values (*W2*) and half of mean values (*W3*). One organ volume was changed for each *W* case and other volumes were fixed to the true individual values. Predicted TIACs of the kidneys, tumor, liver, spleen, remainder, whole body and serum were calculated for both *R* and the 3 *W* cases. The relative differences *RD* between TIACs from *R* and *W* cases were analyzed. Relative differences *RD* values ≤ 10 % were considered as an accurate prediction of TIACs. **Results:** The maximum RDs were < 10% for most of the *W* cases except for wrong liver and kidneys volumes, i.e. twice of mean liver volumes: RD_{liver}=(-10±8)% and RD_{serum}=(6±4)%; twice of mean kidneys volumes: RD_{serum}=(-0.3±8)%, and half of mean liver volumes: RD_{liver}=(6±5)%. **Conclusions:** Estimation of predicted TIAC is little affected when using wrong organ volumes in the PBPK model. Thus, inaccurate determination of individual organ volumes to use in the PBPK model may still be sufficient for treatment planning in PRRT. However, the calculation of absorbed dose could be highly affected due to wrong volume estimation.

EP500

Comparison of carrier-added and non-carrier added Lu-177 DOTATATE in patients with Neuroendocrine Tumours

P. Roach, S. Hain, E. Hsiao, A. Aslani, **D. Bailey**; Royal North Shore Hospital, St Leonards, AUSTRALIA.

Background: In Australia, carrier-added (ca) LuTate ([Lu-177]-DOTA-Octreotate) has been used for over a decade for the treatment of patients with neuroendocrine tumours (NETs). In recent years, non-carrier added (nca) LuTate has become commercially available. nca Lutate has several advantages over the ca product, including a higher specific activity and less generation of waste products, particularly Lu-177m. A comparison of the two products in the same patients has not been previously reported. **Aim:** To compare ca vs nca LuTate in the same patients being treated for NETs. **Methods:** Four patients receiving therapy with ca Lutate who received the nca product in their previous (n=3) or subsequent (n=1) treatment cycle were included in this study. The average time difference between the ca and nca treatments was 10 weeks (range 9-11 weeks). Lutate was obtained from IDB Holland (ca) and ITG Germany (nca). Two experienced Nuclear Medicine specialists independently and blindly reviewed the whole body geometric mean LuTate images obtained at 2 time points (4hrs and 96hrs) post treatment for both the ca and nca products, noting all sites of disease. In the event of disagreement between the readers, a consensus read was subsequently performed. Retained activity (% of injected dose) was also calculated for each product at each of the 2 time points. **Results:** There were 28 sites of disease documented from all imaging available. Reader 1 reported 27 sites of disease (26 true positive, 1 false positive, 2 false negative) on both ca and nca Lutate images. Reader 2 reported 25 sites of disease on ca Lutate scans (24 true positive, 1 false positive, 4 false negative) and 20 sites of disease on nca Lutate scans (20 true positive, no false positive, 8 false negative). There was no statistical difference between nca and ca LuTate in detecting sites of disease by either reader at either time point in the 4 patients. On the consensus read, there was 100% concordance between ca and nca scans in the detection of disease sites. On quantitative analysis, there was no significant difference in calculations of retained activity between ca and nca LuTate (p=0.89). **Conclusions:** On both visual and quantitative analysis, there was no significant difference in the detection of disease sites and overall scan interpretation between ca and nca Lutate performed in consecutive treatment cycles in the same patients. These results suggest that the biodistribution of ca and nca LuTate appears to be equivalent.

EP501

Comparison and Evaluation of n.c.a. ^{177}Lu-[DOTA^{0}, Tyr3] TATE vs n.c.a. ^{177}Lu-[DOTA^{0}, Tyr3] TOC in (GEP-NENs) Treated Patients

G. S. Limouris[1], M. Paphiti[2], M. Souvatzoglou[1], L. E. Moulopoulou[1], R. V. McCready[2]; [1]National and Kapodistrian University of Athens, Athens, GREECE, [2]Royal Sussex County Hosp, Brighton, UNITED KINGDOM.

Aim: To evaluate and compare the dosimetry profile and efficacy of n.c.a. Lu-177 DOTA-TATE vs n.c.a. Lu-177 DOTA-TOC in GEP-NEN patients, initially i.a. treated with DOTA-TATE and after a median progression-free-survival (PFS) of more than 39 mo further i.v. retreated with DOTA-TOC, to confrontate the relapse observed. **Materials and Methods:** The average dose of n.c.a. Lu-177 DOTA-TATE, [Groupe A: 12 cases (63 catheterizations of the hepatic artery)], and n.c.a. Lu-177 DOTA-TOC [Group B: 4 cases (13 i.v. infusions, antecubitally)] administered to each patient was the same, i.e.7.3±2.3 GBq. For both groups repetitions did not exceed 6-fold with treatment intervals of 5-8 weeks to avoid a possible stunning effect. Blood samples were collected 2, 4, 8, 24 hrs p.i. to calculate the residence time in blood and in consequence the red marrow residence time; furthermore 24 hrs urine samples were collected too, to calculate the kidney excretion capability and the biological excretion half time. The % max uptake in organs and tumours was estimated by creating ROIs. Tumour Dosimetric calculations were performed using the OLINDA 1.0 code. **Results:** Non-carrier-added ^{177}Lu-[DOTA0,Tyr3]TATE blood and urinary radioacti-vity, expressed as a percentage of the injected dose was significantly lower compared as to non-carrier-added ^{177}Lu-[DOTA0,Tyr3]TOC, clearly depicted from the created time/activity curves; the tumour uptake (Bkg-corrected) was significantly higher as compared to non-carrier-added ^{177}Lu-[DOTA0,Tyr3] TOC. Absorbed dose kidneys' difference has been measured to be almost the same. The organ average radiation dose (mGy / MBq) of n. c. a. ^{177}Lu-[DOTA0,Tyr3] TATE / TOC was found as follows: (a) Liver tumour of 10 gr spherical mass was estimated to be 33.0/ 13.0 mGy/MBq, (b) Liver 0.19 / 0.55 mGy/MBq, (c) Kidneys 0.46/ 0.66 mGy/MBq, (d) Spleen 1.4 / 1.3 mGy/MBq and (e) Bone marrow 0.030 /0.036 mGy/MBq. **Conclusion:** Comparing the i.a. infused, n.c.a. ^{177}Lu-[DOTA0,Tyr3]-TATE vs the i.v. applicated -TOC (a) 2.53-fold higher dose in tumour was found, (b) 0.69-fold lower dose to kidneys was observed and (c) 0.83-fold in bone marrow, advocating the efficacy profile of i.v. infused-TOC following the -DOTA-TATE tumour relapse and to feasibly continuation of the re-treatment procedure.

EP502

Effect of time-varying radioactivity volume versus static volume in kidney absorbed dose estimates during ^{177}Lu-DOTATATE therapy

M. Sandstrom, U. Garske-Roman, D. Granberg, A. Sundin, M. Lubberink; Nuclear medicine and PET, Uppsala, SWEDEN.

Aim: As in all therapies using ionizing radiation, a patient-specific optimization of the delivered radiation should be performed in therapy with ^{177}Lu-DOTA-D-Phe1-Tyr3-octreotate (^{177}Lu-DOTATATE). To determine absorbed dose to the kidneys, where the self-dose gives the main contribution, the activity concentration in an organ needs to be determined at several occasions. As has been published previously by Sandstrom et al in EJNMMI physics 2015, the functional volume of the kidney varies over time after therapy with ^{177}Lu-DOTATATE. The aim of the present work was to study the influence of the change of the kidney volume over time on absorbed dose estimates during ^{177}Lu-DOTATATE therapy. ***Materials and Methods:*** Thirty patients (17 female and 13 male) with neuroendocrine tumors with high somatostatin receptor expression were included. SPECT/CT over the abdomen were acquired at 24, 96 and 168 h after infusion of 7.4 GBq of ^{177}Lu-DOTATATE. Absorbed doses to the kidneys were calculated from these data in two ways and then compared. Total amounts of radioactivity in the each kidney at each time point were calculated using 42% and 50% isocontour volumes of interest over the entire organ in the SPECT/CT images. In method A, the absorbed dose was calculated directly from the radioactivity concentrations in each measurement. In method B, the radioactivity concentrations were calculated by division of the total organ radioactivity at each time point with the volume from the 24 h measurement. Absorbed doses were than calculated by integration of the time-activity curve and assuming self-dose only. Correlation and agreement between absorbed dose estimates based on method A and B were assessed using regression and Bland-Altman analysis. ***Results:*** No significant differences between left and right kidneys were found, so the remaining results include both kidneys in each patient. The percentage difference between absorbed dose calculation for the right kidney using method A and using method B was 6.0 (-9.3 - 50.3) (Median (Min-Max)) when a threshold of 42 % was used and 7.8 (-3.4 - 46.4) for a 50 % threshold. The difference between method A and B was statistically significant ($P < 0.0001$). ***Conclusions:*** The use of a single organ volume in patients receiving therapy with ^{177}Lu-DOTATATE can result in significant difference in kidney absorbed dose estimates when compared to using a time-varying radioactivity volume. Use of a single volume leads to significant underestimation of absorbed dose to the major part of the kidney.

EP503

Comparison and Evaluation of ^{111}In-Octreotide Relapsed GEP-NENs Patients, Re-Treated With n.c.a. ^{177}Lu-[DOTA^{0}, Tyr3] -TATE

G. S. Limouris[1], M. Paphiti[2], I. Karfis[1], R. V. McCready[2]; [1]National and Kapodistrian University of Athens, Athens, GREECE, [2]Royal Sussex County Hosp, Brighton, UNITED KINGDOM.

Aim: To evaluate and compare the activity/dose uptake profile, efficacy and toxicity of n.c.a. Lu-177 DOTA-TATE in GEP-NETS, initially i.a. treated with high doses of In-111 Octreotide with a median progression-free-survival (PFS) of more than 32 mo, and i.a. retreated with n.c.a. Lu-177 DOTA-TATE, to confrontate the relapse observed. **Materials and Methods:** The average dose of In-111 Octreotide administered to each patient [17 cases (193 catheterizations of the hepatic artery] ranged from 4.07 GBq to 5.92 GBq for each patient; of them 5 pts relapsed and were retreated by extra therapy sessions with n.c.a. Lu-177 DOTA-TATE, in a dosage of 7.3±2.3 GBq. Repetitions of infusions for pts treated with In-111 Octreotide did not exceed 12-folds with treatment intervals of 5-8 weeks to avoid a possible stunning effect. Blood samples were collected 2, 4, 8, 24 hrs p.i. to calculate the residence time in blood and in consequence the red marrow absorbed dose; furthermore 24 hrs urine samples were collected too, to calculate the kidney excretion capability and the biological excretion half time . The % max uptake in organs and tumours was estimated by creating ROIs. Tumour Dosimetric calculations were performed using the OLINDA 1.0 code. **Results:** Retreated pts showed a median progression-free-survival (PFS) of more than 50 mo up to date. The organ average radiation dose (mGy / MBq) of In-111 Octreo-tide vs n. c. a. ^{177}Lu-[DOTA0,Tyr3] TATE estimations were found as follows: (a) Liver tumour of 10 gr spherical mass was estimated to be 10.8/ 33.0 mGy/MBq,

(b) Liver 0.14 / 0.19 mGy/MBq, (c) Kidneys 0.41/ 0.50 mGy/MBq, (d) Spleen 1.4 / 1.2 mGy/MBq and (e) Bone marrow 0.030 /0.040 mGy/MBq. **Conclusion:** Intra-arterially retreating relapsed GEP-NETs with n. c. a. ^{177}Lu-[DOTA0,Tyr3] TATE, followed a complete scheme of 12 sessions with In-111 Octreotide it is well achieved to control the disease and give a further survival time of 50 mo at least.

EP504

Peptide receptor radionuclide therapy in malignant pheochromocytoma and paraganglioma treatment

J. Nematyazar[1], B. Vatankulu[1], E. Demirci[2], S. Asa[3], M. Ocak[4], &. Uslu[1], L. Kabasakal[1]; [1]Istanbul University, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, istanbul, TURKEY, [2]Sisli Etfal Education and Research Hospital Department of Nuclear Medicine, istanbul, TURKEY, [3]Recep Tayyip Erdogan University, Department of Nuclear Medicine, Rize, TURKEY, [4]Istanbul University Faculty of Pharmacy, istanbul, TURKEY.

Aim: Many of Pheochromocytomas (PCC) and paragangliomas (PGL) are benign however 10% of PCC's and 25% of PGL's behave as malignant tumors. The current situation of PRRT in PCC and PGL treatment is limited to a few cases and scarce findings is available in the literature. In this study we aimed to demonstrate the efficacy of PRRT in treatment of malignant PCC and PGL. **Materials and Methods:** Lu-177 DOTA-TATE (PRRT) therapy applied for 17 patients who had no response to conventional treatments with intense diffuse lesion in Ga-68 DOTA-TATE PET-CT(SRS). Response to treatment evaluated with clinically by ECOG-WHO performance score, and follow up imaging results. Also hematologic-renal function results were followed. **Results:** 3,6-7,4 Mbq 177 Lu-DOTA-TATE per cures in 1 to 10 cycles was given for 7 (41%) patients with mPCC and 10 (59%) patients with mPGL diagnosis. No hematologic and renal toxicity was seen in both groups in 6-38 months follow-up. One of 7 patient with PCC didn't show uptake in PRTT despite high uptake in SRS, therefore did not continue to PRRT. In the follow up of remaining 6 patients according to PERCIST criteria in SRS, 2 patients show stable disease, 2 partial response and 2 progression. Also in 10 patients with PGL received PRRT regression seen in 3 patients, stability in 2 patients and progression in 1 patient and 4 patients did not evaluated with SRS because of not completing their treatment cycles up to study date. In PCC patients evaluation according to the clinical performance score improvement in performance score seen in 4 patients in 1 patient with progressive disease who later died deterioration in score was detected and 2 patients had no significant change in performance score. In PGL patients, 2 bedridden patients became active in there daily life, disappearance of the symptoms seen in 5 patients and 1 case with initially extensive disease showed worsening of score and died finally. **Results:** Although PCC/PGL are indolent disease they can be fatal in the presence of metastasis. PRRT application in this patient group showed an improvement in patients' performance score without side effects. In addition with promising results in partial response or stability of disease we predict with more number of patients and long-term follow-up studies in the near future this type of therapy will be a selection in PCC and PGLs' treatment algorithms.

Bone marrow dosimetry for the ^{223}Ra radiopharmaceutical based on skeletal absorbed fractions for alpha in the adult male

N. Benabdallah[1], M. Bernardini[2], C. de Labriolle-Vaylet[3], D. Franck[1], W. E. Bolch[4], **A. Desbrée**[1]; [1]Institut de Radioprotection et de Sûreté nucléaire, Fontenay-aux-Roses, FRANCE, [2]Nuclear Medicine Department, Hôpital Européen Georges Pompidou, Paris, FRANCE, [3]UPMC, Univ Paris 06 Biophysics - Nuclear Medicine Department, Hôpital Trousseau, Paris, FRANCE, [4]Advanced Laboratory for Radiation Dosimetry Studies (ALRADS), J. Crayton Pruitt Family Department of Biomedical Engineering, University of Florida, Gainesville, FL, UNITED STATES.

Purpose: ^{223}Ra-dichloride (Xofigo®, Bayer HealthCare) is the first alpha-emitter radiopharmaceutical that has received approval for the treatment of patients with castration-resistant prostate cancer metastasized to bones. In this treatment, bone marrow is the organ at risk. Therefore, the evaluation of the dose to this region should be performed. However, accurate dosimetry to the bone marrow is difficult because of its heterogeneous and complex structure and because of the short path of alpha particles. Moreover, current dose models do not account for energy or bone-site dependence as shown by alpha-particle absorbed fractions given in ICRP Publication 30. The purpose of this study was to calculate the values of alpha absorbed fraction (AFs) accounting for both their bone-site and particle-energy dependence and to determine the S-value of ^{223}Ra for the bone marrow and bone endosteum. **Methods:** A standard voxelized model of the skeleton for adult male, developed by the University of Florida and realized from microCT images of 40 year male was used to calculate AFs for alpha particle between 2 and 12 MeV. Alpha particles transportations in 32 bone sites were simulated with the MCNP6 Monte Carlo code combined with the internal dose assessment OEDIPE software. The source regions were the trabecular bone volume, active marrow, inactive marrow and trabecular bone surface. The radiosensitive target regions were the active marrow and the endosteum. Then, as the marrow cellularity is dependent of the age and the gender, the evolution of AFs with the marrow cellularity was investigated. **Results:** Values of alpha absorbed fraction were determined for the 32 bone sites and the series of source-target organ couples. Significant differences in AFs were seen between different skeletal sites and energies. The S-values for ^{223}Ra to bone marrow and endosteum obtained using this model were compared to the approximations given in ICRP Publication 30 and exhibits some discrepancies. Finally, a strong dependence on marrow cellularity was observed. **Conclusion:** These results will allow better determining the dose-limiting toxicities to bone marrow due to this new alphatherapy and correlating absorbed dose to therapeutic response.

EP506

Lymphocyte function following Radium-223 therapy in patients with metastasized, castration resistant prostate cancer

V. Barsegian[1], S. Müller[2], D. Möckel[1], P. Horn[3], A. Bockisch[2], M. Lindemann[3]; [1]Institute of Nuclear Medicine, HELIOS-Kliniken Schwerin, Schwerin, GERMANY, [2]Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [3]Institute for Transfusion Medicine, University Hospital Essen, Essen, GERMANY.

Therapy with the alphaemitter Radium-223 chloride (^{223}Ra) is an innovative therapeutic option in patients with metastasized, castration resistant prostate cancer. However, it has been described that this radiotherapy can lead to leukopenia and thrombocytopenia. Recent studies indicated that radiotherapy with beta and gamma emitting isotopes can not only induce numerical but also functional changes of leukocytes. The aim of our current study was to gain insight into the modifications that take place following a therapy with ^{223}Ra, an alpha emitting isotope, at the level of the lymphocyte proliferation as well as to identify a possible anti-microbial immunological impairment. Thus, in 11 patients treated with ^{223}Ra lymphocyte proliferation and the production of pro- and anti-inflammatory cytokines (interferon-γ and interleukin-10) after stimulation with mitogens and recall antigens were tested immediately prior to therapy and at day 1, day 7 and day 28 after therapy using lymphocyte transformation test and ELISpot. Our data indicate that lymphocyte proliferation and the production of interferon-γ and interleukin-10 remained unchanged after therapy. But a moderate reduction in the number of mononuclear cells (lymphocytes, monocytes, natural killer cells) could be observed, reaching a minimum at day 7. In conclusion, the results argue against an impairment of leukocyte functions after ^{223}Ra therapy. In consequence, anti-microbial immune responses most likely remain intact and allow an adequate immune response against pathogens.

EP507

Radium-223 dichloride bone-targeted therapy for metastatic salivary duct carcinoma: a case report

M. Manfredi[1,2], T. Angusti[1], M. Tucci[1], F. Vignani[1], C. Buttigliero[1], M. Airoldi[2]; [1]Azienda Ospedaliero-Universitaria San Luigi Gonzaga, Orbassano (TO), ITALY, [2]Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, Torino, ITALY.

Salivary duct carcinoma (SDC) is a rare pathology, frequently showing Androgen Receptor (AR) overexpression. Patients with this histologic variant benefit from the same androgen deprivation therapy (ADT) used in prostate cancer treatment. Radium-223 dichloride is a new radiopharmaceutical therapy approved for the control of bone pain in patients with castration resistant prostate cancer. Basing on the histological similarity between AR-overexpressing salivary duct and prostate carcinomas, we used Radium-223 treatment on a patient with castration-resistant SDC and osteoblastic bone metastases, achieving beneficial effects. A 75 years old male with AR positive SDC diagnosed in 2006, without other know comorbidity, was referred to our center in January 2015 for the control of bone pain via bone-targeted therapy, because of his incomplete response to analgesic therapy. Previous treatments included loco-regional radiotherapy, chemotherapy and ADT. Due to painful bone lesions, in 2013 the patient underwent palliative vertebral radiotherapy and in 2014 pain control therapy was added (paracetamol 3000mg/day, codeine 90mg/day). Radium-223 therapy was considered as a potential off-label therapeutic approach. A bone scan was performed to evaluate the extent of the pathology and the avidity for diphosphonates, confirming the presence of multiple bone metastases. A total of 6 administrations of 50 kBq/kg every 28 days of Radium-223 were given without delay or suspensions while continuing the planned ADT. During the treatment the patient reported a significant reduction of the bone pain, a better mobility and self-sufficiency with important upgrade in the quality of life. This improvement allowed us to initially reduce and then completely suspend the pharmacological painkiller therapy, even before the end of the Radium-223 treatments. A bone scan analysis was repeated preformed after the therapy showing a remarkable reduction in concentration of HDP in the vertebrae, pelvis, ribs and sternum. The clinical case reported here is, to our knowledge, the first study suggesting a potential beneficial effect of the use of Radium-223 in the treatment of SDC. Given the low frequency of SDC, it is nearly impossible to start a prospective study for the approval of Radium-223 treatment. However, in our opinion, the off-label use of Radium-223 in this rare pathology is well founded, for the good long-time control of the bone pain achievable with minor side effects. Additional studies aimed to the approval of the use of Radium-223 in other than prostate oncologic pathologies, are desirable to further prove the positive effects of this therapy.

EP508

The Features of ^{153}Sm-oxabiphore Kinetics in Bone Metastases at Radionuclide Therapy

D. A. Dzhuzha; National Cancer Institute, Kyiv, UKRAINE.

Aim of the study was to investigate the features of a early kinetics of therapeutic activities of ^{153}Sm-oxabiphore (^{153}Sm-EDTPA analogue) in bone metastases and the possibility of using its for the optimisation of treatment. **Materials and methods:** Results of complex scintigraphic investigations of 36 patients aged 38-78 years (13 males, 23 females) with breast, prostate, renal, and pulmonary cancer who were undergoing radionuclide therapy (RT) of bone metastases with ^{153}Sm-oxabiphore were analysed. The radionuclide studies included subsequent implementation of a radionuclide angioscintigraphy during 1 min after intravenous injection of 4130-4950 MBq of radiopharmaceutical (RP), dynamic scintigraphy during 90 min, and delayed whole body scanning in 2 h after beginning study. **Results**: The feature of angiograms with ^{153}Sm-oxabiphore is the shorting of descending segment and the rapid transform it in "plateau" (I type), which is determined of RP fixation in metastases at first passing of RP bolus through the vessels. At intensive RP fixation the descending segment was absent and the ascending segment transformed directly in "plateau" (II type) or slowly ascending curve (III type). The level of RP fixation at first bolus passing was determined with help of fixation coefficient calculated according the formula: $C_f = 100h/H$, where C_f - fixation coefficient, %; H - the height of the peak of angiogram; h - the height of the peak of angiogram till a low point of the descending segment. The angiograms of I type were registered in 57.9 % of bone metastases, in these cases C_f consisted 51.0-93.6 %, in means - 79.6±1.8 %. The angiograms of II type were determined in 17.5 % of bone metastases, angiograms of III type - in 24.6 %. At whole body scanning a relative accumulation of ^{153}Sm-oxabiphore in bone metastases consisted 105.0-957.0 %, the mean value - 212.8±20.1 %. The significant correlation between the relative accumulation of ^{153}Sm-oxabiphore and ranged C_f was determined ($r=0.57$, $p<0.01$). The control osteoscintigraphies after 4-6 months were made in 10 patients. The significant correlation between types of angiograms and results of RT (progression, stabilization, partial regression) was determined ($r=0.86$, $p<0.01$). **Conclusions:** Considerable variability of the early ^{153}Sm-oxabiphore kinetics in bone metastases was determined. The features of angiograms from bone metastases with intensive accumulation of the radiopharmaceutical are a transitions from the ascending segment to "plateau" or slowly ascending curve. This character of the radiopharmaceutical fixation at angioscintigraphy may be a prognostic factor of the RT efficacy.

EP509

Radiation Protection Issues of liquid based alpha emitters

P. J. O'Sullivan; Maidstone and Tunbridge Wells NHS Trust, Maidstone, UNITED KINGDOM.

Purpose: Radium 223 is being seen as a significant step forward in the treatment of prostate cancer patients with bone metastases. Many nuclear medicine departments across the UK are beginning to roll out services to provide the radionuclide to their patients. For many of these departments, it is the first time they will be dealing with liquid-based alpha emitters and the substantial risks they bring. This work aims to investigate the potential doses from inhalation, ingestion and sharps injuries as well as the potential methods in detecting such contamination. Methods: Volatile spills, sharps injuries, patient body waste and the cremation and resulting ashes of a patient will be studied to find the possible staff dose from radium 223. Monte Carlo simulations will be applied in the study, particularly in the case of sharps injuries to find the absorbed dose in the surrounding tissue. Possible methods such as the use intrinsic gamma camera, whole body scans and faecal measurements will tested to see if they are a practical reality in detecting the presence of contamination. Results: Preliminary calculations show that the annual worker constraint will be breached upon inhalation of 0.869kBq (~ 0.001ml) and ingestion of 60kBq (~0.05ml). In most situations, the inhalation of radium 223 looks unlikely due to the very high vapour but other situations are being studied.Conclusion: The low activities show the need for this work to be carried out so departments can make accurate risk assessments on the use of radium 223.

EP510

Role of psychological status related to pain outcome and bone lesion dosimetry in patients with bone metastatic Castration-Resistant Prostate Cancer (mCRPC) treated with 223Radium

V. Frantellizzi[1], G. A. Follacchio[1], B. Cassano[1], M. Pacilio[2], F. Proietti[1], R. Pani[1], R. Pellegrini[1], G. De Vincentis[1]; [1]Sapienza University of Rome, Rome, ITALY, [2]S. Camillo Forlanini Hospital, Rome, ITALY.

It has been well observed that in men with CRPC and symptomatic bone metastases, 223Radium-Dichloride (223Ra) has shown to improve Overall Survival. Pain is the most common symptom developed by patients with bone metastases with psychological status implications. The purpose of our study was to evaluate the psychological distress, (such as social support, functional status, depression and anxiety), related to trend of pain response and bone lesion dosimetry during 223Ra treatment. 55 consecutive patients affected by bone mCRPC were examined. A total of 195 cycles were administred with 50 KBq/Kg IVq4w of 223Ra. ECOG Performance Status mean value was 1.48 and Gleason Score average value was 8. Mean age was 76.2±6.07. Patients were evaluated with Brief Pain Inventory(BPI) Scale. To examine quality of life (QoL) endpoints, patients were asked to complete the EORTC QLQ-C30 questionnaire and the bone metastasis module, QLQ-BM22. Both were submitted at baseline and after every cycle of therapy. Edmonton Symptom Assessment Scale (ESAS) was used with the same timing to evaluate response to treatment. Absorbed Dose to selected bone lesions in a group of patients during 223Ra treatment was assessed through an image-based dosimetric approach. 55 patients underwent 1 cycle of therapy with 223Ra. Of these 47% had psychological distress, with an average value of 7.8 in BPI Scale for pain outcome. Second cycle was administered to 51 patients. Pain mean value of these was 7.13 and psychological distress was present in 39%. The evaluation of functional scales after third cycle showed that of 38 patients, 32% had psychological distress with a pain average value of 6.4. Analyzing patients that underwent 6 cycles, they showed that 27% had psychological distress and the mean value of BPI had fallen to 5.6. Preliminary data analysis on bone lesion dosimetry suggested a positive correlation between pain, psychological distress and adsorbed dose: first ones decreased with adsorbed dose growing up. 223Ra therapy has an impact on QoL in all its dimensions, in particular as regards psychosocial aspects. In patients with painful bone metastases from prostate cancer there is a strong relationship between pain reduction and improvement of the subjective psychological distress. Even though bone lesion dosimetry is suitable only for single skeletal segments while pain response is a global evaluation parameter, future study on a large cohort of patients will help to understand the real role of internal dosimetry.

EP511

^{223}Ra standardized image. Utility of bone scintigraphy in the response evaluation to treatment with ^{223}Ra

D. Balaguer, P. Abreu, H. Rodríguez, I. Latorre, T. Mut, M. Plancha, M. Guasp, M. Riera, D. Reyes, E. Caballero; Dr. Peset Hospital, Valencia, SPAIN.

Aim: ^{223}Ra is indicated for the treatment of adults with castration-resistant prostate cancer with symptomatic bone metastases and not known visceral metastases. Due to its predominantly α-decay, a standardized distribution image of ^{223}Ra has not been stablished yet. Response to ^{223}Ra treatment has not been assessed by bone scintigraphy with 99mTc-HDP (BS) either, as it was not contemplated in the Alsympca study. This study aims to: 1. Obtain a standardized distribution image of ^{223}Ra. 2. Evaluate qualitatively the therapy response to 223-Ra by BS. Material and methods: 1. To obtain a distribution image of ^{223}Ra we detected the gamma emission of its decay (less than 2%). We searched, according to previous studies, the photons' photopeaks with high probability of emission and the energy intervals that were suitable for the gamma camera Siemens E.CAM 2H. Tests were done with differents photopeaks, combining different parameters of the gamma camera, different time intervals from injection to image acquisition, and different acquisition times. All this was done looking for an image that we could correlate to the baseline BS. 2. A total of 13 patients were enrolled from 14/07/2015 to 01/04/2016, with 43 cycles administered. We evaluated response qualitatively (number and activity of the lesions) with BS after 3 and 6 cycles of treatment, classifying the response in relation to baseline BS in 4 categories: Response (R), stable disease (SD), improvement in some lesions and worsening of other (Imp / Wrs) and Progression (PD). Results: 1. The most suitable image was obtained 4 hours after the injection of 223-Ra, with the detection of 4 photopeaks (82, 154, 269 and 351 Kevs), the use of a high-energy collimator and an acquisition time of 10 minutes for static images, or 4 cm / min for whole body image. 2. We obtained 6 response evaluations after 3 cycles, with 16.7% of R, 16.7% SD, 50% of Imp / Wrs and 16.7% of PD. We need a longer follow up in order to obtain results after 6 cycles. Since this was an exploratory assessment, as it was not contemplated in the Alsympca study, the evaluations had no clinical implications themselves, they did not result in treatment discontinuation. Conclusions: The standardized scintigraphic image of ^{223}Ra can be useful to visualize where the radiopharmaceutical is deposited and thus to assess its influence on the effectiveness. A correlation of these images with the BS after 3 and 6 cycles is necessary.

EP512

Initial experience with ^{223}Ra-dichloride treatment

A. M. Yepes Agudelo, P. Bello Arques, P. Borrelli, P. Olivan Sasot, V. Vera Pinto; HUP La Fe, Valencia, SPAIN.

ObjectiveTo present our experience with ^{223}Ra-dichloride treatment in patients with prostate cancer castration-resistant with bone metastases, without visceral metastases evidence.Material and methodsTreatment was administered to 14 patients, ages ranging from 50 to 82 years, with

prostate cancer painful bone metastases. Gleason score ranged from 5 to 10. All of them had positive bone scintigraphy, and were divided into 4 categories:[[Unsupported Character - Symbol Font •]] 4 Superscan[[Unsupported Character - Symbol Font •]] 8 > 20 metastases[[Unsupported Character - Symbol Font •]] 1 between 6 - 20 metastases[[Unsupported Character - Symbol Font •]] 1 less than 6 lesions^{223}Ra treatment administration protocol used was one dose of 55 KBq/kg/4 weeks intravenous until 6 cycles were completed. Treatment was administered under supervision of a nuclear medicine specialist; patients were discharged with alpha emission radiopharmaceuticals radiological protectionrecommendations.ResultsAmong the 14 patients treated:[[Unsupported Character - Symbol Font •]] Three had finished treatment and are radiologically stable, clinicallybetter and with levels of PSA and alkaline phosphatase diminishing;[[Unsupported Character - Symbol Font •]] Three are still in treatment.[[Unsupported Character - Symbol Font •]] Eight have abandoned treatment due to disease progression that in most of the cases included the onset of visceral metastases and just in one case sustained thrombocytopenia.Adverse effects most frequently presented were mild and transient, consisting in hematological alterations (anemia and thrombocytopenia) in 5 patients. Just one patient presented diarrhea. In 57% of the patients the usage of painkillers was diminished due to the less pain presented. In 29% of them no improvements in pain were achieved, and in 14% the pain was worsened due to bone metastases progression.Conclusion^{223}Ra-dichloride treatment has being a well-tolerated therapy, with few and mild adverse effects. Achieving a satisfactory pain management in the majorityof the patients, therefore achieving a better life quality in those patients.Further analysis with a bigger patients sample and the introduction of this treatment in earlier disease stages is required.

EP513

The Use of Radium-223 Chloride Therapy in Patients with Castration-Resistant Metastatic Prostate Cancer: A District Hospital Experience

N. C. Mcaddy, H. H. Lee, P. O'Sullivan, P. Crawley, S. Beesley, M. Naji; Maidstone Hospital, Kent, UNITED KINGDOM.

Background The ALSYMPCA trial showed that treatment with Radium-223 resulted in improved survival and quality of life in patients with castration-resistant metastatic prostate cancer (CRPC) and symptomatic bone metastases. We report our one-year experience with Radium-223 in a district general hospital, to add to the body of data. We reviewed the pain evolution, symptomatic outcome, haematological profile and side effects on our patients and evaluated the potential use of biochemical markers for follow up. **Methods** Data was collected prospectively on eligible patients with symptomatic bone metastases, who were referred for Radium-223 therapy. A Radium-223 administration regime of 6 cycles in accordance with predefined protocols was used. Blood tests were performed before each treatment cycle. The haematological and general side effects were documented. The PSA, Albumin and ALP were also recorded. Patients were asked to record their pain using a visual analogue scale (VAS) and their quality of life on a scale of 1 to 10 (pre-treatment, mid treatment and post-treatment). Patients were contacted on regular basis to identify any adverse side effects. **Results** Patients, who completed the 6 cycles of Ra-223, reported a measurable improvement in pain with an average fall in pain score of 4. However, treatment effect on the quality of life was rather variable. Improvement was observed in some patients, but remained stable or deteriorated in others. Albumin on average fell by 0.8 points. The ALP dropped in most patients by an average of 270 points (Range 8-816) but the PSA responded variably. In 8 patients, the treatment had to be abandoned, 3/8 unfortunately deceased, 1/8 patient with pre-existing inflammatory bowel disease developed worsening diarrhea and had to stop the treatment. Treatment in the remainder was abandoned due to clinical deterioration. 5/8 patients of the abandoned group had chemotherapy prior to the Radium treatment. **Conclusions** Results in our DGH are comparable to those described in the literature. We observed an overall improvement in the pain score. ALP is shown to be a reliable biomarker but the PSA responded variably. Our data support the safety profile of Radium and only few patients developing significant haematological or general side effects. Our study supports the current indications that when referred early, possibly prior to chemotherapy, patients are more likely to complete 6 cycles and therefore may have better overall outcomes.

EP514

Advanced Prostate Cancer Treatment with 223Ra-dihloride: experience from Drammen, Norway

K. Nikoletic, F. Laszlo; Vestre Viken HF, Nukleærmedisinsk seksjon, Drammen, NORWAY.

Aim: Overview of the history and data regarding patients with advanced prostate cancer treated with ^{223}Ra-dichloride (Xofigo). ^{223}Ra-dichloride is an alpha-particle emitting radiotherapeutic drug used for the treatment of patients with castration-resistant prostate cancer (CRPC), symptomatic bone metastases and no known visceral metastatic disease. Method: We investigated total number of 14 patients (60-88 years old) treated with ^{223}Ra-dichloride in Nuclear medicine Department. Since the most common adverse reaction is hematologic laboratory abnormalities, all patients were investigated for hemoglobin, neutrophil granulocytes and thrombocytes 10 days before each injection. If the values were within recommended, patient was administered with 50 kBq/kg by slow intravenous injection over 1 minute every 4 weeks for 6 doses. Results: Until now 5 of 14 patients completed the treatment with 6 injections. Among 5 patients who completed therapy, 2 had an excellent therapy response with significant decrease in bone pain; 2 had a good response and 1 patient characterized his condition as `unchanged`. All 5 patients who completed therapy had significant fall in ALP values (median decrease of 34.2%), but PSA values before and after the therapy were inconclusive. The ^{223}Ra-dichloride was discontinued in 8 patients. Out of these 8 patients 4 received 3 injections before the therapy was disclosed and each of the remaining 4 patients received 5, 4, 2 and 1 injection before the discontinuation. Treatment was discontinued because of radiologic progression in 5 patients, diarrhea in 1, development of kidney insufficiency of unknown origin in 1 and bone pain progression in 1. One patient is currently undergoing therapy. This patient has received 2 injections and is without complications. Conclusion: ^{223}Ra-dichloride is an additional therapeutic option for patients with CRPC. In our limited group of patients who completed therapy, ^{223}Ra-dichloride was well tolerated with positive effect on bone pain in 4/5 patients and a median decrease of 34.2% in ALP levels. Additional therapeutic results are necessary to estimate future possibilities of the use of ^{223}Ra in patients with symptomatic bone metastases.

EP515

Radium-223: kinetics and therapeutic response against metastatic prostate cancer

I. A. Marques[1,2,3], **A. M. Abrantes**[1,3,4], A. S. Pires[1,3,5], G. Costa[6], F. Caramelo[1,7], E. Tavares-Silva[1,8], M. F. Botelho[1,3,4]; [1]Biophysics Institute, IBILI-Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [2]Faculty of Pharmacy, University of Coimbra, Coimbra, PORTUGAL, [3]CIMAGO, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [4]CNC.IBILI, University of Coimbra, Coimbra, PORTUGAL, [5]Faculty of Sciences and Technology, Coimbra, PORTUGAL, [6]Department of Nuclear Medicine, CHUC, Coimbra, PORTUGAL, [7]Laboratory of Biostatistics and Medical Informatics, IBILI-Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [8]Department of Urology and Transplantation, CHUC, Coimbra, PORTUGAL.

Aim: Study the effects of ^{223}Ra in prostate cancer (PCa) cell lines differing on hormonal receptors. Besides this the kinetics of Ra-223 and ^{99m}Tc-HMDP was also studied. An osteosarcoma (OS) cell line was used as control cell line. **Materials and methods:** Three tumor cell lines PC3 (metastatic PCa), LNCaP (non-metastatic PCa) and MNNG-HOS (OS) were incubated with the ^{223}Ra (0.5 μCi/mL) or ^{99m}Tc-HMDP (25 μCi/mL), in the presence or absence of calcium channel inhibitors. Samples at 5, 30, 60, 90 and 120 min were taken for separating sediment from supernatant. Retention studies were performed after cells radiopharmaceutical uptake. Uptake and retention percentage of ^{223}Ra and ^{99m}Tc-HMDP was calculeted after measuring the radioactivity of both fractions in a well counter, in CPM. Clonogenic assay was performed by irradiating cells with increasing doses (0.25 to 30 mGy), plating 1500 (for PC3) or 2000 (for LNCaP) cells in 6-well plates and waiting for 12 to 20 days (depending on the cell line). At the end, colony formation was evaluated using crystal violet staining and survival factor (SF) calculation. **Results and discussion:** Results show that, at 180 minutes, the percentage of ^{223}Ra uptake by PC3 is twice higher (1.8±0.1%) than by MNNG-HOS (0.97±0.06%). A similar uptake profile was obtained for LNCaP cells (1.59±0.13%). The uptake of ^{223}Ra by PC3 is higher (1.8±0.1%) than the uptake of ^{99m}Tc-HMDP (0.2±0.05%). In MNNG-HOS cell line the same is observed. On the other side, LNCaP cell line showed an uptake profile similar between two radiopharmaceuticals. Preliminary studies show that retention percentage of ^{223}Ra is higher for all cell lines, compared to ^{99m}Tc-HMDP. Preliminary results also suggest that, in presence of the inhibitor, the decrease of uptake it is not the same for all cell lines. Preliminary clonogenic assay results show that survival factor (SF) decreases with increasing ^{223}Ra doses (e.g: for 4 mGy, SF was 32,7±5,8%). **Conclusion:** These results suggest that, although both radiopharmaceuticals are analogues of calcium, the uptake and retention mechanisms may be different. Irradiations of CaP cell lines with ^{223}Ra decrease cell survival in a dose dependent way, at low doses. Thus, this study also enhances the therapeutic potential of ^{223}Ra in the treatment of metastatic PCa. The authors would like to thank Foundation for Science and Technology (FCT) (Strategic Project CNC.IBILI: UID/NEU/04539/2013), COMPETE-FEDER for financial support.

EP516

Considerations Following the Death of Recently Treated Radium-223 Patients

A. Smout, M. Pryor, **P. J. Hinton**; Royal Surrey County Hospital, Guildford, UNITED KINGDOM.

Aim Radium dichloride (Xofigo©) has been licensed for use in the management of metastatic prostate cancer since November 2013. Regularly treating near end of life patients is a new experience in nuclear medicine departments and if a patient dies whilst still radioactive, careful thought is needed about advice given to various groups coming into contact with the body. These groups consist of funeral workers, embalmers and cremation workers. Published excretion data is used as the basis for current advice given, but following count-rate measurements from the cremated remains of three patients we now have some initial data to validate the accuracy of assumptions used. **Methods** As of April 2016, 76 patients have been treated at the Royal Surrey County Hospital with 336 doses of radium-223. Seven patients have died before completing all six cycles and of these, four patients have died whilst still being radioactive. Three were cremated and one was buried. Excretion assumptions are based on published data which states 99% clearance from the blood at 24 hours, 5% urinary excretion, 44-77% bone uptake at 4 hours and a median of 76% whole body excretion at 7 days. Advice to staff handling the corpse is based on this data and simple assumptions involving the time of death after treatment. A calibration factor has been derived for standard contamination monitors using known Ra-223 activity in geometry applicable to patient remains. Assuming that all Ra-223 activity remains in the bones after cremation, a simple model can be derived to estimate the activity remaining in the corpse at death to determine suitable radiation protection advice. **Results** Measurements were made at 30cm from the remains of 3 cremated patients using a standard contamination monitor. These patients died at 17, 39 and 45 days following their last treatment and had an estimated retained 450, 60 and 130 kBq at time of death. **Conclusions** A simple assumption of 25% of the administered activity, decay corrected to the time of death can be used to give an estimate of the activity remaining in the patient at time of death providing death occurs at least one week after treatment. This value can be used to assist in the provision of radiation protection advice to funeral workers, embalmers and cremation workers coming into contact with the corpse.

EP517

Radium-223 in mCRPC: Looking at patients, changes in quality of life and imaging results

M. L. De Rimini[1], G. Mazzarella[1], G. Borrelli[1], M. Bifulco[1], P. Muto[1], V. Montesarchio[2], L. Leo[2], F. Uricchio[3]; [1]Nuclear Medicine AO Ospedali dei Colli - Monaldi, NAPLES, ITALY, [2]Oncology Dept AO Ospedali dei Colli - Monaldi, NAPLES, ITALY, [3]Urology Dept AO Ospedali dei Colli - Monaldi, NAPLES, ITALY.

Introduction: Radium 223 dichloride (^{223}Ra-Alpharadin) is the first alpha particle emitting bone targeting agent approved for use in mCRPC patient (pts) with bone metastases and no visceral metastases. **Aim**: -to confirm ^{223}Ra feasibility in mCRPC pts affected with severe pain and impaired ECOG Performance Status (PS: n.v. = 0), -to report our results in terms of changes of quality of life and -to monitor Bone Scan (BS) imaging changes. **Methods**: 10 mCRPC pts (65-84 yrs; ECOG PS: -8/10 pts = 1-2; -2/10 pts= 3) with multiple bone metastases at baseline BS, no visceral metastases, severe pain with functional limitations, were enrolled for ^{223}Ra therapy (50 kBq/kg, 6 administrations, 4 weeks intervals/each other). Pts underwent WB - SPECT/CT BS at Baseline and 40 days after the end of therapy cycle. At baseline: -ALP ≥ 115 U/L; -Gleason Score at diagnosis: >8 in all pts. **Results**: Alpharadin was generally well tolerated in all pts but, at the 5th dose, 2/10 pts, with severe impairment of physical status from the beginning, showed worsening of PS and thrombocytopenia. They were forced to discontinue therapy, so our results regard the last 8/10 pts. All of them showed pain relief, with a peak at the 3rd-4th week of therapy, and discontinue any pharmacological treatment for pain. No correlations were observed between PS improvement and changes in PSA or ALP, that were no significant anyway. 3/8 pts showing severe movement limitations at baseline underwent full remission of metastases at BS control, with full pain relief and functional recovery. Nevertheless, pain relief occurred in the last 5/8 pts, with no metastases improvement at BS. ECOG results: -2/8 pts PS pre ^{223}Ra =3; post ^{223}Ra =1; -6/8 pts: pre ^{223}Ra = 1-2; post ^{223}Ra =0-1. **Conclusion**: In our experience Alpharadin is generally well tolerate. Worsening in the clinical status can occurre in pts severely compromised already at baseline, due to disease and other therapies. ^{223}Ra can help pts affected with severe pain by inducing effective pain relief and functional PS recovery, modifying pts quality of life. The persistence of metastases at post Alpharadin BS control does not rule out the success of the therapy in terms of pain relief and improvement of quality of life.

EP518

Investigation into the feasability of using EPDs to perform simple dosimetry modelling on Radium-223-dichloride therapy patients

A. H. Shaylor; Maidstone Hospital, Maidstone, UNITED KINGDOM.

Aim: The ability to quantify the dynamic activity distribution and the resulting organ and whole body doses in patients undergoing nuclear

medicine therapies may allow clinicians to monitor the likely efficacy and potential side effects associated with therapeutic procedures. The aim of this investigation is to determine whether Electronic Personal Dosemeters (EPDs) worn by the patient can gather sufficient information to provide useful dosimetric information by modelling the signal mathematically. Ra223 dichloride therapy was assessed in this investigation. **Materials and Methods**: All Ra223 patients assessed for treatment at Maidstone Hospital undergo a nuclear medicine Tc99m HDP bone scan within six weeks. For the purposes of this investigation the activity distribution of the bone scan is assumed to be the same as that of the Ra223 therapy distribution. The signal can then be modelled via Monte Carlo or analytical techniques to various EPDs located at different sites on the body (e.g. ankle, neck). The signal can be simulated for up to one week after administration to assess the cumulated activity of the therapy, and via the assumed tumour distribution, inferred by the bone scan, the total cumulated activity within specific tumours. Different EPD sites and number of EPDs were assessed in this study. **Results**: The cumulated activity distribution was converted to a dose distribution, including a whole body dose. Using EPDs simultaneously at different sites on the body enables the uncertainties associated with individual tumour doses to be substantially lowered. The assessment of whole body dose was adequate using one EPD. **Conclusion**: This investigation assesses the limitations and potential benefits of using EPDs to estimate dose distributions of Ra223 therapies. This work shows that EPDs have the potential to be used to monitor whole body dose and if extended to patient studies would not require additional hospital visits for the patient. Further work could combine early Ra223 gamma camera images with the EPD data. This study concludes that a pilot study is performed with real patient data to see if the potential benefits of this approach can be realised.

EP519

Xofigo theraphy needs interdisciplinary cooperation

R. P. Jóba, S. Czibor, I. Szilvási; Medical Center - Hungarian Defence Forces, Budapest, HUNGARY.

^{223}Radium dichloride (Xofigo) is an effective therapeutic option for patients with symptomatic multiple bone metastasis of castration-resistant prostate cancer without soft-tissue metastasis (mCRPC). Several clinical trials are going on to define pretreatment clinical criteria for the most optimal use of Xofigo in the dynamically changing therapeutic stage. *Objectives:* The aim of our study was to evaluate clinical data before, during and after Xofigo treatment. In the last 21 months 21 patients with mCRPC were treated in our department. The median follow-up period was 4,54±3 months. 7 patients had previous chemotherapy (docetaxel). *Methods:* Bone scintigraphy was performed before and after the last injection of Xofigo.The serum level of prostate-specific antigen (PSA) and alkaline phosphatase (SAP) were measured before and every eight weeks; hemoglobin, the absolute number of granulocytes and thrombocytes were measured before and every second week during the Xofigo treatment. Bone pain was monitored by a subjective scoring system. *Results:* Xofigo treatment had to be finished after 1-3 injection in 4 patients because severe granulo- and/or thrombocytopenia. In 3 patients Xofigo therapy was temporarily suspended (but continued 6-8 weeks later) due to reversible cytopenia. Xofigo-induced critical cytopenia occurred more frequently in patients with previous chemotherapy. Xofigo was also terminated in two other patients (due to newly developed brain metastasis and relapsed peptic ulcer respectively). 10 patients had a full course of Xofigo treatment. The average number of injections was 4,53 per patient. No death occurred during the treatment. In 20 out of 21 patients, metastatic bone pain has significantly decreased. However 2 patients presented severe ischialgia with neurological symptoms. Both patients had the same symptoms in their history long years before. We indicated MRI examination, and in both cases radical nerve compression was found. Serum PSA was slightly increased with theexception of 2 patients. SAP tended to be decreasing continuously, however, it started to rise later in the follow-up period. Bone scintigraphy demonstrated diminishing of abnormally increased focal osteoblastic activity. *Conclusions:* Our experience with a limited number of patients underlines the importance of detailed knowledge of the history of the patients before the planned Xofigo therapy. It needs close interdisciplinary collaboration with uro-oncologists. In patients with previous low back pain and neurological symptoms in the history, neurological examinations MRI included are advised. Previous chemotherapy seems to be increase the risk tof interrupting Xofigo treatment.

EP520

^{223}Ra treatment: potential efficacy parameters and safety

D. Balaguer, P. Abreu, H. Rodríguez, I. Latorre, T. Mut, M. Plancha, M. Guasp, M. Riera, D. Reyes, E. Caballero; Dr. Peset Hospital, Valencia, SPAIN.

Aim: ^{223}Ra is indicated for the treatment of adults with castration-resistant prostate cancer with symptomatic bone metastases and not known visceral metastases. Its approval came after demonstrating particular advantage in survival and control of bone pain. This study aims to: 1. Assess efficacy parameters of ^{223}Ra. 2. Evaluate the toxicity of ^{223}Ra. Material and methods: 1. A total of 13 patients were enrolled in the study from 14/07/2015 to 01/04/2016, with 43 cycles administered. The parameters used to assess efficacy were: alkaline phosphatase (AP) reduction, AP response, PSA response and pain response after treatment. AP reduction was defined as a decrease in AP compared to a baseline elevated value; AP response was reached when the decrease was ≥ 30%, measured 12 weeks after treatment initiation. The same criteria applied to PSA response. Pain response was measured by a visual analogue scale (VAS) before the administration of each cycle. 2. The safety of the ^{223}Ra was assessed after graduating toxicity of each cycle by Common Terminology Criteria for Adverse Events (CTCAE) version 4. Results: 1. AP reduction after treatment initiation occurred in 85% of patients. AP response occurred in 100 % of the 3 patients that reached 12 weeks of treatment. Only a 16.7% PSA response was observed. The most important fact was the reduction of pain (VAS score) in 73% of patients, with an average decrease of VAS after 3 cycles of 69%. 2. ^{223}Ra is safe, the most frequent toxicities were: anaemia (50%), followed by diarrhea (25%), nausea (16.7%) and thrombocytopenia (16.7%). But most of toxicity had a low grade. In fact, the only toxicities ≥ grade 3 were anaemia (8.3%) and thrombocytopenia (8.3%). A G2 dysgeusia was also observed in one patient, this had not been described by the EMA but in our patient it was clearly related to the treatment. Conclusions: 1. The AP response in treated patients, as well as the improvement in pain control may be subrogated factors of efficacy. Prospective studies are needed to asses these factors. 2. ^{223}Ra, unlike other chemotherapeutic agents, has a good safety profile with a low rate of high-grade toxicity. It is important to remark dysgeusia as a previously non described adverse event.

EP521

From the physical to biological dose in patients undergoing to 223RaCl2 therapy

L. Strigari[1], M. Balduzzi[2], V. Dini[3], R. Sciuto[1], A. Soriani[1], A. Tabocchini[3], A. Testa[2]; [1]Regina Elena NCI IFO, Rome, ITALY, [2]ENEA, Rome, ITALY, [3]ISS, Rome, ITALY.

Introduction: The exact correlation between blood dose and the information provided by biological assays is usually difficult to be determined in nuclear medicine treatments, according to the need to select an appropriate calibration curves for biological dosimetry. This study aims at estimating the correlation between the delivered dose to the blood and

the biodosimetry, i.e. the increment in the number of dicentrics and micronuclei in lymphocytes after radium-223 chloride (223RaCl2) therapy in prostate cancer patients with bone metastasis. **Materials and methods:** Patients undergoing 223RaCl2 therapy for skeletal diseases have been enrolled in this prospective trial. Imaging and blood samples collected before and at different times after the first treatment cycle were used to evaluate blood and non-target tissues doses. Calculated dose have been corrected for patient weight and for the quality of radiation using and RBE of 5.4 for Ra223. Blood samples were also used to assess the number of dicentrics and micronuclei from lymphocytes. Haematological toxicity parameters (blood cell count) have been monitored during therapy and analysed along with doses to blood and non-target tissues and results of biological dosimetry. **Results and conclusion**: Based on the calibration curve based on photon doses taking into consideration the RBE of radiation, the estimated dose was 10% lower than the physical ones to non-target tissues based on the number of dicentrics. Moreover, the increase of binucleated cells with micronuclei was in average about 70% per Gy to non-target tissues. Our early results suggest that the "cumulative dosimetric index" reflects the delivered dose to the circulating lymphocytes (non target organ) before and after repeated treatments. The degree of chromosome radiation damage increases with the dose estimated with both physical and radiobiological methods.

Evaluation of Affibody Molecules for Radionuclide Imaging of Carbonic Abhydrase IX Expression In Vivo

J. Garousi[1], H. Honarvar[1], K. Andersson[2], B. Mitran[1], A. Orlova[1], J. Buijs[1], F. Y. Frejd[1], **V. Tolmachev**[1]; [1]Uppsala University, Uppsala, SWEDEN, [2]KTH-Royal Institute of Technology, Stockholm, SWEDEN.

Aim. Carbonic anhydrase IX (CAIX) is overexpressed in tumours under chronic hypoxia and in normoxic renal cell carcinomas. Radionuclide molecular imaging of CAIX expression might identify radioresistant tumours for adjustment of radiation therapy protocols. It could be also used for discrimination of malignant and benign renal tumours. Affibody molecules have demonstrated high potential as imaging probes in preclinical and clinical studies. The aim of this study was to evaluate Affibody molecules and select the best one for imaging of CAIX. **Materials and methods**. Four affibody molecules, ZCAIX:1, ZCAIX:2, ZCAIX:3, and ZCAIX:4 were selected to bind with CAIX with high affinity. The Affibody molecules were labelled with ^{99m}Tc using HEHEHE-tag and with ^{125}I by conjugation with ^{125}I- para-iodo-benzoate. In vitro binding and cellular processing of the traces was studied using CAIX-expressing SK-RC-52 renal carcinoma cells. In vivo biodistribution and imaging experiments were performed at 4 h after injection in BALB/C mice bearing SK-RC-52 xenografts. **Results**. In vitro experiments demonstrated high stability of both labels. All radiolabelled variants demonstrated specific in vitro binding with low nanomolar affinity. In vivo, the tumour uptake of all radiolabelled variants was significantly ($p<0.05$) and appreciably higher than the uptake of control Affibody molecule labelled using the same methods, suggesting highly specific targeting. All variants cleared rapidly from blood, but there were significant differences in biodistribution profiles and appreciable variation of the tumour uptake of different tracers for both labels. There was no correlation between tumour uptake and affinity, but there was correlation between tumour and blood uptakes of ^{99m}Tc-labeled variants. There was remarkable difference in renal retention between radioiodinated variants. ^{99m}Tc-(HE)$_3$-ZCAIX:2 (the tumour uptake of 16±1 %ID/g and tumour-to-blood ratio of 44±7) was the best for imaging of CAIX in disseminated cancer. The variant ^{125}I-ZCAIX:4 (tumour uptake 10.3±0.6%ID/g ,tumour-to-blood ratio of 23±3 and tumour-to-kidney ratio of 2.1±0.5) had the best prospects for imaging of primary renal cell carcinoma. **Conclusion.** Affibody molecules provide specific imaging of CAIX in vivo. The composition of binding site of Affibody molecules influences the blood clearance rate, the uptake in normal tissues and cellular processing in kidneys. ^{99m}Tc-(HE)$_3$-ZCAIX:2 is a potential candidate for development of a tracer for imaging of hypoxia in disseminated cancer. ZCAIX:4 with a non-residualizing label might be used for detection of renal cell carcinoma.

EP523

Structure and receptor affinity of DOTA-Gastrin analogue (CP04) complexes with radiometals

M. Maurin[1], A. Wodynski[2], M. Orzelowska[1], U. Karczmarczyk[1], P. Garnuszek[1], R. Mikolajczak[1]; [1]National Centre for Nuclear Resurch, Radioisotope Centre POLATOM, Otwock, POLAND, [2]Swierk Computing Centre, National Centre for Nuclear Research, Otwock, POLAND.

Introduction: Affinity of the chelator-peptide conjugates to the cell membrane receptors may vary depending on the metal incorporated into the complex. This phenomenon has been observed for the radiocomplexes of DOTA conjugated somatostatin and bombesin analogues [1,2]. So far, there are no such studies for gastrin/cholecystokinin receptor CCK2R. The interactions between the CCK2 receptor and a series of gastrin and mini-gastrin analogues have been investigated experimentally and theoretically and there seems to be a consensus that the last four N-terminal (-Trp-Met-Asp-Phe-) amino acids participate in the receptor binding process. Much less is known about peptides containing radionuclide-chelate carriers. The aim of our project was to investigate the influence of selected metals on the biological activity of radiocomplexes. **Materials & Methods:** The geometry optimization was carried out using DFT/B3LYP/6-311G(d,p) and semi-empirical (PM6). Molecular docking algorithm based on the shape complementarity principles, implemented in the Patchdock webserver, was used in preliminary docking procedure. The ^{68}Ga, ^{90}Y and ^{177}Lu radiolabelling of CP04 was performed in previously optimized conditions [4]. Biological activity of radiocomplexes was compared *in vitro* on human epidermoid carcinoma A431 cell line transfected to express the human CCK2R receptor (A431-CCK2R(+)) and on cells transfected with an empty vector (A431-CCK2R(-) [4]). The *in vivo* comparison was performed in tumour-bearing mice. **Results & discussion:** The results of docking simulation showed that interaction energy between M-CP04 and CCK2R is less negative for Lu-CP04 than for Ga-CP04. Additionally, comparison of patchdock scoring results confirms better shape complementarity of Ga-CP04 (5482) in respect to Lu-CP04 (5004). The in vitro cell investigations revealed the internalization of ca 75% with no significant differences between the complexes. A very similar biodistribution pattern with fast clearance with urine (> 90%ID after 1.5h p.i.v.) was observed for both ^{68}Ga-CP04 and ^{177}Lu-CP04. The uptake ratio of both complexes in CCK2R positive tumour was 1.5-times higher than in the negative one at 0.5h p.i.v. and increased to ca. 4 after 1.5h p.i.v.Due to a lower concentration of ^{177}Lu-CP04 in muscular tissue its T/M ratio was twice higher than for ^{68}Ga-CP04. **References** Reubi J.C., et al., *Eur J Nucl Med* **2000**, *27*, 273-282. EP524

Biological Evaluation of radiolabeled Cetuximab and fragment for the PET imaging tracer of EGFR expression

S. Lee[1], Y. Kim2, E. Cho[1], J. Chung[1], S. Kim[1], S. Oh[1]; [1]ASAN Medical Center, Seoul, KOREA, REPUBLIC OF, [2]SINIL Pharmaceutical Co, Gyeonggi-Do, KOREA, REPUBLIC OF.

Objectives: Generally, [^{18}F]fluoride has short half-life (109 min) to evaluate the intact mAb. Therefore metal radioisotopes such as Cu-64 ($t_{1/2}$, 12 hr) or Zr-89 ($t_{1/2}$, 3.3 day) are widely used for Immuno-PET study. However these radioisotopes show higher radiation exposure in patient than [^{18}F]F-labeled radiotracer. Recently, small size of protein such as affibody, nanobody and Fab fragment have been developed and labeled with Ga-68 or F-18 for the PET imaging because they have short half-life than intact mAb. We developed new [^{18}F]F-labeled Cetuximab fragment ([^{18}F]Fm-329 expressed from E-coli) for tumor imaging and evaluated the in vitro/in vivo properties. **Methods:** N-Succinimidyl 4-[^{18}F]fluorobenzoate ([^{18}F]SFB) was automatically synthesized using AIO chemistry module(Trasis). Three step synthesis and SPE (Solid phase extraction) purification method were used for the synthesis of [^{18}F]SFB. The [^{18}F]SFB which was dissolved in MeCN was obtained from chemistry module and MeCN was completely evaporated. Dried [^{18}F]SFB was dissolved in PBS (pH=7.8) and used to conjugated with Fm-329 and Cetuximab at room temperature for 30 min, respectively. The crude mixture was purified using centrifugal filtration with Amicon®Ultra centrifugal Filter (30K). After washing with PBS buffer, concentrated [^{18}F]Fm-329 was recovered from the centrifugal filter. After formulation, the radiochemical purity and quantification of [^{18}F]Fm-329 and [^{18}F]Cetuximab were evaluated with SEC (size exclusion chromatography)-HPLC and nanodrop, respectively. The binding affinity of radiolabeled Fm-329 and Cetuximab was evaluated with in vitro cell-binding assays with A431 cell line. The biodistribution in the nude mice model bearing A431 tumor xenografts were evaluated using PET/MR. **Results:** [^{18}F]Fm-329 and [^{18}F]Cetuximab were prepared with high labeling yield as 14.8±7.0% and 14.6±2.8% respectively. The in vitro cell uptake of [^{18}F]Fm-329 showed 86.57% binding compare with [^{18}F]Cetuximab which were normalized by protein quantity of cells, independently. The result of blocking study showed that cold Cetuximab inhibited the uptake of [^{18}F]Fm-329 and [^{18}F]Cetuximab to 4.85% and 2.93%, respectively. From the PET imaging analysis, tumor to muscle ratio of [^{18}F]Fm-329 at 2 hr, 3 hr and 4 hr after injection were 4.86, 5.11 and 7.87, respectively. [^{18}F]Cetuximab showed lower tumor to muscle ratio than [^{18}F]Fm-329 as 2.53, 3.45 and 3.58, at the same time point. **Conclusion:** [^{18}F]Fm-329 shows high affinity and good targeting to EGFR over expressed A431 cell line. It is a promising PET radioligand for imaging of EGFR expression.

EP525

In vivo imaging with retargeting immunotherapy components in prostate stem cell antigen-expressing tumor model

R. Bergmann[1], A. Feldmann[1], C. Arndt[1], S. Koristka[1], M. Cartellieri[2], A. Ehninger[2], J. Pietzsch[1], J. Steinbach[1], D. Máthé[3], M. Bachmann[1]; [1]Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY, [2]GEMoaB Monoclonals GmbH, Dresden, GERMANY, [3]Semmelweiss University, Budapest, HUNGARY.

Aim: Retargeted immunotherapy is now becoming a promising modality of cancer treatment. Particularly the prostate stem cell antigen (PSCA) is a target of advanced prostate, bladder and, pancreatic tumors, as well as subgroups of mamma carcinoma, and glioblastoma. The immunotherapy via retargeting strategies requires modified T-cells, conventional and bispecific antibodies, scFv and nanobody based target modules. All these components were optimized for tumor killing efficiency, GMP production, and safety in application. The potential of these components for in vivo imaging were evaluated in a PSCA expressing tumor model using the different radiolabeled anti-PSCA antibody (Ab) formats (conventional Ab 155 kDa, bsAb 55 kDa, scFv based target module 33 kDa, and nanobody based target module 19 kDa).Material and methods: A xenotransplanted s.c. PC3-PSCA-Luc+ tumor model was in NMRI nu/nu mice established. The Abs were conjugated with DOTA and NODAGA, and the average number of chelators per Ab was quantified by MALDI-TOF. The immunoconjugates were radiolabeled with ^{64}Cu, ^{68}Ga, and ^{177}Lu. Radioligand assays were performed to compare cellular binding, internalization and binding parameters for the immunoconjugates using the PSCA expressing cells. In the mouse model were small animal PET/CT, SPECT and biodistribution studies performed to compare the tissue uptake, the pharmacokinetics and the target to background ratios of the different Ab constructs. For anatomical characterization of the lesions were MRI and OI methods applied.Results: Tumors were specifically detected with the radiolabeled Abs already at fore hours after injection. The full mAb showed the highest accumulation in the tumor with a maximal target to background ratio at 48 h p.i. The engineered recombinant bsAb, scFv and target modules showed faster blood clearance, however, with high liver and kidney uptake but with clear visualization of the tumor xenografts after 24 h.Conclusion: The combination of molecular imaging modalities allowed studying the distribution of the radiolabeled components of this anti-PSCA-immunotherapeutic set up together with anatomical characterization. The radiolabeled anti-PSCA antibody formats showed in vivo favorable performance as imaging agents with good contrast and sensitivity for the xenotransplanted subcutaneous PSCA expressing tumors. The molecular weight determined the blood clearance and renal elimination. The full antibody showed excellent performance in visualization of the tumor in the mouse model and after optimization for imaging it should also be useful for radioimmunomonitoring of retargeting strategies in PSCA-positive cancer diseases.

EP526

Radiolabeling of a Cyclic RGD (cyclo Arg-Gly-Asp-d-Tyr-Lys) Peptide Using Sodium Hypochlorite As An Oxidizing Agent

K. Kumar, S. Doll, K. Woolum; Laboratory for Translational Research in Imaging Pharmaceuticals, The Wright Center of Innovation in Biomedical Imaging, Department of Radiology, The Ohio State University, Columbus, OH 43212, Columbus, OH, UNITED STATES.

Aim. Radiolabeling of a tyrosine residue in peptides and proteins is routinely performed by using various oxidizing agents such as Chloramine T, Iodobeads, and Iodogen reagent and radioactive iodide (I^-). The objective of the present study was to develop and optimize a novel radiolabeling method for a cyclic RGD (cyclo Arg-Gly-Asp-d-Tyr-Lys) peptide using sodium hypochlorite as an oxidizing agent. **Materials and Method.** A known amount of carrier-free ^{125}I Na activity was added to a 100 μL of 0.1 M Sodium Phosphate (pH 7.4) buffer solution in a 1.5 mL Eppendorf centrifuge tube followed by sequential addition of cRGDyK peptide and sodium hypochlorite solutions in PBS. The reaction mixture was incubated at room temperature for five minutes and the unreacted sodium hypochlorite was reduced by the addition of sodium metabisulfite. The crude reaction mixture was purified by using a Sep-PaK C_{18} Light cartridge followed by a reversed-phase HPLC method. Final product was analyzed by a reversed-phase analytical HPLC method. **Results and Conclusions.** A rapid radiolabeling method for molecules and biomolecules containing tyrosine residue has been developed. Various parameters including ratio of reagents, reaction time, and pH of the reaction were studied. The study demonstrated that the radiolabeling of the cyclic peptide is fast (i.e, less than five minutes are sufficient) and pH independent. Mono- and di-iodinated cRGDyK formed under all conditions and varied with the ratio of the reagents. Total percentage of the iodinated cRGDyK (mono- and di-iodinated cRGDyK) varied between 40 to 90% depending on the conditions. Excess cyclic peptide over equal molar ratio of sodium iodide and sodium hypochlorite yielded in predominant amounts of mono iodinated cRGDyK, i.e., >60% under 2:1:1 ratio of cRGDyK: sodium iodide: sodium hypochlorite and >88% under 5:1:1 ratio of cRGDyK; sodium iodide: sodium hypochlorite.

EP527

Synthesis and evaluation of a ^{68}Ga-labeled affibody molecule for imaging carbonic anhydrase IX expression with positron emission tomography

J. Lau, J. Pan, H. Kuo, C. Zhang, F. Benard, **K. Lin**; BC Cancer Agency, Vancouver, BC, CANADA.

Objective: Affibody molecules are a class of small proteins (MW = ~ 7 k) that have been explored extensively for targeted therapy and imaging. Tolerant to high temperatures, extreme pH, and structural modifications, these scaffolds typically exhibit nano to picomolar affinities to their targets of interest. An oncogene that has garnered significant interest as both a therapeutic and diagnostic marker for cancer is carbonic anhydrase IX (CA-IX). CA-IX is a cell surface enzyme that promotes survival under low oxygen conditions and is overexpressed within the hypoxic milieu of solid tumours. Z09781, a potent CA-IX-targeting affibody molecule, was previously radiolabeled with ^{99m}Tc for SPECT imaging and showed excellent tumour-to-background contrast (Honarvar et al. Eur J Nucl Med Mol Imaging 2014; 41 (Suppl. 2): S176). To explore the use of Z09781 for imaging with PET, herein we present the synthesis and evaluation of a ^{68}Ga-labeled Z09781 derivative (Cys[^{68}Ga-NOTA]Z09781) for CA-IX targeted imaging. **Methods:** The affibody molecule Cys-Z09781 was obtained by standard Fmoc solid-phase peptide synthesis. A cysteine residue was introduced at the N-terminal domain of the affibody to facilitate site-specific conjugation of maleimido-mono-amide-NOTA. For radiolabeling, Cys[NOTA]Z09781 was labeled with $^{68}GaCl_3$ in 2 M HEPES buffer (pH 5.0) and 5% glycerol by microwave heating for 1 min. The radiolabeled product was subsequently purified by PD10 column before being used for in vivo evaluations. PET/CT imaging and biodistribution studies were performed at 2 h post-injection using HT-29 tumour xenograft-bearing immunodeficient mice. **Results:** Cys[^{68}Ga-NOTA]Z09781 was obtained in 64-73% decay-corrected radiochemical yields with 16.7 MBq/μg specific activity and > 99% radiochemical purity. Imaging and biodistribution studies showed that Cys[^{68}Ga-NOTA]Z09781 was predominantly excreted through the renal pathway, with the kidneys retaining majority of the radioactivity (96.1 ± 10.4 %ID/g at 2 h p.i.). Cys[^{68}Ga-NOTA]Z09781 allowed for clear delineation of HT-29 tumour xenografts in PET/CT images. With the exception of the kidneys and bladder, the highest uptake of activity was observed in tumour (1.05 ± 0.15 %ID/g at 2 h p.i.). The corresponding tumour-to-muscle and tumour-to-blood ratios were 11.8 ± 3.35 and 9.78 ± 1.59 respectively. **Conclusion:** We successfully synthesized and radiolabeled an affibody molecule with ^{68}Ga for CA-IX targeted imaging. Tracer pharmacokinetics and tracer uptake was assessed in a human hypoxia cancer model. Cys[^{68}Ga-NOTA]Z09781 enabled good visualization of HT-29 tumour xenografts with good contrast, and is promising for imaging CA-IX expression with positron emission tomography.

EP528

Physicochemical and biological characterization of SubstanceP fragments labeled with ^{177}Lu

A. Majkowska-Pilip[1], E. Gniazdowska[1], A. Rawicz-Galińska[1], M. Bednarczyk[1], P. Koźmiński[1], T. Budlewski[2], A. Bilewicz[1]; [1]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [2]Central Clinical Hospital of the Ministry of Interior, Warsaw, POLAND.

Aim: Gliomas, particularly WHO grade IV glioblastoma multiforme (GBM), is one of the most common and aggressive primary type of the cancer of the central nervous system. Despite of all current forms of treatment such as advanced surgery techniques, radiation therapy and chemotherapy, the life expectancy of patients diagnosed with GBM is only 12 to 15 months. The neuropeptide SubstanceP (SP) is the physiological ligand of the nerokinin1(NK1) receptor consistently overexpressed by glioblastoma cells. The aim of the work was to study physicochemical (lipophilicity, stability) and biological (K_D, IC_{50}) properties of different SP fragments labeled with β^- emitter - Lu-177. **Methods:** The ^{177}Lu-DOTA-SP fragments conjugates consist of central metal ion ^{177}Lu coordinated by macrocyclic ligand DOTA previously coupled with different SubstanceP fragments such as SP(1-11), [Thi^8,Met$(O_2)^{11}$]SP(1-11), SP(4-11), SP(5-11), [Thi^8,Met$(O_2)^{11}$]SP(5-11). The synthesized conjugates were characterized *in vitro* by partition coefficients (log P), in the *n*-octanol/PBS (pH 7.40) system. Stability of the complexes were investigated in different physiological solutions, namely phosphate buffered saline (PBS), histidine, cysteine, human serum (HS) and cerebral spinal fluid (CSF) using HPLC and ITLC methods. The biological properties (K_D, IC_{50}) were characterized using cell line T98G. **Results:** All studied conjugates are formed with good yield and high radiochemical purity. The obtained lipophilicity values of the ^{177}Lu-DOTA-SP fragments are in the range from -2.5 to -5.0. The shorter SP fragments are characterized by higher lipophilicity values, while the replacement of amino acids in positions 8 and 11, respectively Phe and Met by the Thi and Met(O_2) leads to lipophilicity decreasing. The studied conjugates are stable in PBS buffer, as well as in 10 mM histidine and/or cysteine solutions. Stability studies in HS showed in the case of shorter SP fragments quicker enzymatic biodegradation comparing to that of SP molecules containing all 11 amino acids. However, stability studies in CSF showed no enzymatic biodegradation of tested compounds. All studied conjugates bind specifically to NK1 receptors expressed on glioblastoma cells with affinity in the nanomolar range. **Conclusions:** To summarize, the conjugates containing shorter SP fragments are characterized with higher lipophilicity values what can allowed more effective migration into GBM tissue or into the walls of post-surgery cavity. The disadvantage of these conjugates is their poor stability in HS, however due to their total stability in CSF, they can be considered as potential radiopharmaceuticals for local administration directly to glioblastoma tumours. Support by Grant 011/01/M/ST406756 is acknowledged.

^{18}F-FDG-Aoe-LIKKP-Pyr-A: A new peptide radiotracer for apoptosis imaging

D. Beiki[1], S. Khoshbakht[2], S. Shahhosseini[3], F. Kobarfard[3], O. Sabzevari[2], M. Amini[4]; [1]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF, [2]Dpartment of Radiopharmacy, School of Pharmacy, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF, [3]Dpartment of Medicinal Chemistry, School of Pharmacy, Shahid Beheshti University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF, [4]Dpartment of Medicinal Chemistry, School of Pharmacy, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF.

Aim: Specific biochemical changes occur in cells undergoing apoptosis that provide potential targets for molecular imaging agents and imaging of apoptosis can provide a good way to predict effectiveness of cancer chemotherapy. Clinical information obtained from targeting of phosphatidyl serine (PS) would help to diagnosis and therapy of apoptosis related pathologies. A few LIKKPF peptides with acceptable affinity for PS have been already introduced for apoptosis imaging. We herein report the synthesis of a new LIKKPF peptide radiotracer with more affinity for PS for detecting apoptosis. Materials and Methods: The peptides were synthesized on solid phase using standard Fmoc strategy, conjugated with aminooxy (Aoe), and then was considered for the radiolabeling procedure with ^{18}F-FDG. Biological properties were determined in vitro using camptothecin treated Jurkat cells and in vivo using liver apoptosis mouse model induced via intraperitoneal (IP) injection of lipopolysaccharide (LPS). Also, Log P values determination, biodistribution studies and PET/CT imaging were performed. Results: The radiochemical purity

was >95% (100°C, 30 min, pH 5-5.5). Log P value for ^{18}FDG-Aoe-LIKKP-Pyr-A prepared by Fmoc-(4-pyridyl)-D-Ala-OH was -0.92. K_d of peptide was determined with value 0.52 μM. Biodistribution results showed 3 times liver uptake for apoptotic mice compared to normal mice. PET/CT images were in a good agreement with biodistribution results. The activity ratio of liver to kidney was 0.17 and 0.61 in normal and apoptosis mouse model, respectively. Conclusion: ^{18}FDG-Aoe-LIKKP-Pyr-A showed good affinity to PS and might be a potential radiotracer for the detection of apoptosis.

EP530

Preparation and biological evaluation of ^{99m}Tc-HYNIC-LIKKPF for the detection of apoptosis

D. Beiki[1], S. Khoshbakht[2], S. Shahhosseini[3], F. Kobarfard[3], O. Sabzevari[2], M. Amini[4]; [1]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF, [2]Dpartment of Radiopharmacy, School of Pharmacy, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF, [3]Dpartment of Medicinal Chemistry, School of Pharmacy, Shahid Beheshti University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF, [4]Dpartment of Medicinal Chemistry, School of Pharmacy, Tehran University of Medical Sciences, TEHRAN, IRAN, ISLAMIC REPUBLIC OF.

Aim: Radioligands that have affinity and bind to phosphatidyl serine (PS) are good candidates for noninvasive imaging of apoptosis. Because of limitations of Annexin V (as a most studied imaging agent for apoptosis), there is a need to develop radioligands with better biodistribution profile for this purpose. Materials and Methods: HYNIC-LIKKPF was successfully synthesized via Fmoc strategy and the compound was considered for the radiolabeling procedure with Tc-99m. Then, stability and Log P values of radiopeptide were determined. Finally, binding studies, biodistribution studies and SPECT/CT imaging were performed. Results: The radiochemical purity and Log P value were >95% and -0.92, respecteviely. ^{99m}Tc-HYNIC-LIKKPF was stable in human serum for at least 2 hr at 37°C. Although the affinity of radiolabeled LIKKPF was less than original phage peptide, the level of binding to apoptotic cells was 2.5 times higher than control cells. Biodistribution studies showed higher liver uptake of radiopeptide in apoptotic non-treated mouse model compare to normal and pre-treated mouse. The in vivo imaging results were consistent with biodistribution studies. Conclusion: ^{99m}Tc-HYNIC-LIKKPF has less affinity to PS compare to original phage peptide, but high enough for specific binding to apoptotic cells in vitro and in vivo. Less affinity of radiolabeled LIKKPF might be attributed to hydrophobicity of peptide. The future peptides should be more hydrophobic compare to LIKKPF.

EP531

Anti-VEGFR2 monoclonal antibody ramucirumab: comparison of selected radiolabeling methods

J. Janousek, P. Barta, F. Trejtnar; Faculty of Pharmacy in Hradec Kralove, Hradec Kralove, CZECH REPUBLIC.

Aim: Vascular endothelial growth factor (VEGF) is one of the most important regulator of angiogenesis, including tumor neovascularization. VEGF binds to two types of receptors with tyrosine-kinase activity of which VEGF receptor 2 (VEGFR2) is a key receptor in tumor neoangiogenesis. Ramucirumab (RAM) is a novel therapeutic anti-VEGFR2 monoclonal antibody (Mab) directed against the extracellular domain of VEGFR2 that inhibits binding of its natural ligand VEGF. Several types of cancer (e.g. gastric, pancreatic, lung or breast cancer) are known for their overexpression of VEGFR2. The MAb RAM labeled with appropriate radionuclides could be potentially used for scintigraphic imaging and targeted radiotherapy of oncological diseases. The aim of this work was to develop convenient radiolabeling method for selected radionuclides and to evaluate radiochemical purity and stability of radiolabeled products. Materials and methods: Two methods of RAM radiolabeling were evaluated in experiments. The first tested method was the optimization of the direct labeling with ^{99m}Tc based on the reduction of disulfide bridges in RAM molecule with 2-mercaptoethanol. The second method was radioiodination (^{131}I) according to chloramine-T protocol. The radiochemical purity of the prepared antibody was tested by instant thin layer chromatography on silica gel (ITLC) immediately after labeling. To evaluate the stability the samples were analyzed on various times by size-exclusion high-performance liquid chromatography (SE-HPLC) with radiometric detection. The preparations were incubated 8-24 h at 4°C. Results: The introduced methods enabled effective labeling of RAM with either ^{99m}Tc or ^{131}I. The obtained radiolabeled preparations exhibited sufficiently high stability. Radioiodination method provided slightly higher radiochemical purity after labeling. However, we observed higher stability provided by direct labeling method with ^{99m}Tc under the used conditions. Conclusion: The tested methods are convenient for radiolabeling of RAM. The developed radiolabeled preparations may be used in further preclinical studies to evaluate biological behavior of labeled RAM in vitro or in vivo. This project was supported by Charles University: GAUK(998216/C/2016), SVV(260293) and PRVOUK P40.

Development of a new multimodal diagnostic nanosystem based on inorganic nanoparticles as a potential radiopharmaceutical in SPECT-MRI or PET-MRI imaging

A. Delgado Garcia, Sr., M. Cano Luna, R. Nuñez Lozano, S. Sanz Viedma, T. Amrani, E. Ramos Moreno, M. Martinez del Valle Torres, G. De la Cueva Méndez, J. Jiménez-Hoyuela García; INSTITUTO INVESTIGACIÓN BIOMÉDICA DE MÁLAGA (IBIMA), MALAGA, SPAIN.

Aim: Nanotechnology offers interesting tools that could help to overcome the handicaps of traditional radiopharmaceuticals: greater specificity through selective tropism to targeted tissues, and higher capacity of loading isotopes, to improve sensitivity and decrease toxicity and dosimetry in patients. The aim of this work is to develop a multimodal imaging system (PET - MRI or SPECT - MRI) based on inorganic nanoparticles (NPs) and assess their potential application as radiopharmaceutical. Material and Methods: Monodisperse NPs were synthesized, with a superparamagnetic iron oxide core (SPION) and silica coating, with different particle sizes (10-100 nm) and specific surface functionalization. These NPs were PEGylated to increase its circulation time and to provide a platform for subsequent functionalization with additional ligands that may improve their PK-PD and biodistribution. Magnetic properties were determined by measurements of magnetization and transverse relaxivity (T2), and its loading capacity of atoms of gallium, indium and zirconium was determined by two different methods: (1) cold, using chlorinated salts, determined by mass spectrometry with Inductively Coupled Plasma (ICP) and (2) labelling with radioactive isotopes Ga-67, In-111 and Zr-89, quantifying radiochemical purity (RCP) by thin layer chromatography (TLC) using a gamma-radioactivity single trace scanner. Loading kinetics was monitored at room temperature by performing measurements at different times (1, 3, 6, 24 and 48 hours). Moreover, the stability of said labelling was analyzed under physiological conditions, in PBS and fetal bovine serum (FBS). Results: Characterized NPs have shown good properties as

MRI T2 contrast agent. In addition, they have good intrinsic capacity for strong adsorption of metals (Ga, In and Zr), without using chelating agents, which allows a considerable loading of these isotopes. The union of these metals to the surface of the NPs is stable over time (up to 48h) in the tested conditions (PBS and FBS), and presents no variations of RCP during that period. Discussion: We have developed a potential multimodal diagnostic nanosystem (PET - MRI or SPECT - MRI) based on NPs composed made of SPION - Silica with intrinsic capacity for the adsorption of different radioisotopes (Ga, In and Zr). This system allows us to generate different particle sizes (10-100 nm) and to modulate its colloidal stability (PEGylation) and other PK-PD parameters through further functionalization, all of them key aspects of controlled biodistribution.

EP533

Development of a new purification protocol for radiosynthesis of 2-deoxy-2-[^{18}F]fluoroacetamido-D-glucopyranose

M. Martinez Pozo, A. Makino, T. Mori, H. Okazawa, Y. Kiyono; University Of Fukui, FUKUI, JAPAN.

Aims: The diagnosis of infection and the ability to distinguish infection from inflammation by nuclear medicine remain as a challenge. A wide variety of radiotracers are under pre-clinical development, however the clinical imaging agents most currently employed, 2-[^{18}F]fluoro-2-deoxy-D-glucose ([^{18}F]FDG) and radiolabelled leucocytes, are non-specific and may accumulate at sites of sterile inflammation or other lesions, resulting in high rate of false positive results. We had reported the radiosynthesis of 2-deoxy-2-[^{18}F]fluoroacetamido-D-glucopyranose ([^{18}F]FAG) [1], which was able to distinguish infection from inflammation in animal models despite the final radiochemical yield and specific activity were low. Furthermore, we developed new precursors with same efficiency of [^{18}F]fluoride incorporation under similar radiosynthesis conditions. The aim of the current study was to increase the final specific activity through modifications introduced to the original purification protocol. **Methods:** Non-radioactive FAG, as well as bromo and tosylate precursors were synthesized in our laboratory. Radiosynthesis of [^{18}F]FAG was performed using microwave heating followed by alkaline hydrolysis. Final [^{18}F]FAG was purified by high-performance liquid chromatography using: 1) an amino-bonded silica phase column or 2) an amino-bonded silica phase column plus a C18 bonded silica phase column. **Results:** Radiosynthesis of [^{18}F]FAG using bromo or tosylate as a precursors showed similar radiochemical yields, radiochemical purities and synthesis times. Purification using only amino-bonded silica phase column gave specific activity values of $1.4\pm0.3\times10^{-3}$ and $2.1\pm0.2\times10^{-3}$ GBq/μmol for bromo and tosylate precursors respectively. Whereas, when amino column was followed by a C18 column the specific activity values obtained were $7.8\pm4.4\times10^{-2}$ and $8.0\pm1.9\times10^{-2}$ GBq/μmol for bromo and tosylate precursors respectively. Further analysis by ESI-MS found that purification using amino column was affected by a common by-product, identified as the deprotected mono-acetylated precursor, which co-eluted with [^{18}F]FAG. A second purification through a C18 bonded silica phase column help to separate this by-product and can explain the observed increment by ten-fold in the final specific activity. **Conclusion:** There were not significant differences regarding the use of bromo or tosylate precursor for radiosynthesis of [^{18}F]FAG. The inclusion of a C18 bonded silica phase column after the amino-bonded silica phase column help to increase by 10-fold the specific activity of final [^{18}F]FAG. **Reference:** [1] ME Martínez et al. (2011) Nucl Med Biol; 38:807-17.

EP534

In-use stability of ^{99m}Tc-tilmanocept (Lymphoseek®), a sentinel lymph node detection agent

R. L. Green; Cardinal Health Nuclear Pharmacy Services, Dublin, OH, UNITED STATES.

Aim: ^{99m}Tc-tilmanocept (Lymphoseek®) is an US FDA and EMA approved agent for guiding sentinel lymph node biopsy in clinically node negative breast cancer, melanoma, and oral cavity squamous cell carcinoma. During the radiolabeling of tilmanocept, ^{99m}Tc sodium pertechnetate is added to the product vial and the mixture is allowed to stand at room temperature. According to the product information, the radiolabeled tilmanocept is then to be diluted with sterile normal saline (in the EU) or a phenol-stabilized phosphate-buffered saline (in the US) to bring the vial to the appropriate volume for the desired injection(s). The currently approved expiry time for the radiolabeled solution is 6 hours after compounding. The aim of this study was to evaluate the in-use stability by instant thin layer chromatography (ITLC) radiochemical purity (RCP) testing of ^{99m}Tc-tilmanocept beyond 6 hours, which may allow additional flexibility in surgical scheduling. **Material and methods:** Two different lots of product were radiolabeled using ^{99m}Tc sodium pertechnetate, followed by dilution using normal saline as the diluent in the preparation of ^{99m}Tc-tilmanocept. Vials from each lot were radiolabeled then tested over the following time points: 1, 3, 6, 9, 12, 15, 18, 21, 24 hours. RCP was determined in duplicate measurements by ITLC. **RESULTS:** Lymphoseek was stable throughout the course of the study with RCP values in excess of 99%, independent lot number. **CONCLUSIONS:** Based upon RCP results, ^{99m}Tc-tilmanocept solution for injection is stable in sterile normal saline diluent for at least 12 hours.

EP535

Improving of volumetric activity of the standard generator of technetium-99m

A. S. Rogov, V. S. Sкuridin, E. S. Stasyuk, E. A. Nesterov, V. L. Sadkin, N. E. Villa, E. A. Ilina; National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Introduction:Short-lived radionuclide technetium-99m is a daughter product ß-decay of ^{99}Mo isotope. For its rapid separation of ^{99}Mo in everyday medical practice is used mobile generators of technetium-99m. The basis of the generator column filled with a chromatographic alumina, which is applied to the source of molybdenum-99 isotope. From daily generator allocate technetium-99m getting the eluate followed by a gradual decrease in activity. Generators based on the activation of molybdenum-99 produced by (n,γ) nuclear reactor IRT-T have an increased mass of sorbent. This leads to the necessity of increasing volume of NaCl needed to obtain the drug with a given activity. Aim:Development of the generator of technetium-99m-based activation molybdenum-99, with a minimum amount of NaCl used for the production of the drug. Methods:We know many different methods of application of molybdenum-99 to the surface chromatographic sorbent. However, for the manufacture suitable generators of technetium-99m from a less active as raw material using the method of charging the generator flow method. To increase the sorption mass of molybdenum-99 on our generator column were tested methods of pre-processing of sorbent to increase the active of adsorption centers. The dependence of the mass sorbed from solution passing time through the generator column. The dependence of sorbed mass from the solution passing time through the generator column. Result:The results showed that pre-acid treatment of the sorbent allowed to increase its capacity for molybdenum-99 by 15%. Slow flow rate of the solution through sorbent increases sorption performance by 10%. Considering the data suggested that a charging generator column with combining techniques. As an additional condition prompted to change the direction of the charging generator column. Conclusions:The combination of these techniques increase sorbent charging capacitance with a change direction it possible to increase sorption capacity of chromatographic alumina used by more than 38%. Due to changes in the direction of the charging generator appeared significant time interval, and the interaction of the sorbent solution containing molybdenum-99. Subsequent analytical studies have shown that the

content of active and inactive impurities in the product is at the upper limits of normal. The indicator radiochemical purity meets the requirements of the pharmaceutical articles on receiving the drug. Managed to increase the volumetric activity of generators technetium-99m is produced on the basis of activation of molybdenum-98 without the use of sophisticated methods of isotope concentration. Acknowledgment:The work was supported by the state on behalf of the Ministry of Education of Russia(RFMEFI57514X0034).

M2M: New Targets

EP536

Radioiodinated compounds for Auger therapy

E. Lemos Pereira[1,2], A. Paulo[1], M. Oliveira[1], F. Mendes[1], P. Raposinho[1], A. Belchior[1], I. Correia[3], J. Lavrado[4]; [1]C2TN, Lisbon, PORTUGAL, [2]FCT-UNL, Caparica, PORTUGAL, [3]IST-UL, Lisbon, PORTUGAL, [4]iMed-Ulisboa, Lisbon, PORTUGAL.

Aim: The design of Auger-emitting radiopharmaceuticals for DNA-targeted therapy is an emerging field in contemporary Radiopharmaceutical Chemistry. Our research work aimed to contribute for the progress of this field by studying the potential of ^{125}I-labelled Acridine Orange (AO) derivatives for Auger therapy. **Methods:** For this purpose, and based on the DNA-intercalation properties of AO, we've synthesized three new alkyl-iodobenzamide AO derivatives. The ^{125}I-labeled congeners were synthesized via the corresponding tributilstannyl derivatives, and were obtained in high *in vitro* stability and radiochemical purity (> 95%) after HPLC purification. The interactions of the compounds with calf thymus DNA and with plasmid DNA were evaluated. Cellular uptake assays, as well as radiocytotoxicity analysis were also conducted. **Results:** All three compounds showed high affinity to DNA, acting mainly as intercalators. Evaluation of ϕX174 plasmid DNA showed induced double-strand breaks (DSB) yields in the range 0,07-0,09 and 0,05-0,04. Cellular uptake assays revealed good uptake rates, at 4 hours incubation. Preliminary radiocytotoxicity and DNA damage in living cells results suggested more than 35% cell death, which is certainly a consequence of its ability to produce DSB in the cellular DNA, as shown by the γ-H2AX assay. **Conclusion:** These results led us to conclude that the produced DNA damage from two of the synthesized compounds was mainly due to direct effects of emitted Auger electrons.

EP537

In Vitro Mouse and Human Serum Stability of A Heterobivalent Dual-Target Probe Which Has Strong Affinity To GRP and NPY1 Receptors on Tumor Cells

K. Kumar, A. Ghosh, V. Gaja, N. Raju, M. Tweedle; Laboratory for Translational Research in Imaging Pharmaceuticals, The Wright Center of Innovation in Biomedical Imaging, Department of Radiology, The Ohio State University, Columbus, OH 43212, Columbus, OH, UNITED STATES.

Aim. The objective of the present study was to determine the in vitro stability of a hetero bivalent dual-target probe (t-BBN-BVD15-DO3A), which has shown strong affinity to GRP and NPY1 receptors, in mouse and human serum at 37°C. **Materials and Method.** A hetero bivalent dual-target probe, t-BBN-BVD15-DO3A (where a GRP targeting ligand J-G-Abz4-QWAVGHLM-NH2 and Y1 targeting ligand INP-K [ε-J-(α-DO3A-ε-DGa)-K] YRLRY-NH2 were coupled) that recognizes both GRPR and Y1 receptors was synthesized, purified, and characterized. Mouse serum collected from fresh blood, Human Serum (MP Biomedicals), PBS (Gibco), and ^{153}GdCl3 (Perkin Elmer) were used in these studies. A known amount of a ^{153}Gd labeled (t-BBN-BVD15-DO3A) sample was mixed with mouse or human serum and incubated at 37°C. The degradation of the ^{153}Gd(t-BBN-BVD15-DO3A) was monitored with time by a Reversed-Phase HPLC method. The method involves using an Agilent HPLC which is interfaced with a Radioisotope Detector (RID) and a Chem Station software. Results and Conclusions. A ^{153}Gd labeling method and an analytical method for monitoring degradation of the dual-target probe in mouse and human serum were developed. Stability of the dual-target probe in mouse or human serum with time was monitored by the reduction in the main peak area. For example, the percentages of the main peak areas of the dual-target probe in mouse serum with time in minutes (in parenthesis) were: 92.4 (23), 94.9 (67), 75.7 (127), 66.8 (200) and 0.27% (1140). An estimated half-life of the dual-target probe in mouse serum is 3.2 hrs. In comparison, the dual-target probe is found to be more stable in human serum with estimated half-life > 5 hrs. A probable mechanism of degradation of the dual-target probe in mouse serum is proposed.

EP538

A systematic study of ^{64}Cu production on Ni target with 11 MeV protons

L. Auditore[1], E. Amato[2], R. Gentile[2], P. Coppolino[2], S. Baldari[2]; [1]University Hospital G. Martino, MESSINA, ITALY, [2]University of Messina, MESSINA, ITALY.

Aim: ^{64}Cu is a promising theranostic nuclide for PET and nuclear medicine treatments of cancer. Relevant ^{64}Cu activities can be obtained by the nuclear reaction ^{64}Ni(p,n)^{64}Cu on (95%-99%) ^{64}Ni enriched targets. After irradiation, the target contains ^{64}Cu mixed with other isotopes such as ^{60,61,62}Cu and ^{55,57,58,61}Co. A valuable reduction of contaminants can be achieved by properly choosing beam parameters, target composition, thickness and shape, irradiation and cooling times. This work aims to provide a systematic study of the ^{64}Cu production with Ni enriched targets, evaluating the contribution of all the competing channels when changing proton energy (through a degrader), target thickness and irradiation/cooling times. Materials and methods: ^{64}Cu production from a 95% ^{64}Ni enriched target irradiated by protons (E_{max} = 11 MeV) was considered. Yields at the End Of Bombardment (EOB) were estimated using both the TALYS code and an analytical approach based on the EXFOR experimental data libraries and on a Bragg curve in Ni estimated with MCNPX. Yields$_{EOB}$ were provided as a function of target thickness, beam energy and irradiation/cooling times. A validation of our theoretical estimations was obtained through a comparison with experimental data available in literature. Results: a good agreement was found between our calculation results and the experimental data; the observed deviations are attributable to the existing differences between TENDL and EXFOR excitation functions. For a thick target irradiated at 11 MeV, ^{64}Cu yields$_{EOB}$ of 10.11/7.73 mCi/μAh were evaluated using TALYS and the analytical approach, respectively. ^{60,61,62}Cu and ^{55,57,58,61}Co contaminants are also produced. Reducing proton energy to 5 MeV, ^{64}Cu yields$_{EOB}$ lowers to 0.92 mCi/μAh, ^{60}Cu and ^{55,57,58}Co are not produced or detectable, ^{61}Cu and ^{61}Co lowers to less than 1E-03 mCi/μAh, ^{62}Cu ($T_{1/2}$=9.67 m) lowers to about 1E-02 mCi/μAh, and can be reduced choosing a proper cooling time. Conclusion: ^{64}Cu production by means of the ^{64}Ni(p,n) reaction allows to obtain a ^{64}Cu yield of clinical interest. A theoretical systematic study like ours provides a pathway to optimize production while reducing contaminants acting on proton beam energy, target thickness, irradiation and cooling times.

EP-28 – Sunday, October 16, 2016, during Exhibition hours, e-Poster Area

M2M: PET/CT & Miscellaneous

Factors Influencing the Pattern and Intensity of Myocardial FDG Uptake in Oncologic PET-CT Imaging

B. Fallahi, B. Moasses Ghaffari, D. Beiki, A. Fard-Esfahani, M. Eftekhari; Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: Myocardial FDG uptake is highly variable, ranging from quite intense to minimal distribution, in oncologic whole body FDG PET-CT studies. Intense or heterogeneous myocardial FDG uptake is undesirable as it may interfere with the visual or quantitative evaluation of tumoral invasion and metastases in pericardium, myocardium or adjacent mediastinal structures. The diet, as well as many other factors, is assumed to influence the myocardial FDG uptake. Using a multivariate model, we tried to identify and predict the main factors influencing cardiac FDG uptake in patients referred for oncologic PET-CT evaluation. Methods: A total of 214 patients referred for oncologic FDG PET/CT scan were enrolled in our study. Patients were randomly allocated into two groups according to the diet they were instructed to follow during 24-hour period before imaging. One hundred and seven cases with a routine diet (RD) and the same number of patients with a low carbohydrate high fat (LCHF) diet were included. All patients in both groups were also instructed to fast 6 hours before imaging. Weight, height, blood glucose, heart rate, systolic and diastolic blood pressure were measured before radiotracer injection. Visual and quantitative analysis were done after imaging and the pattern of FDG uptake as well as standardized quantitative value of cardiac uptake was determined for each case. Results: The frequency of undesirable cardiac FDG uptake in the LCHF group was significantly less than RD group (17% vs. 72%, $p<0.001$). The univariate analyses showed male gender, BMI>=30 as well as consumption of cardiochemotoxic agents, benzodiazepines and beta blockers were significantly associated with higher intensity of myocardial FDG uptake, while this undesirable finding was less evident in cases with diabetes mellitus. A multivariate logistic regression model including all of the mentioned variables revealed the diet was the only significant independent factor that predicted undesirable myocardial FDG uptake ($p<0.001$). Conclusion: LCHF diet 24 hours before PET-CT imaging is the only controllable independent factor influencing the intensity and pattern of myocardial FDG uptake and is recommended to achieve optimal suppression of cardiac FDG uptake.

EP540

Prognostic Value of Volumetric Parameters of PET-CT With Stage IIIB-IV Non-Small Cell Lung Cancer

B. YUSUFOGLU[1], C. Bilir[2]; [1]RECEP TAYYIP ERDOGAN UNIVERSITY Teaching and Education HOSPİTAL, RIZE, TURKEY, [2]Sakarya University School of Medicine, Department of Medical Oncology, Sakarya, TURKEY.

Abstract Objective:PET-CT has been used for staging of lung cancer,particularly in case of exclusion and operability of distant metastasis.Although PET-CT is often used for response to treatment; clinically,prognostic and predictive importance of basal PET-CT haven't exactly been known.As well as TLG value in PET-CT is parameter associated with SUVmean and MTV values of tumoral region,information about its clinical importance is not sufficient yet.We investigated the relation of this parameter,which hasn't been specified in routine PET-CT reporting, with oncological outcomes in advanced stage NSCLC. Methods:All patients TLG values of primary tumor, lymph nodes and measurable lesions in metastatic regions were calculated by being measured in accordance with RECIST criteria, reviewing basal PET-CT results of 76 NSCLC patients who was diagnosed and treated in our hospital between the years 2013-2015. SUVmax, SUV mean, MTV and TLG values were calculated for primary tumor, lymph nodes and metastatic regions separately. Results:The average of age of 76 patients was 64(34-84) years and they consisted of 68 males and 8 females patients. While 41 patients were diagnosed with adenocarcinoma, 35 patients were diagnosed with squamous cell carcinoma. While there wasn't a significant difference between two groups in respect to their biochemical and hemogram parameters,which are among general characteristics; just the patients diagnosed with adeno Ca were younger (62 vs 67,8;$p=0.03$). Among PET-CT parameters, a statistical relation of only SUVmax and SUVmean values was identified with PFS. But, PET-CT parameters were not related to PFS in subgroup analyzes of SCC tumor type. In adenocancer subtype, mediastinal TLG and WB TLG values were significantly correlated with each other in addition to the SUVmax value. Similarly, a relation of PET-CT parameter with only adeno Ca subtype was found. Conclusion:Although PET/CT has often been used for staging of lung cancer,prognostic importance of many PET parameters in exclusion of metastasis hasn't been known exactly. The most important finding of our study are that there is not prognostic and predictive importance of PET-CT in SCC; whereas, especially TLG values of primary tumor, WB TLG and mediastinal metastatic lymph nodes are significant and important for both PFS and OS in lung adeno Ca. As well as the number of our cases is small, provided it is supported with large-scale studies that PET-CT is more beneficial to patients diagnosed with lung adenocarcinoma; calculation of value of PET-CT indication and TLG value in this subtype may take an important place in terms of clinical practice.

EP541

Detection of Primary Tumor by FDG PET/CT in Cancer of Unknown Primary

P. Ozcan Kara[1], Z. Koc[1], E. Yaman Sezer[2]; [1]Mersin University Faculty of Medicine Department of Nuclear Medicine, Mersin, TURKEY, [2]Mersin University Faculty of Medicine Department of Oncology, Mersin, TURKEY.

Abstract Aim: Cancer of unknown primary tumors is a heterogeneous group of patients who presented with metastatic involvement of a distant organ without a documented primary site despite detailed investigation. Aim of this retrospective study is to estimate the detection ratio of FDG PET/CT in cancer of unknown primary patients. Materials and Method: Twenty five patients (13M, 12F; mean: 61,84 ±12,16 years old) with diagnosis of distant metastasis according to histopathology and/or MRI/ultrasonography were included into this retrospective study. Results: The patients presented brain (n=10), bone lesion (n=3), liver (n=6), lymph node (n=5) and pleural lesions (n=1) with additional metastatic sites in 19 patients (mean SUVmax:5,91 ±3,5). The primary tumor was determined by FDG PET/CT in 21/25 patients (84%) (lung (n=6), primary brain (n=2), renal cell carcinoma (n=2), thyroid (n=2), rectum (n=3), pancreaticobilier (n=2), subcutaneous tissue (n=1), base of tongue (n=1), sinus priformis (n=1) and lymphoma (n=1)) and two patients with suspicious primary site (colon (n=1), nasopharynx (n=1)) were present. Eight patients were out of follow up. Four patients had documented primary site which we pointed out in FDG PET/CT. Conclusion: Previous studies report 20-50% detection rate for identification of primary tumor in patients with CUP. However new generation multislice scanners may provide higher detection ratio's. The detection rate of FDG PET/CT might be higher than previously reported according to this study however prospective studies in large series are warranted. Key Words: Unknown primary, metastasis, FDG, PET/CT.

EP542

The Value of ^{18}F-fdg Pet/Ct and Cea Among Patients With Colorectal Carcinoma in Detecting Disease Recurrence

A. Barrenechea, I. S. Bandong, F. G. M. Estrada; St. Luke's Medical Center, Quezon City, PHILIPPINES.

Surveillance for colorectal carcinoma recurrence in patients who have undergone surgery and adjuvant treatment with chemotherapy or radiotherapy is usually initiated with elevated serum carcinoembryonic antigen (CEA) levels. Previous studies have shown, however, that elevated CEA is less sensitive in detecting recurrence as recurrence is also seen in patients with normal CEA levels. We evaluated the utility of FDG-PET/CT in patients with suspected recurrence of CRC by comparing PET/CT performance to CEA levels. METHODS: An ambispective cross-sectional design was done on 183 adult patients diagnosed with colorectal adenocarcinoma and who had previous surgical resection, with or without chemotherapy or radiotherapy, and who underwent PET/CT using ^{18}F-FDG from July 2013 to September 2015 at a PET center of a local tertiary hospital. Eighteen patients (10 males, 8 females, with ages ranging from from 28 to 87 years and a mean age of 63.72 years) were included as these patients were the only ones who had histopathologic confirmation or clinical follow-up proving disease recurrence. RESULTS:The FDG-PET/CT study yielded a true positive in detecting recurrence in 11 (61%) out of the 18 patients, a true negative in 5(28%) patients, a false negative in 0 (0%) patients and a false positive in 2(11%) patients. The sensitivity, specificity, and positive predictive value (PPV) of the FDG-PET/CT study for establishing recurrence were 100, 71 and 85%, respectively. In contrast, these parameters were 82, 29 and 64%, respectively, for CEA levels. No significant association was noted between CEA levels and PET/CT scan as well as $SUV_{max.}$ CONCLUSIONS: FDG PET/CT is a highly sensitive and specific tool for detecting recurrence in patients with colorectal carcinoma when compared to CEA and is able to provide a more accurate diagnosis even in patients that show a negative CEA on surveillance.

EP543

Outcome of PET/CT ^{18}F-Choline in high risk prostate cancer patients

H. Lavados, R. PRUZZO, H. AMARAL, E. HERNANDEZ, B. MORALES, A. HAEGER, R. FERNANDEZ, A. HURTADO, R. GALAZ; Nuclear Medicine and PET/CT Center, PositronMed and Arturo Lopez Perez Foundation, Santiago, CHILE.

Introduction: Prostate cancer in high-risk patients (PSA >20 ng/mL, Gleason score ≥ 8 and T≥2 cm represent 20-30% of the total of this neoplasm. The lymph nodal involvement in this group is about 15-40%. One of the limitations is of the limitations is that conventional diagnostic tools (CT, bone scan) is the accurate staging. Positron emission tomography with ^{18}F-Choline (PET/CT ^{18}F-Choline) seems to be a more precise tool to evaluate these patients. However, there are few studies evaluating the outcome of this technique in the context of management protocols and study. Objective: To assess the outcome of PET/CT ^{18}F-Choline in staging high risk prostate cancer patients. Patients and method: A total of 39 high risk prostate cancer criteria patients. 64 years old (53-74). PSA 18.9 ng/ml. Patients with histological diagnosis of high-risk prostate cancer. Radical prostatectomy performed and bilateral extended lymphadenectomy with PET/CT ^{18}F-Choline as a method of pre-staging. Pre surgical PET/CT ^{18}F-Choline and histopathology information were compared, including the resected lymph nodes. Sensitivity, specificity, positive predictive value and negative predictive value were calculated. Results: In this series the following values were obtained: sensitivity: 64%, specificity: 92%, positive predictive value: 77% and negative predictive value: 85%. Conclusions: Although this series represents a small number of patients, PET/CT with ^{18}F-Choline is a noninvasive test that provides more information about the lymph nodes involvement and presence of distant metastases in high-risk prostate cancer, allows a better staging than conventional techniques. Although the sensitivity in our series is low, it is higher than reported values for other conventional imaging techniques. Moreover the high specificity and negative predictive value allow foreseeing high degree of confidence if an abnormal PET/CT ^{18}F-Choline, effectively presents lymph nodal involvement or distant metastases, which determines a more accurate clinical management.

EP544

Usefulness of 68Ga-PSMA as agent theragnostic in metastatic breast cancer

S. S. MEDINA ORNELAS, F. O. GARCIA PEREZ; INSTITUTO NACIONAL DE CANCEROLOGIA, MEXICO CITY, MEXICO.

BACKGROUND Selective inhibition of angiogenesis is a key strategy in breast cancer. This process requires early identification when first-line therapy fails. Current research indicates that PSMA is related to angiogenesis of many solid tumors. However studies are limited in the use of this agent in metastatic breast cancer PURPOSE Demonstrate PSMA expression in tumor neovasculature of primary and metastatic breast cancer sites, to assess the potential use as theragnostic agent, regardless of the hormonal status and histology. PATIENTS AND METHODS Six patients of our institution with breast with estrogen receptors and progesterone (+) cancer, 3 patients were Her-2neu (+), and 3 patients Her-2neu (-), metastatic to bone confirmed by bone scintigraphy were evaluated by PET / CT with 68Ga-PSMA one month prior to receiving QT cycle; the purpose of assess the degree of avidity of metastatic lesions, under the hypothesis of the neovasculature of the tumor microenvironment of metastasis in breast cancer RESULTS Of the six patients evaluated similar uptake patterns were obtained in 3 of them: 1. Infiltrating ductal carcinoma; ki-67 30%, Her-2 (-) multiple bone metastases were observed 2. Infiltrating ductal carcinoma; ki-67 70%, Her-2 (+); multiple bone metastases were observed and primary lesion 3. Infiltrating ductal carcinoma; ki-67 40%, Her-2 (+); multiple bone metastases were observed and primary lesion 4. invasive lobular carcinoma; ki-67 5% Her-2 (-); not greedy bone metastases were observed PSMA, but two liver metastases unsuspected 5. invasive lobular carcinoma; ki-67 5% Her-2 (-); not greedy bone metastases were observed by PSMA 6.- Infiltrating ductal carcinoma; ki-67 70%, Her-2 (+); multiple bone metastases were observed and primary lesión CONCLUSSION Expression levels in tumor neovasculature PLASMA differ between the primary site and metastasis. Our study showed expression of PSMA in the primary site in 50% of patients; while metastatic sites were observed in 100%. A PET / CT with 68Ga-PSMA demonstrating metastatic disease can help in the selection of tumors with high expression of PSMA to provide targeted therapy with 177 Lu-PSMA, particularly in patients with invasive ductal carcinoma regardless of the status of the Her-2neu, with failure to second-line treatment

EP545

Prognostic value of staging ^{18}F-FDG PET-CT in patients diagnosed with non-small cell lung cancer

P. García-Talavera[1], C. Montes[2], F. Gómez-Caminero[1], L. Diaz[1], R. Ruano[1], B. Pérez[1], E. Martín[1], M. Martín[1], P. Tamayo[1]; [1]Nuclear Medicine Department. Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN, [2]Radiation Protection Department. Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN.

AIM Assessing the prognostic value of staging ^{18}F-FDG PET-CT in patients with non-small cell lung cancer by means of SUVmax (maximum

standardized uptake value), MTV (metabolic tumour volume) and TLG (total lesion glycolysis). In addition, studying differences in these parameters depending on cell histology. MATERIAL AND METHODS Twenty patients were included (18 men). Mean age: 67.4 ± 8.3 years old (50-86). All of them were diagnosed with histologically proved non-small cell lung cancer. Histopathology: Adenocarcinoma (8), squamous cell carcinoma (9), others (3). Initial staging (AJCC 7th edition): IA (3), IB (1), IIB (1), IIIA (5), IIIB (3), IV (7). A PET-CT (Biograph mCT Flow) was performed in all patients, one hour after intravenous administration of ^{18}F-FDG (5MBq/kg). The following parameters were determined: SUVmaxT (tumour), SUVmaxN (nodes) and SUVmaxM (metastases) of the highest metabolic lesion, as well as sum of all MTVs and all TLGs. SUVmax was obtained by means of "syngovia" software and TLG and MTV, with a homemade software. The Kaplan-Meier method was used to perform survival analysis (overall and free progression survival) and the log-rank test was applied to compare survival curves. RESULTS Overall survival (OS) was 9.9 ± 3.8 (2-16 months) and free progression survival (FPS), 8.1 ± 4.7 (1-16). Regarding OS, there were statistically significant differences depending on MTV (χ^2=6.046; p=0.014), with a cut-off value of 75. Regarding FPS there were statistically significant differences depending on MTV (χ^2=5.825; p=0.016) and TLG (χ^2=6.793; p=0.009), with cut-off values of 75 and 650, respectively. Results (mean ± s.d), depending on histology, are shown in the table. There were significant differences (Kuskall-Wallis) among different types of histology in TLG (p=0.003) and SUVmaxT (p=0.080). Squamous cell carcinoma shows higher values of TLG and SUVmaxT than adenocarcinoma (Mann Withney's test: U=12.0; p=0.021 and U=9.5; p=0.011, respectively). CONCLUSIONS This study indicates that staging ^{18}F-FDG PET-CT could be a prognostic tool in non-small cell lung cancer patients. Specifically, MTV could detect those patients at a higher risk of death; furthermore, MTV and TLG could indicate a higher probability of disease progression. Lesion histology has a significant influence on TLG and SUVmaxT, showing higher values in squamous cell carcinoma.

EP546

18F FDG PET/CT accuracy in the evaluation of residual axillary disease after neoadjuvant therapy depends on breast cancer subtypes

L. Gilardi[1], S. Baio[1], M. Colandrea[1], S. Fracassi[1], P. Rocca[1], L. Travaini[1], V. Galimberti[1], M. Colleoni[1], G. Paganelli[2], C. Grana[1]; [1]European Institute of Oncology, Milan, ITALY, [2]Istituto Scientifico Romagnolo per lo Studio dei Tumori IRST-IRCCS, Meldola, ITALY.

Purpose: The aim of our study was to prospectively investigate the role of pre-operative 18F FDG PET/CT in the prediction of axillary lymph node response to neoadjuvant therapy (NT) in patients with breast cancer. Methods: Seventy patients with primary breast cancer clinically classified as cT2-T4a-c cN0-N3 M0 and with a positive baseline PET/CT scan in the axillary lymph nodes received neoadjuvant therapy. A second PET/CT was performed before surgery, with sentinel node biopsy (SNB) in the case of pathological FDG uptake disappearance in axilla (with subsequent axillary lymph node dissection - ALND - if the sentinel node was positive) and with a direct ALND in the case of persistent FDG uptake. Results: FDG PET showed high specificity and positive predictive value for the detection of axillary disease persistence (94% and 86%, with 95% confidence interval of 79-99% and 57-98% respectively), while sensitivity, negative predictive value and overall accuracy were only 31%, 52% and 59%, respectively. Stratifying for subtypes, higher negative predictive value and overall accuracy were significantly associated with non-luminal breast cancer ($p < 0.001$ and 0.0013, respectively).Conclusions: Overall, PET/CT turned out to be inadequate to preclude surgical axillary staging after neoadjuvant treatment. However, the high specificity suggests that the procedure does have a role in the selection of patients who can directly undergo ALND, avoiding SNB. The overall accuracy of PET/CT in this setting depends on breast cancer subtypes.

EP547

Normal Distribution Pattern and Physiological Variants of Ga-68-PSMA PET/CT

E. Demirci[1], O. Sahin[2], M. Ocak[3], B. Akovalı[2], J. Nematyazar[2], L. Kabasakal[2]; [1]Department of Nuclear Medicine, Sisli Etfal Training and Research Hospital, istanbul, TURKEY, [2]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, istanbul, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University,, istanbul, TURKEY.

OBJECTIVES: Glu-NH-CO-NH-Lys-(Ahx)-[68Ga(HBED-CC)] (Ga-68-PSMA) is a novel PET tracer and binds to extracellular component of Glutamate carboxypeptidase II, which is also called prostate specific membrain antigene (PSMA) due to high expression in prostate cancer. Initial experience with Ga-68-PSMA suggests that PSMA PET/CT can be used for imaging of advanced prostate cancer. In this study we aimed to present detailed biodistribution of Ga-68-PSMA, as well as physiological and benign variants of this novel tracer. METHODS: We performed retrospective analysis of 40 patients who underwent PSMA PET/CT between January and August 2015 at our department and who had no evidence of residual or metastatic disease on PSMA PET/CT and conventional imaging methods. Additionaly 16 patients who underwent PSMA PET/CT for any indications other than prostate cancer included in the study to evaluate physiological uptake in the normal prostate gland. Median, minimum-maximum, mean, standart deviation of SUVmax and SUVmean values were calculated for visceral organs, bone marrow and lymph nodes and mucosal areas. Any physiological variants or benign lesions with Ga-68-PSMA were noted. RESULTS: Ga-68-PSMA uptake was noted in kidneys, parotid and submandibular glands, duodenum, small intestines, spleen, liver, lacrimal glands, mucosal uptake in nasopharynx, vocal cords, pancreas, stomach, mediastinal blood pool, thyroid gland, adrenal gland, rectum, vertebral bone marrow, testes and calculated meanSD of SUVmax were 55.623, 19.66.5, 19.595.3, 18.36.6, 17.77.4, 13.515.87, 12.94.9, 11.44.1, 5.562.63, 5.641.87, 5.52.5, 5.12.3, 4.31.67, 4.21.96, 3.61.6, 3.62.25, 3.61.58, 2.860.93 respectively. Celiac lymph nodes showed slightly Ga-68-PSMA uptake in 24 of 40 patients without presence of any other pathologic lymph nodes in abdominal and pelvic areas and calculated meanSD of SUVmax were 3.62.02. Kidneys demonstrated DMSA-like high cortical uptake in 39 patients and showed reduced uptake in atrophic kidney of one patient. High uptake was observed in the gallbladder wall of 4 patients (SUVmax ranged from 10.7 to 40.1). In 2 of 40 patients, calcified choroid plexus showed minimal but visible uptake. Slightly elevated uptake was noted in breast parenchyma in 3 of 8 patients who had gynecomastia. Osteophytes of 2 patients showed slight uptake. Analysis of normal-sized prostate glands, in patient group who had PSMA PET/CT for indications other than prostate cancer (n=16), demonstrated a slight physiological uptake in prostate glands (SUVmax: 5.51.6, range: 3.5-8.3) CONCLUSION: This study demonstrates normal distribution pattern, range of SUVs and physiological variants of Ga-68-PSMA. Additionally, several potential pitfalls were documented.

EP548

A potential pitfall in 68 Ga-PSMA PET/CT: Anthracosis

T. Elri, M. Aras, Y. S. Salihoglu, R. U. Erdemir, M. Cabuk; Bulent Ecevit University School of Medicine, Department of Nuclear Medicine, Zonguldak, TURKEY.

Case Presentation: A 72 year-old prostate cancer patient with known bone metastases was referred to 68 Ga-PSMA PET/CT due to increased serum tumor markers [PSA = 21.36 ng/ml (normal levels = 0.04-4 ng/ml)] and newly detected liver metastases on recent abdominal CT. In addition to intense PSMA avid bone and liver metastases, PET/CT also revealed hilar

mass in the left lung and accompanying mediastinal lymphadenopathies with intense radiopharmaceutical uptake. The hilar mass was bronchoscopically biopsied to exclude second primary lung malignancy. The histopathological analyses of this mass was reported as anthracosis. The follow up 68 Ga-PSMA PET/CT performed three months after the initial scan revealed progressed lesions in the bone and abdomen. However significant regression was observed in the aforementioned thoracic lesions. Discussion: 68 Ga-PSMA PET/CT is a relatively new imaging modality, and there is no enough information about the PSMA avidity of extraprostatic malignancies and benign conditions yet. It was reported that 68 Ga-PSMA PET/CT alone could not gave us the opportunity to reliably discriminate primary lung cancer from lung metastases of prostate cancer. On the other hand, although chronic inflammatory processes of the lung are well known reasons for false positive FDG PET/CT reporting, to our knowledge, 68 Ga-PSMA uptake in the benign conditions of the lung has not been reported yet. Our case showed that inflammatory conditions of the lung such as anthracosis may cause false positive reporting in 68 Ga-PSMA PET/CT. Conclusion: It should be kept in mind that benign conditions of the lung such as anthracosis may cause intense radiopharmaceutical uptake on 68 Ga-PSMA PET/CT and may lead to misdiagnosis. Histopathological analysis should be performed in the suspicion of second primary lung malignancy as this was the case in our patient.

EP549

The Detection of Prostate Cancer Relapse in Patients after Radical Prostatectomy with PSA Level < 2,0 ng/ml According to ^{11}C-Choline PET/CT

D. M. Pursanova[1], I. P. Aslanidis[2], O. V. Mukhortova[2], T. A. Katunina[2], V. I. Shirokorad[3], D. A. Roshchin[4]; [1]A.N.Bakoulev Scientific Center for Cardiovascular Surgery of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION, [2]Bakoulev Scientific Center for Cardiovascular Surgery, Moscow, RUSSIAN FEDERATION, [3]Moscow City Oncology Hospital №62, Moscow, RUSSIAN FEDERATION, [4]N.Lopatkin Scientific Research Institute of Urology and Interventional Radiology – Branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

The detection of extrapelvic metastases in prostate cancer (PCa) patients with early biochemical relapse (PSA <1,0-2,0 ng/ml) after radical prostatectomy is crucial for selecting patients for salvage radiotherapy. Purpose: To evaluate the usefulness of ^{11}C-Choline PET/CT in patients after radical prostatectomy with low PSA level for detection of PCa relapse. To identify predictive factors of a positive ^{11}C-Choline PET/CT. Materials and methods: PET/CT was performed in 61 patients on PET/CT scanner (Biograph-64, Siemens) 10 min after injection of ^{11}C-Choline (400-700 Mbq). The mean PSA value in the group was 0.93 ±0.54 (0.21-1.98) ng/ml, median - 0.91 ng/ml. Results: Overall, ^{11}C-Choline PET/CT detected PCa relapse in 30% (18/61) of cases. There was no statistical difference between PET-positive (n=18) and PET-negative (n=43) patients according to age, time to biochemical relapse after surgery, Gleason score and ongoing hormone therapy. The detection rate of relapse according to ^{11}C-Choline PET/CT showed correlation (p=0,007) with serum PSA: positive PET/CT results were obtained in 30% (18/61) patients with PSA <2,0 ng/ml, in 23% (12/53) - with PSA <1,5 ng/ml, in 17% (6/36) - with PSA <1,0 ng/ml, and in 20% (3/15) - with PSA <0,5 ng/ml. PSA doubling time <6 months, stage ≥T3 and N1 were significantly associated with an increased probability of positive PET/CT findings (<0,05 for all). All these parameters were found to be independent predictive factors for PET-positive result at simple linear regression analysis. The combination of mentioned predictors, except N1, was statistically significant in the prediction of a positive PET/CT at multiple linear regression analysis. Local relapse was detected in 61% (11/18) patients: prostate bed (2) and pelvic lymph nodes (9). Distant metastases were identified in 28% (5/18) cases: lymph nodes (3), bone (1) and lungs (1). In 11% (2/18) cases both local and distant metastases were diagnosed: regional and extrapelvic lymph nodes (1), regional lymph nodes and bone (1). Conclusion: ^{11}C-Choline PET/CT was able to detect and correctly identify the localization of PCa relapse (local and distant) in 30% of patients with PSA <2,0 ng/ml, and therefore was useful in choice of further therapeutic approach. Pathological stage (≥T3, N1), trigger PSA and short PSA doubling time were found to be significant predictors for PET-positive result and should be considered in patient selection for ^{11}C-Choline PET/CT.

EP550

^{68}Ga-PSMA PET imaging of adenoid cystic carcinoma

T. J. W. Klein Nulent[1], S. M. Willems[2], R. de Roos[3], G. C. Krijger[3], F. F. T. Ververs[3], R. J. van Es[1], B. de Keizer[3]; [1]department of oral and maxillofacial surgery, UMC Utrecht, Utrecht, NETHERLANDS, [2]department of pathology, UMC Utrecht, Utrecht, NETHERLANDS, [3]department of nuclear medicine and radiology, UMC Utrecht, Utrecht, NETHERLANDS.

Introduction: ^{68}Ga-PSMA PET imaging has been shown to be positive in several types of malignancies. We present the first results of ^{68}Ga-PSMA PET imaging in patients with local recurrence or metastatic adenoid cystic carcinoma (ACC), a rare tumour originating from the salivary glands. *Methods:* 5 patients with known or suspected local recurrence or metastatic ACC were retrospectively analised. Also primary tumours wers immunohistochemically (IHC) stained for PSMA expression. *Results:* All patients showed pathological PSMA binding in known or new sites of metastatic ACC. Mean SUVmax value of ACC was 7,73 (range 2,42 - 12,97). Mean SUVmax of the normal parotid gland in these patients was 14,04 (range 6,88 - 31,37). IHC was strongly positive for PSMA in 3/5 patients. *Conclusion.* ^{68}Ga-PSMA PET imaging might be a usefull and better imaging modality in staging and follow-up of ACC. Due to the high PSMA expression of these tumours ACC might also be candidate for treatment with ^{177}Lu-PSMA.

EP551

The Impact of Time-of-Flight Acquisition on Shortened Dynamic 18F-FLT PET Quantification

X. Liu, J. Zhang, P. Subramanian, B. Ramaswamy, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

Aim: To investigate the impact of Time-of-Flight (TOF) information on kinetic ^{18}F-FLT PET quantification combined with shortened acquisition. To establish an optimized dynamic FLT PET imaging protocol for accurate FLT kinetics quantification for therapy response assessment. Materials and Methods: 30min-dynamic and whole-body FLT PET were acquired on a Gemini TF 64 system (Philips). Dynamic PET data were reconstructed twice following a 26-frame protocol (8x15s, 6x30s, 5x1min, 5x2min, 2x5min), with and without TOF information separately. Maximum activity concentrations (Bq/mL) from tumors and plasma (descending aorta) were obtained via 3D ROI. Ki values were calculated from both TOF (Ki_TOF) and non TOF (Ki_NTOF) data sets using Patlak Analysis by in-house developed software based on different data acquisition durations (Td) (10, 12, 14, 16, 20, 25, 30min) and different linear regression onset time (T0) points (1, 2, 3, 4, 5min). SUV_{max} of the tumors were collected from WB images (SUV_{max}_TOF). Ki_TOF of the shortened data series were compared with Ki_TOF as well as Ki_NTOF of the 30min-data sets. Ki_TOF of the 30min-data sets and Ki_NTOF of the 30min-data sets were compared to each other as well as SUV_{max}_TOF values. Pearson product-moment correlation coefficient (R) of 0.9 was

chosen as a limit for the correlation coefficient. A total of 26 data sets were evaluated. Results: Ki_TOF from image series with shortened Tds compared Ki_TOF of the 30min series showed that the correlation increased as Td increased from 10 to 25min. It revealed weak correlation for series with Td≤14min (R=0.70±0.07, 0.75±0.05, 0.86±0.03 at Td=10, 12, 14min) and excellent correlations when Td≥20min (R=0.97±0.00, 0.99 ±0.00 at Td= 20, 25min) regardless of T0 value. When Td=16min, strong correlation of Ki was shown only when T0≤3min (R=0.92, 0.90, 0.90, 0.88, 0.86, 0.89 at T0=1, 2, 3, 4, 5min). Comparisons between Ki_TOF of all tested Tds and Ki_NTOF from the 30min series revealed poor correlations independent from the T0 value (R=0.39±0.10, 0.41±0.10, 0.50 ±0.06, 0.55±0.05, 0.67±0.03, 0.75±0.02, 0.81±0.01 at Td= 10, 12, 14, 16, 20, 25, 30). When comparing Ki_TOF and Ki_NTOF of 30min data to SUV_{max}_TOF, strong correlations were discovered with Ki_TOF (R=0.92±0.01) while weak correlations were indicated with Ki_NTOF (R=0.86±0.03) no matter of T0 value (Fig. 1B). Conclusion: A 16min-long dynamic ^{18}F-FLT PET acquisition with TOF is capable of accurately estimating Ki values, which highly correlate to WB SUV_{max}. The use of TOF in dynamic FLT PET acquisition may introduce variation in Ki values when compared to non TOF.

EP552

Density-threshold for FDG-PET/CT-based N-staging in lung cancer patients

P. Flechsig[1], P. Frank[1], C. Kratochwil[1], L. Schwartz[2], U. Haberkorn[1], F. Giesel[1]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]Columbia University, New York, NY, UNITED STATES.

Purpose: Mediastinal N staging done by integrated ^{18}F-FDG-PET/CT in lung cancer patients is not always accurate. In order to reduce the need for invasive staging procedures, additional surrogate parameters for the detection of malignant lymph node infiltration would be helpful. The purpose of this study was to evaluate if semi-automated density measurements in mediastinal lymph nodes can improve preclinical N-staging, irrespective of the specific lung cancer entity. Methods: This retrospective study was approved by the institutional review board. 248 histologically proven lymph nodes in 122 lung cancer patients were investigated. Non-contrast enhanced ^{18}F-FDG-PET/CT was performed before surgery/biopsy. Lymph nodes analyses were performed on the basis of FDG-uptake and volumetric CT histogram analysis for metric lymph node sampling. Results: Of the 248 lymph nodes, 118 were benign, 130 malignant. Malignant lymph nodes had a significantly higher median CT density (>30HU) compared to benign lymph nodes (9.3 HU, $p < 0.05$), irrespective of the histological subtype. The discrimination between different malignant tumour subtypes by means of volumetric density analysis failed. Irrespective of the malignant subtype, a possible cut off value of 20HU may help differentiate between benign and malignant lymph nodes. Conclusion: Density measurements in unclear mediastinal and hilar lymph nodes with equivocal FDG uptake in PET might serve as a possible surrogate parameter for N-staging in lung cancer patients, irrespective of the specific lung cancer subtype. This could also help to find possible high yield targets in cases where invasive lymph node staging is necessary.

EP553

Evaluation of the disease state and effectiveness of radiotherapy with F-18 FDG PET/CT in locally advanced cervical cancer

E. Acar[1], H. Durak[1], Z. Arıcan[2], &. Görken[2], G. Çapa Kaya[1]; [1]Dokuz Eylül University, School of Medicine, Department of Nuclear Medicine, İzmir, TURKEY, [2]Dokuz Eylül University, School of Medicine, Department of Radiation Oncology, İzmir, TURKEY.

PURPOSE: The purpose of this study was to compare F-18 FDG PET/CT findings in patients with locally advanced cervical cancer before-and-after radiotherapy (RT). METHODS: We retrospectively evaluated 41 patients (mean age: 57.3, range:29-81) with cervical cancer referred to the Department of Nuclear Medicine between January 2009 and December 2015. There were 39 patients with squamous cell carcinoma, 1 with adenocarcinoma, 1 with poorly differentiated invasive carcinoma. All patients were treated with radiotherapy. F-18 FDG PET/CT was performed at baseline and at 12 weeks after the completion of RT. We compared the primary tumor area, regional lymph nodes and distant metastases before-and-after RT. RESULTS: For all patients, the average pretreatment SUVmax was 12.7 ±5.3 in the primary lesion area. 24 patients (58%) had regional lymph node metastases, and SUVmax values were 4.1 ±5.1. Four patients with mild F-18 FDG uptake in mediastinal lymph nodes were considered suspicious for metastasis. After treatment; 15 patients (36.5%) had no pathological uptake in the whole body, 21 patients (51%) had no pathological uptake in the cervix. Primary lesion area SUVmax was 2.6 ±3.4 ($p<0.01$). In 11 patients (27%) regional lymph node metastasis was observed, 10 of these patients (24.6%) had lymph node metastases at baseline F-18 FDG PET/CT imaging. After RT, SUVmax values of the regional lymph nodes decreased to 1.6 ±3.2 (p:0.004). After treatment 11 patients (27%) showed distant metastatic disease, 1 patient (2.4%) was suspicious for distant metastasis. The most frequent metastatic sites were; bone, lung, liver, abdominal/mediastinal/cervical lymph nodes and intraabdominal implants. 1 patient showed spleen metastasis. CONCLUSION: In 51% of patients with cervical cancer complete response was observed after RT in primary tumor area. 27% patients developed metastatic disease in the short term. After RT, SUVmax value of primary lesion area and regional lymph nodes showed statistically significant reduction. Suggesting that the treatment is successful.

EP554

Breast Incidentalomas detected by ^{18}F-FDG PET/CT

I. P. Carvalho, R. Sousa, S. C. Vaz, P. Ratão, F. N. Brandão, M. R. Carvalho, T. C. Ferreira, L. Salgado; Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, PORTUGAL.

Aim: To evaluate the frequency and clinical significance of focal and unilateral breast lesions incidentally found on ^{18}F-fluorodeoxyglucose positron emission tomography (^{18}F-FDG PET/CT). Material and Methods: We retrospectively reviewed 5149 ^{18}F-FDG PET/CT performed at our department from January 2014 to January 2016, of which 2174 studies were performed on female patients (pts). All pts in whom the report mentioned unilateral and focal ^{18}F-FDG increased uptake and presence of findings on the CT component were selected. The reports from pts with the following criteria were excluded: under 18 years old (11 pts), known history of breast cancer (427 pts), occult primary tumors (23 pts), known breast disease from other malignancies (13 pts) and bilateral low-grade breast FDG uptake. We included 1699 study reports from 1642 women. In order to assess the clinical significance of breast lesions we recorded follow-up data (mammography, ultrasound and biopsy results). The data was analyzed using descriptive statistics. Results: On 1699 ^{18}F-FDG PET/CT studies performed, we identified 13 focal and unilateral breast lesions in 12 pts (incidence of 0.71%). The median age of the 12 women was 66 (range: 33-79 y). All the pts were referred for staging of tumours: malignant cutaneous melanoma (3/12), lung cancer (2/12), ovarian cancer (2/12), scapular chondrosarcoma (1/12), endometrial cancer (1/12), thyroid cancer (1/12), non-Hodgkin lymphoma (1/12) and Hodgkin lymphoma (1/12). The average of maximum

standard uptake value (SUVmax) of breast lesions was 3.37 (range: 1.5-13.8; median 2.59). The follow-up data was available in 6 out of 12 pts. Breast lesion biopsy was performed in 4 pts: 3 lesions were malignant (one moderately differentiated invasive breast carcinoma (SUVmax 2.4 and BI-RADS 6), one breast carcinoma not otherwise specified (SUVmax 13.8 and BI-RADS 6) and one poorly differentiated invasive breast carcinoma (SUVmax 3.2 and BI-RADS 6); the benign lesion was a fibroadenoma (SUVmax 2.6 and BI-RADS 4A). One patient did not require further follow-up (BIRADS 1) and one patient refused to perform biopsy. In the other 6 pts, breast lesions were not considered for further study in 4 and in the other 2 follow-up data were not available. Conclusion: According to our study, breast incidentalomas with focal increased FDG uptake on PET/CT are uncommon (incidence of 0.71%). From the 6 lesions studied, breast malignancy was confirmed in 3. However, the small size of the sample does not allow a definitive assessment of clinical significance. Further studies are needed.

EP555

Role of FDG - PET/CT in the diagnostics of changes in the lung parenchyma, suspicious of radiation pneumonitis

A. K. D. Demirev, Sr.[1,2]; [1]City Clinic Oncology Sofia, Sofia, BULGARIA, [2]University Hospital Aleksandrovska Sofia, Sofia, BULGARIA.

Radiation Pneumonitis /RP/ is an adverse complication of radiotherapy /RT/ and can sometimes limit the application of the already planned radiation dose. It is often associated with radiotherapy of lung carcinoma and is occasionally caused by radiation therapy of breast carcinoma and lymphomas located in the mediastinum, respectively in about 5-50%, 5-10%, and 1-5% of all cases. PET-CT with 18F - FDG hybrid imaging emerges lately as a prospective modality for early diagnostics of RP. Aim of this study was to summarize the initial data from the diagnostic application of PET-CT in patients suspicious of RP and to derive criteria, which can help differentiate RP from early recurrence of the disease and/or residual tumor. The current study included 23 patients (out of 220 patients with RT in the thracic region) examined between 2012 and 2015, who had metabolic (PET) and morphological (CT) changes consistent with RP. We additionally defined the metabolic activity or the maximum standardized uptake value (SUVmax) in the lung parenchyma of 20 patients without RT. In our patient group 13/23 of the patients had serial examinations - 9/13 before and after RT, 4/13 more than 6 months after RT. The rest of the patients 10/13 had a single examination up to 6 months / more than 6 months after RT. All patients had considerably increased metabolic activity or a tendency towards increased metabolic activity in the lung parenchyma involved in the irradiated area with a mean of SUVmax3,45 /ranging between 1 and 7,1/. The control group had a physiological background metabolic activity of respectively SUVmax0.61 +/- 0.11. The difference in the metabolic activity between the two groups was statistically significant ($p < 0{,}0001$). The particular metabolic changes in the patients suspicious of RP involved diffusely increased metabolic activity coinciding with the morphological changes in the irradiated area. 3/23 patients had a proven recurrence of the primary neoplastic process in the irradiated area. The metabolic changes in those patients involved - increase in the metabolic activity at follow up or lack of tendency towards normalization after chemotherapy, which implied the existence of still viable tumor cells. Our initial experience in the diagnostic application of 18F-FDG PET/CT in patients suspicious of RP, allows us to summarize the following - PET/CT is a reliable imaging modality in the diagnostics of RP. Through its sequential use, we can differentiate inflammatory changes related to RP from early recurrence of the primary neoplastic process

EP556

Implications of PET/CT in radiotherapy treatment planning of Head&Neck disease

O. Ferrando[1], E. Giovannini[2], R. Leoncini[2], T. Scolaro[3], F. Foppiano[1], A. Ciarmiello[2]; [1]Department of Medical Physics - ASL5 Spezzino, La Spezia, ITALY, [2]Department of Nuclear Medicine - ASL5 Spezzino, La Spezia, ITALY, [3]Department of Radiotherapy - ASL5 Spezzino, La Spezia, ITALY.

Aim. To evaluate the role of PET/CT respect to conventional CT in radiotherapy treatment planning for head and neck disease. Methods and Materials. We have analysed a set of 31 patients with histological diagnosis of head and neck cancer who underwent conformal-3D Radiotherapy. The anatomical area of this disease was divided in: oropharyngeal, laryngeal and oral cavity cancer. Gross tumour volumes were delineated on CT images (CT_GTVs) by an expert radiation oncologist blinded to PET data. Successively another set of target volumes was defined taking into account the combined PET/CT information (PET_GTVs). 3D-Radiotherapy planning was performed on CT_GTVs and the dose-volume histograms also for PET_GTVs were analysed at the aim to evaluate any changes in the dosimetric parameters. The study also analysed the difference between CT_GTVs and PET_GTVs volumes. Results. In the cohort of the analysed patient 9 had the nodal stage changed by inclusion of PET data. 1 patient had negative PET/CT and for 1 patient PET reveals distant metastasis. For two patients lynphonodal gross tumour volumes should not being identified without PET information. 3D-Radiotherapy planning implemented on CT_GTVs showed that, in 37% of the irradiated patients, PET_GTVs and BTVs (Biological Target Volume) underdosages would be in the range -69%±38% and -81%±20% of the prescribed dose respectively. Mean values of PET_GTV volumes were smaller than CT volumes: 109 ±110 cm^3 versus 130 ± 98 cm^3 ($p < 0.03$). The mean mismatching fraction between CT volumes and PET volumes was 0.41. Conclusions. In radiotherapy treatment planning of head and neck disease PET/CT provide a more precise target definition and prevent exclusion of pathologic areas. In our population addition of PET information to CT avoids significant underdosages of gross tumour volumes and biological tumour volumes in 37% of the patients. The most serious underdosages are observed in oropharyngeal and oral cavity cancer groups. In the laryngeal cancer group CT_GTVs overlaps PET_GTVs therefore for these patients the PET involvement allows a target volume reduction with a consequent better critical organ preservation and lower toxicity.

EP557

Low risk and high risk recurrent prostate cancer in 3D Volumetric lymph node assessment based on CT and PSMA11-PET/CT

M. Vinsensia[1], C. Kratochwil[1], J. Moltz[2], M. Eiber[3], A. Afshar-Oromieh[1], U. Haberkorn[1], F. Giesel[1]; [1]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY, [2]MeVis Fraunhofer, Bremen, GERMANY, [3]Department of Nuclear Medicine, Technical University Munich, Munich, GERMANY.

Introduction PSMA11-PET/CT is a powerful method of detecting early nodal metastases in patients with biochemical relapse. On this retrospective investigation the volume, dimensions and SUVmax of nodes identified by Glu-urea-Lys-(Ahx)-[^{68}Ga(HBED-CC)] (^{68}Ga-PSMA11) was evaluated and identified alongside their initial risk profile. Methods All PET/CT images were acquired 60±10 min after intravenous injection of 68Ga-PSMA-11 (mean dose 176 MBq). In 44 patients with recurrent prostate cancer and PSA relapse, 96 PSMA-positive lymph nodes were identified. These patients were classified based on their risk profile by the initial diagnosis in either low risk (Gleason Score≤6) or high risk group (Gleason Score>6). Fifty one PSMA-positive lymph nodes from 20 high

risk patients and 45 PSMA-positive lymph nodes from 22 low risk prostate cancer patients were identified. Using semi-automated lymph node segmentation software (MeVis, Bremen, GER), the node volume, short and long axis dimensions were measured and compared to the maximum standardized uptake value (SUVmax). By morphologic criteria alone, round nodes greater than or equal to 10 mm would be considered positive, meanwhile lymph node with PSMA uptake (SUVmax) more than 2.0 would be considered PSMA-positive. Results The mean volume of ^{68}Ga-PSMA-positive nodes in high risk group was 0.8 ml (range 0.3-38.0 ml) and 0.6 ml (range 0.1-7.8 ml) in the low risk group. The mean short axis diameter in high risk group was 8.8 mm (range 4.1-36.0 ml) and 7.5 ml (range 2.1-22.0 ml) in the low risk group. High risk group presented mean SUVmax of 17.5 (range 3.1-102.4), meanwhile the low risk group′s mean SUVmax was 12.9 (range 2.7-74.3). From 51 PSMA-positive lymph nodes from the high risk group, 21 lymph nodes (41%) were positive based on diameter >10mm on CT. Meanwhile on the low risk group, only 14 out of 45 PSMA-positive lymph nodes (31%) were positive based on the morphologic criteria. Based on PSMA11-PET/CT, 4 out of 20 patients (20%) from the high risk group and 10 out of 22 patients (45%) from the low risk group were upstaged from N0 to N1. These patients had PSMA-positive nodal metastases that are smaller than 10 mm and therefore missed by the conventional morphologic criteria. Conclusion 68Ga-PSMA-11 PET provides a better assessment of the nodal metastases status in patients with recurrent prostate cancer, especially in the low risk group. Morphological imaging strongly underestimates lymph-node involvement compared to PSMA-molecular staging in both, low- and high-risk group.

EP558

Biokinetic study of ^{18}F-fluorocholine uptake to differentiate malignant and physiologic uptake of ^{18}F-fluorocholine in prostate cancer metastases

M. Wondergem[1,2], R. J. J. Knol[1], F. M. Van der Zant[1], T. Van der Ploeg[1], J. Pruim[2,3], I. J. De Jong[2]; [1]Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS, [2]University Medical Center Groningen, Groningen, NETHERLANDS, [3]Stellenbosch University, Tygerberg Hospital, Stellenbosch, SOUTH AFRICA.

Introduction ^{18}F-fluorocholine-PET/CT is widely used in patients with prostate cancer. Knowledge of the biokinetic behaviour of ^{18}F-fluorocholine in malignant lesions and physiologic tissue is helpful in distinguishing malignant from physiologic ^{18}F-fluorocholine uptake and, furthermore, may elucidate the best time point after ^{18}F-fluorocholine administration for acquisition of PET/CT images. We studied characteristics of ^{18}F-fluorocholine uptake in tissues of importance to detect lymph node and bone metastases. Methods One hundred subsequent patients with histopathologically proven prostate cancer were prospectively included in the study. Dynamic PET/CT images of the pelvic area were acquired in the first 10 minutes followed by total body images at 45-60 minutes post injection. SUV measurements on different time-points were performed on lymph node metastases, normal lymph nodes, bone metastases, normal bone marrow, blood pool, adipose tissue, intestine and muscle. Results The dynamic data show a nearly stable ^{18}F-fluorocholine activity in all tissues from 2 minutes post injection. However significant changes in ^{18}F-fluorocholine uptake between early and late time-points are observed. A decrease in tracer uptake in non-malignant lymph nodes and blood pool is detected together with an increase in muscle, bone metastases and non-malignant bone. A statistically significant decrease of the tumour-to-background ratio (TBR) between bone metastases and muscle and malignant lymph nodes and muscle is observed at the late time-point compared to the early time-point. Conversely, an increase of the TBR between malignant lymph nodes and the blood pool is demonstrated. ROC-analysis showed that $SUV_{max,early}$ is the best predictor of malignancy in lymph nodes (cut-off 2.0) and $SUV_{max,early}$ and $SUV_{max,late}$ (cut-off 2.5 and 2.9 respectively) are the best predictors of malignancy for bone lesions. Conclusion According to our data, a dual time-point acquisition protocol would be best for detection of lymph nodes metastases. The $SUV_{max,early}$ is the best characteristic to discriminate malignant from non-malignant lymph nodes. For detection of bone metastases data acquisition at an early time-point is favourable over a later acquisition which is hampered by accumulation of activity in muscle. Both $SUV_{max,early}$ and $SUV_{max,late}$ can be used to discriminate malignant bone lesions from non-malignant bone.

FDG-PET/CT in Multiple Myeloma: Correlation Between SUV and Standard Prognostic Scoring System in Multiple Myeloma

B. Østergaard[1], A. L. Nielsen[2], O. Gerke[2], J. T. Asmussen[3], T. Plesner[4], P. Holdgaard[5], T. E. J. Ormstrup[6], A. Alavi[7], N. Abildgaard[1], P. F. Høilund-Carlsen[2]; [1]Department of Hematology, Odense University Hospital, Odense, DENMARK, [2]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [3]Department of Radiology, Odense University Hospital, Odense, DENMARK, [4]Department of Hematology, Vejle Hospital, Vejle, DENMARK, [5]Department of Nuclear Medicine, Vejle Hospital, Vejle, DENMARK, [6]Department of Radiology, Vejle Hospital, Vejle, DENMARK, [7]Department of Radiology, Perelman School of Medicine, University of Pennsylvania, Pennsylvania, PA, UNITED STATES.

Aim: FDG-PET/CT is a promising methodology for staging, prognostication and response evaluation in multiple myeloma (MM). High intensity of FDG uptake at diagnosis is associated with more aggressive disease and reduced overall survival. However, it is unknown to which degree this type of functional information correlates with established clinical prognostic biomarkers in MM, including the international scoring system (ISS) and the revised ISS (R-ISS). We aimed to elucidate this. Material and method: As a part of an ongoing prospective study evaluating new imaging technologies in MM we examined data from the first 35 included patients with treatment demanding MM. Patients were enrolled at diagnosis and studied at baseline with 18F-FDG-PET/CT prior to any given anti-myeloma treatment. The lesion with the highest FDG uptake was analysed by a semi-quantitative dedicated software (ROVER, ABX, Radeberg, Germany) to yield the values of lesion volume, SUVmax, SUVpeak, SUVmean and cSUVmean (SUVmean corrected for partial volume effect). Finally, SUVmax was standardized to the liver uptake of FDG according to the Deauville criteria. Results: One patient had incomplete ISS data. Thus, 34 patients were included. Of these, 19, 11, and 4 patients were stratified to ISS groups I, II and III, respectively, while 9, 24, and 1 patients were stratified to the revised ISS groups R-ISS1, R-ISS2, and R-ISS3, respectively. SUVmax values ranged between 3.6 MBq/ml and 27.8 MBq/ml. Six patients had Deauville score 3, 12 had Deauville score 4, and 6 had Deauville score 5. SUVmax standardized to liver uptake was inversely correlated with ISS (p=0.03), but not with R-ISS (p=0.85). This observation we interpret as an incidental finding. Absolute values of SUVmax, SUVpeak, SUVmean, and cSUVmean were not correlated to either ISS or R-ISS (p = 0.3-0.8). Conclusion: There were no significant correlations between FDG uptake and ISS or R-ISS scores. This indicate that the potential prognostic value of high FDG uptake is independent of conventional prognostic markers in multiple myeloma and raises the question whether serum biomarkers or quantitative molecular imaging provide the best and most accurate expression of MM disease activity and extent. We will examine this in detail when all data from the ongoing investigation will soon become available.

EP560

Vescicular Monoamine Transporter Expression in Pheochromocytomas and Paragangliomas according to Scintigraphy and Positron Emission Tomography behavior

S. CHIACCHIO[1], A. Bacca[2], A. Pucci[3], D. Lorenzini[4], G. Puccini[5], M. Gennaro[5], E. Tardelli[5], F. Betti[1], G. Bernini[2], D. Volterrani[1]; [1]Regional Center of Nuclear Medicine-OSPEDALE SANTA CHIARA, PISA, ITALY, [2]Department of Clinical and Experimental Medicine-OSPEDALE SANTA CHIARA, PISA, ITALY, [3]Department of Histopathology-OSPEDALE SANTA CHIARA, PISA, ITALY, [4]Department of Diagnostic, Interventional and Vascular Radiology and of Nuclear Medicine-OSPEDALE SANTA CHIARA, PISA, ITALY, [5]Regional Center of Nuclear Medicine-University of Pisa, PISA, ITALY.

Aim: The expression of vesicular catecholamine transporters (VMAT1, VMAT2) in pheochromocytomas (PHEOs) and paragangliomas (PGLs) and relationships with 18F-DOPA PET/TC and 123I-MIBG uptake are unknown. Therefore the objective of this study was to correlate VMAT1 and VMAT2 expression with the functional imaging in patients with PHEOs, extra-adrenal abdominal PGLs (APGLs) and head/neck PGLs (HNPGLs). Patients and Methods: This observational study involved 31 consecutive patients with PHEO (n=17) and PGL (n= 14) (14 men and 17 women), aged 40.7 yrs (age range 14-67 yrs) who undergone surgery over a 3-year (2010-2013) time. They had been admitted in our Hypertension Unit for signs and/or symptoms of catecholamine excess (n=20), mass incidentally discovered (n=3) or for mass-related disturbances (n=11). All patients underwent the same diagnostic work-up, including 24-h urinary methanephrines measurement, magnetic resonance (MR) and/or computed tomography (CT) and 123I-MIBG scintigraphy (n=20). Starting from 2011, 14/31 patients performed 18F-DOPA PET/TC. Three patients underwent both procedures. Histopathology and immunohystochemistry of the excised tumor was performed in all patients. The number of VMAT1 and VMAT2-immunoreactive cells in tumors was semi-quantitatively evaluated according to the immunoreactivity scoring system by Fottner et al. (2010). Human adrenal glands were used as positive controls. Results: VMAT1 immunostaining was found in all tumors, except two PHEOs. VMAT1 immunoreactivity was higher in PGLs than in PHEOs, though at not significant extent. VMAT2 was high in all but two negative tumors (PHEOs). Normal 123I-MIBG uptake was associated to either high, intermediate, low or absent VMAT1/2 immunoreactivity. Patients that underwent 18F-DOPA PET/CT had a high score level of both VMATs and were detected by the technique in all cases. Conclusions: VMAT receptors do not seem essential for 123I-MIBG uptake and other pathways for the vescicular storage of catecholamines might be hypothesyzed. Alternatively, an unknown interaction between VMAT and other transporters or surface receptors could be taken into account. Patients submitted to 18F-DOPA PET/CT (almost all with PGL) showed both VMAT highly expressed and the radiotracer uptake proved to be always present. Thus, we cannot know if this uptake would been observed also in presence of low or absent receptor immunoreactivity. In summary, VMAT1 and VMAT2 are highly expressed in most tumors, though VMAT1 immunoreactivity is predominant in PGLs rather than in PHEOs. VMAT1 and VMAT2 receptors play an important role but are not essential for radiotracer uptake, at least in 123I-MIBG scintigraphy.

EP561

Eomesodermin/Bcl6-expressing T-cells Play Essential Roles in Progressive State of Hashimoto's Thyroiditis

M. Stefanic[1], S. Tokic[2], M. Suver Stevic[2], L. Glavas-Obrovac[3]; [1]Clinical Institue of Nuclear Medicine and Radiation Protection, Osijek University Hospital, Osijek, CROATIA, [2]Dept. of Clinical Laboratory Diagnostics, Osijek University Hospital, Osijek, CROATIA, [3]Dept. of Medicinal Chemistry and Biochemistry, School of Medicine Osijek, University J J Strossmayer, Osijek, CROATIA.

Introduction. There is an increasing appreciation for the role of cytotoxic $CD8^+$ T-cells in Hashimoto's thyroiditis (HT), an autoimmune thyroid disorder manifesting in chronic thyroid inflammation, and subsequently, hypothyroidism. Recently, much has been learned on molecular mechanisms underlying cytotoxic T-cell development; however, the importance of several lineage master regulators that play a central role in the generation and preservation of terminally differentiated $CD8^+$ T-cells has remained unknown in HT. Subjects and Methods. We assessed mRNA expression levels of several transcription factors, including eomesodermin (Eomes), Bach2, Bcl6 and Tcf7 in untouched T cells across three different outcomes of HT (hypothyroid, untreated HT-hypothyroid HT undergoing hormone replacement therapy-spontaneously euthyroid HT). Granzyme B (GZMB) mRNA expression was representative of cytolytic effector molecules. The study included 30 HT patients (56±13.8 yr) and 10 euthyroid, TPOAb-negative, age and body mass index-matched healthy controls (47±12.6 yr). T-lymphocytes were isolated from peripheral blood mononuclear cells, total mRNA was extracted from $CD3^+$ T-cells and gene expression was studied in triplicate by TaqMan RT-qPCR relative to TBP products [2 (-delta delta Ct) method]. Results. Significantly higher expression levels of Eomes [P=0.044, Mann-Whitney test, median 2.15 fold, interquartile range 1.29-3.42], Bcl6 [P=0.001, 1.94 (1.37-2.49)] and GZMB mRNA [P=0.028, 3.12 (1.52-5.9)] were found in T-cells of the HT patients (n=30) when compared to the controls. For Bcl6, increased transcript abundance was observed in severely affected, hypothyroid patients, both L-thyroxine-treated [1.96 (1.37-2.61), n=10] and untreated [2.08 (1.67-2.46), n=9], but not in spontaneously euthyroid HT individuals [1.41 (1.13-1.99), n=11; Kruskall-Wallis P=0.0026, Bonferroni-Dunn's post-hoc test]. Both Eomes (Spearman's rho=0.34, P=0.034) and Bcl6 transcript levels (rho=0.35, P=0.026) increased with age. Increased T-cell Eomes mRNA expression was strongly associated with decreased residual thyroid volume (rho=-0.47, P=0.011) and high GZMB expression (rho=0.71, $P=10^{-5}$) in the HT group. Conclusions. Our findings suggest potential novel functions for cytolytic/follicular helper T-cell transcription factors Eomes and Bcl6 in the context of HT, particularly in aged individuals and aggressive disease forms characterized by thyroid injury. $Eomes^+$ T-cells may be associated with the development of thyroid atrophy. Integrating the role of $CD8^+$ T cell subtypes will be an important new goal in understanding the pathogenesis of HT and in devising new therapeutical targets.

EP562

The Relationship Between Repeated Brown Adipose Tissue Evidence in Sequential PET/CT Examinations and Air Temperature Change

S. Isgoren, T. hekimsoy, g. daglioz gorur, h. demir; Kocaeli University School of Medicine Department of Nuclear Medicine, KOCAELI, TURKEY.

AIM: The aim of our study was to investigate the rate of repeated brown adipose tissue (BAT) existence in sequential PET/CT scans and the affect of outdoor air temperature of the study date on BAT positiveness in this group. METHODS: PET/CT studies which are performed between 2012 and 2016 in our Nuclear Medicine unit were analyzed and 77 patients (29 male, 48 female) who underwent more than one PET/CT scans and had BAT existence in at least one of them were included in this study. A total of 219 PET/CT studies of these patients were investigated and 106 studies (48,4%) of them were BAT-positive while the remaining 113 studies (51,6%) were negative. Outdoor air temperature values on the days of PET/CT scans were evaluated for each group. RESULTS: In 10 patients (13%) BAT was detected in all their PET/CT scans (23 PET/CT studies) while the remaining 67 patients (87%) had both BAT-positive and negative PET/CT scans (196 PET/CT studies). When analyzing the effect of temperature on BAT-positive (106 studies) and negative (113 studies) studies, there was a significant temperature difference between these

two groups (p<0,01). When PET/CT scan is repeated on patients with known BAT evidence, 48,4% of sequential studies were BAT-positive and outdoor air temperature was lower on the date of these studies (12,4±5,6 °C) while it was higher (17,4±6,8 °C) in BAT-negative study group. CONCLUSION: In summary, temperature is a highly affecting factor of persistence of BAT evidence on FDG-PET/CT in repeated studies. To prevent patients who are known to have a BAT in their previous PET/CT scans from being exposed to cold can be a solution to avoid existence of metabolically active BAT in sequential PET/CT studies.

EP563

A PRISMA based systematic literature review for revealing the impact of nuclear physicians' information behaviour on PET/CT oncological imaging

E. Persakis[1,2], P. Kostagiolas[2], I. Datseris[1], D. Niakas[3]; [1]Department of Nuclear Medicine - PET/CT, Evaggelismos General Hospital, Athens, GREECE, [2]Department of Archives, Library Science and Museology, Faculty of Information Sciences and Informatics, Ionian University, Corfu, GREECE, [3]School of Social Science, Hellenic Open University, Patras, GREECE.

Aim: Studying the information seeking behaviour and preferences of nuclear physicians is rather important for their everyday medical practices. This work aims to study the nuclear physicians' information seeking behavior and preferences to satisfy the information needs in order to explore the impact on PET/CT oncological imaging. Based on the above we discuss the essential role doctors' online literacy skills have in interpretation and documentation of the results of PET/CT. Materials and Methods: In terms of theoretically framing our research endeavor the macro model for information seeking behaviour by Wilson is employed. Through this methodology the three key information seeking layers of nuclear physicians are addressed and studied, i.e. medical practice information needs, utilization of information resources and presence of information seeking barriers. The analysis through the systematic literature review is based on PRISMA protocol. Therefore, a number of queries related to our research aims are formulated and addressed to Medline and other relevant databases in order to identify, select and critically appraise the relevant research studies for the impact of nuclear physicians' information preferences on PET/CT oncological imaging. Results: After the initial selection based on PRISMA method, a number of sixty eight papers have met the predefined inclusion criteria and included in the analysis. Overall, the most important information needs of nuclear physicians are related to differential diagnosis for a PET/CT finding, as well as the procedure of PET/CT oncological imaging. Nuclear physicians mostly utilize Internet and other online scholarly resources as well as electronic medical record (EMR). Barriers when seeking information mostly reported in the literature included information seeking skills, time constraints and cost. The literature emphasizes the need for an efficient utilization of healthcare information in PET/CT procedure. Conclusion: Medical schools and formal associations of Nuclear Medicine may develop educational programs for enhancing nuclear physicians' online information literacy skills. Internet and online scholarly resources are integrated into physicians' routines in PET/CT oncological imaging. Studying nuclear physicians' information preferences may contribute to the association between oncological imaging and other medical specialties, the communication between nuclear physician and referring physician, the relation of doctor - patient, prognosis and health related quality of life of oncological patients as well.

EP564

Consequences of 18F-FDG extravasation

C. Findlay[1], S. Allwood-Spires[2], C. McKeown[1], G. Gillen[1]; [1]West of Scotland PET Centre, Glasgow, UNITED KINGDOM, [2]Department of Clinical Physics, Glasgow, UNITED KINGDOM.

Aim Extravasation of 18F-FDG can cause image artefacts and localised tissue dose, potentially leading to tissue necrosis. A retrospective analysis of 25 patients who had tissued injections was made to quantify activity and localised tissue dose to the injection site. Methods Twenty-five patients with tissued injections were analysed. The radioactivity present at the extravasation site was quantified and tissue dose calculated using the specific dose factor for 18F. Results Radioactivity within the injection site ranged from 0.07MBq to 129MBq. Tissue doses ranged between 6mGy to 608mGy. Of the 25 cases, 8 had more than 10% of the injected activity at the extravasation site. In most cases where a high activity was tissued, the activity was spread over a large volume and so the localised tissue dose received was not high. The highest dose received from a tissued injection from this sample, estimated at 608mGy, is well below the level at which erythema is likely to occur. Deterministic effects of radiation on the skin are expected to occur from a dose of 2Gy upwards [1]. Conclusions Evidence from this patient sample has shown that despite what can sometimes be striking appearances on patient images, the dose from 18F-FDG tissued injections is unlikely to result in tissue necrosis. Is Dual Time Point Imaging Necessary For Discrimination of adrenal benign lesions versus malignant masses: A Study Comparing Standart Methods with Dual Time Point FDG PET-CT Imaging

P. Ozcan Kara[1], Z. Koc[1], T. Kara[2], B. Kaya[3]; [1]Mersin University Faculty of Medicine Department of Nuclear Medicine, Mersin, TURKEY, [2]Mersin University Faculty of Medicine Department of Radiology, Mersin, TURKEY, [3]Necmettin Erbakan University Faculty of Medicine Department of Nuclear Medicine, Konya, TURKEY.

Objectives: Discrimination of adrenal benign lesions versus malignant masses is essential, especially in patients with cancer, for choosing the appropriate treatment approach and assessing prognosis. This prospective study was designed to investigate the clinical role of whole-body positron emission tomography/computed tomography (PET/CT) by using 2-[18F]fluoro-2-deoxy-D-glucose (FDG), for the evaluation of adrenal lesions and to compare the standart methods proposed in the literature such as SUVmax value, tumour/liver SUV (T/L SUV) ratio, visual analysis with dual time point imaging method to distinguish benign from malignant lesions in various cancer patients. Materials and methods: A total of 48 patients (26 male and 22 female) who had confirmed primary malignancies underwent PET/ CT examinations for cancer screening, staging, restaging, and detection of suspected recurrence. A SUVmax cutoff value of 4.2 and T/L SUV ratio of 1.68 which have been identified in a recent study by our group were used. Of the 48 patients, 62 adrenal lesions (25 benign and 37 malignant adrenal lesions) were shown by CT. On visual analysis of PET/CT imaging, adrenal uptake was based on a three-scale grading system. For final assessment standards of references for adrenal malignant lesions was based on biopsy, interval growth, or reduction after chemotherapy. An adrenal lesion, which remained unchanged on clinical and imaging follow-up was decided as a benign lesion. Results: In adrenal malignant lesions maximum standardized uptake value (SUVmax: 7.89) was higher than that of adrenal benign lesions (SUVmax: 2.92, P< 0.0001). Dual time point imaging were performed in 19/48 patients. Of the 19 patients 14 had malignant and 5 had benign adrenal lesions. All 21 malignant adrenal lesions from 14 dual phase patients had higher SUVmax over time and all 6 benign lesions from 5 dual phase patients had lower SUVmax at the late image. Conclusion SUV or T/L SUV ratios per se are semiquantitative parameters that reflect metabolic activity, but are not specific markers of malignancies. As the uptake of 18F-FDG in malignancies is expected to increase over time, dual time point acquisition could be potentially useful in partially

overcoming the relatively low specificity of the SUVmax. Combined information obtained from PET/CT (SUVmax, T/L SUV ratio, visual analysis is recommended for better differentiation. Although, dual time point imaging of FDG PET/CT seems to be very effective especially in surrenal lesions, addition of dual phase study is not necessary and recommented in only indeterminated lesions.

EP566

Role of F-18 FDG PET-CT scan in evaluation of cases with unexplained weight loss

A. A. ZADE, S. RAI, V. A, R. B; NUECLEAR HEALTHCARE, NAVI MUMBAI, INDIA.

Aim: F-18 FDG PET-CT scan has an established role in staging, restaging and assessing treatment response of various malignancies. It also has a proven role in cases of metastases from unknown primary malignancy and Pyrexia of Unknown Origin. Unexplained weight loss (UEWL) is one of the presenting complains in cases suffering from granulomatous infection like tuberculosis and various malignancies. The present study was undertaken to evaluate the role of PET-CT scan as a one stop diagnostic imaging modality for identifying infective focus/malignancy in cases of UEWL Materials & Methods: This was a retrospective audit of 70 consecutive cases (43 males, 27 females) of UEWL. The mean age of the studied population was 59.4 ± 13.9 years. Each patient underwent a F-18 FDG whole body PET-CT scan using standard acquisition parameters. The scans were reviewed by two experienced nuclear medicine physicians and the findings were noted. Diagnosis was made by histopathological evaluation and/or other appropriate tests as deemed necessary on case to case basis. Results: During the study period, 70 patients were evaluated. One patient was lost to follow-up and hence not included in the final analysis. In 64 % (44/69) patients, no focus of hypermetabolism was visualized on the scan. These patients were followed up for a mean period of 13 months during which no malignancy or infective focus was identified as a cause of weight loss. The PET-CT scan revealed hypermetabolic foci in 36 % (25/69) patients. They were further evaluated and were diagnosed with granulomatous infection (n=12), non-hematological malignancies (n=7) & lymphoma (n=4). In one case false positive FDG uptake was noted in base of tongue due to lymphoid hyperplasia and in another due to interstitial lung disease. The sensitivity, specificity, positive predictive value, negative predictive value & accuracy of F-18 FDG PET-CT scan was 100%, 96%, 92 %, 100% & 97 % respectively. Conclusion: F-18 FDG PET-CT scan has a promising role in evaluation of cases with unexplained weight loss.

18F-DOPA PET/CT physiological distribution and pitfalls: experience in 215 patients

F. F. CALABRIA[1], A. Chiaravalloti[2], M. Jaffrain-Rea[3], M. Zinzi[4], P. Sannino[4], G. Minniti[5], D. Rubello[6], O. Schillaci[7,4]; [1]IBFM Italian National Research Council - PET/MRI Unit., Catanzaro, ITALY, [2]2)Department of Biomedicine and Prevention, University "Tor Vergata", Rome, Italy., Rome, ITALY, [3]3)Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, Italy., l'Aquila, ITALY, [4]IRCCS INM Neuromed, Molise, ITALY, [5]6)Unit of Radiation Oncology, Sant'Andrea Hospital, University "La Sapienza"., Rome, ITALY, [6]7)Department of Nuclear Medicine, Santa Maria Della Misericordia Hospital, Rovigo, Italy., Catanzaro, ITALY, [7]2)Department of Biomedicine and Prevention, University "Tor Vergata"., Rome, ITALY.

Purpose of the report. F-18-DOPA Positron Emission Tomography/Computed Tomography (PET/CT) is an importanti diagnostic tool in the management of patients with low grade brain tumors, movement disorders or somatic neuroendocrine tumors. The purpose of our study was to describe the physiological distribution of the tracer in the whole body to discuss the abnormal sites of F-18-DOPA uptake that we met in our clinical practice. Materials and Methods. We examined 215 patients with F-18-DOPA PET/CT. Among these, 161 were submitted to a brain scan and 54 undergone a whole body scan. Results. The physiological distribution was negligible in the brain, with the exception of basal ganglia, while greatest activity was noted in liver, pancreas, other exocrine glands and the urinary system. Several sites of tracer uptake (5.5%) were collected, not related to the diseases under study. Some of these findings were due to inflammation while in the majority of cases the uptake was linked to benign tumors of the brain or in the endocrine or exocrine glands. Conclusion. It is mandatory to consider the possibility of F-18-DOPA uptake in conditions such as inflammation or benign tumors. Correlation with history, physical exam, labs, CT, MRI and histology are necessary to obtain the correct diagnosis. Keywords: *PET/CT; 18F-DOPA; brain tumor; pitfalls; tumor recurrence; molecular imaging.*

EP568

Evaluation Of Factors Affecting On Development Of Brown Adipose Tissue Detected By F-18 FDG PET-CT

S. Isgoren, t. hekimsoy, g. daglioz gorur, h. demir; Kocaeli University School of Medicine, KOCAELI, TURKEY.

AIM: Brown adipose tissue (BAT) is a type of adipose tissue found in mammals and can be detected by PET/CT scan with high F-18 FDG uptake generally in cervical, supraclavicular, paraaortic, paravertebral and suprarenal area. The aim of our study was to investigate the factors affecting on development of BAT. METHODS: We *retrospectively analyzed* 3409 patients (mean age: 55±18; 56,5% male, 43,5% female), who underwent PET/CT scan between the *1st January 2014* and 31st December 2015 in our clinic. Factors possibly affecting on development and metabolism of BAT including age, gender, body mass index (BMI), fasting blood glucose level, clinical indication for PET scanning, season, month and air temperature of the study date were evaluated. Additionally, maximum *standardized* FDG *uptake values* (SUVmax) of BAT and liver *were determined in each BAT-positive study and SUVmax ratios of BAT to liver were calculated.* RESULTS: Brown adipose tissue was detected 121 (3,5%) of all patients. When analyzing possible factors affecting on development of BAT, there was no significant difference with age, BMI, fasting blood glucose level and clinical indication for PET scanning between the BAT-positive and -negative patients (p>0,05). When *SUVmax ratios of BAT to liver and air temperatures of the study dates compared in BAT-positive patient group, no relationship was observed (p> 0,05).* Nevertheless, incidence of BAT-positive patients was significantly correlated with gender, month, season and air temperature (p<0,01). CONCLUSION: In this study, we found that BAT is more likely to develope in low temperatures especially in winter (46% of all BAT-positive patients) following autumn (35%) and spring (35%) while it is least seen in summer (4%). Also, BAT incidence is higher in women (66% of all BAT-positive patients) than men (34%) although the patient population is consisted of mostly men in our study.

EP569

Preoperative parallel PET/MR improves the prediction of the disease free survival in patients with breast cancer

I. LIM, J. Park, W. Noh, H. Kim, K. Park, S. Lee, I. Ko, K. Kim, B. Byun, B. Kim, C. Choi, S. Lim; Korea Cancer Center Hospital, Seoul, KOREA, REPUBLIC OF.

Aims: The aim of this study was to determine whether PET/MR could predict disease-free survival (DFS) in patients with operable breast cancer. Methods: Seventy-eight patients with breast cancer were enrolled. All patients underwent preoperative parallel PET/MR: whole body PET/CT at 1 h after 18F-FDG injection, breast dynamic contrast enhanced MR, and breast PET/CT at 2h after 18F-FDG injection sequentially in prone position. All patients were analyzed by diverse parameters (maximum SUV at 1 h [SUV1], maximum SUV at 2 h [SUV2], retention index of SUVmax [RI], metabolic tumor volume [MTV], total lesion glycolysis [TLG], initial slope of the enhancement curve [IS], transfer constant [K^{trans}], reflux constant [K_{ep}], extravascular extracellular space volume fraction [Ve], and initial area under the curve [iAUC]) . A relationship between covariates and DFS after operation was analyzed using Kaplan-Meier method and multivariate Cox proportional-hazard regression method. Results: The median follow-up of 78 patients was 55 months (31-67 months), and 9 (11.5 %) patients developed recurrence or metastasis. Among parameters, higher RI (p = 0.0010), lower K^{trans} (p = 0.0046), and lower Ve (p = 0.0035) were significantly associated with poorer DFS. In contrast, SUV1, SUV2, MTV, TLG, IS, K_{ep}, and iAUC were not. On multivariate analysis, RI (p = 0.016; HR = 5.20; CI 1.4-19.7), and K^{trans} (p = 0.035; HR = 0.22; CI 0.054-0.89) were found as independent predictors of DFS. Patients with higher RI and lower K^{trans} revealed a significantly higher recurrence rate (66.7 %) than the rest of patients (6.9 %, P<0.0001). Conclusion: RI and K^{trans} measured by preoperative parallel PET/MR can predict DFS in patients with operable breast cancer. The combination of these parameters could improve patients care because this application might specify the high risk group.

EP570

Reproducibility of MR-based Attenuation Maps in PET/MRI and the Impact on Response Evaluation in Lung Cancer

A. Olin[1], C. N. Ladefoged[1], N. H. Langer[1], S. H. Keller[1], J. Löfgren[1], A. E. Hansen[1], A. Kjær[1], S. W. Langer[2], B. M. Fischer[1], F. L. Andersen[1]; [1]Dept. of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK, [2]Dept. of Oncology, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK.

AIM: MR-based attenuation correction (MR-AC) in PET/MRI systems is a prerequisite in quantitative PET. Reliable PET images are strongly linked to the reproducibility of the attenuation maps (μ-maps). This study investigated the reproducibility of thoracic μ-maps by examining how potential inconsistencies and artifacts affected PET quantification in patients with non-small cell lung cancer (NSCLC). *MATERIAL AND METHODS:* Ten NSCLC patients underwent two to five chest PET-MRI examinations within ≤22 days using a Siemens Biograph mMR. Each examination consisted of two consecutive [^{18}F]-FDG PET/MRI scans, where two vendor implemented Dixon-based μ-maps were acquired with fixed patient positioning. A total of 82 μ-maps were evaluated visually for quality and occurrence of categorized artifacts by two PET/MRI experienced physicians. Artifacts were rated on a scale from one to four, with three and four indicating artifacts with potentially severe impact on PET quantification. Only PET data from the first scan of each examination were used to analyze the quantitative effect of μ-map reproducibility. The μ-map acquired simultaneously with this PET data (μ-map_A) and the subsequently acquired μ-map (μ-map_B) were registered by rigid transformation, and two PET images (PET_A and PET_B) were reconstructed. Every tumor was outlined by a volume of interest (VOI) defined as a 40% isocontour of the maximum standardized uptake on PET_A. Minor manual VOI adjustments were done if considered appropriate, e.g. to exclude adjacent physiological uptake. The VOIs drawn on PET_A were transferred to the corresponding PET_B. The relative differences between mean (SUV_{mean}) and maximum standardized uptake (SUV_{max}) in PET_A versus PET_B were calculated. *RESULTS:* All μ-maps included artifacts rated one or two. The frequency of μ-maps with artifacts rated three or four was 18/82 (22%) and involved six patients. Of these 18 μ-maps, eight were categorized with metal artifacts (one patient), two with body contour delineation and lung border artifacts (two patients), and eight with tissue misclassification artifacts (three patients). The average±SD relative difference between the SUV_{mean} in PET_A versus PET_B was 2.4±8.6% (min: -15.6%, max: 35.6%) across all patients. Similar results were found for SUV_{max}. *CONCLUSION:* Artifacts were frequently observed in the MR-based μ-maps causing potential impact on the PET-based tumor quantification. The quantitative evaluation showed a large variance and range in the relative difference between tumor uptakes (SUV_{mean} and SUV_{max}) in PET_A versus PET_B. Thus, inconsistencies of μ-maps may have an impact on the PET quantification and should be taken into consideration, especially in response evaluation.

EP571

18F-DOPA-PET/MRI image fusion for target volume definition in patients with recurrent glioblastoma treated with proton therapy

A. Palucci[1], D. Amelio[2], S. Agostini[1], A. Palermo[1], D. Donner[1], E. Bagatin[1], G. Carbone[1], M. Erini[1], M. Amichetti[2], F. Chierichetti[1]; [1]Nuclear Medicine Dpt - S. Chiara Hospital APSS, Trento, ITALY, [2]Proton Therapy Centre - Trento Hospital - APSS, Trento, ITALY.

Aim: Target volume definition for high grade gliomas is a crucial process when steep dose gradient techniques, such as proton therapy (PT), are employed. Aim of the study is to investigate the impact of 18F-DOPA on target volume definition in recurrent glioblastoma (rGBM) patients (pts) undergoing re-irradiation with PT, an advanced modality of external radiation therapy that allows to keep low the radiation burden on the healthy tissues. Material and Methods: We investigated the differences in volume and shape of MRI vs F18-DOPA-PET-CT-derived gross tumor volumes (GTVs) of 10 rGBM pts re-irradiated with PT between January and December 2015. All pts were previously treated with standard of care (surgery and adjuvant radio/chemotherapy). For target definition all pts received morphological MRI with contrast enhancement and 18F-DOPA PET-CT study. We used the pathological distribution of F-DOPA in brain tissue to identify the so-called Biological Tumor Volume (BTV). Such areas were assessed using a tumor to normal brain ratio > 2. Moreover, any area of enhancing tumor on MRI was employed to identify the MRI-GTV. Definitive GTV included any area of contrast enhancement plus any pathological PET uptake regions. Clinical target volume (CTV) was generated by adding to GTV a 3-mm uniform margin. CTV was expanded by 4 mm to create Planning target volume (PTV). Results: Integrating 18F-DOPA-PET uptake into the delineation of GTVs allowed the detection of pathological uptake outside the enhancing tumor areas in all investigated pts yielding to larger treated volumes. Even though MRI- and DOPA-PET-derived GTVs show similar shape in most of the pts, the congruence of MRI and PET signals is mild. The PT irradiation of PET-integrated target volumes provided a median progression-free survival of 6.4 months, while the 3-, 6- and 9-month PFS rates were 80%, 67% and 22%, respectively. 6- and 12-month survival after PT rates were 100% and 60%, respectively. Conclusions: Target volume definition for rGBM undergoing PT re-irradiation may yield significantly differing results depending upon the imaging modality used for target contouring. The integration of both MRI and F-DOPA PET-CT may help to improve GTV coverage. Despite the small number of patients and the retrospective nature of the study clinical results seem promising suggesting that PT with multimodal imaging contouring process may be more effective for tumor control respect to the standard planning based to anatomical imaging only.

EP572

Evaluation of a fast MR-protocol for simultaneous ^{18}F-FDG PET/MR imaging of patients with lymphoma

J. Grueneisen[1], L. Sawicki[2], B. M. Schaarschmidt[2], A. Wetter[1], V. Ruhlmann[1], L. Umutlu[1]; [1]University Hospital Essen, Essen, GERMANY, [2]University Hospital Dusseldorf, Dusseldorf, GERMANY.

Aim: The aim of this study was to evaluate a diagnostic performance of a fast MR-protocol for integrated ^{18}F-FDG PET/MR imaging, used for pretreatment staging, therapy monitoring and surveillance of patients with lymphoma in comparison to ^{18}F-FDG PET/CT. Material and Methods: A total of 48 consecutive lymphoma patients underwent 52 clinically indicated PET/CT and subsequent PET/MR examinations. For PET/MRI readings, a whole-body fast MR-protocol was implemented, comprising (1) a transversal DWI (EPI) sequence, (2) a transversal T2w HASTE sequence and (3) a transversal post-contrast T1w VIBE sequence. Two readers separately evaluated both examinations and were instructed to identify the total number of tumor lesions. The standardized uptake value (SUV) for all ^{18}F-FDG-avid lesions was determined in PET/CT and PET/MRI, using volume of interest (VOI) analysis. Agreement between PET/CT and PET/MRI regarding SUVmax and SUVmean was tested using Pearson's product-moment correlation. Results: Malignant lesions were present in 28 of the 52 examinations. Both, PET/CT and PET/MRI enabled correct identification of disease presence in all 28 cases. A total of 106 18F-FDG-avid lymphoma lesions were analyzed for the comparison of the PET component in PET/CT and PET/MRI. Determined SUVs were significantly higher in PET/MRI than in PET/CT (SUVmax: 9.3 ± 6.1 vs 6.9 ± 4.3; $p < 0.05$; SUVmean: 5.1 ± 3.3 vs 4.1 ± 2.7; $p < 0.05$), however, there was a strong correlation between SUVmax and SUVmean of the two imaging modalities ($R = 0.87$, $p < 0.001$ and $R = 0.91$, $p < 0.001$). Estimated mean scan duration of whole-body PET/CT examinations as well as for the fast protocol for whole-body PET/MR imaging amounted to 17.3 ± 1.9 min and 27.8 ± 3.7 min, respectively. Furthermore, calculated mean effective-dose for a whole-body PET/CT scan was 64.4% higher than for a fast-PET/MRI examination. Conclusion: The FAST-protocol for PET/MR imaging offers an equivalently high diagnostic performance for staging lymphoma patients in comparison to PET/CT with only a slightly prolonged examination time. With regard to patient comfort related to scan duration and a markedly reduced radiation exposure, fast-PET/MRI may serve as a powerful alternative to PET/CT for a diagnostic work-up of patients with lymphomas.

EP573

The effect of discrete tissue classes and neglecting bone in soft tissue sarcoma PET/MRI patients: Evaluation with PET/CT data

C. H. Holland[1], C. N. Ladefoged[2], A. Loft[2], K. F. Andersen[2], L. Højgaard[2], F. L. Andersen[2]; [1]King's College London, London, UNITED KINGDOM, [2]Rigshospitalet, Copenhagen, DENMARK.

INTRODUCTION: A prominent difficulty with PET/MRI is inaccurate attenuation correction. Current standards discretise the tissue compartments into four tissue classes, disregarding variations within tissue types, and failing to segment both bone and tumour values. This study assesses the effect of this, using patients scanned on PET/CT by assessing each tissue class by itself, progressively bridging the gap between the gold-standard CT and the PET/MRI-simulated Dixon-sequence. METHODS: Four patients with FDG-avid histopathological verified high-grade soft tissue sarcoma scanned on a whole-body PET/CT system (Biograph TruePoint 64, Siemens Healthcare) were included in this study. The patients were injected with 300 MBq of [^{18}F]-FDG. The PET/CT images were discretised into the classes: bone, lung, tumour, air, soft tissue and fat. These classes were combined to create four additional mu-maps: pseudoDixon (setting air, soft tissue, fat and lung to predetermined HU values equivalent to Dixon, with bone to soft tissue value); Dixon+bone (as pseudoDixon with bone at original HU value); Dixon+tumour (as pseudoDixon with tumour at original value); CT-bone (original CT with bone at soft tissue value). Mean and variance %-deviation within the tumour relative to PET/CT were calculated for each of the four mu-maps, both globally as well as within ROIs extending consecutively away from bone. RESULTS: The average %-deviation in global mean PET signal was -6.4±2.6% (pseudoDixon), -4.6±2.6% (Dixon+bone), -6.6±1.5% (Dixon+tumour), and -1.7±0.2% (CT-bone) from PET/CT. ROI analysis in the tumours showed a clear gradient with the largest error close to the bone and smallest away from bone for pseudoDixon (-32.7% to -6.0%), Dixon+tumour (-24.2% to -6.3%) and CT-bone (-28.9% to -0.5%). The gradient was only significant within 2 cm of bone. No such marked gradient existed for Dixon+bone (-4.9% to -5.5%). CONCLUSION: The analyses of the global tumour signal showed a systematic underestimate of signal for all constructed mu-maps, greatest for those setting both bone and other tissues to Dixon values, though these errors were generally below 10%. Comparing results of different mu-maps also suggests the errors introduced by standardising different tissue classes is to first approximation summative, with standardising fat and soft tissue having a generally larger effect than setting bone to soft tissue value. However, ROI analysis demonstrated that setting bone to soft tissue value introduces overwhelmingly large errors in attenuation correction for signals in bone's immediate proximity indicating that in using Dixon maps, signals in and near bone should be interpreted with great caution.

EP574

Feasibility of using ZTE to generate an accurate MR-based attenuation map for head and neck PET/MR studies: Similarity analysis to CT-based attenuation map

K. Lee, G. Zaharchuk, P. K. Gulaka, C. **S. Levin**; Stanford University, Stanford, CA, UNITED STATES.

Simultaneous PET/MR imaging systems have shown promise to provide simultaneous functional and morphological evaluation of a variety of pathophysiological conditions. However, challenges in MR-based attenuation correction (MRAC) methods still pose a problem for accurate quantification of PET images due to the difficulty of imaging and segmenting bone with MR sequences. To overcome this, the zero echo time (ZTE) MR sequence was introduced to acquire the fast-decaying MR signal from bone. Accurate attenuation coefficients for bone in the head and neck area are particularity important because a big portion of the head and neck area is bone, and lesions in the area are usually in or proximate to the bone. We investigate the feasibility of using MRAC incorporated with the ZTE sequence (ZTE-MRAC) by comparing the similarity of bone-added ZTE-MRAC to a CT-based attenuation map (CTAC), the gold standard for photon attenuation. This study is the first demonstration of similarity evaluation of a ZTE-MRAC μ-map to improve PET quantification accuracy in PET/MR for lesions in the head and neck area. Three patients with head and neck cancer underwent PET/CT scans (mCT PET/CT, Siemens Healthcare, TN), followed by PET/MR scans (SIGNA PET/MR, GE Healthcare, WI) that included ZTE- and Dixon-based MRAC sequences. Segmentation for bone was performed on the ZTE images and added on to Dixon-MRAC sequence to generate ZTE-MRAC. Multi-modality matching (MMM) registration between ZTE-MRAC and CTAC was performed before applying the similarity test. Using the segmented bone from the CT attenuation maps (μ-map), dice similarity coefficient (DSC) was calculated as the evaluation metric for the spatial overlap accuracy, being 1 for the perfect overlap and 0 for no overlap. We observed an average DSC of 0.65 (STD=0.18) when ZTE-based bone information was incorporated in the MRAC μ-map, compared to the CT-based μ-map. We found that PET quantification accuracy with ZTE-MRAC is superior to the Dixon-based bone-free MRAC. We also observed that it was difficult to distinguish air from bone

in certain regions leading to inaccurate ZTE-MRAC generation and lower DSC in those areas. Further improvements in quantification could be obtained by performing rigorous registration between ZTE-MRAC and CTAC. Future work will include the comparison of PET data quantification when Dixon-based bone-free MRAC, ZTE-MRAC, and CTAC are used for PET image reconstruction, respectively.

EP575

Strategies for acceleration of a new MLEM algorithm for emission-based photon attenuation correction in PET

A. Mihlin, C. **S. Levin**; Stanford University, Stanford, CA, UNITED STATES.

We have developed the first ever maximum likelihood expectation maximization method for joint estimation of emission activity distribution and photon attenuation map from PET emission data alone. We call this new method “EMAA” (expectation maximization estimation of activity and attenuation). The method is appealing since: (i) it guarantees monotonic likelihood increase to a local extremum, (ii) does not require arbitrary parameters, and (iii) guarantees the positivity of the estimated distributions. Such image estimation methods are typically very computationally intensive, due to the need to traverse all existing LORs. This is in contrast with estimation of just emission activity distribution, where only LORs with detected counts are traversed. Hence, acceleration is critical for clinically practical joint image estimation. We report on strategies for acceleration of EMAA, which include: graphics processing unit (GPU) based implementation, ordered subset expectation maximization (OSEM), use of time of flight (TOF) data, and "Adjusted OSEM" - an extension of OSEM for this joint image estimation problem. The methods are evaluated using a PET signal computationally generated via Monte-Carlo simulation of a three dimensional XCAT phantom, with no random- and scattered coincidences. For a Philips GEMINI LXL system geometry with 400 ps TOF resolution, these methods accelerate EMAA by 10^6 compared with a single CPU implementation. Thus, reducing joint estimation duration to just 7 minutes, for an estimated emission activity distribution root mean square error of 1%, compared with the true emission image.

EP576

A Radiofrequency-penetrable PET Insert for Simultaneous PET/MRI

C. Chang, B. J. Lee, R. D. Watkins, I. Kwon, C. S. Levin; Stanford University, Stanford, CA, UNITED STATES.

Objectives Simultaneous PET/MRI has shown great potential in disease characterization. However, the high cost of the commercial integrated PET+MR systems limits its dissemination, and hence its long-term impact. To address this challenge, we have developed a proof-of-concept radiofrequency (RF)-penetrable PET neural insert that may be inserted into (and removed from) any existing MR system. This work reports the performance characterization results of this insert system. Methods The PET insert consists of a ring of 16 detector modules, each shielded in a copper Faraday cage with 1 mm inter-module gaps for the RF field to leak through. PET detectors are powered by electrically-floating batteries. Inside each detector, the electrical signal of the photodetectors is converted into an optical signal and sent out through 20-meter length optical fibers to the data acquisition system in the next room. Eliminating long electrical cables and isolating the power line of the PET ring minimize the mutual interference between PET and MRI. Energy, timing resolution and phantom image quality were evaluated both outside and inside a 3T MRI bore with standard imaging pulse sequences [(spin-echo (SE), gradient-echo (GRE) and echo-planar imaging (EPI)] running to study the impact of the operating MRI on PET performance. B_0, B_1 maps, signal-to-noise ratio (SNR) and the uniformity of MRI phantom images were evaluated with and without the PET insert to study the impact of the operating PET on MRI. Simultaneous PET/MR phantom images were acquired with the built-in body coil serving as both RF transmitter and receiver. Results The energy resolution at 511 keV and the timing resolution of the PET insert are 15.6 ± 0.2% and 5.3 ± 0.2 ns FWHM, respectively, both outside and inside of MRI with insignificant differences for the spin-echo and gradient-echo pulse sequences. The B_0 field inhomogeneity is smaller than 0.02 ppm in 3T with or without the PET insert inside the MRI bore. Hot rods with 2.8 mm diameter can be resolved in the reconstructed images acquired with the insert outside or inside the MRI system. With the MRI auto-prescan procedure to calibrate the transmitter gain, simultaneous PET/MR images were successfully acquired using the built-in body coil with only -3.5 dB degradation of the MR image SNR. Further MR image SNR improvements are expected with a custom receiver coil located inside the PET insert rather than using the MR built-in body coil as receiver as well as transmitter.

EP577

Hybrid 18F-FDG PET/MR imaging usefulness in disease activity assessment in patients with sarcoidosis

D. Jurgilewicz[1], M. Mojsak[1], P. Szumowski[1], B. Kubas[1], B. Kuklinska[2], M. Hladunski[1], A. Amelian-Filonowicz[1], R. Mroz[1], J. Mysliwiec[1]; [1]Medical University, Bialystok, POLAND, [2]University Hospital, Bialystok, POLAND.

Background: Sarcoidosis is a multi-organ disease characterized by the appearance of inflammatory granulomas in various organs. Lungs and intrathoracic lymph nodes are the most common locations of the disease, but changes may be presented also in the eyes, skin, liver, spleen, muscles, bones and salivary glands. Hybrid imaging technic which enables simultaneous whole body molecular magnetic resonance and metabolic positron emission tomography (PET/MR) is a promising tool in evaluation of the stage of sarcoidosis. Aim:The purpose of the study is the evaluation the utility of 18F-fluorodeoxy-d-glucose (18F-FDG) PET/MRI in staging of sarcoidosis. Materials and Methods: 18F-FDG PET/MR study was performed in 31 patients (F/M: 12/19, mean age: 45 (25-69) treated in Department of Lung Diseases, with computed tomography (CT) diagnosed and histologically confirmed pulmonary sarcoidosis. PET scans were obtained 60 min after injection of 295 ± 45 MBq ^{18}F-FDG). All patients underwent 18F-FDG PET/MR study with additional subsequent CE-MRI of the thorax at 3T in the prone position using Biograph mMR scanner (Siemens) with proper MR sequences: T1 VIBE, T2 HASTE, T2 BLADE. The obtained images were analyzed with visual and semi-quantitative methods. Disease staging based on presence and number of FDG-avid nodes was performed by two nuclear medicine and one radiology experienced specialists. Quantitative assessment was performed by calculation of SUV_{max}. Results: 18F-FDG PET/MR confirmed metabolically active disease in the lesions localized by CT in all patients. Eighteen (58%) patients were classified as phase I, thirteen (43%) as phase II pulmonary sarcoidosis. Increased 18F-FDG uptake in PET/MR study, with SUV_{max}: 2,43-9,00, as a new additional metabolically active foci were found in: abdominal lymph nodes in 10 patients (30%), cardiac left ventricule in 1 patient (3%), musculo-sceletal system in 1 patient (3%). Additionally, in nine patients with nonspecific neurological symptoms, mainly headache, changes in maxillary sinus were found on MR images. Conclusion: 18F-FDG PET/MR is useful method in the assessment of inflammatory activity of sarcoidosis and is promising diagnostic tool in clinical staging of the disease and patient selection for optimal treatment strategy.

EP578

Comparison of PET/CT and PET/MR-based ^{68}Ga-DOTATOC standardized uptake values

E. Ilan[1,2], A. Sundin[2,3], I. Velikyan[2,3], M. Sandström[1,2], H. Ahlström[2,3], M. Lubberink[1,2]; [1]Medical Physics, Uppsala University Hospital, SWEDEN, [2]Department of Surgical Sciences, Uppsala University, SWEDEN, [3]Medical Imaging Centre, Uppsala University Hospital, SWEDEN.

Objectives Quantitative imaging using PET/MR is challenged by the lack of bone visualisation in MR-based attenuation correction (MRAC). The geometry of integrated PET-MR scanners presents further challenges for quantification, especially for scatter correction for tracers with large uptake variations such as ^{68}Ga-DOTATOC. In most studies comparing PET/CT and PET/MR, both images were acquired after a single tracer injection, which compromises comparisons because of redistribution of the tracer between scans. The aim of this study was to compare standardized uptake values (SUV) in tumour and liver in patients with neuroendocrine tumors (NETs) imaged with ^{68}Ga-DOTATOC on PET/CT and PET/MR after separate injections on consecutive days. Materials and methods Four patients diagnosed with disseminated gastroenteropancreatic NETs underwent ^{68}Ga-DOTATOC whole-body PET/CT (Discovery ST) and PET/MR (Signa, both GE Healthcare) at 1 h post injection of circa 200 MBq ^{68}Ga-DOTATOC on consecutive days. Images were reconstructed using OSEM with settings optimized to provide similar image resolution across scanners. MRAC was based on a two-point Dixon gradient echo sequence. PET/MR images were reconstructed both with and without time-of-flight (ToF), whereas PET/CT was without ToF. Tumour volumes of interest (VOIs) were drawn using 50 % isocontours. A subsample of healthy liver was delineated using a spherical 20-ml VOI. Correlation and agreement between PET/CT and PET/MR SUV values was assessed using linear regression and Bland-Altman analysis. Results Mean time to imaging after ^{68}Ga-DOTATOC injection was 70 ± 2 min for PET/CT and 72 ± 5 min for PET/MR. Seven lesions could be delineated. Moderate correlation was found between PET/CT and PET/MR tumour SUV values, with Pearson correlation (R^2) 0.75 and 0.60 for non-ToF and ToF, respectively. On average, PET/MR SUV values were 1.2% (SD 22) lower and 23% (SD 14) higher than PET/CT values, without and with ToF, respectively. ToF consistently resulted in higher tumour SUVs. High correlation was found between PET/CT and PET/MR liver SUV values, with R^2 0.94 and 0.81 for non-ToF and ToF. On average, PET/MR liver SUV was 2.7% (SD 6.5) lower and 6.5% (SD 11) higher than PET/CT values, without and with ToF. ConclusionOur study showed moderate correlation between PET/CT and PET/MR ^{68}Ga-DOTATOC tumour SUV values based on a dual-injection protocol. Differences may be attributed partly to MRAC, but also to sub-optimal scatter correction for ^{68}Ga-DOTATOC. Along with the inclusion of more patients to allow for more robust conclusions, optimization of scatter correction will be part of further studies.

EP579

Evaluation of Psoriatic Arthritis of the Hands with Integrated ^{18}F Fluoride PET/MRI

T. D. Poeppel, A. Koerber, M. Forsting, A. Bockisch, A. Sabet, N. Guberina; Universitaetsklinikum Essen, Essen, GERMANY.

Aim: Psoriatic arthritis is a common comorbidity of psoriasis vulgaris and affects approximately 25% of all patients with psoriasis. Early and effective detection of psoriatic arthritis is essential to guide therapeutic management and to prohibit joint destruction. The purpose of our study was to evaluate the contribution of integrated ^{18}F fluoride PET/MRI to the combined assessment of active inflammation and morphological features in psoriatic arthritis of the hands. Methods: 21 patients with a history of psoriasis vulgaris and active pain of joints of the hands were included. All patients underwent a dual time point protocol 5 and 90 min after injection of 150 MBq of ^{18}F fluoride in a Biograph mMR PET/MRI scanner (Siemens Healthcare, Germany). Estimation of inflammation was based 1) on a combined MRI score (0 = not present, 1 = moderate, 2 = extensive: synovitis, tendonitis, bone oedema, soft tissue oedema, bone erosions, joint space narrowing, joint subluxation, interphalangeal ankylosis, effusion), and 2) on ^{18}F fluoride uptake in terms of maximal SUV (SUVmax). Results: 134/357 joints showed signs of inflammation in MRI. Joints most often affected were: distal interphalangeal joint (47%), carpometacarpal joint (28%), proximal interphalangeal joint (17%). Mean SUVmax was 4.9 ± 3.0. Pearson's correlation coefficient demonstrated significant correlation between MRI score and SUVmax ($p < 0.05$; $r = 0.525$). Conclusions: Integrated ^{18}F PET/MRI provides information about inflammatory activity and morphological features in early as well as in advanced stages of psoriatic arthritis. Signs of inflammation in MRI and PET are closely related.

EP581

18F-FDG PET/MRI In Lymphoma: Discordance Between Standardised Uptake Value (SUV) and Apparent Diffusion Coefficient (ADC)

A. Mallia[1], U. Bashir[2], J. Stirling[1], S. Jeljeli[1], J. Joemon[1], V. Goh[3], G. Cook[1]; [1]Cancer Imaging Department, King's College/St. Thomas' Hospital, London, UNITED KINGDOM, [2]Cancer Imaging Department, King's College, London, UNITED KINGDOM, [3]Cancer Imaging Department, King's College/Department of Radiology, Guy's & St Thomas' Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Introduction: PET/MRI systems have the potential to more accurately assess nodal and extra-nodal disease in patients with lymphoma. Evidence from other tumour types suggests there is a close relationship between diffusion weighted MRI derived apparent diffusion coefficient (ADC, reflecting cellular density) and PET derived standardised uptake value (SUV, measuring metabolic activity). Conflicting reports regarding the relationship of these two parameters remain in lymphoma. **Aim:** To explore the correlation between MRI ADC and PET SUV measurements in lymphoma patients at staging. **Methods:** Prospective patients with proven lymphoma were recruited and staged using 18F-FDG PET/MRI prior to commencement of therapy. Quantitative measurements were performed by drawing a region of interest (ROI) around lymph nodes ≥1cm in short axis diameter within major nodal stations. A maximum of 2 nodes per involved nodal station were measured. A concordant node was defined as having an ADC minimum (ADCmin) measurement of ≤1 together with a SUVmax ≥2.5. Other combinations of measurements were considered as discordant and indeterminate. ADCmin, ADCmean, SUV maximum (SUVmax) and SUV mean (SUVmean) were recorded and correlation assessed using Spearman statistics. **Results:** 17 patients (mean age 56.4 years, 9 male, 8 female) were recruited of which 14 satisfied the inclusion criteria based on nodal size. 59 nodes were evaluated (12 Non-Hodgkin's Lymphoma (NHL), 32 Hodgkin's Lymphoma (HL), 1 Mantle, 2 MALT, 6 T-Cell Lymphoma (TL), 6 Follicular Lymphoma (FL). 52 nodes (88.1%) were concordant and 7 nodes (11.9%) were discordant (n=2, low ADC/low SUV all localised in the inguinal region, n=5, high ADC/high SUV all localised within the mediastinum). Overall, the SUVmax ranged from 0.8 to 40 mg/ml (median 8.95 mg/ml) and the ADCmin ranged from 215 to 2629 (median 662 $X10^{-6}mm^2/S$). No statistically significant correlation was found between pre-treatment SUVmax/ADCmin (R= 0.004)(P= 0.9), SUVmean/ADCmean (R= -0.11)(P= 0.4), and SUVmax/ADCmean (R= -0.16)(P= 0.2) with and without the discordant nodes (R= -0.02)(P= 0.8), (R= -0.17)(P= 0.2), (R= -0.19)(P= 0.2), respectively. A weak inverse correlation was found between the SUVmean and ADCmean when excluding the discordant nodes (R= -0.39)(P= 0.03) in patients with HL (29 nodes). **Conclusions:** No correlation was found between SUVmax and ADC in treatment naïve lymphoma patients even if discordant nodes were

excluded. Only a weak negative correlation between SUVmean and ADCmean in patients with HL was noted. Our results confirm that ADC and SUV represent different pathological processes.

EP582

Impact of overfeeding with saturated and polyunsaturated fat on hepatic [^{11}C]palmitate uptake and fat content using PET-MR

K. Heurling[1], A. Moreno[1], J. Kullberg[1], F. Rosqvist[1], G. Antoni[1,2], J. P. Eriksson[2], P. Nordeman[2], M. Sprycha[2], H. Wilking[2], A. Gronowski Edner[2], H. Ahlström[1], H. Ahlström[1,2], M. Lubberink[1,2], U. Risérus[1]; [1]Uppsala University, Uppsala, SWEDEN, [2]Uppsala University Hospital, Uppsala, SWEDEN.

Aim Obesity is characterized by an increase in the fatty acid oxidation pathway in the liver, which may be influenced by the type of fat in the diet. We have previously shown that overfeeding saturated fatty acids (SFA), promote liver fat accumulation in contrast to polyunsaturated fatty acids (PUFA). The present study aimed to investigate dietary effects of SFA vs PUFA on liver fatty acid uptake and liver fat content, using [^{11}C]palmitate PET-MR. **Materials and methods** Ten subjects underwent a baseline [^{11}C]palmitate PET-MR scan before randomization to one of two interventions: overfeeding with a diet high in either SFA or PUFA for 8 weeks. A single bed-position dynamic PET scan was performed during 60 min, covering the splanchnic bed, on a GE Healthcare Signa PET-MR. The protocol included collection of discrete arterial blood samples at 5, 10, 15, 20, 30 and 45 min post injection for measurement of whole-blood and plasma radioactivity concentrations and fraction of unmetabolized [^{11}C]palmitate. Quantification of [^{11}C]palmitate was performed using an image derived input function based on average radioactivity concentrations in ascending aorta and portal vein and corrected for metabolites and plasma-whole-blood ratio. The accumulation rate constant K_i was estimated using Patlak analysis using the 3-10 and 10-60 min post injection intervals. Liver fat content was determined using water-fat separated MRI and large region of interest analysis. After the intervention, the [^{11}C]palmitate PET-MR procedure was repeated. Changes in liver fat content, [^{11}C]palmitate K_i, and standardized uptake values at 30 min were assessed, and differences between PUFA and SFA challenges were analyzed using the Mann-Whitney U test. **Results** There were no differences in [^{11}C]palmitate K_i change estimated using the 3-10 min ($p=0.548$) or 10-60 min intervals ($p=1.000$), or standardized uptake value change ($p=0.548$), between the two interventions. A tendency to larger increase in liver fat content was seen in the group receiving SFA compared to PUFA, though not statistically significant ($p=0.063$). **Conclusion** Despite the small sample size, a tendency of larger accumulation of liver fat was seen after SFA vs PUFA, in line with previously shown effects. However, neither SFA nor PUFA overfeeding affected [^{11}C]palmitate uptake, indicating that hepatic fatty acid uptake is not a main determining factor for palmitate-induced liver fat accumulation. Future studies are needed to address whether the proportion of [^{11}C]palmitate metabolism due to de novo fatty acid synthesis, oxidation or esterification were affected by the intervention, in spite of unaffected total uptake.

^{89}Zr-Trastuzumab-DM1: A Novel Probe for Positron-Emission Tomography (PET) Imaging of the Delivery of T-DM1 (Kadcyla) to HER2-Positive Breast Cancer

N. Al-saden, R. Reilly, C. Chan; University of Toronto, Toronto, ON, CANADA.

Background: Our aim was to construct a novel molecular imaging probe (^{89}Zr-labeled T-DM1) to visualize the delivery of trastuzumab-DM1 (T-DM1; Kadcyla, Roche) to HER2-positive breast cancer (BC) by positron-emission tomography (PET). T-DM1 is an antibody-drug immunoconjugate (ADC) approved for treatment of trastuzumab-resistant HER2-positive BC. **Methods:** T-DM1 was modified with desferrioxamine (DFO) for chelating ^{89}Zr by reaction with a 14-fold excess of p-NCS-Bz-DFO for 30 min at 37°C. The number of DFO per T-DM1 molecule was quantified spectrophotometrically at 430 nm following reaction with $FeCl_3$. Purity and homogeneity were assessed by SDS-PAGE and size-exclusion (SE)-HPLC. ^{89}Zr labeling was performed at a specific activity of 2μCi/μg in 2 M sodium carbonate/0.5 M HEPES buffer, pH 7.0 at RT for 60-90 mins. Radiochemical purity was determined by instant thin layer-silica gel chromatography (ITLC-SG) and SE-HPLC. HER2 immunoreactivity was measured in a saturation binding assay using SK-BR-3 human BC cells. Results: T-DM1 was modified with 3.0 ± 0.2 DFO chelators. SDS-PAGE and SE-HPLC revealed a pure and homogeneous immunoconjugate. The labeling efficiency with ^{89}Zr was >95%.^{89}Zr-p-NCS-Bz-DFO-T-DM1 exhibited preserved HER2 immunoreactivity with high affinity binding (K_d = 4.9 ± 0.4 nM). **Conclusions/implications:** A novel ^{89}Zr-labeled probe of T-DM1 was produced that exhibited high affinity binding to HER2 on human BC cells. This agent has application for PET imaging of the delivery of T-DM1 to tumours in patients with HER2-positive BC. Imaging may inform on those patients likely to benefit from T-DM1 treatment. Supported by the Ontario Institute for Cancer Research (OICR) Smarter Imaging Research Program.

Evaluation of radiolabeled NOTA-RGD-GE11 heterodimeric peptide as a probe for dual integrin and epidermal growth factor receptor-targeted tumor imaging in a lung tumor xenograft model

H. Yu, K. Lin, J. Chen, M. Wang, W. Lin; Institute of Nuclear Energy Research, Taoyuan, TAIWAN.

Objective: This study aims to evaluate ^{68}Ga-NOTA-RGD-GE11 heterodimeric peptide as a PET probe for dual integrin and epidermal growth factor receptor (EGFR)-targeted tumor imaging in lung carcinoma-bearing mouse model. **Methods:** ^{68}Ga-NOTA-RGD-GE11 was prepared by labeling the NOTA peptide conjugate with freshly eluted ^{68}Ga and purified using reversed-phase high-performance liquid chromatography. Subcutaneous tumor xenografts were produced by inoculation of NCI-H292 lung cancer cells in the left flank of 6-week-old nude male mice under anesthesia. Biological characterization studies of ^{68}Ga-NOTA-RGD-GE11 including in-vitro competitive binding assay, cellular uptake and dynamic nanoPET/CT imaging of NCI-H292 tumor-bearing mice were performed (0-2 h post-intravenous injection). **Results:** ^{68}Ga-NOTA-RGD-GE11 was prepared in high radiochemical yield (>85%, decay corrected) and radiochemical purity (>95%). The binding affinities of NOTA-RGD-GE11 to integrin and EGFR were confirmed by competitive binding assay. The accumulations of ^{68}Ga-NOTA-RGD-GE11 in NCI-H292 cells increased with time. Dynamic nanoPET/CT imaging studies in NCI-H292 lung carcinoma-bearing mice clearly delineated the tumor lesions. ROIs analysis showed that the accumulations of ^{68}Ga-NOTA-RGD-GE11 in NCI-H292 xenografts were increased with time. Tumor-to-muscle ratio was 3.23±0.98 at 2 h post-injection. **Conclusion:** In this study, the ^{68}Ga-NOTA-RGD-GE11 heterodimeric peptide was successfully prepared with high yield and radiochemical purity. Both results of cellular uptake and PET/CT imaging showed that ^{68}Ga-NOTA-RGD-GE11 was accumulated in tumor cells with desirable uptakes. ^{68}Ga-NOTA-RGD-GE11 is demonstrated as a potential radioprobe for dual integrin and EGFR-targeted tumor imaging. These results warrant further investigation of this heterodimeric peptide's biological characters.

EP585

18F-Fluorodeoxymannose (FDM) is a Potential New Tracer for Inflammatory Bowel Disease

S. R. Christiansen[1,2], S. Hess[1,2,3], B. B. Olsen[1], C. Baun[1], N. Langkjær[1], P. Høilund-Carlsen[1,2]; [1]Odense University Hospital, Odense, DENMARK, [2]University of Southern Denmark, Odense, DENMARK, [3]Hospital of Southern Jutland, Esbjerg, DENMARK.

AIM: Invasive endoscopies are the current gold standard in inflammatory bowel disease (IBD). PET/CT may be a viable alternative, but controversies remain regarding FDG for imaging bowel disease. Macrophages are predominant in chronic inflammation and 18F-Fluorodeoxymannose (FDM) has been suggested instead of FDG for macrophage imaging. We present preliminary results from a feasibility study comparing FDG and FDM uptake *in vitro* in macrophages and *in vivo* in an IBD-mouse model. **MATERIAL AND METHODS:** THP-1 monocytes were differentiated into naïve M0 macrophages with PMA (phorbol 12-myristate 13-acetate). The macrophages were then incubated with FDG and FDM (30 min, 45 min, 60 min, 75 min, 90 min, 120 min, 180 min) and the uptake quantified and compared. Male C57BL/6 mice were subjected to different concentrations (2% and 4%) of Dextran Sulphate Sodium (DSS) in a predetermined schedule over a period of 37 days, a well-established rodent model for IBD. Only the 2% mouse survived the entire study. On day 36, all mice underwent 15-minute static PET/CT scans with FDG (60-75 minutes after injection) and on day 37 all mice underwent a 90-minute dynamic PET/CT scan with FDM. Afterwards, the mice were sacrificed and used for biodistribution analysis. Tracer uptake in the bowel was assessed and quantified. **RESULTS:** *In vitro* there was no significant difference in macrophage uptake between FDM and FDG. The uptake for both tracers increased over time and after 180 minutes reached 0.52%±0.02% of added FDM vs 0.50%±0.03% of added FDG. Biodistribution in two normal control mice and one 2% IBD-mouse showed an increased uptake in the colon of the colitis mouse compared to the two controls (28.0% of IA/g (injected activity per gram) compared to 12.75%±2.95). Analysis of FDG and FDM scans at days 36 and 37 of a colitis mouse showed an increased uptake in absolute values of FDM compared to FDG. The ratios of organ specific values (intestine/liver, intestine/bladder) were similar in FDM compared to FDG, although the intestine/heart ratio was 61.8% larger in FDM compared to FDG. **CONCLUSION:** *In vitro,* macrophages showed similar uptake of FDM and FDG. *In vivo,* both FDM and FDG were able to visualize IBD. Preliminary biodistribution results showed higher overall FDM uptake including in the bowel of an IBD mouse compared to controls and, thus, potentially better target-to-background delineation for FDM. Overall, our results suggest FDM as a potential tracer for macrophage imaging in IBD, but further studies are needed.

RadTag a new biarsenical imaging probe for radiolabelling of biologicals

M. Schou[1], J. Häggkvist[1], L. Tari[1], M. Tóth[1], A. Westermark[1], H. Ingemyr[1], J. Malmquist[1], C. Halldin[1], P. Ström[2], A. Lundqvist[3], V. Hruby[4], M. Cai[4], **S. P. S. Svensson**[5]; [1]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, SWEDEN, [2]BioPercept AB, Lund, SWEDEN, [3]Karolinska Institutet, Institute for Oncology, Stockholm, SWEDEN, [4]Department of Chemistry, University of Arizona, Tucson, AZ, UNITED STATES, [5]Department of Physics, Chemistry and Biology, Linköping, SWEDEN.

Aim The radiolabeling of biologicals for PET imaging has so far been hampered by a lack of generalised radiolabeling methodology. We have developed a novel approach for this purpose, RadTags, which enables rapid, specific, and simple radiolabeling of biologicals based on the biarsenical-tetracystein system. One unique characteristic of the methodology is that RadTags may be labeled with any isotope of choice, using established radiolabeling technology, allowing imaging using the same constitutionally distinct molecular probe in a variety of settings, from the test tube to the clinic. The aim of the present study was to show proof-of-principle in a variety of studies, including *in vitro* radioligand binding studies and *in vivo* microPET nuclear imaging of melanoma tumors in xenograft mice. **Materials and methods** Melanin stimulating hormone (MSH) was modified to enable site-specific labeling using the biarsenical-tetracysteine methodology. Radiolabeled RadTag (^{3}H or ^{11}C) was efficiently prepared by *O*-methylation of the desmethyl phenolic precursor using either or [^{3}H]methyl nosylate or [^{11}C]methyl triflate under mild alkaline conditions. The modified MSH analog (NDP-MSH) was reacted with Radtag (^{3}H or ^{11}C) in an aqueous buffer according to a published procedure. The radiochemical purity of [^{11}C]RadTag-NDP-MSH was >95%. *In vitro* radioligand binding characterization of [^{3}H]-RadTag-NDP-MSH was performed using B16F10 melanoma cells or transfected cells. *In vivo* [^{11}C]RadTag-NDP-MSH microPET imaging of melanoma tumors was performed in B16F10 xenograft mice. **Results** The reaction of radiolabeled Radtag with NDP-MSH proceeded with near quantitative conversion after a ten minute incubation at room temperature. Both NDP-MSH and RadTag-NDP-MSH bind with low nM affinity to MC1 receptors, showing that modification of NDP-MSH does not influence the primary pharmacology of the peptide analogue. In the *in vivo* microPET experiment, [^{11}C]RadTag-NDP-MSH successfully visualized the melanoma tumor with a tumor/muscle ratio of about 1.5 at 60 minutes. **Conclusion** Our data shows that the new biarsenical RadTags may be successfully used for rapid multimodal radiolabeling of biologicals for *in vivo* molecular imaging.

EP587

Non-invasive determination of the beta cell mass with PET and SPECT with radiolabeled exendin in a spontaneous mouse model for type 1 diabetes

L. Joosten, M. Brom, O. C. Boerman, M. Gotthardt; Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim The beta cell mass (BCM) plays a key role in the development and progression of diabetes, but the onset of beta cell loss and the relationship between loss of beta cell mass and beta cell function still needs to be unraveled. A non-invasive method to determine the BCM *in vivo* would allow measurement of the BCM during the development and progression of type 1 and 2 diabetes. Exendin-3 is a stable glucagon-like peptide-1 (GLP-1) analogue with high affinity for the GLP-1 receptor (GLP-1R). Recently, targeting of the GLP-1 receptor on beta cells was proven to be a successful method to determine the beta cell mass *in vivo* in rats with chemically induced beta cell loss. In a first clinical proof-of-principle study these preclinical data were confirmed. In this study we compared the *in vivo* BCM quantification of SPECT with PET in non-obese diabetic (NOD) mice and correlated this with exendin uptake determined *ex vivo* and with immunohistochemical determination of the BCM. **Materials and methods** NOD mice (n = 14) of 6, 12 and 18 weeks old were injected intravenously with 3-5 MBq ^{68}Ga-NODAGA-exendin-3 and 1 h p.i. PET/CT was acquired. Two days later mice received 15 MBq ^{111}In-exendin-3 and SPECT/CT images were acquired 1 h p.i.. Animals were euthanized after SPECT/CT and pancreas and relevant organs were dissected, weighed and the radioactivity in the organs was measured in a gamma counter. The pancreas was fixed in formalin, embedded in paraffin and sections were stained immunohistochemically to determine the BCM by morphometric analysis. **Results and conclusion** Both PET and SPECT visualized the pancreas. The correlation (Pearson) between the BC area (μm^2) and pancreatic uptake of ^{111}In-exendin measured ex vivo (%ID/g) was 0.72 ($p = 0.0036$). Quantification of exendin uptake by SPECT resulted in a better correlation (Pearson $r = 0.95$, $p < 0.0001$)

with tracer uptake measured by ex vivo counting compared to quantification with PET (Pearson r = 0.69 , p = 0.0068). Furthermore, a better correlation between BCM and image quantification was observed for SPECT than for PET (Pearson r = 0.66, p = 0.0108 and r = 0.28, p = 0.32, respectively). In conclusion, the BCM can be determined accurately with SPECT and PET. This study shows a preference for SPECT in preclinical imaging to achieve a more reliable measurement of the real BCM in this model for type 1 diabetes.

EP588

Radiolabeling and biodistribution study of engineered antibody-like protein with Tc-99m for tumor therapy

D. Lee, D. Choi; Korea Atomic Energy Research Institute, Jeongeup, KOREA, REPUBLIC OF.

Recently, antibody-like scaffold proteins have received a great deal of interest in diagnosis and therapy applications. Since antibody-like scaffold proteins possess intrinsic features that are often required for tumor imaging and therapy, they have potential to be used as platforms for integrating imaging and therapeutic functions. Intrinsic issues that are associated with therapeutic application of antibody-like scaffold proteins, particularly in cancer treatment, include an efficient and straightforward radiolabeling for understanding in vivo biodistribution and excretion route, and monitoring therapeutic responses. Herein, to investigate the biodistribution and blood clearance, antibody-like scaffold protein, repebody, was successfully radiolabeled with the [99mTc(OH2)3(CO)3]+ (99mTc-tricarbonyl) by using a site-specific direct labeling method via hexahistidine-tag, which is a widely used for general purification of proteins with His-affinity chromatograpy. Repebody is antibody-like scaffold that consist of highly diverse leucine-rich repeat (LRR) modules, it has been constructed to bind to interleukin-6 for cancer therapy. For 99mTc labeling to repebody, we first prepared 99mTc-tricarbony. Synthesis of 99mTc-tricarbonyl precursor achieved yields more than 90%. The result of radio-TLC, the Rf value for 99mTc-tricarbonyl was 0.0 and 0.3~0.4 using a saline and solvent mixture (methanol 99%, HCl 1%) as the eluent, respectively. And then, the repebody was radiolabeled with 99mTc-tricarbonyl at 37oC for 1 h. After radiolabeling, for remove unconjugated 99mTc-tricarbonyl, simple purification step was performed using 10 kDa cut-off filter system. Radiochemical purity was determined by radio-TLC. The radiochemical purity of radiolabeled repebody with 99mTc (99mTc-repebody) was estimated to be greater than 99% and the specific activity was 925 MBq/mg. 99mTc-repebody was highly stable up to 24 h for both in vivo SPECT/CT and in vitro histidine challenge study. Biodistribution results showed that most of intraperitoneal doses of 99mTc-repebody were found in kidneys, and other organs were found with subsequent remaining. SPECT/CT images showed that most radioactivities were presented in the kidneys at early time point. These results were well matched with biodistribution data. These biodistribution studies of repebody will be useful for development of therapy strategy along with their systemic information.

EP589

A ^{99m}Tc radiolabeled tenascin-C binding aptamer for in vivo visualization of glioblastoma tumor

L. Kang[1], Y. Huo[1], R. Wang[1], X. Xu[2]; [1]Peking University First Hospital, Beijing, CHINA, [2]Academy of Military Medical Sciences, Beijing, CHINA.

Objective: Aptamers are small molecule DNA or RNA fragments that fold into well defined 3D structures with high specificity and affinity towards target molecules. DNA aptamer, GBI-10 was found to bind with tenascin-C, an overexpressed extracellular protein in the tumor matrix. In this study, a new tumor-targeted agent of radiolabeled aptamer with technetium-99m (^{99m}Tc) was developed, and its serum stability and in vivo imaging in glioblastoma tumor bearing mice was further evaluated. **Methods:** A six carbon amine group was linked at the 3' end of GBI-10 so that this aptamer could be radiolabeled with ^{99m}Tc via the conjugation to NHS-MAG3. Radiolabeled yield and purity were evaluated by HPLC. Agarose gel electrophoresis was performed to evaluate the stability of ^{99m}Tc-GBI-10 in human fresh serum. Cellular uptake assays were carried out in the U-251 cell line to evaluate tumor uptake in vitro. Further, in vivo imaging of ^{99m}Tc radiolabeled GBI-10 was performed in glioblastoma tumor models. **Results:** Aptamer GBI-10 was synthesized with CpG solid phase synthesis methodology. GBI-10 was modified with amine group and PS backbone. After conjugated with NHS-MAG3, GBI-10 was successfully labeled with ^{99m}Tc with high radiolabeling efficiency (95%) and radiochemical purities (>98%). Shown by gel electrophoresis, ^{99m}Tc-GBI-10 had high stability in fresh human serum. In cellular uptake assay, this radiolabeled aptamer showed significantly higher uptake in U-251 cells than ^{99m}Tc-pertechnetate. After system administration, ^{99m}Tc-GBI-10 showed high accumulation in tumor during 12 h. There was significant difference between radiolabeled GBI-10 and ^{99m}Tc-pertechnetate in U-251 tumor bearing mice, which suggested the specific binding ability of radiolabeled GBI-10 in glioblastoma tumor. **Conclusion:** ^{99m}Tc radiolabeled aptamer GBI-10 has good stability in serum and is considered a promising agent capable of detecting tenascin-C in tumors.

EP590

In vivo PET Imaging of the changes in a rat fluid-percussion-induced traumatic brain injury model with [11C]PBR28 and [18F]flumazenil: A preliminary study

Z. WANG[1], C. Yang[1], K. Ghosh[1], S. Kumar[1], P. Padmanabhan[1], C. Halldin[2,1], B. Gulyás[1,2]; [1]Nanyang Technological University, Singapore, SINGAPORE, [2]Karolinska Institutet, Stockholm, SWEDEN.

Background and Objectives: Lateral fluid-percussion-induced (LFPI) traumatic brain injury (TBI) model in rat is a commonly used experimental animal model to study the cellular and molecular changes of TBI observed in humans. It is capable of reproducing the physiological, pathological and behavioural aspects under different clinical conditions in rodents. It is also useful in tracking the longitudinal changes in the brain due to the primary and secondary injuries. Recent developments in Positron Emission Tomography (PET) imaging provide us with the possibility of qualitatively and quantitatively mapping of the cellular and molecular changes induced by TBI in both humans and animals in vivo. For instance, [^{11}C]PBR28, can monitor the neuroinflammatory response in a rat TBI model. Density changes of the γ-aminobutyric acid-type A ($GABA_A$) system can be detected with the [^{18}F]flumazenil radioligand. This study aimed to investigate (i) whether the combination of the two radiotracers ([^{11}C]PBR28 and [^{18}F]flumazenil) allows reliable quantification of the molecular changes *in vivo* in a rodent TBI model and (ii) whether there are any demonstrable changes related to the primary and secondary injuries which can be observed with the two radioligands. To our best knowledge, this could be the first rodent study that used two radioligands for the LFPI TBI rat model. **Materials and Methods:** Four Sprague-Dawley rats were used for this study. After the LFPI procedure, Day 3 post-op and Day 14 post-op 3D dynamic PET scans were performed using the nanoScan PET/MRI scanner (Mediso, Hungary) at SEMC Singapore. The animals were scanned first with [^{11}C]PBR28 for 60 minutes, followed 80 minutes later by a 90 minutes long PET scan with [^{18}F]flumazenil. The PET datasets were analyzed using the image fusion tool and Px Rat (W.Schiffer) template in PMOD (PMOD Technologies, Switzerland). **Results:** It is clear that there is an increased uptake of [^{11}C]PBR28 on Day 14 caused by the LFPI procedure in the right hemisphere, whereas the uptake of [^{18}F]flumazenil was decreased on Day 14. When comparing the left and right hemispeheres using an area-under-the-curve measure, the differences between left and right hemispheres for [^{11}C]PBR28 were obvious. However, the differences

were not noticeable for [^{18}F]flumazenil. **Conclusions:** Although the PET datasets were limited in this study, our results demonstrate that it is possible to quantify the molecular changes with PET imaging with [^{11}C]PBR28 and [^{18}F]flumazenil in a TBI rodent model. Further studies are underway to explore the exact nature and timecourse of the changes.

EP591

xCT as Molecular Target for Oxidative Stress Imaging in PET

M. Colovic[1,2], H. Yang[1], H. Merkens[2], C. Zhang[2], K. Lin[2], F. Benard[2,3], P. Schaffer[1,3]; [1]TRIUMF, Vancouver, BC, CANADA, [2]British Columbia Cancer Research Centre, Vancouver, BC, CANADA, [3]Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.

Aim The system x_c^-, cystine/glutamate antiporter, has been shown to be upregulated under increased intracellular oxidative stress (OS), thus supplying the cell with cysteine, the rate-limiting substrate required for the synthesis of the antioxidant glutathione (GSH). We have developed a PET tracer targeting the transmembrane subunit of the system x_c^-, xCT. The goal of this study was to correlate 5-[^{18}F]-fluoroaminosuberic acid (^{18}FASu) uptake levels with xCT expression *in vitro* and *ex vivo*, as well as to understand xCT expression levels relative to other cellular markers of oxidative stress. **Materials and methods** xCT expression levels *in vitro* and in harvested tumour tissues and other organs, such as brain and pancreas, were determined using Western blot (WB) experiments. The protein expression levels were determined in untreated samples as well as under induced OS conditions. The ^{18}FASu uptake study was preformed using an array of cancer cell lines, including 3 different types of breast cancers (MDA-MB-231, MCF7, ZR-75-1). Uptake was measured in the presence and absence of *L*-ASu and sulfasalazine (SSZ) as blocking agents. Thiols (GSH and cystine) and reactive oxygen species (ROS) levels were determined in untreated cells lines as well as after treatment with diethylmaleate (DEM, an OS-inducing agent) and SSZ (system x_c^- inhibitor). Intracellular thiol levels were determined using commercially available fluorescence-based kit detecting free thiol groups on macromolecules. ROS levels were estimated using a 10-acetyl-3,7-dihydroxyphenoxazine-based assay. **Results** Our results to date indicate that xCT expression is positively correlated to ROS and thiol levels. Moreover, *in vitro* ^{18}FASu uptake seems to be following the same trend. In DEM-treated breast cancer cells, xCT protein expression increased, as did thiol content as well as ^{18}FASu uptake; while SSZ treated cells demonstrated reduced tracer uptake as well as a decline in cysteine and GSH content. Among the breast cancer cell lines studied, MDA-MB-231 had the highest xCT expression and also the highest ^{18}FASu uptake. More detailed ROS level measurements, *in vivo* tracer uptake, and its correlation to protein expression in tumour tissues are under investigation. **Conclusion** Our work suggests that xCT expression is positively correlated to increases in ROS and thiol levels. These increases are also correlated with increased ^{18}FASu uptake. Utilizing xCT as a molecular target, ^{18}FASu PET may provide functional information useful for clinical cancer care, including an ability to non-invasively establish cell and/or tissue OS responses for early detection, disease staging, and treatment monitoring for known and novel therapies.

EP592

In Vivo Biodistribution Of Labeled Adult Human Mesenchymal Cells (^{99m}Tc- ahMSC$_S$) Administered Via Intra-Articular In Animal Model. Preliminary Results

A. Abella[1], E. Fernández[1], A. Montellano[2], T. Martinez[1], R. Rabadan[3], P. Ros[3], L. Meseguer-Olmo[4]; [1]Unidad de Radiofarmacia. Hospital Clinico Universitario Virgen de la Arrixaca., Murcia, SPAIN, [2]Servicio de Medicina Nuclear. Clínica Belén, Murcia, SPAIN, [3]Servicio de Traumatología. Hospital Clinico Universitario Virgen de la Arrixaca., Murcia, SPAIN, [4]UCAM Universidad Católica San Antonio de Murcia., Murcia, SPAIN.

AIM Adult human mesenchymal stem cells from bone marrow (ahMSC_S) have an active role in cell therapy. Intravenous administration is currently in question due to drawbacks as the massive cell trapping in the pulmonary parenchyma and the lack of viability of these cells in the bloodstream. In previous study we compared the scintigraphic biodistribution of 99mTc-ahMSC_S after intravenously (IV) and intra-articular (IAR) administration in animal model. Surprisingly, pulmonary activity was not detected when the injection was performed by this second via. We intend to find out which route follows the extracavitary activity detected when using the IAR administration. MATERIAL AND METHODS Two New Zealand male rabbits (3.5-4k) were used. With an interval of two weeks, 2.9 x106 / 0.5 ml of 99mTc-ahMSC_S (6.05 Bq / cell) and 74 MBq / 0.5ml of anhydrous sodium phytate (Phytacis®) were injected via intra-articular (knee joint) and 6 x 9.2 MBq/ 0.1 ml of 99mTc nanocolloidal human albumin (Nanocoll®) subcutaneously around the joint. After acquisition of dynamic images every 30 s for 25 min, whole body static images in previous projection at 1, 6 and 24 hours were acquired, previous sedation. Immunosuppressive agents were not administered. All animals survived the experiment. RESULTS Lymphatic drainage was observed with ipsilateral inguinal lymph visualisation without pulmonary or hepatic uptake in dynamic images obtained after subcutaneous administration of 99mTc- nanocolloidal human albumin around the joint. On the other hand, liver activity was observed after IAR injection of 99mTc-phytate as following administration of 99mTc-ahMSC_S. CONCLUSION Results seem to confirm that the activity detected in different organs after IAR administration migrates from the cavity through the circulatory system. However, the absence of pulmonary activity after IAR administration of 99mTc-ahMSC_S do not allow to establish a correspondence of this activity with the extracavitary cell migration.

EP593

Origin Of The Activity Detected By Scintigraphy After Intra-Articular Administration Of Labeled Adult Human Mesenchymal Stem Cells (^{99m}Tc- ahMSC$_S$) In An Animal Model

A. Abella[1], E. Fernández[1], T. Martinez[1], C. Martinez[2], B. Revilla-Nuin[3], R. Rabadan[4], L. Meseguer-Olmo[5]; [1]Unidad de Radiofarmacia. Hospital Clinico Universitario Virgen de la Arrixaca., Murcia, SPAIN, [2]Experimental Pathology Laboratory (LAPE). IMIB-Arrixaca and CIBERehd., Murcia, SPAIN, [3]Unidad de genómica. IMIB-Arrixaca and CIBERehd, Murcia, SPAIN, [4]Servicio de Traumatología. Hospital Clinico Universitario Virgen de la Arrixaca., Murcia, SPAIN, [5]UCAM Universidad Católica San Antonio de Murcia., Murcia, SPAIN.

AIM Nuclear medicine imaging is an attractive technique in terms of non-invasive *in vivo* human mesenchymal stem cells (ahMSC_s) tracking after labeling with a radiopharmaceutical. Our previous work on intra-articular (IAR) administration of ^{99m}*Tc* ahMSC_s in an animal model pointed out that the extra-articular activity migrates from the cavity through the bloodstream; our purpose is to check the origin of such extracavitary activity by histological detection of ahMSC_s after IAR administration of ahMSC_s labeled with 99mTc-HMPAO in an animal model. MATERIAL AND METHODS Samples from synovial membrane and several organs (lung, heart, spleen, liver, stomach, intestine, colon, kidney, urinary bladder, gallbladder and bone marrow) were analyzed by immunohistopathology and molecular biology in search of the presence of ahMSC_s. Paraffin embedded (for H&E and anti-CD90 examinations) and fixed RNA-later (for study the molecular expression of human GAPDH) samples were employed. RESULTS The presence of ahMSC_s was confirmed only in the synovial membrane. No signs of ahMSC_s, either by immunohistopathology or molecular biology, were observed in stated organs. CONCLUSION Histological analysis pointed out the absence of human ahMSC_s in extracavitary area, confirming the trapping of ahMSC_s in the cavity and the lack of migration to other organs. Scintigraphic activity detected outside the joint could be due to the efflux of 99mTc-HMPAO from the cells after administration.

EP594

Effects of intratumoral versus intravenous injection on the breast tumor targeting and tissue uptake distribution of ^{177}Lu-labeled bombesin peptide analog

S. Okarvi, I. Jammaz; King Faisal Specialist Hospital & Research Centre, Riyadh, SAUDI ARABIA.

Aim: It is important to explore new and effective targeted routes of administration to enhance tumor targeting efficacy and reduce systemic toxicity. One main drawback of traditional intravenous (i.v) administration of radiopeptide is the high accumulation in nontarget tissues leading to low concentration in target tissue (tumor). Direct intratumoral (i.t) administration of radiopeptide is a new treatment exemplar which may be particularly beneficial for treating accessible solid tumors especially in early stages. The obvious rationale behind this approach is that the topical administration of radiopeptides improve the concentrations of agents in the target site while lowering their localization in healthy tissues. The purpose of the current study was to evaluate breast tumor targeting potential of ^{177}Lu-labeled bombesin (BN) analog in xenografted nude mice after i.t and i.v injection. *Materials and Methods*: In the present study a novel BN analog was synthesized by solid-phase synthesis following Fmoc/HBTU chemistry and manually coupled to DOTA ligand to facilitate labeling with ^{68}Ga/^{177}Lu. After labeling DOTA-GGC-BN(7-14) with ^{177}Lu in the presence of 0.1M NH_4OAc buffer (pH 4-5) in vitro cell binding was performed on various breast cancer cell lines including MCF7, T47D and MDA-MB-231. For in vivo tumor targeting the radiopeptide was administered by i.t and i.v injections in two groups of nude mice with subcutaneously grown MCF7 breast tumors. *Results:* ^{177}Lu-DOTA-GGC-BN exhibited a high and specific binding towards various human breast cancer cell lines with binding affinities below 20nM. Also a significant internalization (~20%) into cancer cell lines was observed. Following i.t injection into nude mice 36%ID/g of the radioactivity was localized in the breast tumor over 2 h whereas uptake in other major organs including kidneys was quite low (<1%ID/g). Tumor to blood, muscle and kidney ratios were found to be 252, 360 and 36. When i.v mode of administration was utilized a totally different and variable tissue uptake behavior was observed in terms of accumulation in nontarget tissues (up to 7%ID/g). The uptake in the tumor was below 2%ID/g. *Conclusion*: i.t administration of ^{177}Lu-DOTA-GGC-BN makes high amount of radioactivity retained in tumor with significantly lower radioactivity retained in normal tissues and provides a more effective targeting of BN receptor-expressing breast tumors. It is expected that direct i.t injection may offer less systemic exposure than i.v delivery and serve as an effective procedure to deliver high radiation dose specifically to tumors. Future studies should discover more usefulness of this inventive mode of administration.

EP595

Design and construction of a hybrid HER2/neu peptide for targeting human breast carcinoma

S. Okarvi, I. Jammaz; King Faisal Specialist Hospital & Research Centre, Riyadh, SAUDI ARABIA.

Objectives: HER2/neu is a member of the epidermal growth factor receptor family of transmembrane tyrosine kinases. The HER2/neu gene is amplified and overexpressed in a variety of malignancies, including breast and ovarian cancers. This overexpression can result in ~200-fold increase concentration of the HER2/neu in tumor versus normal tissue. The E75 epitope (HER2/neu 369-377) is immunogenic peptide derived from HER2/neu protein, which is overexpressed in many breast cancer patients. Another peptide that has shown potential for targeting HER2/neu expressing tumors is based on KCCYSL sequence. In the current study, we have combined the sequences of these two important peptides and formulate a hybrid HER2/neu peptide in an attempt to target breast tumors. Methods: The HER2/neu hybrid peptide (Ac-GGC-ALA-E75+KCCYSL) was synthesized by Fmoc/HBTU based peptide synthesis chemistry. The HER2/neu peptide was radiolabeled with ^{99m}Tc via GGC- chelating sequence by ligand exchange method. In vitro tumor cell binding was performed on HER2/neu expressing SKBR3 and MCF7 human breast cancer cell lines and in vivo tumor targeting was conducted on nude mice carrying MCF7 breast tumor xenografts.Results: The structure and purity of HER2/neu peptide was confirmed by mass spectrometry and HPLC analysis. The hybrid HER2/neu peptide radiolabeled efficiently with 99mTc (90%) and exhibited a high binding affinity to HER2/neu expressing SKBR3 and MCF7 cell lines (kd=<50 nM). In nude mice with MCF7 xenografts, the radiopeptide displayed efficient clearance from the blood and uptake in most of the major organs was low to moderate range (below 4%ID/g), with the exception of the kidneys, which retained the highest radioactivity (up to 14%ID/g). The accumulation in the tumor was found to be 2.10±0.67, with good tumor to blood and tumor to muscle ratios of 1.1 and 5.3. The excretion of radiopeptide was observed through the renal and hepatobiliary pathways. Conclusions: Our initial findings suggest that the hybrid HER2/neu peptide hold certain favorable in vitro and in vivo characteristics that may makes it useful for the diagnosis of HER2/neu positive tumors. Nonetheless further studies are required to assess the full diagnostic potential of this new emerging class of peptides for tumor targeting.

EP596

Investigation of experimental melanoma tumors using the novel melanin specific radiotracer ^{68}Ga-NODAGA-Procainamide (PCA)

G. Trencsényi[1,2], G. Nagy[2], A. Vida[3,4,5], J. Angyal[6], N. Dénes[1], J. P. Szabó[1], T. Kovács[3,4,5], I. Garai[1,2], P. Bai[3,4,5], I. Kertész[1]; [1]University of Debrecen, Department of Nuclear Medicine, Debrecen, HUNGARY, [2]Scanomed Ltd., Debrecen, HUNGARY, [3]University of Debrecen, Department of Medical Chemistry, Debrecen, HUNGARY, [4]MTA-DE Lendület Laboratory of Cellular Metabolism, Debrecen, HUNGARY, [5]Research Center for Molecular Medicine, Debrecen, HUNGARY, [6]University of Debrecen, Department of Periodontology, Debrecen, HUNGARY.

Aim: Malignant melanoma is the most aggressive form of skin cancer. The early detection of primary melanoma tumors and metastases using non-invasive PET imaging determines the outcome of this disease. Previous studies have shown that benzamide derivatives specifically bind to melanin pigment. The aim of this study was to synthesize and investigate the melanin specificity of the novel ^{68}Ga-labeled NODAGA-Procainamide (PCA) *in vitro* and *in vivo* using PET techniques. Methods: Benzamide derivative procainamide (PCA) was conjugated with NODAGA chelator and was labeled with Ga-68 (^{68}Ga-NODAGA-PCA). The melanin specificity of ^{68}Ga-NODAGA-PCA was investigated under *in vitro*, *ex vivo* and *in vivo* conditions using amelanotic Melur and melanotic B16-F10 melanoma cell lines. By subcutaneous and intravenous injection of melanoma cells tumor-bearing mice were prepared (n=20), on which 20 days after tumor cell inoculations ($3x10^6$) biodistribution studies and small animal PET/CT scans were performed after intravenous injection of ^{68}Ga-NODAGA-PCA (11.3±0.2 MBq) and ^{18}FDG radiotracers (10.1±0.3 MBq). Results: ^{68}Ga-NODAGA-PCA was produced with excellent radiochemical purity (98%<) and with high specific activity (14.9±3.9GBq/μmol), at all cases. *In vitro* experiments showed that ^{68}Ga-NODAGA-PCA uptake of B16-F10 cells was significantly (p<0.01) higher then Melur cells. *Ex vivo* organ distribution and *in vivo* PET/CT studies using subcutaneous and metastatic tumor models showed significantly (p<0.01) higher ^{68}Ga-NODAGA-PCA uptake in B16-F10 primary tumors and lung metastases in comparison with amelanotic Melur tumors. In B16-F10 melanoma models more than 10-fold higher tumor-to-background ratios were found by using ^{68}Ga-

NODAGA-PCA when it was compared to the ^{18}FDG accumulation. Conclusion: ^{68}Ga-NODAGA-PCA showed specific binding to the melanin producing experimental primary and metastatic B16-F10 melanoma tumors. Therefore, ^{68}Ga-NODAGA-PCA is a suitable diagnostic radiotracer for the detection of melanoma tumors and metastases *in vivo*.

EP597

Comparative in vitro and in vivo studies of Ga-68-labeled melanin-specific Procainamide (PCA) using different chelators

G. Trencsényi[1,2], G. Nagy[2], A. Vida[3,4], N. Dénes[1], J. P. Szabó[1], T. Kovács[3,4], I. Garai[1,2], P. Bai[3,4,5], J. Varga[1], I. Kertész[1]; [1]University of Debrecen, Faculty of Medicine, Department of Nuclear Medicine, Debrecen, HUNGARY, [2]Scanomed Ltd., Debrecen, HUNGARY, [3]University of Debrecen, Department of Medical Chemistry, Debrecen, HUNGARY, [4]MTA-DE Lendület Laboratory of Cellular Metabolism, Debrecen, HUNGARY, [5]Research Center for Molecular Medicine, Debrecen, HUNGARY.

Purpose: Previous studies have shown that benzamide derivatives conjugated with different positron emitting radionuclides (Ga-68, F-18) specifically bind to melanin pigment of melanoma tumors. Ga-68 chelating agents have high influence on the radiochemical and physiological properties of Ga-68 labeled melanin-specific procainamide (PCA). The aim of this study was to compare the melanin specificity of ^{68}Ga-labeled PCA using HBED-CC and NODAGA chelators under *in vitro* and *in vivo* conditions. Methods: Benzamide derivative procainamide (PCA) was conjugated with HBED-CC and NODAGA chelators and was labeled with Ga-68. The melanin specificity of ^{68}Ga-NODAGA-PCA and ^{68}Ga-HBED-CC-PCA was investigated *in vitro* and *in vivo* using amelanotic (Melur) and melanotic (B16-F10) melanoma cell lines. Tumor-bearing mice (n=10) were prepared by subcutaneous injection of B16-F10 melanoma cells. 20 days after tumor cell inoculation and 90 min after intravenous injection of the radiotracers small animal whole body PET/MRI (Mediso nanoScan PET/MRI) scans were performed. Results: *In vitro* experiments showed that ^{68}Ga-NODAGA-PCA uptake of B16-F10 cells was significantly (p 0.001) higher than the ^{68}Ga-HBED-CC-PCA accumulation after 30 and 90 min incubation time. *In vivo* PET/MRI studies using subcutaneous tumor models showed significantly (p 0.001) higher ^{68}Ga-NODAGA-PCA uptake (SUVmean: 0.46±0.05, SUVmax: 1.96±0.25, T/M ratio: 40.69±5.87) in B16-F10 primary tumors in comparison with ^{68}Ga-HBED-CC-PCA where the SUVmean, SUVmax and T/M ratios were 0.13±0.02, 0.56±0.11 and 11.43±0.45, respectively. Conclusion: ^{68}Ga-labeled-PCA using NODAGA chelator showed specific binding to the melanin-producing experimental B16-F10 melanoma tumors. Because of its high specificity and sensitivity ^{68}Ga-NODAGA-PCA is a promising radiotracer for clinical and preclinical melanoma research.

EP598

Imaging response to therapy using PET imaging with the novel PSMA PET tracer, ^{68}Ga-THP-PSMA, in Du145-PSMA prostate cancer xenografts

A. Weeks, J. Young, N. K. Ramakrishnan, K. Sunassee, G. Mullen, V. Goh, P. Blower, G. Cook; King's College London, London, UNITED KINGDOM.

There are now several effective treatments for metastatic prostate cancer that prolong survival but response rates remain less than 50%. There is frequently a delay in changing therapy as current imaging methods are poor at differentiating responders from non-responders at an early enough time point to effectively guide therapeutic transition and limit toxicity in non-responders. Imaging of prostate specific membrane antigen (PSMA) in prostate cancer is emerging as a specific and sensitive technique for the staging of prostate cancer but to date no data exists for therapy monitoring. Aim: The purpose of this pre-clinical study was to evaluate response to Docetaxel, a first line chemotherapeutic agent used in men with metastatic prostate cancer, using the novel PET tracer ^{68}Ga-THP-PSMA and our hypothesis was that measuring changes in PSMA expression can monitor therapeutic effect. Method: Expression of PSMA was confirmed in DU145-PSMA cells by flow cytometry. SCID-beige mice were injected subcutaneously in the right flank with DU145-PSMA cells. Tumours were measured 2-3 times per week until the mean diameter was 0.5-1cm. Mice then underwent a pre-treatment microPET/CT scan with ^{68}Ga-THP-PSMA 15 min after IV tail vein injection of 5-10 MBq. Mice were then treated on day 1 and day 5 with 3mg/kg clinical grade Docetaxel administered intravenously. Sham treated animals were administered sterile saline under the same regimen. PET/CT scans were repeated at 14 days after which mice were sacrificed and tumour and muscle samples were weighed and gamma counted to provide tumour to muscle ratios (TMR). Regions of interest were drawn manually on the whole tumour using PET and CT images and refined using global thresholding. ^{68}Ga-THP-PSMA uptake per unit volume was calculated from percentage of injected dose (%ID/mm^3). Uptake in pre-treatment images were compared to 14 day images for change in uptake after therapy. Results: Ex-vivo gamma counting demonstrated reduced TMRs in Docetaxel treated mice (n=5) compared to sham-treated (n=3) (7.7:1 and 15.3:1, respectively, p=0.048). PET images of Docetaxel treated animals (n=5) showed a trend of a greater mean decrease in uptake compared to sham treated animals (n=3) (-4.7×10^{-4} %ID/mm^3 and -1.0×10^{-5} %ID/mm^3, respectively). Conclusions: These preliminary data demonstrate that ^{68}Ga-THP-PSMA uptake is reduced in prostate tumour xenografts treated with Docetaxel and may be suitable as an agent for PET imaging of therapy response.

EP599

Diagnosis with resource to image of bladder cancer: an in vivo evaluation of ^{99m}Tc-PEI-MP

S. M. Ferreira[1], A. M. Abrantes[2], M. Laranjo[2], J. Casalta-Lopes[3], A. C. Gonçalves[4], A. B. Sarmento-Ribeiro[4], J. Zeevaart[5], W. Louw[5], C. Pais[6], I. Dormehl[7], M. F. Botelho[2]; [1]Biophysics Unit, Faculty of Medicine, University of Coimbra; Centre of Molecular and Environmental Biology, School of Sciences, University of Minho; Nuclear Medicine Course, School of Allied Health Technologies of Porto's Polytechnic Institute, Coimbra, Braga, Porto, PORTUGAL, [2]Biophysics Unit, Centre of Investigation on Environment, Genetics and Oncobiology; Institute for Biomedical Research on Light and Image; Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [3]Biophysics Unit, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [4]Centre of Investigation on Environment, Genetics and Oncobiology; Applied Molecular Biology and Hematology Group; Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [5]Radiochemistry Department, NECSA, Pretoria, SOUTH AFRICA, [6]Centre of Molecular and Environmental Biology, School of Sciences, University of Minho, Braga, PORTUGAL, [7]Department of Internal Medicine, University of Pretoria, Pretoria, SOUTH AFRICA.

Introduction and Aim: Previous in vitro studies with ^{99m}Tc-PEI-MP (polyethyleneiminomethyl phosphonic acid) using a human cell line of transitional cell carcinoma of the bladder, demonstrated the affinity of PEI-MP to bladder cancer cells, revealing that ^{99m}Tc-PEI-MP could be an excellent agent for imaging in vivo. The aim of this work was to explore in vivo the potential of ^{99m}Tc-PEI-MP for diagnosis of bladder cancer. Material and Methods: The radiochemical purity of ^{99m}Tc-PEI-MP was evaluated hourly until 5 hours after the radiolabelling, using ascendant thin-layer chromatography (ITLC-SG/acetone and Whatman 3MM/citrate buffer). The in vivo studies were performed using 2 groups

of balb/c nu/nu mice without tumour and other 2 with xenografts of bladder carcinoma, injected with ^{99m}Tc-PEI-MP or ^{99m}Tc-Pertechnetate. After injection, were acquired dynamic (60 images/10 seconds each) and static images (10 minutes each, every 30 minutes until 120 or 240 minutes). For biodistribution proposes, mice were euthanized 120 and 240 minutes after injection and organ samples where weighted and counted in a well-counter to obtain percentage injected activity per gram of organ. The ratios tumour/muscle, tumour/bladder, tumour/liver, tumour/lung and tumour/bone were determined considering the origin of the bladder cancer and the target organs of distant metastasis. Results: The images and biodistribution studies demonstrated the uptake of ^{99m}Tc-PEI-MP by the kidneys and bladder. Also it was verified the uptake by the lungs. The biodistribution studies demonstrated the uptake by the liver, gallbladder and bilis indicating other route of excretion. It was verified the uptake by the xenograft of bladder carcinoma in the images and biodistribution studies. Tumour/muscle ratio was >1 for ^{99m}Tc-PEI-MP, but tumour/bladder, tumour/liver, tumour/lung and tumour/bone ratios were significantly <1. Conclusions: ^{99m}Tc-PEI-MP is mainly excreted through the renal system, and a small part through the hepatobiliary system. The retention in the lung may be related with the large size of the complexes, being trapped in the blood capillaries. The uptake by the xenograft of bladder carcinoma demonstrated the affinity of PEI-MP by bladder cancer cells, and may be also related with the enhanced permeability and retention effect. The tumour/muscle ratio >1 may be an advantage for imaging with ^{99m}Tc-PEI-MP to determine the muscle invasiveness of the bladder cancer. The tumour/bladder, tumour/liver, tumour/lung and tumour/bone ratios <1, theoretically would indicate that the tumour and metastases would appear as could lesions and possible to identify in the images with ^{99m}Tc-PEI-MP.

Performance evaluation for stable adsorbent in acidic eluent as a ^{68}Ge/^{68}Ga generator column material

j. Lee[1,2], J. Park[1], M. Hur[1], S. Yang[1], K. Yu[3], S. Kim[2]; [1]korea atomic energy research institute, Jeollabuk-do Jeongeup-si, KOREA, REPUBLIC OF, [2]Dongguk University-Gyeoungju, Gyeoungju, KOREA, REPUBLIC OF, [3]Dongguk University-seoul, Seoul, KOREA, REPUBLIC OF.

Aim The adsorbent is the key component for radioisotope generator column system. Especially inorganic ion-exchangers such as amorphous zirconium phosphate (am-ZrP) were studied extensively for the application to the adsorption and desorption of ^{68}Ge/^{68}Ga, due to their selectivity for the specific ions, acid resistant and radiation stabilities. In this study, various zirconium phosphates (ZrP) were synthesized to select acid resistant column material. **Materials and methods** Various ZrP derivatives were prepared using a common sol-gel and hydrothermal method. ZrP-1 was synthesized with 50 mL of 3 M zirconium (IV) propoxide solution and 100 mL of 5 wt% phosphoric acid then stirred for 20 h at room temperature. ZrP-2 was obtained in addition with sodium hydroxide based on solution of ZrP-1 as the following procedure. 5 mL of a 0.1 M NaOH solution was added to the ZrP-1 suspension. Crystalline ZrP-3 and ZrP-4 were prepared from ZrP-1 by refluxing and calcination at 450 °C for 24 h. The SEM-EDX was used in order to observe the morphology of ZrPs at the submicroscale. The crystal structure was measured with X-ray diffraction. N_2 gas adsorption and desorption were obtained using the BET. Finally, hydrodynamic size and zeta-potential of ZrPs were measured in 0.1N-HCl aqueous solution by Zeta-sizer. The stability of the ZrPs was evaluated in 0.1N-HCl aqueous solution as the acidic eluent. The adsorption and desorption of ^{68}Ge & ^{68}Ga measured using the acid resistant am-ZrP by chromatography method. **Results and Conclusion** Am-ZrP and crystalline-ZrP were prepared as column materials with either sol-gel method or hydrothermal process to evaluate as ^{68}Ge/^{68}Ga generator column material. Am-ZrP showed good performances in stability, surface area as well as weight loss test. Am-ZrP also had the acceptable features in adsorption and desorption ability of Ga-68 >70% elution yield and Ge-68 <10^{-3}% breakthrough. This am-ZrP column material has a high potential as a ^{68}Ge/^{68}Ga generator adsorbent.

EP601

Preparation and preliminary evaluation of 90Y-tropolonate-Lipiodol as a potential radiopharmaceutical for hepatocellular carcinoma therapy

N. Lepareur[1,2], J. Edeline[1,2], N. Noiret[3,4], V. Ardisson[1,2], E. Garin[1,2]; [1]CLCC Eugene Marquis, Rennes, FRANCE, [2]INSERM U991, Rennes, FRANCE, [3]ENSCR, Rennes, FRANCE, [4]ISCR UMR CNRS 6226, Rennes, FRANCE.

Aim Hepatocellular carcinoma (HCC) ranks third in terms of cancer mortality worldwide, with an increasing incidence in western countries. Due to often late detection and underlying hepatopathy, it is a pathology for which curative treatment is only accessible to a minority of patients. Radiolabelled Lipiodol has shown promising results for selective internal radiotherapy of inoperable hepatocellular carcinomas. Literature has shown that yttrium-90 is a radionuclide of choice for HCC treatment. We thus propose a new labelling of Lipiodol with yttrium-90 as a potential treatment modality for HCC. **Materials and Methods** Two tropolonate ligands have been investigated, tropolone and 4-isopropyltropolone (β-thujaplicine). Various conditions have been investigated (pH, temperature, reaction time···) to prepare yttrium-90 radiocomplexes based on these tropolonate ligands. Lipiodol labelling yield and *in vitro* stability have been determined by counting of organic and aqueous phases, over a period of 15 days. MTT assay has been done to assess efficacy of the yttrium-90 labelled compound. *In vivo* biodistribution in hepatoma bearing rats has also been investigated. **Results** Two lipid-soluble tropolonate radiocomplexes were successfully prepared and used to label Lipiodol. Preparation is quick and efficient, at room temperature, in just five minutes. These complexes were successfully extracted into Lipiodol. At 72h, 30 to 50% of the activity is released into the aqueous phase, indicating a lack of stability or a lack of lipophilicity of the complexes. *In vivo*, at 72h, the ID/g in the tumour is still 7.54 ± 4.31% with a 3.3 tumour/healthy liver ratio, indicating a preferential and sustained uptake in the tumour. **Conclusion** A new simple and reliable method for the ^{90}Y-labelling of Lipiodol has been demonstrated. Ligand optimisation is however still necessary to obtain a more stable complex.

EP602

Influence of ethanol on automated radiolabelling using NaCl post-processing

M. Meisenheimer, **E. Eppard**, S. Kürpig, M. Essler; University Hospital Bonn, Bonn, GERMANY.

Objectiv: Recent studies showed that addin ethanol to the reaction mixture improves radiolabelling with trivalent radiometals in terms of amount of precursor, reaction time, reaction temperature, specific activity and radiolysis. With regard to clinical application this effect is of practical interest in radiopharmacy. The aim of this study was to evaluate if it is possible to combine the positive effect of ethanol especially in terms of radiolysis and amount of precursor to automated systems with NaCl-post processing. Methods: 68Ga was obtained from a 1 year old 1.85 GBq

68Ge/68Ga-generator (iThemba South Africa). Radiolabelling was performed on an automated Ga-labelling cassette module (Gaia, Elysia-Raytest, Germany). PSMA-11 from ABX (Radeberg, Germany) and DOTATOC from ANASPECT (USA). The standard labelling protocol was used without modifications. Quality control was performed using radioHPLC and radioTLC. Results: Utilization of additional ethanol on an automated cassette module can be achieved by adding ethanol directly to the buffer solution without further modifications of the standard procedure. It was found that the amount of radiolysis side products was already decreased by adding 5 % ethanol to the reaction mixture. Further increase of the ethanol amount also effects the amount of precursor needed. Conclusion: The utilization of the effect of ethanol decreased radiolysis to a minimum. It was possible to combine the positive effects of ethanol on radiolabelling with the standard labelling procedure of an automated cassette module system. The whole process guarantees safe preparation of highly pure ^{68}Ga-Peptide for clinical application.

EP603

Development of a loop reactor system for the optimization of radiolabeling conditions

D. Szikra[1,2], G. Nagy[2], G. Trencsényi[1,2], J. Varga[1], I. Garai[1,2]; [1]University of Debrecen, Debrecen, HUNGARY, [2]Scanomed Ltd., Debrecen, HUNGARY.

Aim: The determination of optimal labeling conditions is important for efficient routine radiopharmaceutical production and for the comparison of newly developed chelators. Manual labeling is time consuming and the reproducibility of the results are often low. A capillary system was built to enable the fast optimization of labeling conditions of various chelators with ^{68}Ga and ^{44}Sc. It was designed to handle small (10 ul) reagent volumes for scouting experimets and to be able to scale up to several hundred microliters for production. Materials and methods: The system consists of three electronically actuated HPLC valves interconnected with teflon capillaries and controlled by an Arduino Mega card. The liquid is moved by the aid of a double syringe pump. The reagents are coinjected into a heated PEEK loop and - after the predetermined reaction time - injected onto a HPLC column for analysis or purification. Results: The dependence of RCY on pH and chelator concentration was determined for various chelators (DOTA, NOTA, NOPO) labeled with ^{68}Ga and ^{44}Sc. The effects of temperature and reaction time was also studied. $^{44}Sc^{3+}$ and ^{44}ScDOTA was separated on a reversed phase column, using 0,01 M oxalic acid eluent. DOTA could be labelled with ^{44}Sc in ammonium acetate buffer at pH 3 - 4 down to 3 micromolar chelator concentration.

EP604

Separation study of scandium radionuclides from excess of calcium

D. Pawlak, L. J. Parus, T. Dziel, P. Garnuszek, R. Mikołajczak; National Centre for Nuclear Research Radioisotope Centre POLATOM, Otwock, POLAND.

Introduction. Scandium is a chemical element with only one naturally occurring isotope of atomic mass 45, one +3 oxidation state and chemistry similar to lanthanides. ^{47}Sc could be used for therapy while ^{43}Sc and ^{44}Sc with the half-lives of 3.89h and 3.93h , respectively, longer than that of ^{18}F and ^{68}Ga, might be advantageous in diagnostic imaging. They can be produced in a cyclotron by reactions: ^{44}Ca(p,n)^{44}Sc, ^{40}Ca(α.n)^{43}Sc, ^{43}Ca(p,n)^{43}Sc and ^{42}Ca(d,n)^{43}Sc. Herein we present separation of the microgram quantities of Sc from milligrams of Ca using the commercially available resin DGA (Triskem International) which we proved earlier to separate Sc/Ti [1] pair and was used for separation of Ca/Sc [2]. MethodsThe studies were carried out using the 10 mL solutions containing 20 mg of Ca and 0.3, 2.3 or 10 μg of Sc and tracer amounts of ^{45}Ca (600kBq) and ^{46}Sc (50kBq). Each solution was introduced on a column containing 100 mg of DGA resin with flow rate from 0.4 to 1.0 mL/min. The column was washed with 5 ml of 5 M HNO_3 to remove calcium and finally scandium was eluted with 10 mL of 0.1 M HCl or 0.15 M NaCl or 1:1 (v:v) mixture of 0.15 M NaCl and 0.3 M ascorbic acid. The contents of ^{46}Sc and ^{45}Ca were measured in each collected fraction. ResultsFor all eluents used the recovery of scandium was high and amounted to 92.95 ± 3.52% for 0.1 M HCl, 81.15 ± 4.65% for 0.15 M NaCl and 85.59 ± 4.02% for a NaCl/ascorbic acid mixture.There was no significant effect of flow rate on the recovery of scandium or elution profile. However, for higher amount of scandium the elution volume was smaller. The content of ^{45}Ca in all scandium fractions was below detection limit (approx. 100 Bq) corresponding to the calcium content of less than 3 ppm. ConclusionThe DGA resin seems to be promising for separation of Sc from Ca. The preliminary results obtained using mixture Ca/^{45}Ca/^{46}Sc need to be verified on cyclotron irradiated targets. Accelerating PET tracer development: Establishment of a combinatorial-like, high-throughput development approach using condensation reactions and high-throughput screening

E. Nyberg L'Estrade[1,2,3], M. Palner[2], I. Nyman Petersen[1], S. H. Keller[4], S. Lehel[4], B. Dall[4], J. Langgaard Kristensen[1], M. Erlandsson[3], T. Olsson[3], G. M. Knudsen[2], M. M. Herth[1,2,4]; [1]Department of Drug Design and Pharmacology, Faculty of Health and Medicine, University of Copenhagen, Copenhagen, DENMARK, [2]Neurobiology Research Unit, Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK, [3]Strålningsfysik, Nuklearmedicinsk Fysik, Skånes Universitetssjukhus, Lund, SWEDEN, [4]Department of Clinical Physiology, Nuclear Medicine & PET, Copenhagen University Hospital, Copenhagen, DENMARK.

The aim The development of new PET-tracers is still largely a "trial-and-error game". Usually, it takes several years until the ideal tracer candidate is identified. In this work, we aim to accelerate this process combining more combinatorial-like labeling approaches with high-throughput *in vivo* screening. The feasibility of such a combinatorial-like approach was described within our group in 2014[1]. In this work, we aim to expand the combinatorial-like labeling approach from reductive aminations to condensation reactions. Furthermore, we aim to establish a high-throughout screening methodology at our high-resolution tomograph (HRRT) and prove its feasibility to perform quantitative PET scans with 4 research animals simultaneously. *Materials and methods* Precursor building blocks and references compounds have already been published. ^{11}C-Labeling was performed at a phenylpiperazine building block and subsequently condensated with a set of halide-oxindole derivatives[2,3,4,5]. High-throughput *in vivo* screening is conducted in a multi-rodent rack, making it possible to scan four rodents simultaneously. To evaluate the feasibility in respect to quantitative PET measurements of this approach, PET images reconstructed and evaluated towards their accuracy. *Results* The combinatorial-like approach could successfully been applied to condensation reactions. Compared with our previously published labeling strategy, the new strategy showed clear advantages in a preclinical set-up (faster and more efficient). High-throughput *in vivo* scanning using the newly developed multi-rodent rack resulted in satisfactorily PET data

even though a global underestimation of PET activity of ±5% was observed. This set-up allowed us to label and evaluate 4 compounds within one week. Each tracer was evaluated in 2 baseline and 2 blocking experiments. This set-up resulted in an extensive time reduction. *Conclusion* We believe that the proposed development set-up accelerates PET tracer development, at least in this specific synthesis and screening set-up. *References* 1) Herth *et al*., *RSC Adv.*, 2014, 4: 21347-21350 2) Herth *et al*., *ACS Chem. EP606

Comparative studies on ^{64}Cu-complexing modern bifunctional chelator for $\alpha_v\beta_3$ integrin targeting and in vivo cancer imaging

P. T. Huynh[1], S. Sarkar[1], N. Soni[1], Y. S. Ha[1], W. Lee[1], H. Ahn[1], G. I. An[2], J. Yoo[1]; [1]Kyungpook National University, Daegu, KOREA, REPUBLIC OF, [2]Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Abstract: Aim: Successful applications of copper radioisotopes towards metal based imaging or therapy have brought copper-based radiopharmaceuticals in focus of various researchers creating a need for the perfect bifunctional chelators (BFCs). An ideal BFC is capable of forming strong conjugation with disease-specific peptides or antibodies, and simultaneously have the ability to form stable complex with the central metal ion. The study presented here measured how the nature of BFCs affects various properties of ^{64}Cu-bioconjugates, ^{64}Cu-BFC-c(RGDyk), starting from its synthesis to biophysical nature, in vivo integrity, biodistribution pattern, or tumor targeting attitude which thereafter revealed the most appropriate chelator for radio-copper based medical applications. **Materials and methods:** 'Available the best BFCs', NOTA-Bn-NCS, TE2A-Bn-NCS, CB-TE2A, PCB-TE2A and PCB-TE2A-Bn-NCS was first conjugated with c(RGDyk) and consequtively radiolabeled with ^{64}Cu. All biophysical properties like specific activity, partition coefficient, integrin receptor binding affinity were measured under identical experimental condition for preliminary examination. In vivo stability studies were conducted subsequently in SD rat to evaluate the most robust ^{64}Cu-complex. Finally biodistribution and microPET imaging studies of ^{64}Cu-bioconjugates were accrued in U87MG xenograft tumor model to evaluate the most potent chelator. **Results:** Non cross-bridged chelators were radiolabeled at 50 ^{o}C whereas cross-bridged macrocycles required approximately 80 ^{o}C for quantitative radiolabeling. Various biophysical properties can provide insights towards the vivo biodistribution pattern and afford good preliminary indications in most of the cases. Current study highlighted that in vivo pharmacokinetics especially tumor targeting efficacy depends on the structural features of the bioconjugates specially the linker, aqueous solubility and in vivo stability of the bioconjugates. High in vivo stability of cross bridged compounds, ^{64}Cu-PCB-TE2A-Bn-NCS-c(RGDyK), ^{64}Cu-CB-TE2A-c(RGDyK) and ^{64}Cu-PCB-TE2A-c(RGDyK) leads to higher tumor uptake of these macrocycles in compare to non-cross bridged compounds. Clearance rate is highly depended on the water solubility of the compounds. The presence of extra NCS functionality in ^{64}Cu-PCB-TE2A-Bn-NCS-c(RGDyK) may provide additional stability, but simultaneously decreases clearance rate and hence not recommended for in vivo applications. For ^{64}Cu-CB-TE2A-c(RGDyK), although at initial time points tumor uptake was noticed to be higher but activity cleared out fast from tumor decreasing tumor to organ ratio. We found cross-bridged bioconjugates with excellent in vivo stability with no linker arm is more potent in designing ideal BFCs. **Conclusion:** In terms of higher tumor uptake and faster clearance from non-targeted organs, ^{64}Cu-PCB-TE2A-c(RGDyk) evolved to be absolutely potent for future peptide based clinical studies.

EP607

Automation of [^{18}F]AlF radiolabeling using a commercially available platform

L. Allott, C. Da Pieve, D. R. Turton, G. Smith; Institute of Cancer Research, Sutton, UNITED KINGDOM.

Background: The aluminium^{18}F-fluoride ([^{18}F]AlF) method for radiolabelling biologically relevant molecules has generated significant interest owing to the capacity to combine metal-based radiochemistry with the excellent decay characteristics of fluorine-18. Many examples of peptides, proteins and biorthogonal reporters radiolabelled with [^{18}F]AlF methodology can be found in the literature. With translation to clinical application, our study aimed to devise a general method for the automated [^{18}F]AlF radiolabelling of azamacrocycle-containing molecules (e.g. tetrazines, peptides and small proteins). Materials and Methods: The GE Tracerlab FX FN (GE Healthcare platform) was chosen for the study of automated radiochemistry development. The optimisation of the methodology was performed using a NODA containing tetrazine and then applied to a focused group of biomolecules. In a typical production: non-purified ^{18}F[F$^-$] target water was diluted in sodium acetate (50 mM, pH 4); reservoir 3 was loaded with a solution containing the precursor (30 nmol), $AlCl_3$ (26 nmol in 0.5 M sodium acetate, pH 4) and sodium acetate (25 mM, pH 4); reservoir 4 was loaded with an organic co-solvent (1 mL); reservoirs 6 and 9 were loaded with water (5 mL). The buffered ^{18}F[F$^-$] solution was transferred into the reactor followed by the addition of reservoir 3 and 4 contents. The reactor was heated to 105°C for 15 min followed by cooling with compressed air to 50°C (ca 3 min). Water was added to the reactor from reservoir 6 to dilute the reaction mixture which was transferred into a holding vessel attached at V12. The system was pressurised to allow slow loading of the reaction mixture (ca 8 mL) onto a pre-equilibrated HLB cartridge (1 mL, 30 mg). The HLB was subsequently washed with water from reservoir 9 and dried under a flow of nitrogen. The cartridge was removed and the pure product eluted by hand in a minimal volume of ethanol (ca 60 μL). Results: [^{18}F]AlF radiolabelling was performed using a commercial automated platform with a RCY of 25-46% (decay corrected at end of reaction). Total synthesis time was ca 30 min yielding products with radiochemical purities higher than 98%. Conclusions: The automated [^{18}F]AlF radiolabelling of various azamacrocycle-conjugates was efficiently achieved and can be used to facilitate routine back-to-back production for clinical applications.

EP608

Preparation of 68Ga labelled HBEDCCPSMA in a fully automated system using a cassette based module: our initial experience

C. Capelo, Sr.; IPO Porto, Porto, PORTUGAL.

Aim: During the past few years, the application of ^{68}Ga-labeled peptides has attracted considerable interest for cancer imaging due to the physical characteristics of ^{68}Ga (t½=68 min, β^+ = 1899 keV) and the availability of reliable GMP-compliant ^{68}Ge/^{68}Ga generators. Moreover, the half-life of ^{68}Ga matches the pharmacokinetics of the small PSMA inhibiting peptides. PET imaging of the prostate-specific membrane antigen (PSMA) using ([68Ga]Ga-PSMA-HBED-CC) has gained highest clinical impact. The aim of this work is to describe the preparation of ^{68}Ga labelled PSMA-HBED-CC using a fully automated cassette based system and report on our initial experience. All patients had an histopatological confirmation of prostate cancer **Material and Methods**:.In [68Ga]-PSMA-HBED-CC we used a cassette based automated synthesis module (PharmTracer, Eckert&Ziegler); the^{68}Ge/^{68}Ga generator (ITG) with nominal activity

of 1.11-1.85 GBq and elution solvent HCl 0.05M. Preconcentration: SCX cartridge, elution with NaCl/HCl mixture (3 ml) Labelling buffer: sodium acetate/hydrochloric acid buffer pH 4.5+/-0.1 (400 μl) Precursor amount: 10-20 μg Reaction time/Incubation: 5 min at 95°C at pH ~4 Purification by SepPak C-18 light, product elution from C18 cartridge with ethanol/water solution (50%) into product vial and dilution with saline PET/CT imaging: PSMA PET/CT images were obtained imediatly after injection during 10 min (3 min/bed/1 bed) and 60 min after injection 3 min/bed/7beds with a dose of 120-185 MBq. The images were aquired with a S*iemens Biograph 6 PET/CT*. Results: Between October 2015 and April of 2016, we performed 16 synthesis of ([68Ga]Ga-PSMA-HBED-CC) . We had better results achieving higher specific activity using precursor amount> 10 μg, the synthesis time was 14+/-3min.The success rate of the synthesis was very high(two of them failed). We performed PET/CT imaging in 44 patients and we could detect PSMA-positive lesions suspicious of recurrence in 26 of 44 patients with biochemical relapse after radical prostatectomy. Conclusions: Early detection of metastases or recurrent prostate cancer is very relevant in terms of clinical staging, prognosis and therapy management and the use of [68Ga]Ga-PSMA-HBED-CC seems to be very promissory in this setting. The radiosynthesis of this radiopharmaceutical as described it prove to be a fast, reliable and robust method, with high reproducibility, which make it suitable for clinical use in Nuclear Medicine.

EP609

Development and Optimization of A Novel Automated Loop Method for Production of ^{11}C-Nicotine for Pharmacokinetics and PET Imaging Studies

K. Kumar, V. Gaja; Laboratory for Translational Research in Imaging Pharmaceuticals, The Wright Center of Innovation in Biomedical Imaging, Department of Radiology, The Ohio State University, Columbus, OH, UNITED STATES.

Aim. The objective of the present study was to develop and optimize a novel automated loop method for production of ^{11}C-Nicotine for Pharmacokinetics (PK) and Positron Emission Tomography (PET) imaging studies for uptake of nicotine in the human brain. **Materials and Method.** The ^{11}C-Carbon Dioxide, $^{11}CO_2$, was produced by the $^{14}N(p,\alpha)^{11}C$ reaction using a GE PETtrace 880 cyclotron, 16.5 MeV, 25 uA beam for 30 minutes. In the automated synthesis process, the $^{11}CO_2$ was trapped in a stainless steel coil at -180°C, converted into ^{11}C-methane by using H_2/Ni catalyst at 400°C, and finally $^{11}CH_4$ was passed through an I_2 oven at 750°C to produce $^{11}CH_3I$. The Porapack column adsorbed ^{11}C-methyl iodide was transferred into a stainless steel loop loaded with 2 mg (±) nornicotine dissolved in 1:1 DMF:DMSO (100 μL) mixture. The loop was heated at 100°C for 5 min, reaction mixture was cooled to room temperature, and injected into a semi-preparative reversed-phase (RP) HPLC system to remove unreacted $^{11}CH_3I$ and (±) nornicotine. The final product was analyzed by a RP-HPLC method. **Results and Conclusions.** In the present work, gas-phase produced $^{11}CH_3I$ precursor was used instead of ^{11}C-Formaldehyde or $^{11}CH_3I$ produced by the lithium aluminum/HI method. This method did not require using a base which resulted a clean reaction. The reaction conditions were optimized by varying purity and flow of the gases, reaction times and temperature. An efficient reversed-phase semi preparative HPLC method was developed for selectively removing $^{11}CH_3I$ and the starting material, (±) nornicotine. Additionally, a reversed-phase HPLC method with a shorter run time (<10 minutes) was developed and validated for the analysis of the final product, ^{11}C-Nicotine. Overall radiochemical yield of the reaction (from EOB and decay corrected) was 40% with a radiochemical purity (RCP) >99.9%.

EP610

Engineering and Evaluation of A Novel Antibody Fragment As A Potential PET Imaging Agent in Mice

K. Kumar[1], S. Doll[1], K. Woolum[1], S. Kothandaraman[1], H. Ding[1], M. Tweedle[1], M. Williams[1], N. Long[2], B. Sullivan[2], T. Magliery[2], E. Martin, Jr.[3]; [1]The Wright Center of Innovation in Biomedical Imaging, Department of Radiology, The Ohio State University, Columbus, OH, UNITED STATES, [2]Department of Chemistry and Biochemistry, The Ohio State University, Columbus, OH, UNITED STATES, [3]Department of Surgery, The Ohio State University, Columbus, OH, UNITED STATES.

Aim. The full size humanized antibody 3E8 binds tightly to the adenocarcinoma marker TAG-72, a mucinous glycoprotein, but is not suitable for PET and SPECT imaging due to slow blood clearance. The objective of the present study was to engineer, radiolabel with ^{125}I and ^{124}I, and evaluate a novel antibody fragment (3E8.G_4S) with a weighted average M.W. of 68 kD as a potential PET imaging agent. Evaluation parameters involved in this study were: pharmacokinetics, bio distribution, and PET imaging in mice. **Materials and Method.** The novel antibody fragment, 3E8.G_4S, was prepared by shortening the linker between the 3E8 variable domains from a previously constructed scFv. The engineered antibody fragment was characterized by gel permeation and the size-exclusion chromatography. Radiolabeling with ^{125}I (for pharmacokinetics studies) and ^{124}I (for bioD and PET/CT studies) was accomplished using the Iodogen method, the radiolabeled materials were purified by a PD-10 column, and analyzed for radiochemical purity and for stability using paper and size-exclusion chromatographic methods. All pharmacokinetics studies were conducted on normal balbC mice and bio distribution and micro PET/CT imaging studies were conducted on balbC nude mice bearing TAG-72 expressing LS174T human colon carcinoma xenograft tumors. **Results and Conclusions.** Gel Permeation and Size-Exclusion chromatography data showed that the fragment exists as a mixture of diabody and higher oligomers (i.e., mixture of tri- and tetra-body). Enriched diabody and oligomeric fractions were isolated. The fragment mixture, the enriched diabody, and the oligomer were radiolabeled. Stability of the radiolabeled fragment was assessed from 2-8° C storage for 50 days, and the fragment was found to be remarkably stable. Blood clearance kinetics of the ^{125}I labeled the fragment, the enriched diabody, and the oligomer showed fast clearance, almost complete within 24 h. The order of clearance rates of the three molecules was: enriched diabody > fragment mixture > oligomer. Bio distribution studies using ^{125}I labeled enriched diabody and fragment showed significant uptake in the tumor, (2.10±0.66%, at 44 h, n =3, for the enriched diabody) and (6.61±0.89%, at 48 h, n =5 for the fragment). PET imaging studies of the tumor bearing mice (n=3) using ^{124}I labeled fragment were conducted at 22 and 46 h.

EP611

Biodistributions of Copper-61 labelled Silica Nanospheres using NOTA, DOTA & SAR Bifunctional Chelators

A. H. Asad[1,2], L. Morandeau[1], S. V. Smith[1], N. Zia[3], P. S. Donnelly[3], R. I. Price[1,4]; [1]Sir Charles Gairdner Hospital, Perth, AUSTRALIA, [2]Physics & Astronomy, Curtin University, Perth, AUSTRALIA, [3]School of Chemistry and Bio21 Molecular Science and Biotechnology Institute, The University of Melbourne, Melbourne, AUSTRALIA, [4]School of Physics, University of Western Australia, Perth, AUSTRALIA.

Aim: To evaluate the biological pathway of Cu-61 labelled silica nanospheres (Si NS) in healthy nude mice via μPET imaging and biodistribution. The new sarcophagine MeSar-Ph-NCS, NOTA-NCS and DOTA-NCS were conjugated the nanospheres and then radiolabelled with ^{61}Cu. Methods: Cu-61 was produced from the $^{64}Zn(p,\alpha)^{61}Cu$ reaction and converted into $^{61}Cu(OAc)_2$, pH 6.5, followed by radiolabelling

of the conjugated MeSar-Ph-NCS-Si NS for 2 h at 37 °C. The same conditions were used for the other BFCs. The radiolabelled Si NS were then washed repeatedly with 0.1 NaOAc (pH 6.5) to remove any free ^{61}Cu and resuspended in the same buffer for injection in animals. Results: Radio-TLC and gamma counting confirmed the successful radiolabelling of BFC-NCS-Si NS with ^{61}Cu after washing step. *In vitro*; ^{61}Cu-radiolabelled BFC-NCS-Si NS were all found to be stable in saline (> 93% ; 4 h). However, incubation of the ^{61}Cu labelled BFC-NCS-Si NS in FBS at 37°C all showed a significant decrease of radiochemical purity to 84% at 4 h. Then mice were injected with Cu-61 labelled Si NS via retro-orbital and $^{61}CuCl_2$ was used the control. Animals were imaged at 1 and 4 then dissected and the organs counted in a gamma counter. The majority of the radioactivity was found in the liver and spleen; values of (26.6 ± 0.6[SD] %ID/g) (12.3 ± 3.1%ID/g) respectively via μPET ROI analysis. When dissected organs were analysed the activities present were considerably higher. The liver was measured at 38.5 ± 8.1, 48.1 ± 4.5 and 44.5 ± 6.0%ID/g for ^{61}Cu-MeSar-Ph-NCS-Si NS, ^{61}Cu-NOTA-NCS-Si NS and ^{61}Cu-DOTA-NCS-Si NS, respectively. While the spleen was measured at 43.3 ± 9.3, 63.6 ± 4.1 and 70.2 ± 8.8%ID/g for ^{61}Cu-MeSar-Ph-NCS-Si NS, ^{61}Cu-NOTA-NCS-Si NS and ^{61}Cu-DOTA-NCS-Si NS, respectively. Each group of ^{61}Cu-radiolabelled BFC-NCS-Si NS plus controls ($^{61}CuCl_2$) were also evaluated by quantitative μPET imaging at 1h and 4h post-injection. The results were broadly similar between 1h and 4h time-points, particularly in liver and spleen. Conclusion: The novel sarcophagine MeSar-Ph-NCS conjugated to Si NS and labelled with Cu-61 for the first time. The behaviour of this radiotracer was compared with Si NS labelled using NOTA and DOTA. Overall biological profiles were similar. However, the spleen showed substantially higher accumulation of Cu-61 when radiolablling with NOTA and DOTA compared to the new cage compound suggest the new compound is better suited for nanospheres labelling.

EP612

A Novel Cancer Imaging Tracer for Fumarate Respiration

Y. Nakagami[1,2], D. Kano[1], M. Kusumoto[1], Y. Kojima[1]; [1]National Cancer Center, Chiba, JAPAN, [2]Yokohama City Universty, Yokohama, JAPAN.

Aim: In recent years, cancer cells have been making the fumarate respiration does not in the normal cells of the mammalian cells are reported. Visualization of the fumarate respiration should be promising a new PET probe based on unique accumulation mechanism. In this study, we aimed to develop new imaging tracer for the fumarate respiration, 11C-labeled fumaric acid was synthesized. Materials and Methods: Riss et al. elaborated novel carboxylation methods for the synthesis of 11C-labeled carboxylic acids using boronic acid esters. In this approach, boronic acid esters are quite stable to air and moisture and therefore are easily handled and stored. Consequently, it is relevant to full automated PET tracer synthesis. The synthesis of 11C-labeled fumaric acid was performed as follows. The precursor compound was prepared by copper-catalyzed mono-boration of ethyl propiolate. Radiosynthesis was achieved by copper-catalyzed 11C carboxylation of boronic acid ester. No-carrier-added 11CO2 was produced on a cyclotron. Production of 11C-fumaric acid was performed at the automated multi-purpose synthesizer. Cyclotron-produced 11CO2, trapped on a column cooled with liquid N2, was released by purging the column with N2 gas at room temperature and directed into a reaction vessel containing (*E*)-ethyl 3-(4,4,5,5, -tetramethyl-1,3,2-dioxabolane-2-yl) acrylate, CuI, Kryptofix-2.2.2, KF and TMEDA in DMF. The reaction mixture was, heated at 100 degrees centigrade for 5 minutes, and then rapidly cooled to room temperature, and then quenched with formic acid. The clude product was directed with water. Then the diluted solution was loaded onto two Sep-Pak Plus PS-2 cartridges connected in series. The cartridges were washed with water and the yielded ester was eluted with MeCN to second reaction vessel. To the reaction vessel was added aqueous NaOH and heated at 80 degrees centigrade for 2 minutes. After cooled to room temperature, the reaction mixture was neutralized with KH2PO4 buffer. The crude 11C-Fumaric acid was then loaded onto a semi-preparative HPLC column. The HPLC fraction containing 11C-Fumaric acid was collected into product vial. The product obtained as an aqueous solution which can be administered directly. Results and Conclusions: The overall reaction takes about 25 minutes from the end of bombardment. The optimization of the reaction conditions resulted in radiochemical yield (4.2-8.6 percents). No radiochemical impurities were detected by HPLC. Biodistribution in tumor-bearing mice were examined. Furthermore, -in vivo images were obtained using a small animal PET scanner. 11C-Fumaric acid showed high uptake in the tumor tissue.

EP613

Evaluating A Thin Layer Chromatography Method To Separate 18F-choline Of Its Main Metabolite 18F-betaine

M. VILLAR[1], M. TOSCANO[1], M. GALMÉS[2], G. BARCELÓ[3], F. VEGA[1], C. PEÑA[1,4], S. RUBÍ[1,4]; [1]HOSPITAL SON ESPASES, PALMA DE MALLORCA, SPAIN, [2]HOSPITAL QUIRONSALUD PALMAPLANAS, PALMA DE MALLORCA, SPAIN, [3]INSTITUTO DE INVESTIGACIÓN SANITARIA DE PALMA(IDISPA), PALMA DE MALLORCA, SPAIN, [4]INSTITUTO DE INVESTIGACIÓN SANITARIA DE PALMA(IDISPA), Palma de mallorca, SPAIN.

^{18}F-choline is a PET radiotracer used in diagnosis of prostate and brain neoplasms. After its intravenous injection, radiolabelled choline is oxidized by choline oxidase into its main plasma metabolite, ^{18}F-betaine. If PET quantification through kinetic modelling of ^{18}F-choline uptake is intended, the plasma input time-activity-curve of the parent tracer must be obtained, i.e., the fraction of the total plasma radioactivity corresponding to the nonmetabolized ^{18}F-choline at each time point has to be known. Hence our aim was to develop an easy-routine Thin Layer Chromatography (TLC) method to separate and quantify the relative fractions of ^{18}F-choline and ^{18}F-betaine. MATERIALS AND METHODS As a first step, we optimized a TLC-system to separate a cold standard solution of choline and betaine, using iodine vapor staining as visualization method. Based on previous knowlegde about separation of these quaternary ammonium compounds, we tested Silica-Gel-60(SG60) and Aluminum-oxide as layers, and four eluents: (1)MeOH/0.5%NaCl/NH_3, (2)MeOH/Acetone/HCl, (3)MeOH/NH_3 and (4)MeOH/H_2O. We determined the Rf (retention factor) values for choline and betaine, after which SG60-MeOH/NH_3 was selected as the most suitable system because of its resolution. Thereafter, we proceeded to apply this TLC-system to radioactive ^{18}F-choline/^{18}F-betaine samples. We obtained ^{18}F-betaine through the chemical oxidation of an ^{18}F-choline sample with potassium permanganate and, at different incubation time points, aliquots were spotted on TLC plates for its analysis on a radio-TLC-scanner. The same were repeated diluting the oxidized samples in an acetonitrile-deproteinized plasma matrix before their TLC-analysis, in an attempt to simulate the in-vivo blood sampling conditions. RESULTS The Rf-values for choline and betaine cold standards on the selected TLC-system were Rf=0 and Rf=0.77 respectively. Radiochromatograms of ^{18}F-choline/^{18}F-betaine oxidation solution showed two separated and well-defined peaks, one at the origin (Rf=0) and the other one at Rf=0.82-0.89, both of them fairly in agreement with which had been previously observed in the TLC-analysis of cold standards. Radioactivity proportion of the first peak (^{18}F-choline) on radiochromatograms at 5, 20, 40 and 60 minutes oxidation times was 57%, 46%, 32% and 25% respectively, while the second peak (^{18}F-betaine) increased accordingly throughout the incubation period. Comparable results were obtained when the method was applied to ^{18}F-choline/^{18}F-betaine samples previously diluted in plasma matrix. CONCLUSION An easy-routine TLC method to separate ^{18}F-choline from ^{18}F-betaine and to measure their relative fractions is developed. The presented method is

suitable for being implemented in a conventional Radiopharmacy Unit and it may be an useful tool for metabolite correction in ^{18}F-choline-PET quantification.

EP614

Preparation of 18F-Fluoromethylcholine in a fully automated radiochemical synthesizer: a tertiary university hospital experience

E. KARAYEL[1], H. Pehlivanoğlu[1], A. Aygün[1], R. Tutar[2], A. Kurt[1], M. Ocak[3], L. Kabasakal[1], K. Sönmezoğlu[1]; [1]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, İstanbul University, ISTANBUL, TURKEY, [2]Department of Physicochemistry, Engineering Faculty, Istanbul University, ISTANBUL, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University, ISTANBUL, TURKEY.

Purpose: Choline is a quaternary precursor for the biosynthesis of phospholipids, which are essential components for all membranes. Within the cell, choline can be phosphorylated, acetylated or oxidized. The phosphorylation of choline is catalyzed by the enzyme choline kinase. Phosphorylcholine is an intracellular storage pool of choline and is further incorporated into phosphatidylcholine (Lecithin) a major phospholipid of all membranes. Tumor cells with high proliferation rate will have high uptake of choline to keep up with increased demands for the synthesis of phospholipids. Therefore, 18F Fluoromethylcholine was introduced as a potential PET tracer to image various cancers. We present our preliminary results of synthesizing and quality control by using a fully automated radiopharmaceutical synthesis device at Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul since May 2015.**Materials and Methods:** The radiosynthesis was performed by using a fully automated synthesizer (Trasis, all-in-one, Belgium). Automated synthesis of fluorocholine includes two synthetic steps: fluorination and purification. Radiochemical purity is determined by ITLC using Acetonitrile/NaCl (1:1) and PR-HPLC (Shimadzu) using 9mM H2SO4.The residual solution impurities are determined by Gas Chromatography (GC-Shimadzu).**Results:**The radiochemical impurity was higher than 95% by ITLC and RP-HPLC. The residual solution impurities were as follows: N,NDimethylforamide (DMF) <880ppm, Acetonitrile (ACN) < 410 ppm, Dimethylaminoethanol (DMAE) <300 ppm, Ethanol <5000 ppm. Non-decay corrected yield was higher than 22 %.**Conclusion:**The synthetiser and described methods allow us a satisfactory automated preparation of 18F Fluoromethylcholine with desired QC parameters that is a suitable radiopharmaceutical for human use.

EP615

Microwave-assisted ^{68}Ga-labeling of PSMA$^{HBED-CC}$

S. Pfaff[1,2], E. Schaier[1,2], M. Hartenbach[1], M. Mitterhauser[1,3], M. Hacker[1], W. Wadsak[1,2]; [1]Department of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Inorganic Chemistry, University of Vienna, Vienna, AUSTRIA, [3]LBI for Applied Diagnostics, Vienna, AUSTRIA.

Aim: ^{68}Ga labeled radiotracers have gained remarkable interest during the last decade due to the good availability of this PET nuclide. As a result of the development of various new ^{68}Ga labeled radiotracers, several devices for their production have emerged as well. The motivation behind developing new synthesizers is increasing the efficiency in terms of radiochemical yield and reaction time. One technique for enhancing the conversion is microwave irradiation which enables faster and more efficient heating compared to the conventional heaters and moreover, impedes a temperature gradient from the surface of the vessel to the internal reaction mixture. Accordingly, microwave supported ^{68}Ga incorporation into DOTATOC was successfully accomplished by Velikyan et al. (1). Hence, this study deals with microwave assisted complexation of $^{68}Ga^{3+}$ to PSMA$^{HBED-CC}$ and evaluation of the impact on conversion and reaction time. Materials and methods: The syntheses of ^{68}Ga-PSMA$^{HBED-CC}$ (precursor PSMA-11 in GMP grade, ABX, Germany) were performed using a microwave synthesizer (petwave, CEM, USA). For pH adjustment a 1.5 M HEPES buffer solution (Sigma-Aldrich, Missouri) was used. $^{68}Ga^{3+}$ was obtained from a ^{68}Ge/^{68}Ga-generator (100 mCi, Obninsk, Russia; 50 mCi, GalliPharm, EZAG, Germany) using a fractionized protocol. $^{68}Ga^{3+}$ complexation was accomplished evaluating different parameters as power (25 W, 50 W, 75 W, 100 W) and precursor concentration in the reaction mixture (0.84 μM and 1.68 μM). The solution was exposed to microwave irradiation until a pre-selected temperature of 95°C was reached. Results: Preliminary experiments for a precursor concentration of 0.84 μM and power settings of 25 W, 50 W, 75 W and 100 W showed conversions of 68% (n=3), 59% (n=3), 61% (n=2) and 63% (n=2) could be obtained, respectively, within less than one minute. Likewise, the same conditions were tested for a concentration of 1.68 μM, with respective conversions of 86% (n=2), 95% (n=3), 96% (n=3) and 97% (n=3). Conclusion: Microwave heating is feasible for ^{68}Ga-labeling of PSMA$^{HBED-CC}$ and achieves a striking conversion within a few seconds, which could make it an attractive tool for PET Tracer production. Especially the dramatically shortened reaction time gives reason to evaluate this approach further for clinical applications. (1) Velikyan, I. *et al. Bioconjugate Chem.* 15, 554─560 (2004)

EP616

Evaluation of a novel radiolabeled anti-fibroblast activation protein (FAP) antibody fragment as a PET imaging agent

M. Martic[1], D. T. Ho[2], A. Lipman[2], A. M. Wu[3], S. Chandra[4]; [1]Novartis AG, Basel, SWITZERLAND, [2]ImaginAb Inc., Inglewood, CA, UNITED STATES, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA, UNITED STATES, [4]Novartis Institute for Biomedical Research, Cambridge, MA, UNITED STATES.

Objectives: The objective of this work was to evaluate a novel fibroblast activation protein (FAP)-specific antibody fragment as a potential FAP imaging agent in a tumor xenograft-bearing mouse model. **Methods:** A panel of anti-FAP antibody fragments was isolated using phage display technology and screened by ELISA for positive FAP binding and lack of binding to dipeptidyl-peptidase 4 (DPP4). Selected clones were further engineered to support site specific radiolabeling. A single fragment with the most favorable properties was selected for subsequent *in vitro* and *in vivo* work. *In vitro* binding assessment was performed by ELISA on both FAP positive (LOX-IMVI) and non-expressing (Daudi) cell lines. FAP on- and off-rates were determined by Surface Plasmon Resonance (SPR). The antibody fragment was radiolabeled with Zr-89 via a site specifically conjugated bi-functional chelate, or I-124 (non-site specific labeling). PET imaging of isoflurane anesthetized mice carrying a single subcutaneous tumor xenograft (shoulder region) was performed at 0-2 hrs (dynamic scan), 4 (6), 8 and 20 hrs p.i. Following each PET scan, a 10 min CT scan was performed for anatomical reference. Biodistribution was performed at 8 hrs p.i. (Zr-89) and at 20 hrs p.i. (I-124). **Results:** 99% pure engineered antibody fragment was murine/human cross reactive with the binding affinity K_D = 0.8nM. The data show only a minor impact on FAP binding, depending whether site specific (Zr-89) or non-site specific radiolabeling (I-124) was performed. Radiolabeling efficiency with Zr-89 was 98-99% and radiochemical purity of the injected compound was 99.9%. For I-124, radiolabeling efficiency was 83% and radiochemical purity was 97%. The tumor-to-blood ratio at 8 hrs p.i. was approx. 4:1 for Zr-89 and approx. 1:1 for I-124 labeled variants. FAP+:FAP- tumor ratio at 8 hrs p.i . was approx. 2.5:1 for Zr-89 and approx. 5:1 for I-124 labeled variants. Results show predominantly renal excretion and rapid blood clearance with $t_{1/2}$ = 0.2 hrs. Prior to translating this novel imaging tracer to humans, studies in additional FAP-relevant animal models will be conducted.

EP617

Sterility test of [18F]-Fludeoxyglucose automatic infusion systems: Intego® (Medrad) and Posijet® (Lemer Pax)

M. Lefebvre[1], C. Bianchi[1], C. Louet[1], C. Lemarie[2], O. Morel[3], O. Couturier[4], A. Vanniet-Cahouet[1], F. Lacoeuille[4]; [1]CHU Angers Department of pharmacy, Angers, FRANCE, [2]CHU Angers Department of bacteriology, Angers, FRANCE, [3]ICO Paul Papin Angers Department of nuclear medicine, Angers, FRANCE, [4]CHU Angers Department of nuclear medicine, Angers, FRANCE.

Intego and Posijet are PET (positron emission tomography) automated systems used for the fractionation and injection of [18F]-Fludeoxyglucose (FDG). Fractionations are realized from a multidose vial, in a shielded compartment within the automated system and stored until the end of its use. Two sterile kits are needed for the fractionation and injection of FDG to the patient: A mother solution kit (one kit per vial) allowing to get the correct FDG activity and a single patient kit (one kit per patient) with or without 0,22 μm filter, linking the mother solution kit to the patient catheter. The aim of this work was to validate the aseptic conditions during the fractionation and the injection process for both automated systems. The microbiological controls of the samples were performed at two levels. Each day, FDG residual solution was withdrawn (1-4mL) under a laminar flow hood (n=25 samples). Others samples were realized by purging mother solution kits' catheter (n=20). All samples were inoculated into paediatric haemoculture vials. After the radioactive decay, all haemoculture vials were transmitted to bacteriology laboratory, for a ten days incubation. In parallel, the FDG vials utilization datas were collected in order to identify potential causes of contamination (time of utilization, quantity of injected patients, manual dilution of the vial, incident). During the study, an average of 6 patients (minimum 3, maximum 9) were injected per multidose vial. In order to decrease volumic activity (MBq/mL) for the first injected patients a manual dilution of FDG vials prior fractionation and injection by the posijet system was needed in 78% of the case. This dilution step can be a potential contamination source. The average time of utilization of a FDG vial were 214 min (± 60 min) and 198 minutes (± 44 min) for the Posijet and Intego systems respectively. No contamination due to aerobic germ was found on FDG vials originating from Posijet (n=12) or Intego (n=13), neither on mother solution kits used for Posijet (n=10) and Intego (n=10) systems. Our results show the maintaining of sterility of FDG solution in automatic injector environment and in medical devices needed for FDG administration.

EP618

Production of ^{68}Ga-DOTATOC, ^{68}Ga-DOTANOC and ^{68}Ga-PSMA-HBED-CC with an automated multi-purpose synthesis module

S. Migliari[1], A. Sammartano[1], M. Scarlattei[1], G. Baldari[1], C. Cidda[1], G. Serreli[2], O. Ortenzia[2], C. Ghetti[2], L. Ruffini[1]; [1]Nuclear Medicine and Molecular Imaging Department, University Hospital, Parma, ITALY, [2]Medical Physics Unit, University Hospital, Parma, ITALY.

Development of new ^{68}Ga-based agents for in vivo visualization of specific molecular targets, along with important technical advances in isotope production and their labeling method is one of the driving forces of the expansion of clinical PET. Ga-68 has gained attention as one of the ideal research based PET radioisotopes because of on-site production from the ^{68}Ge/^{68}Ga generator and the automated synthesis systems of Ga-68 conjugated probes. These automated systems have advantages over the manual methods which have resulted in their increasing installation in radiopharmacies, but researchers are difficult to adapt them to synthesize their own radiopharmaceuticals. The aim was to investigate the flexibility and efficiency in synthesizing three different ^{68}Ga-radiopharmaceuticals (^{68}Ga-DOTATOC, ^{68}Ga-DOTANOC and ^{68}Ga-PSMA-HBED-CC) using a unique multi-purpose automated synthesis module. We validated the process of synthesis for ^{68}Ga-DOTATOC, ^{68}Ga-DOTANOC and ^{68}Ga-PSMA-HBED-CC, performing it with the automated synthesis module Scintomics GRP® (Good Radiopharmaceutical Practice). Reaction yield was calculated and the quality of the final product was assessed after each synthesis by ITLC-SG and HPLC methods to monitor the performance and efficiency of the synthesis. A TiO_2-based generator was eluted with 0.1M HCl and the $^{68}GaCl_3$ purified using a cationic-exchange cartridge. Peptides were labeled at 95°C for 10min in HEPES buffer solution and the final product was purified with reversed-phase cartridge.RCP and CP were measured by instant thin-layer chromatography, high-performance liquid chromatography (Ultimate 3000 Thermofisher) and gas-chromatography (TRACE 1300 Thermofisher) according to Ph. Eur. We also evaluated pH, sterility/endotoxins and the radionuclidic purity using the HPGe detector (Ortec GEM30P4-76). The mean yield of labelling reaction was 63.78%, 60.43%, 65.53% and RCP was 98.54%, 100%, 99.90% for ^{68}Ga-DOTATOC, ^{68}Ga-DOTANOC and ^{68}Ga-PSMA-HBED-CC respectively. The Ge-68 breakthrough was $7.15*10^{-6}$%, $6.66*10^{-5}$%, $4.8*10^{-5}$%, and the specific activity was 15.93 GBq/μmol, 15.94 GBq/μmol, 15.46 GBq/μmol for ^{68}Ga-DOTATOC, ^{68}Ga-DOTANOC and ^{68}Ga-PSMA respectively. The pH was 7, the ethanol in the final product was less than 10%V/V as the spot of HEPES less intense than the corrisponding reference solution (200μg/V) for all the batches. Bacterial endotoxin testing was accordant for the three radiopharmaceuticals as the LAL-test <0.25 EUm/ml. The results showed a reliable ^{68}Ga-agents output with high labelling purity. Our system provides flexibility and efficiency of the same synthesis method using a unique automated synthesis module for ^{68}Ga-DOTATOC, ^{68}Ga-DOTANOC and ^{68}Ga-PSMA, through the same synthesis process, reagents and solvents, except peptides to label. The system is GMP compliant and well suited for use in a hospital based radiopharmacy.

Preparation and preclinical evaluation of ^{111}In-tiuxetan-Anti MUC1 as a radioimmunocongugate for diagnosis of breast cancer by SPECT

B. Alirezapour[1], L. Mansoori[2], J. Solati[2], E. Maadi[1], N. Soltani[1], S. Abbas Abadi[3], F. Bolorinovin[1], S. Moradkhani[1], A. Satari[1], G. Aslani[1], M. Pouladi[1]; [1]Nuclear Science and Technology Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Biology, Karaj branch, Islamic Azad University, Karaj, Iran, Karaj, IRAN, ISLAMIC REPUBLIC OF, [3]Faculty of pharmacy, University of Debrecen, Debrecen, HUNGARY.

Aim: Radioimmunoscintigraphy (RIS) has attracted considerable clinical application in tumor detection. Underglycosylated MUC1 antigen is one of the early hallmarks of tumor genesis and is overexpressed in more than 80% of breast cancers. PR81 is a new murine anti-MUC1 monoclonal antibody (mAb). In this study, as the first step, we have developed an efficient indirect labeling method of PR81 with ^{111}In ($T_{1/2}$ = 67 h, gamma emitting major photo peak at 171 keV) through using tiuxetan (MX-DTPA) bi-functional chelator and performed preliminary biodistribution studies in mouse bearing breast adenocarcinoma. **Methods:** Anti-MUC1 (PR81) was conjugated with tiuxetan (MX-DTPA) (Macrocyclics), the average number of the chelator conjugated per mAb was calculated and total concentration was determined by spectrophotometrically. Tiuxetan-Anti-MUC1 was labeled with ^{111}In then Radiochemical purity and immunoreactivity, internalization study by MCF7 cell line and serum stability of ^{111}In-tiuxetan-Anti-MUC1 were determined. The biodistribution studies and radioimmunoscintigraphy were performed in female

BALB/c mouse bearing breast carcinoma tumor (^{111}In -tiuxetan-Anti-MUC1 i.v., 100 μl, 25±5 μg mAb , 12, 24, 48 and 72h). **Results:** ^{111}In-tiuxetan-Anti MUC1 was prepared (RCP >97% ± 0.7, Specific activity 4.8 ± 2.1 μCi/μg). Conjugation reaction of chelator (50 molar excess ratio) to antibody resulted in a product with the average number of chelators attached to a mAb (c/a) of 3.7 ± 0.9. Labeling yield with ^{111}In in 400μg concentration of bioconjugate was 96.2% ± 3.2. Immunoreaction of ^{111}In-tiuxetan-Anti MUC1 complex towards MUC1 antigen was determined by RIA and the complex showed high immunoreactivity towards MUC1. *In vitro* and *in vivo* stability of radioimmunoconjugate was investigated respectively in PBS and blood serum by RTLC method. *In vitro* stability was more than 92% ± 1.43 in PBS and 83% ± 2.82 in serum over 24 h. The Immunoreactivity of the radiolabeled Anti-MUC1 towards MCF7 cell line was done by using Lindmo assay protocol. Under these conditions, the immunoreactivity of the radioimmunoconjugate was found to be 0.79. The biodistribution of ^{111}In-tiuxetan- Anti-MUC1 complex in the mice with normal and breast tumor at 12, 24, 48 and 72 h after intravenous administration, expressed as percentage of injected dose per gram of tissue (%ID/g). Biodistribution and imaging studies at 12, 24, 48 and 72 h post-injection revealed the specific localization of complex at the site of tumors. **Conclusion:** ^{111}In -tiuxetan-Anti-MUC1 is a potential compound for molecular imaging of SPECT for diagnosis and follow up of MUC1 expression in oncology.

Formulation of a GMP Quality Kit for the Preparation of ^{111}In-DTPA-NLS-Trastuzumab Injection

V. A. Prozzo, C. Chan, R. M. Reilly; University of Toronto, Toronto, ON, CANADA.

BACKGROUND: ^{111}In-DTPA-NLS-trastuzumab is routed to the nucleus of HER2-positive breast cancer cells where Auger electrons emitted by ^{111}In are damaging to DNA. The gamma emissions of ^{111}In permit SPECT imaging to assess delivery of ^{111}In-DTPA-NLS-trastuzumab to tumours for radioimmunotherapy. Thus, ^{111}In-DTPA-NLS-trastuzumab is a potential theranostic agent for HER2-positive breast cancer. To advance ^{111}In-NLS-trastuzumab to a Phase I/II clinical trial, studies were conducted to develop a kit under GMP conditions to prepare clinical quality ^{111}In-DTPA-NLS-trastuzumab injection. The solubility and tendency of these immunoconjugates (ICs) to aggregate are major challenges in designing these kits. METHODS: Trastuzumab (Herceptin) was buffer-exchanged into 0.1 M $NaHCO_3$, then reacted with a 10-fold molar excess of benzylisothiocyanate DTPA (bzDTPA). The ICs were then buffer-exchanged by ultrafiltration into 0.1 M $NaPO_4$ buffer with or without 0.01% polysorbate-20 (PS-20). Purified DTPA-trastuzumab was modified with maleimide groups for conjugation to nuclear localization sequence (NLS) peptides by reaction with a 5- or 10-fold molar excess of sulfo-SMCC in 0.1 M $NaPO_4$ buffer with or without 0.01% PS-20. Following re-purification, the ICs were reacted with a 50-, 60- or 75-fold molar excess of NLS peptides with a terminal thiol group. The DTPA-NLS-trastuzumab ICs were purified and buffer-exchanged into 0.1 M or 0.05 M NH_4OAc buffer with or without 0.01% PS-20. Final protein concentration was determined by measuring UV absorbance at 280nm, adjusted to 5.0 mg/mL and 1 mL aliquoted into single vials (kits). The kits were labeled with 111-137 MBq of ^{111}In. Desired specifications are 2-7 DTPA and 5-11 NLS per trastuzumab, >90% labeling efficiency, <5% aggregation assessed by SDS-PAGE and K_a and B_{max} values within 0.1-3.6x10^7 L/mol and 0.3-5x10^6 HER2/cell respectively. RESULTS: Eight kits (RG001-8) were manufactured. Production revealed addition of PS-20 to buffers reduced aggregate formation in the kits. Final reaction conditions of 10-fold molar excess of bzDTPA, 5-fold SMCC and 60-fold NLS peptides were finalized. DTPA substitution level ranged from 2-4 bzDTPA/trastuzumab, labeling efficiency was 75+/-16%, 0-11 NLS per trastuzumab, <5% aggregation, and the K_a and B_{max} were within 0.1-3.6x10^7 L/mol and 0.3-5x10^6 receptors/cell respectively. CONCLUSION: Careful selection of reaction conditions was required to obtain a kit for preparation of ^{111}In-DTPA-NLS-trastuzumab injection exhibiting low (<5%) IC aggregation. Kits met specifications for DTPA and NLS substitution and exhibited preserved HER2 binding, but further optimization is required to increase the labeling efficiency to >90% for clinical use. This research was supported by the Canadian Breast Cancer Foundation

Radiolabeling and quality control of ^{111}In-CHX-A-DTPA-trastuzumab for Radioimmunoscintigraphy

B. Alirezapour[1], H. Hadad Dabaghi[2], H. Ansari Ramandi[2], A. Ghamoushi Ramandi[2], M. Hashemizadeh[1], E. Maadi[1], A. Jalilian[1], S. Rajabifar[1], S. Moradkhani[1], H. Masoumi[1], A. Rahiminejad[1]; [1]Radiation Application Research School, Nuclear Science and Technology Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Science, Karaj Branch, Islamic Azad University, P.O. Box 31485-313, Karaj, IRAN, ISLAMIC REPUBLIC OF.

Radiolabeled monoclonal antibodies have shown great promise for cancer diagnosis and therapy. Trastuzumab (trade name; Herceptin) is a humanized IgG1 monoclonal antibody directed against the extracellular domain of the Human Epidermal Growth Factor Receptor2 (HER2). HER 2 receptor is overexpressed in 20-30% of the early-stage breast cancers and these patients may be candidates for Herceptin treatment. we attempted to label trastuzumab with ^{111}In ($T_{1/2}$ = 67 h, gamma emitting major photo peak at 171 keV) through using (CHX-A-DTPA) bi-functional chelator (CHX-A-DTPA) and performed preliminary biodistribution studies in normal mice. **Methods:** Trastuzumab was conjugated with CHX-A-DTPA (Macrocyclics), the average number of the chelator conjugated per mAb was calculated and total concentration was determined by spectrophotometrically. CHX-A-DTPA-trastuzumab was labeled with ^{111}In then Radiochemical purity and immunoreactivity, internalization study by SkBr3 cell line and serum stability of 111In-CHX-A-DTPA-trastuzumab were determined. The biodistribution studies and radioimmunoscintigraphy were performed in normal mice (111In-CHX-A-DTPA-trastuzumab i.v., 100 μl, 25±5 μg mAb , 12, 24, 48 and 72h). **Results:** ^{111}In-CHX-A-DTPA-trastuzumab was prepared (RCP >98% ± 0.6, Specific activity 4.2 ± 1.1 μCi/μg). Conjugation reaction of chelator (50 molar excess ratio) to antibody resulted in a product with the average number of chelators attached to a mAb (c/a) of 4.1 ± 0.8. Labeling yield with ^{111}In in 400μg concentration of bioconjugate was 95.2% ± 2.2. Immunoreaction of ^{111}In-CHX-A-DTPA-trastuzumab complex towards HER2 antigen was determined by RIA and the complex showed high immunoreactivity towards HER2. *In vitro* and *in vivo* stability of radioimmunoconjugate was investigated respectively in PBS and blood serum by RTLC method. *In vitro* stability was more than 91% ± 1.3 in PBS and 81% ± 2.5 in serum over 24 h. The Immunoreactivity of the radiolabeled trastuzumab towards SkBr3 cell line was done by using Lindmo assay protocol. Under these conditions, the immunoreactivity of the radioimmunoconjugate was found to be 0.75. The biodistribution of ^{111}In-CHX-A-DTPA-trastuzumab complex in the normal mice at 12, 24, 48 and 72 h after intravenous administration, expressed as percentage of injected dose per gram of tissue (%ID/g). The accumulation of the radiolabeled antibody in lungs, liver, spleen and other tissues demonstrates a similar pattern to the other radiolabeled anti-HER2 immunoconjugates. **Conclusion:** ^{111}In-CHX-A-DTPA-trastuzumab is a potential compound for molecular imaging of SPECT for diagnosis and follow up of HER2 expression in oncology. **Keywords:** Trastuzumab, Indium-11, Monoclonal Antibody, Bio-distribution, Breast Cancer cancer.

EP622

Comparison Between ^{99m}Tc Radiolabeled siRNA Singlet and Duplex in Serum Stability and Cellular Uptake by HepG2 Cells

L. Kang[1], Y. Huo[1], R. Wang[1], X. Xu[2]; [1]Peking University First Hospital, Beijing, CHINA, [2]Academy of Military Medical Sciences, Beijing, CHINA.

Objective: The antisense single strand and small interference double strands RNA have been applied in some gene therapy studies. However the in vivo stability of these probes is important to their effect. This study was to compare the stability and activity between ^{99m}Tc labeled siRNA singlet and duplex in vitro. **Methods:** Both of sense and antisense RNA of siRNA were synthesized with 2'-OMethyl modification. The 21mer antisense RNAs were conjugated with bifunctional chelator S-Acetyl NHS-MAG3. Some antisense MAG3-RNAs were annealed with sense RNAs and then radiolabeled with ^{99m}Tc, while some antisense MAG3-RNAs were radiolabeled without annealing. The labeling efficiencies under different reaction conditions including reaction time and input of $SnCl_2{\cdot}2H_2O$ were evaluated. The serum stability and HepG2 cellular uptake was investigated at different time points. **Results** The labeling efficiency reached 73.4%±3% (n=5) at room temperature, and the RNA recovery rate was always higher than 98%. Longer reaction time than 1h seemed not improving the efficiency significantly, and much dose of $SnCl_2{\cdot}2H_2O$ could produce too much technetium collide to lead to decrease of labeling efficiency. In the incubation in fresh serum for 6h, the radiochemical purity of labeled duplex was no less than 90%, while that of singlet decreased to 76.4% in room temperature. The gel electrophoresis result showed more degradation of singlet probes than the duplex probes, especially at 6h. The uptake of ^{99m}Tc-duplex by HepG2 cells with and without liposome transfection increased quickly within 6 hours, and reached maximum separately 50.22±2.6% and 32.86±3.1% (n=4). However the uptake of ^{99m}Tc-singlet attained similar ratios compared to the duplex. There existed no significant difference in the cellular uptake between them (P>0.05). **Conclusions:** ^{99m}Tc-siRNA duplex showed higher serum stability than the ^{99m}Tc-singlet RNA, suggesting more suitable for the in vivo usage, while they have a similar cellular affinity.

Autoradiographic and Kinetic Evaluation of ^{99m}Tc-DTPA-can225IgG, a Tracer for the Canine EGF-Receptor

N. Berroterán-Infante[1,2], J. Fazekas[3,4], C. Rami-Mark[1], J. Singer[4], F. Andreae[5], W. Wadsak[1,2], E. Jansen-Jarolim[3,4], M. Mitterhauser[1,6]; [1]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Inorganic Chemistry, Univerity of Vienna, Vienna, AUSTRIA, [3]Department of Comparative Medicine, Messerli Research Institute, University of Veterinary Medicine Vienna, Medical University of Vienna and University of Vienna, Vienna, AUSTRIA, [4]Comparative Immunology and Oncology, Institute of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, AUSTRIA, [5]piChem R&D, Graz, AUSTRIA, [6]LBI for Applied Diagnostics, Vienna, AUSTRIA.

Background & Aim: The Epidermal Growth Factor Receptor (EGFR) has become an interesting target for cancer therapeutics and diagnostics, since its overexpression is associated in the formation and progression of several tumors. Therefore, identification of the expression status of EGFR in a tumor, is critical for patient selection for antibody-targeted therapy. In collaboration with the University of Veterinary Medicine, recently a caninized cetuximab-derived antibody for the EGFR (can225IgG) was synthesized and labeled with ^{99m}Tc [1,2]. In consequence, aim of this work was to evaluate the uptake of the newly developed tracer in canine mammary carcinoma tissue as well the binding kinetics in cell lines expressing the EGFR.Materials and Methods: ^{99m}Tc-DTPA-can225IgG was prepared as previously reported [2]. For autoradiography experiments, canine mammary carcinoma frozen sections were incubated with the freshly prepared radiotracer and subsequently exposed to phosphor imaging. The same sections were stained with cresyl violet after 24 hours and two vicinal sections were stained with hematoxyllin/eosin and for EGFR expression, respectively. Binding kinetics of the radiotracer were also evaluated in real-time using Ligand Tracer® (Ridgeview Instruments) with two cells lines expressing the EGFR (HT29: human colorectal carcinoma and SH1b: canine mammary carcinoma). Briefly, cells were cultivated on the oblique plane of a petri dish and an aliquot of the tracer was added; association of the tracer was evaluated over the time with addition of "cold" antibody at different concentrations. Results: Autoradiography experiments showed uptake of the labeled antibody to EGFR+ tumor sections and the radioactivity uptake was correlated immunohistochemically with the expression of the EGFR. Kinetic binding data showed a high dependency of the observed association rate constant and the radioligand concentration. Nevertheless, addition of "cold" antibody did not show any significant blocking, probably due to the typical low off-rate constant of antibodies. Conclusions: The presented results, together with previous *in vitro* evaluations [2], point towards a suitability of the new tracer, ^{99m}Tc-DTPA-can225IgG, for future *in vivo* evaluations. Alternate radiolabelled meal formulations for assessing gastric emptying by scintigraphy for patients suffering from gastroparesis

A. Bodin-Hullin, P. Garrigue, Q. Sala, S. Gonzalez, A. Gouillet-Patiri, S. Gabriel, O. Mundler, V. Vitton, B. Guillet; APHM, Marseille, FRANCE.

Gastric emptying scintigraphy is the gold standard for the diagnosis of gastroparesis[1]. [^{99m}Tc]technetium radiolabelled scrambled eggs (SE) are most often used as the ingested solid phase. Consequently, patients allergic or reluctant to eggs are not eligible to gastric emptying scintigraphy using this formulation. According to the absence of recommendation and poor literature for this purpose, we aimed at formulating two egg-free and soy-lecithin-based alternate meals: a microwave-baked chocolate mug-cake (MC) and a scrambled tofu (ST). Six healthy volunteers underwent gastric emptying scintigraphy after ingesting MC, ST or SE (control) radiolabelled with 37MBq [^{99m}Tc]technetium sulphur colloids on three consecutive days, and they were asked for their favourite meal formulation. The protocol was approved by our Institutional Review Board and we obtained informed consent from the subjects. Radiochemical purity of [^{99m}Tc]technetium sulphur colloids was ≥90%. Meals were prepared by the same person during the study period. Images were acquired 10min, 30min, 1h, 2h, 3h and 4h after ingestion. All SPECT images (Siemens Signature) were interpreted independently by two experienced, blinded nuclear medicine physicians. The interpretation resulted in the calculation of a gastric retention index for each time point, of emptying half-times and lag phase times for each scintigraphy using the Elashoff curve fit method. A two-way ANOVA test was used to compare gastric retention indexes obtained with the three formulations. Emptying half-times and lag phase times were finally compared between the test and control meals (MC *vs* SE and ST *vs* SE) by Kruskal-Wallis test followed by a Dunn's multiple post-hoc test. The alternate meals were well tolerated by all volunteers, although the MC was largely preferred. Scintigraphic images obtained with both tested formulations were overall similar to the control meal and gastric retention indexes did not change significantly between formulations (% of overtime variation to SE: MC 7.75±7.1%; ST 7.17 ±5.8%; P=0.6618, *ns*). Emptying half-times (SE: 79.0±20min; MC: 81.0 ±29min; ST: 70.5±24min) and lag phase times (SE: 23.5±6.1min; MC:

24.5±8.5min; ST: 16.5±5.3min) were not significantly different between formulations (respectively P=0.6964 and P=0.1564). As a conclusion, these formulations are interesting as solid phases, compared to liquid test formulations that have been recently experimented[2]. In the absence of any commercialized and standardized formulation, we can consider both MC and ST as serious alternatives to classic SE for patients allergic or reluctant to eggs when gastric emptying scintigraphy is indicated. In vivo tracking of ^{111}In-oxine labeled mesenchymal stem cells following infusion in rats with radiation skin lesions

O. E. Klementyeva, **O. E. Klementyeva**, T. A. Astrelina, A. O. Malysheva, K. A. Petrosova, K. E. Ternovskaya; Federal Medical Biological Agency Federal State Budget Institution State Research Center "Burnasyan Federal Medical Biophysical Center", Moscow, RUSSIAN FEDERATION.

Studies on the biology of stem cells and regenerative medicine quickly displaced in the direction of their clinical application. Mesenchymal stem cells (MSCs) provide an opportunity to recovery the functions of organs by replacing damaged cells and tissues and can be a good alternative to other methods of treatment. However, many aspects of the biology of stem cells and their behavior in the body after administration is still beyond our understanding. Scintigraphy using cells labeled with a radionuclide is the most appropriate method for studying of cell tracking and whole-body biodistribution studies. Indium-111 oxine internalizes non-specifically into cells. Thanks to the long half life of Indium-111, SPECT tracking cell for 10 days after a single administration is possible. Given that Indium-111 oxine was approved for clinical application for labeling white blood cells to track sites of inflammation since more than 20 years ago, it was an acceptable extension to label stem cells for noninvasive tracking. **Aim.** Preparation of MSC's labeled by complex of ^{111}In-oxine and investigation of biodistribution in experimental animals. **Materials and methods.** 3.75 MBq of ^{111}In-oxine were added in MSC suspension (10^6 cells). Resulting mixture was incubated for 30 min. During incubation, gently swirl the cell suspension periodically to prevent sedimentation of the cells. After the incubation, the cells were centrifuged. After centrifugation, remove the supernatant containing unbound ^{111}In-oxine and measure the amount of radioactivity in the pellet and in the supernatant to calculate the labeling efficiency. For biodistribution *in vivo* studying ^{111}In-oxine MSC were injected to the tail vein of rats with radiation skin lesions (110 Gy irradiation of skin surface for 380 s). The radiometry of dissected organs was made in 3 and 24 h post injection. **Results.** Labeled efficiency was 82.8±1.2%. After 3 h p.i the accumulation of ^{111}In- oxine labeled MSCs in liver, kidney and lungs was 4.4 ± 0.8%, 1.6% ± 0.1, 6.2 ± 1.4%, respectively. After 24 hours, the accumulation of these organs decreased by half. It should be noted that over time, the accumulation of ^{111}In-oxine MSC in foci of radiation injury increases. The ratio of pathology area/ normal skin was 1.2 - 1.4 after 24 hours p.i. **Conclusions.** From the preliminary results we can conclude that the ^{111}In-oxine can be used as promising agent for MSC tracing in vivo.

Radiolabeling and quality control of ^{67}Ga-DTPA-Cetuximab for Radioimmunoscintigraphy

B. Alirezapour[1], H. Hadad Dabaghi[2], A. Ghamoushi Ramandi[2], H. Ansari Ramandi[2], N. Soltani[1], M. Hashemizadeh[1], F. Bolorinovin[1], G. Aslani[1], P. Ashtari[1]; [1]Radiation Application Research School, Nuclear Science and Technology Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Science, Karaj Branch, Islamic Azad University, P.O. Box 31485-313, Karaj, IRAN, ISLAMIC REPUBLIC OF.

Radiolabeled monoclonal antibodies have shown great promise for cancer diagnosis and therapy. Cetuximab monoclonal antibody is an epidermal growth factor receptor (EGFR) inhibitor used for the treatment of metastatic colorectal cancer, metastatic non-small cell lung cancer and head and neck cancer. we attempted to label cetuximab with radioactive gallium-67 (^{67}Ga) is cyclotron produced, decays by electron capture (EC) with t1/2 = 77.9 h accompanied with γ-rays, mainly 93, 184 and 296 keV, and is suitable for SPECT imaging. In the present study, ^{67}Ga labeled cetuximab through using bi-functional chelator (p-SCN-Bn-DTPA) was prepared followed by the cellular and biodistribution studies. **Methods:** Cetuximab was conjugated with p-SCN-Bn-DTPA (Macrocyclics), the average number of the chelator conjugated per mAb was calculated and total concentration was determined by spectrophotometrically. DTPA-Cetuximab was labeled with ^{67}Ga then Radiochemical purity and immunoreactivity by SW480 cell line and serum stability of ^{67}Ga-DTPA-Cetuximab were determined. The biodistribution studies and radioimmunoscintigraphy were performed in normal mice (^{67}Ga-DTPA-Cetuximab i.v., 100 µl, 25±5 µg mAb , 12, 24, 48 and 72h). **Results:** ^{67}Ga-DTPA-Cetuximab was prepared (RCP >98% ± 0.8, Specific activity 3.9 ± 1.1 µCi/µg). Conjugation reaction of chelator (50 molar excess ratio) to antibody resulted in a product with the average number of chelators attached to a mAb (c/a) of 3.8 ± 1.2. Labeling yield with ^{67}Ga in 400µg concentration of bioconjugate was 96.2% ± 2.7. Immunoreaction of ^{67}Ga-DTPA-Cetuximab complex towards EGFR antigen was determined by RIA and the complex showed high immunoreactivity towards EGFR. *In vitro* and *in vivo* stability of radioimmunoconjugate was investigated respectively in PBS and blood serum by RTLC method. *In vitro* stability was more than 90% ± 1.9 in PBS and 80% ± 1.5 in serum over 24 h. The Immunoreactivity of the radiolabeled cetuximab towards SW480 cell line was done by using Lindmo assay protocol. Under these conditions, the immunoreactivity of the radioimmunoconjugate was found to be 0.79. The biodistribution of ^{67}Ga-DTPA-Cetuximab complex in the normal mice at 12, 24, 48 and 72 h after intravenous administration, expressed as percentage of injected dose per gram of tissue (%ID/g). The accumulation of the radiolabeled antibody in lungs, liver, spleen and other tissues demonstrates a similar pattern to the other radiolabeled anti-EGFR immunoconjugates. **Conclusion:** ^{67}Ga-DTPA-Cetuximab is a potential compound for molecular imaging of SPECT for diagnosis and follow up of EGFR expression in oncology. **Keywords:** Cetuximab, ^{67}Ga, Monoclonal Antibody, Bio-distribution, Colon cancer.

The standard method for testing Radiochemical Purity of ^{99m}Tc-HMPAO is not compatible with its shelf life: validation of a quicker quality control method

T. Scotognella, V. Lanni, V. Nicoloso, D. Fortini, D. Di Giuda, A. Giordano; Institute of Nuclear Medicine, Università Cattolica del S. Cuore and Policlinico A.Gemelli, Rome, ITALY.

Technetium-99m exametazime (^{99m}Tc-HMPAO), prepared with the reconstitution of a cold kit, is widely used in the evaluation of regional cerebral blood flow with SPECT as well as in the investigation of inflammatory diseases by *in-vitro* leukocyte labelling. The Radiochemical Purity (%RP) assessment of ^{99m}Tc-HMPAO performed with the standard method, as specified in the product characteristics (SPC), is time consuming, exceeding the useful radiopharmaceutical shelf-life (30 minutes). Our aim is to propose an alternative quality control method of ^{99m}Tc-HMPAO in order to reduce the time required to test the radiochemical purity. **Materials and methods:** Our tests required the reconstitution of the kit with 5 ml (1,11 GBq) of fresh $^{99m}TcO_4^-$ freshly eluted from a ^{99}Mo/^{99m}Tc generator already used in the previous 24 hours. When necessary, preparations were diluted with sodium chloride solution 0,9% to obtain a 5 ml solution. According to the manufacturer instructions, the standard quality control technique consisted of two chromatographic systems: a TLC-SA

(Agilent) strip 2x20cm developed with methyl-ethyl-ketone (MEK) and a second strip (2x20cm) developed with an 0,9% sodium chloride solution. We compared the standard protocol, requiring approximately 30 minutes, with a quality control method employing the same TLC-SA and mobile phases, but with smaller strips, measuring 0,7x7cm (micro TLC-SA), requiring approximately 10 minutes. Three tests for each method were performed. For both procedures, the strips were analysed by autoradiochromatography (Cyclone Plus®, Perkin Elmer); %RP and stability of 99mTc-HMPAO were calculated for each preparation immediately after the labelling and after 15, 30 and 45 minutes. The Wilcoxon test was employed to compare quality control results of the proposed method with the standard one. **Results** Similar mean values of % RP were obtained using the micro TLC-SA and the standard TLC-SA: t_0= 92,2% ± 2,6, and 93,7% ± 3,4, respectively, p=0,75; t_{15}= 93,4% ± 1,8 and 90,3% ± 1,9, respectively, p=0,25; t_{30}= 91,3 ± 0,7 and 88,7% ± 1,3, respectively, p=0,25; t_{45}= 86,6% ± 5,7 and 87,2% ± 4,2, respectively, p=0,75. No significant differences were found between these two acquisition methods in the measurements performed at t_0, t_{15}, t_{30} and t_{45}. **Conclusions:** We introduced a new method for the assessment of ^{99m}Tc-HMPAO radiochemical purity: a rapid, and accurate analysis technique, yielding optimal RP results before the administration of the radiopharmaceutical. If tested on a larger sample size and once demonstrated its reliability, the micro TLC-SA test could become a reasonable alternative to the registered SPC method.

EP628

Complete validation of the granulocytes radiolabeling method using Leukokit with inroduction of a density gradient medium

C. MAUREL, **R. de LEMPS**, J. MARTI, M. RAZZOUK - CADET, C. GRANGEON; CHUN - Hopital de l'Archet, NICE, FRANCE.

Introduction: Scintigraphy with radiolabeled autologous White Blood Cells (WBCs) is a widely used method to detect infection sites. WBCs can be radiolabeled using a disposable medical device, Leukokit®, under Good Manufacturing Practices conditions. This kit contains all the material to realize the separation of leucocytes from the patient's blood and their labelling before re-injection. In order to increase scintigraphy specificity, we decided to introduce a GMP grade ready-to-use density gradient medium, Ficoll-Paque Premium®, to isolate granulocytes only. The aim of this study was to validate our Leukokit® process completed with Ficoll Plaque Premium® by carrying out routine quality controls, cell viability, cell subset recovery test and aseptic filling tests (sterility). **Material & Method:** Over a period of 3 months, 20 samples of blood intended for radiolabeled autologous WBCs scintigraphy were collected and treated with Leukokit®. Leucocyte-rich plasma was added to Ficoll Plaque Premium® after blood sedimentation. The cell pellet was labelled by ^{99m}Tc-HMPAO (950 MBq) obtained from a fresh eluate of ^{99m}Tc-pertechnetate. The labelling efficiency (LE) was determined by measuring the amount of radioactivity in the supernatant and the pellet of the labelling suspension after centrifugation. A LE between 40% and 80% was expected. Cell viability was performed using Trypan blue exclusion test. The number of granulocytes injected was quantified with a haemocytometer slide. Stained smears (May Grünwald Giemsa) were observed with a microscope under oil immersion at 100-fold magnification. Three consecutive sterility tests were performed according to the method described in the most recent European Pharmacopeia using media fills. **Results:** The mean of labelling efficiency was 70% and the cell viability was 97.7%. An average of $5.4x10^7$ granulocytes was injected. Erythrocyte/WBC ratio was 1.8 and granulocytes/WBC ratio was 0.94. All media fill tests were sterile. **Conclusion:** These results confirm that we can validate the process of Leukokit® completed with Ficoll Plaque Premium®. According to the *Guidelines for the labelling of leucocytes with 99mTc-HMPAO* of de Vries and al (2010), our quality controls were satisfactoring: LE > 50%, sterility test (negative), cell viability (>96%) and cell subset recovery test (in final cell suspension erythrocyte/WBC ratio <3). Measurement of in vitro 99mTc cell efflux within the first hour after labelling (<10%) and in vivo lung uptake will be tested in a further study to complete our results.

EP629

Modification of radioactive labelling leukocytes from small volume of blood

M. Matějů; Charle University, Prague, CZECH REPUBLIC.

Introduction: Scintigraphy with labelled autologous white blood cells is used to detect suspected sites of acute inflammation or infection including also inflammatory bowel disease and fever of unknown origin- the most frequent indications to leukocyte scintigraphy in paediatric age. In adults leukocytes are obtained from 40-60 ml of venous blood. In children, the amount of blood depends on the patient weight. Aim: Description of radioactive labelling leukocytes with ^{99m}Tc-HMPAO from small volume of blood in childhood. Materials and methods: Procedure of radioactive labelling leukocytes includes some phases: collection of blood, isolation of mixed leukocytes, isolation of cell free plasma, labelling of leukocytes with ^{99m}Tc-HMPAO, quality control and reinjection. We used the auxiliary material supplied with the kits for labelling. Our modification of labelling white blood cells takes smaller amounts of blood for paediatric patients and adolescents. We usually took only twice 15 ml of blood (i.e. total of 30 ml) in adolescent patients. We took 16 ml of blood mostly for paediatric patients. We also added a smaller volume of auxiliary solutions for sedimentation of blood: ACD solution and 6 % hydroxyethyl starch solution. We identified the indication, the sedimentation time, sedimentation volume, radiochemical purity, activity of ^{99m}Tc-HMPAO used for the radiolabelling, the final activity injected and the labelling yield for each patient. Results: These results are based on our study group of 33 children weighing up to 35 kg and the group of 21 adolescents (with indications e.g. Crohn's disease, ulcerative colitis, fever, inflammation of unknown origin, etc.), who were administered autologous leukocytes labelled with ^{99m} Tc-HMPAO. The labelling efficiency of the radiopharmaceutical was 94.10 % +/- 3.38 %, the yields of radiolabelled leukocytes were 71.90 % +/- 5.68 % and the average sedimentation's volume is 7.38 ml +/- 2.27 ml for children. The administrated dose ranged between 150 - 350 MBq. The labelling efficiency of the radiopharmaceutical was 94.55 % +/- 3.82 %, the yields of radiolabelled leukocytes were 69.91 % +/- 5.66 % and the average sedimentation's volume is 9.6 ml +/- 3.45 for adolescents. The administrated dose ranged between 350 - 500 MBq. Conclusion: Modification of labelling white blood cells means smaller amounts of blood. Our long experience has shown that this modification provides leukocyte labelling efficiency high above the limit values. The results of our method proved that our modification is functional. Our method is mainly used in paediatric patients and adolescents.

EP630

An Ornithine based Peptide motif: DO3A-Asp-Arg-Asp-Orn for SPECT imaging of $\alpha_v\beta_3$ integrin

S. Rangaswamy[1,2], R. Varshney[1], A. Kaul[1], S. K. Ghumman[2], A. K. Mishra[1]; [1]Institute of nuclear medicine and allied sciences, Delhi, INDIA, [2]Department of Chemistry University of Delhi, Delhi, INDIA.

Aim: The integrin are extracellular matrix (ECM) ligands and cell-surface ligands, constitute superfamily of cell adhesion receptors. They mainly constitute laminin basement formed from fibrilar networks of collagens are associated with active processes such as

wound healing and angiogenesis. Several *in vivo* and *in vitro* studies demonstrates the relationship between regulation of integrin expression and cancer. Integrins have been widely studied and formulated, integrin $\alpha_v\beta_3$ as a tumor progression marker. RGD a well-known marker for these integrin has been modified by replacing glycine *via* aspartic acid group and introduction of unnatural amino acid ornithine at C-terminal of the peptide chain, which will aid in better accumulation at tumor site and less susceptible to peptidic cleavage at the physiological conditions. **Methods:** The peptide sequence was synthesized manually using solid phase peptide synthesis (SSPS) with the help of Fmoc-chemistry on rink amide resin to yield Asp-Arg-Asp-Orn-sequence. The N-terminal of aspartic acid was alkylated with the help of chloroacetylchloride in the presence of DIPEA in solid phase. The chloro- derivative was conjugated to DO3A in presence of K_2CO_3. After the completion of the synthesis, the peptide conjugate was cleaved from resin using TFA cocktail to give the desired ligand. The peptide conjugate (DO3A- Asp-Arg-Asp-Orn) was purified by HPLC to give the pure product at R_t =7.9 min. DO3A- Asp-Arg-Asp-Orn was prepared with more than 75% yield by SSPS and was characterized using mass spectrometry giving $[M]^+$ peak at 904.4. **Results:** The synthesized ligand has been characterized by mass spectroscopic technique and purified by HPLC. Radiolabelling efficiency with ^{99m}Tc was achieved more than 98% and the radio conjugate did not exhibit any dissociation under physiological condition. The molecular modelling studies shows G-Score of -9.8 which is better in comparison with RGD (known for selectivity towards $\alpha_v\beta_3$ integrins). Cell uptake studies on U-87MG cell line suggests high specificity of the ligand towards $\alpha_v\beta_3$ integrins. The *in vivo* biodistribution and blood kinetics studies exhibited rapid clearance of the radiolabelled complex and follows hepatobiliary and renal route of clearance. The substantial accumulation at tumor site with tumor to muscle ratio being 1.92±0.16 in 1 h which increases to 4.01±0.21 in 4 h. **Conclusion:** We have successfully synthesized and characterized the ligand DO3A- Asp-Arg-Asp-Orn, which displays better binding with respect to cRGD a known $\alpha_v\beta_3$ integrin receptor imaging as displayed in molecular docking studies. The ^{99m}Tc- DO3A- Asp-Arg-Asp-Orn holds a promising future mammalian carcinomas expressed by $\alpha_v\beta_3$ integrin.

EP631

Particle size measurement by Dynamic Light Scattering of ^{99m}Tc-radiolabelled rhenium sulphide nanocolloids

R. Ramos-Membrive[1], N. Viedma[2], G. Quincoces[1], I. Peñuelas[1]; [1]Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Universidad de Navarra, Pamplona, SPAIN.

Introduction & Aims ^{99m}Tc-nanocolloids are routinely used in nuclear medicine for Sentinel Lymph Node (SLN) localization and as detection tool in staging of breast cancer. SLN is influenced by several factors; being the particle size the most important. The aim is to evaluate particle size (PS) and the polydispersity (PdI) of ^{99m}Tc-labelled rhenium sulfide nanocolloids during the maximum time stated in the summary of product characteristics (SPC) and the possible effect of changing reconstitution physicals and chemical parameters. **Materials & Methods** Five rhenium sulfide nanocolloids kits (Nanocis®) were used. Two were prepared according to the manufacturers' instructions, incubated in a boiling water bath during 30' and cold up 5' in current water. We added to one of them 5 ml of 0.9% NaCl (NC) and to the other 1100 MBq of freshly eluted ^{99m}Tc sodium pertechnetate in 5 ml (^{99m}Tc-NC) . Two kits were prepared as described but incubated for 30 min at 100°C using a dry heating system, or at RT respectively. A kit was prepared adding 5ml of NaCl 0,9% and incubated at RT. Radiochemical purity (% RCP) of all three ^{99m}Tc- NC was analysed by radio-TLC. PS and PdI were evaluated for all kits by Dynamic Light Scattering (DLS) using a Zetasizer S90 system immediately after incubation and 30, 60, 90, 120 and 240 min later. Each measurement was performed in triplicate. **Results:** Radiochemical purity was >95% for all ^{99m}Tc- NC kits. The PS mean percentage distribution, throughout the period of validity, following manufacturers' instructions was 53.33±0.91 nm for ^{99m}Tc- NC and 57.23 ±1.85 nm for NC. ^{99m}Tc- NC showed 55.58±0.68 nm using the dry heating system. ^{99m}Tc- NC incubated at RT showed higher mean percentage distribution (72.79±0.71 nm) than the other two ^{99m}Tc-NC. NC incubated at RT presented the largest PS (86.81 ±2.85 nm). The kits incubated 100°C presented similar PdI s 0.209 ± 0.003. ^{99m}Tc- NC and NC reconstituted at RT showed PdI 0.180 ± 0.009 and s 0.211 ± 0.017 respectively. **Conclusions:** Particle size of all samples were similar throughout the period of validity and showed homogenous polidispersity in all cases. The summary of product characteristics of rhenium sulfide nanocolloid establishes the mean percentage of particle size distribution as 100nm. The results showed smaller particle size than 100 nm, significant differences between ^{99m}Tc- radiolabelled and unlabelled kits and a clear relationship of the particle size and the incubation temperature.

EP632

Development of radiopharmaceutical based on mini-antibody for early cancer detection

V. Skuridin[1], **E. Stasyuk**[1], O. Bragina[1], M. Usubov[2,1], V. Chernov[3,1], M. Larkina[2], R. Zelchan[3,1], A. Rogov[1], I. Sinilkin[1,3], L. Larionova[1]; [1]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [2]Siberian State Medical University, Tomsk, RUSSIAN FEDERATION, [3]Tomsk Cancer Research Institute, Tomsk, RUSSIAN FEDERATION.

At present early detection and targeted intervention on cancer is the most important problem in modern functional medicine. The usage of specific antibody, beyond question, is one of the most perspective methods to achieve these purposes. The recombinant antibodies to HER2-nea-antigen, which belong to one of the most specific cancer marker, are regarded as the most perspective object for application in medical diagnostics. Aim: Technetium-99m labelling in the structure of the antibody, which is fixed with chelator, and obtaining on its basis new radiopharmaceutical is the most significant aim for cancer diagnostics. Methods: The bifunctional chelator was formed on the basis of 2,5-dioxopyrrolidin-1-yl-6-(di(pyridin-2-ylmethyl)amino)hexanoate to label mini-antibodies. On the one hand, the chelator containing nitrogen atoms, after its reduction up to IV/V valent state, is able to form stable coordinate link with technetium-99m. On the other hand, bifunctional chelator is able to form stable peptide link with antibody. The stannous chloride produced by Sigma-Aldrich (USA) was used as ^{99m}Tc reducing agent eluated from the technetium generator «^{99m}Tc-GT-TOM». The 1% ascorbic acid solution produced by Merck (Germany) was introduced in the reaction feed as stabilizer. The radiochemical impurity determination was carried out by the thin-layer chromatography procedure on the silica gel plates of "Sorbfil" type. The distribution of ^{99m}Tc activity along the length in chromatograms was determined by the radiometer "GammaScan-01A". Result: The novel procedure of bifunctional chelator synthesis and the reaction of synthesized chelator addition to a mini-antibody were developed as the result of the conducted studies. Necessary and sufficient quantity of reducing agent and auxiliary components were determined for the effective ^{99m}Tc labelling into the structure of the obtained compound. The preliminary tests of the functional usefulness of the mini-antibody labelled with ^{99m}Tc were carried out using the positive and the negative Her-2/neo of breast adenocarcinoma cell lines. Conclusion: The conducted in vitro studies showed significant differences in the intensity of drug inclusion in benign and malignant cells, that indicates the functional usefulness of the obtained drug.

EP633

Synthesis and evaluation of [^{123}I]iodoanthraquinones for breast tumor

J. Park[1], B. Kim[1], J. Lee[1], M. Hur[1], K. Yu[2], S. Yang[1]; [1]Korea Atomic Energy Research Institute, Jeongeup, KOREA, REPUBLIC OF, [2]Dongguk University-seoul, Seoul, KOREA, REPUBLIC OF.

Aim : As a specific inhibition of tyrosine inhibitor, anthraquinones are a natural chemotherapeutic compound and have a lot of the various biological activities such as anticancer, antivirus, antiflammatory, antiproliferative effect. In addition, recent studies showed that anthraquinones have been proven to inhibit estrogen receptor α expressing breast cancer cells as an anticancer agent. In this study, [^{123}I]anthraquinones(emodin and aloe emodin) have been synthesized and evaluated for cell uptake using an overexpressing estrogen receptor MCF-7. **Material and Method :** The labeling of [^{123}I]anthraquinones was carried out the each of emodin and aloe emodin (2 mmol) in 200 μL of DMF was mixed with [^{123}I]NaI solution (37 MBq) at pH 12 and Chloramin T of 10 mg. And then mixture was stirring for 10 minutes at room temperature (27°C). [^{123}I]anthraquinones were purified by a RP-HPLC using ammonium acetate. In order to compare the biological evaluation of target agents (emodin and aloe emodin) and reference agents (iodoemodin, iodoaloe emodin), we were determined by morphological change and MTT assay using MCF-7. The growth of breast cancer MCF-7 cells were checked in the presence of various concentrations of target agents and reference agents ranging from 12.5 μM -200 μM for 24 hr. The cellular uptake of [^{123}I]anthraquinones were evaluated using tumor cell lines such as MCF-7, HepG2, CT26 cells. SPECT image was obtained with MCF-7 bearing balb/c mice **Results and Conclusion :** The radiochemical yield of product was approximately >85% and radiochemical purity was >98% by the analytical HPLC system. The results showed significant inhibition of MCF-7 proliferation in a dose and time dependent manner following treatment concentrations of target agents (emodin, aloe emodin) and reference agents (iodoemodin, iodoaloe emodin). While cell death of iodoemodin was smaller than emodin, cell death of iodoaloe emodin was larger than aloe emodin (emodin IC_{50}: 79.92 μM, iodoemodin IC_{50}: 119.33 μM, aloe emodin IC_{50}: 107.46 μM, iodoaloe emodin IC_{50}: 82.86 μM). In addition, the results of [^{123}I]anthraquinones were showed that [^{123}I]iodoaloeemodin (ID%: 4.63% at 15 min) was more significant uptake than [^{123}I]iodoemodin (ID%: 1.16% at 30 min) in MCF-7. Finally, the activity of [^{123}I]anthraquinones was concentrated on MCF-7 bearing left leg of balb/c mice. In this study, we successfully synthesized and evaluated [^{123}I]anthraquinones as inhibitors of estrogen receptor. This results suggests [^{123}I]anthraquinones is expected potent breast cancer imaging reagent.

EP634

Study of a Gglucose Derivative Labeled with Technetium-99m as Potential Radiopharmaceutical for Cancer Diagnosis

R. Zelchan[1,2], **V. Chernov**[1,2], A. Medvedeva[1,2], I. Sinilkin[1,2], E. Stasyuk[2], A. Rogov[2], E. Il'ina[2], V. Skuridin[2], O. Bragina[2]; [1]Tomsk Cancer Research Institute, Tomsk, RUSSIAN FEDERATION, [2]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Purpose: to study possibility of using 1-thio-D-glucose labeled with 99mTc for cancer imaging in the experiment. Materials and method: study was performed in cell culture of normal CHO (Chinese hamster ovary cells CHO) and malignant tissues MCF-7 (human breast adenocarcinoma MCF-7). In the tubes with the cells in an amount of 3 million was added 25MBq 1-thio-D-glucose labeled with 99mTc and incubated for 30 minutes at room temperature. Thereafter, a centrifugation of the tube with the cells the supernatant was removed. Then radioactivity in tubes with normal and tumor cells was measured. In addition, the study included 10 mice of C57B1/6j lines with tumor lesion of the right femur. For neoplastic lesions model in mice was used carcinoma Lewis. Following anesthesia, mice were injected intravenously with the 25MBq 1-thio-D-glucose labeled with 99mTc. After 15 minutes planar scintigraphy was performed in a matrix of 512x512 pixels for 5 minutes. Results: in measuring the radioactivity of normal and malignant cells after incubation with the 1-thio-D-glucose labeled with 99mTc it was found that the radioactivity of malignant cells is higher. The mean values of radioactivity levels in normal cells were 0.3 ±0.15MBq. The mean values of the level of radioactivity in the malignant cells were 1.07±0.6MBq. All examined animals were revealed increased accumulation of the 1-thio-D-glucose labeled with 99mTc at the tumor site. The accumulation of the 1-thio-D-glucose labeled with 99mTc in the tumor was on average twice as high as compared to the symmetric region. Conclusion: The present study demonstrated that 1-thio-D-glucose labeled with 99mTc is a prospective radiopharmaceutical for the cancer visualization. In addition, high accumulation of the 1-thio-D-glucose labeled with 99mTc in the culture of cancer cells and in animals tumor tissue demonstrates malignant tumor tropism of the radiopharmaceutical.

EP635

Experimental Studies of the ^{99m}Tc-PDA-DTPA Complex for Myocardium Imaging

S. Sazonova[1], E. Nesterov[2], V. Skuridin[2], S. Minin[3], E. Stasyuk[2], E. Ilina[2], Y. Lishmanov[1], J. Ilushenkova[1], S. Tsibulnikov[1]; [1]Research Institute for Cardiology, Tomsk, RUSSIAN FEDERATION, [2]Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [3]State Research Institute of Circulation Pathology, Novosibirsk, RUSSIAN FEDERATION.

Diagnosis of viable myocardium is an important task of cardiology influencing the treatment strategy of coronary artery desease. The ^{123}I-labeled fatty acids are the agents used clinically for myocardial metabolism imaging. High cost and limited availability of cyclotron-produced ^{123}I, makes ^{99m}Tc-labeled fatty acids more desirable for the purpose. *Purpose:* To perform experimental studies of new ^{99m}Tc-fatty chemical systems based on modified diethylene triamine pentaacetic acid (DTPA). *Methods.* We used DTPA as a chelate agent for radioactive technetium-99m labeling of pentadecanoic acid by previously described method (E.A.Nesterov et al // Eur J Nucl Med Mol Imaging 2015. V. 42 (Suppl 1) S1-924). The model for the assessment of functional suitability of the radiopharmaceutical included 5 rats with 45 minutes acute coronary occlusion, followed by 120 minutes of myocardium reperfusion. At 60 minute before the end of the reperfusion 70MBq of ^{99m}Tc-PDK-DTPA was injected to each rat into femoral vein. Zones of myocardial necrosis and hibernation were assessed by morphological staining techniques, following by radiometry of myocardial samples with varying degrees of damage. The radiometry of spleen, lung, liver and kidney was also performed. *Results.* The radiochemical purity of synthesized ^{99m}Tc-PDK-DTPA was 97 ±0,5%. The radiometry of internal organs showed maximum uptake in kidneys (16,8±0,2 %/g of injected dose). The uptake of ^{99m}Tc-PDK-DTPA in spleen, lung and liver was low (0,2±0,03%/g, 1,2 ±0,05%/g, 1,6±0,05%/g of injected dose respectively), in heart (healthy myocardium) - 2,1±0,07%/g. Heart/lung = 1.77; heart/liver = 0.52; heart/kidney = 0.12. The uptake of ^{99m}Tc-PDK-DTPA in necrotizing (0,2±0,02%/g) and hibernating (0,22±0,03%/g) myocardium did not differ significantly. The ratio hibernation/necrosis was 1,15. *Conclusion.* Eventually one can say that modified DTPA-molecules are functionally suitable for myocardial imaging, but it does not allow to differentiate necrotizing and hibernating myocardium. This work was supported by the Russian Federation represented by the Ministry of Education and Science of Russia (project № RFMEFI60414X0071).

Targeting the human A3R in a mouse xenograft model using [18F]FE@SUPPY

T. Balber[1,2], J. Singer[1,3,4], M. Dumanic[1], J. Fazekas[3,4], N. Berroterán-Infante[1,5], C. Vraka[1], E. Jensen-Jarolim[3,4], W. Wadsak[1], M. Hacker[6], H. Viernstein[2], M. Mitterhauser[1,7]; [1]Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Pharmaceutical Technology and Biopharmaceutics, Faculty of Life Sciences, University of Vienna, Vienna, AUSTRIA, [3]Department of Immunology and Oncology, Institute of Pathophysiology and Allergy Research, Center of Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, AUSTRIA, [4]Department of Comparative Medicine, Messerli Research Institute of the University of Veterinary Medicine Vienna, Medical University Vienna and University Vienna, Vienna, AUSTRIA, [5]Institute of Inorganic Chemistry, University of Vienna, Vienna, AUSTRIA, [6]Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [7]Ludwig Boltzmann Institute for Applied Diagnostics, Vienna, AUSTRIA.

Aim: The human adenosine-3-receptor (hA3R) is highly expressed in human colon cancer tissue as well as in colon cancer cell lines, suggesting this receptor as a tumor marker. The aim of the present study is the investigation of pharmacokinetics of [^{18}F]FE@SUPPY, a hA3R antagonist, in mice and the design of a xenograft model to investigate the potential of [^{18}F]FE@SUPPY to serve as a PET-tracer for oncology. **Methods:** *In vivo* blood stability was analyzed using radioHPLC. Therefore, 18MBq±2 [^{18}F]FE@SUPPY were injected r.o. into healthy Balb-c mice and animals were sacrificed at different time points (10, 20, 40, 70 min). *Ex vivo* biodistribution was assessed after 70 minutes. To select appropriate human tumor cell lines, we analyzed their hA3R expression with Western Blot and flow cytometry. For the xenograft model, 2x10^6 cells were injected s.c. into immunocompromised mice (SCID/beige). After 12 days, a tumor was formed and animals were injected with 13.8MBq±4 of [^{18}F]FE@SUPPY r.o.. *Ex vivo* autoradiography was performed with removed tumor tissue after 70 minutes. **Results:** Analysis of blood stability revealed 32.3% intact tracer after 5min and 11.4%, 5.6%, 2.4%, 2.3% after 10, 20, 40 and 70min, respectively (n=2). Highest %ID/g was found in organs of metabolism (2.7%ID/g ± 0.2 in kidney, 14.6%ID/g ± 0.2 in liver and 162.8%ID/g ± 37.5 in gall bladder, each n=3). The HT29 cell line (human colorectal adenocarcinoma) was identified to express high amounts of the hA3R protein (ΔMFI 53.6±22) and was therefore used for the xenograft model. *Ex vivo* autoradiography showed 1.96 fold higher uptake in tumor mass derived from HT29 cells compared to a hA3R-negative tumor (CHO-K1) (n=2). **Conclusion:** *In vivo* stability data in blood indicates metabolism in mice. The assessment of metabolism in organs of interest is in progress. Previous *in vitro* stability tests using human plasma and human liver microsomes suggested sufficient stability of [^{18}F]FE@SUPPY for the time interval of a PET scan in humans. Uptake of [^{18}F]FE@SUPPY in hA3R positive tumor, derived from HT29 cells, was not as prominent as expected. PET imaging and blocking experiments are in progress. Recently performed *in vitro* autoradiography revealed a 2.6 fold increased uptake of [^{18}F]FE@SUPPY in human colorectal carcinoma tissue slices compared to healthy mucosa derived from the same patient, encouraging the potential of [^{18}F]FE@SUPPY to serve as a PET-tracer for oncology.

EP637

Radiolabelling, SPECT/CT imaging and ex vivo studies of a nasal nano-vaccine for shigellosis based on S. flexneri Outer Membrane Vesicles

R. Ramos Membrive[1], A. Camacho[2], G. Quinoces[1], Y. Pastor[2], J. Irache[2], C. Gamazo[2], I. Peñuelas[1]; [1]Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Universidad de Navarra, Pamplona, SPAIN.

Introduction & Aims Shigellosis is one of the leading causes of diarrhea worldwide. The use of an acellular vaccine against shigellosis based on outer membrane vesicles (OMVs) obtained from supernatants of BEI-inactivated *Shigella flexneri* cultures showed full protection of mice against an experimental SF infection. OMVs can reach and activate lymph nodes in gastrointestinal tract by nasal administration. The aim is optimization of ^{125}I and ^{99m}Tc radiolabelling of OMVs and biodistribution studies by molecular imaging and *ex vivo* counting in BALB/c after nasal administration. **Materials & Methods** Two mg of OMVs were incubated with [^{125}I]NaI and iodo beads ™. ^{125}I-OMV were purified using tangential filtration concentration unit (TFCU), tangential centrifugation or dialysis. Radiochemical purity (%RCP) was analyzed by radio-TLC. For biodistribution studies, 0.0074MBq of ^{125}I-OMV (n=6) and 0.16MBq of ^{125}I$^-$ (controls,n=2) were used per animal by nasal administration. For *ex-vivo* counting, 4mice (3 ^{125}I-OMV+1 ^{125}I$^-$) were perfused at 24h and 4 (3 ^{125}I-OMV+ 1 ^{125}I$^-$) at 48h, organs were extracted and activity was measured in a gamma counter. For ^{99m}Tc-radiolabelling, 10mg of OMVs were pre-tinned with $SnCl_2{\cdot}2H_2O$ and labeled for 30 minutes with freshly eluted $^{99m}TcO_4^-$. Different $SnCl_2{\cdot}2H_2O$ concentrations ranging from 0.005 to 1.0 mg/mL were used for radiolabelling optimization. %RCP was analyzed by radio-TLC. For biodistribution studies, 1.4MBq of ^{99m}Tc-OMVs (n=6) and 1.26MBq $^{99m}TcO_4^-$(controls,n=2) were used per animal. SPECT/CT studies were performed 1h and 24h post-administration. For *ex-vivo* counting, mice were sacrificed, perfused, organs excised and gamma-counted at 24h. **Results:** Tangential centrifugation and dialysis %RCP were not enough to be administered (<50%). Using TFCU purification %RCP was > 80% but most of ^{125}I-OMVs got blocked at the TFCU´s membrane and low activity of ^{125}I-OMVs purified could be administered. After dissection+ counting nasal uptake was 0.2 and 0.05 % of injected dose (%ID) at 24h and 48h, while thyroid uptake was 0.70 and 1.30 of %ID respectively. RCP was >95% for ^{99m}Tc-OMVs using [$SnCl_2$]=0.5 mg/mL. SPECT/CT images showed nasal focal uptake and incorporation to intestine 1h post-administration; $^{99m}TcO_4^-$ presented abdominal focal activity. At 24h $^{99m}TcO_4^-$ had no biodistribution changes and ^{99m}Tc-OMVs nasal focal uptake remained, confirmed by dissection/counting ratios (0.45 %ID). **Conclusions:** The antigen complex could be hardly radiolabelled with ^{125}I with low radiochemical yield, while ^{99m}Tc-OMVs presented RCP >95% with no need of purification. The increase of thyroid uptake indicate ^{125}I-OMVs radiolabelling is not stable *in vivo.* Activity found in nose and intestine suggested OMVs were able to reach gastrointestinal lymph nodes.

EP638

Radiolabeling and Biodistribution study of GLP-1 with I-125

M. Hernandez Fructuoso[1], C. Beltrán Gracia[2], B. Santos Montero[1], C. Hernández Pascual[3], R. Simó Canonge[3], S. Aguadé Bruix[4], J. Castell Conesa[4], J. Herance Camacho[5]; [1]Radiopharmacy Unit, Hospital Universitari Vall d'Hebron - Institut de Diagnòstic per la Imatge, Barcelona, SPAIN, [2]Radiopharmacy Unit, Hospital Universitari Vall d'Hebron, Barcelona, SPAIN, [3]Endocrinology Department, Hospital Universitari Vall d'Hebron, Barcelona, SPAIN, [4]Nuclear Medicine Department, Hospital Universitari Vall d'Hebron, Barcelona, SPAIN, [5]Hospital Universitari Vall d'Hebron, Institut de Recerca, ISCIII, Barcelona, SPAIN.

Aim: Retinal neurodegeneration is an early event in the pathogenesis of diabetic retinopathy (DR). Glucagon-like peptide-1 (GLP-1) receptor agonists have been proposed for the treatment of DR. The aim of this study is to label GLP-1 with I-125 and to determinate its biodistribution (BD) upon topical administration to the New Zealand white rabbits eyes. **Materials and Methods:** Standard chloramine T method was used to iodinate GLP-1. We checked different amounts of GLP-1 (100,200,300 and 400μg) at different times of reaction (1,2,5 and 7 minutes) at room temperature. Purification method was performed using size exclusion column (PD-10) and the elution profile was validated using GLP-1, ^{125}I-GLP-1 and ^{125}INa.

All the eluates were counted in a gamma-counter. (Cobra II, Packard). SA and RCP were determinated using a HPLC (Agilent 1100 series). In vitro stability of GLP-1 radiolabelled in eye drop formulation was evaluated using PD-10 and HPLC. One 40-μL drop of ^{125}I-GLP-1 was administered to 24 rabbits at right eye. BD studies were made using the cut&count technique by collecting tissues for ex vivo analysis and measured them in a gamma-counter during 5 minutes. Blood, right kidney, liver, stomach, urine, thyroid gland, testicles, crystalline lens right and left, retina right and left, sclera right and left, vitreous right and left, cornea right and left, iris right and left and Conjunctivae right and left were analysed. **Results:** ^{125}I-GLP-1 was proper labelled at 5 minutes using 300 μg with 95% chemical yield. Isolation of ^{125}I-GLP-1 by PD-10 was efficient and RCP was > 95%.The SA was around 15GBq/ μmol. BD studies demonstrated that ^{125}I-GLP-1 was distributed in different organs and tissues but principally in intraocular compartments (retina and crystalline lends).The BD results have been corrected by blank value, gamma radiation counter efficacy and normalized with non-treated group. **Conclusion:** The labelling of GLP-1 has been achieved with ^{125}I using a clhoramine T method with high chemical yield and radiochemical purity. On topical administration, ^{125}I-GLP-1 is absorbed and distributed to all eye compartments, principally in retina. Based on this biodistribution, topical drops administration GLP-1 appears to be highly attractive for treatment of diabetic retinopathy.

EP639

^{68}Ga-labeled, zirconia-based nanocarrier systems for PET-nanomedicine and theranostic purposes

A. Polyak[1], L. Naszalyi Nagy[2,3], J. Mihaly[3], S. Görres[1], I. Leiter[1,4], A. Wittneben[1], J. P. Bankstahl[1], M. Zrinyi[2], T. L. Ross[1]; [1]Hannover Medical School, Hannover, GERMANY, [2]Semmelweis University, Budapest, HUNGARY, [3]Hungarian Academy of Sciences, Budapest, HUNGARY, [4]University of Veterinary Medicine, Hannover, GERMANY.

Introduction. Biocompatible ceramic material zirconia is used for several biomedical applications, such as dental and chirurgical implants, but under certain circumstances this inorganic material can be formed to biodegradable pharmaceutical constituents, as well. Our research teams have developed a zirconia based drug delivery nanoparticle system which has been successfully tested as a SPECT-tracer base and beta-emitter radionuclide colloidal carrier candidate. In our latest studies we successfully developed a DOTA bifunctional chelator conjugated nanoparticle (NP) variant which proved to be suitable for further PET imaging and PET image guided therapeutic investigations. Methods. Solid zirconia nano-sized particles of 95 nm (±19 nm; solid content = 2.45 mg/ml) have been synthesized in ethanol. Synthesis was based on a method previously described by Widoniak et al. (*Eur.J.Inorg.Chem.* 2005. 3149-55). DOTA bifunctional chelator was adsorbed on the surface of zirconia NPs in ethanol and the product was dialyzed into 1M ammonium acetate buffer pH4.1. For particle characterization, TEM and SEM (transmission and scanning electronmicroscope) and DLS (dynamic light scattering) methods were used. For ^{68}Ga-radiolabeling, DOTA-conjugated NPs were incubated for 20 mins at 95 °C in HEPES buffer (pH:4). Radiolabeling efficiency was checked by thin layer chromatography (TLC). For biodistribution studies, *Mus Musculus* C57BL/6N mice were injected with 18 MBq activity of the ^{68}Ga-labeled nanosystem. Animals were scanned Siemens Inveon μPET/CT. Results. The ^{68}Ga-labeled NPs showed proper radiolabeling stability in their original suspension and in blood serum. Imaging studies of the new ^{68}Ga-nanosystem confirmed a RES-biodistribution profile characterized by nano-sized colloids. Most of the activity has been accumulated in the liver, while activities of kidneys and bladder have been increased slowly postinjection (p.i.). Low lung uptake could be observed during the tracing period, indicating the lack of *in vivo* aggregated colloid fraction. Conclusions. After a successful DOTA-chelated ^{68}Ga-labeling procedure of zirconia NPs, our first *in vivo* experiments with μPET/CT confirmed that the new ^{68}Ga-DOTA-NP complex had durable radiochemical and colloidal stability p.i., therefore our new method offers the opportunity to examine further specifically targeted and drug payload carrier variants of these zirconia NP systems using PET/CT imaging.

EP640

Targeted liposomal drug delivery system for radionucleosides - a theranostic approach

A. T. J. Vogg[1], R. Dóczi[2], K. Szigeti[3], I. Horváth[3], D. Máthé[4], M. Roller[1], A. Morgenroth[1], N. Bornwasser[1], U. Königs[5], F. M. Mottaghy[1], Z. Varga[6]; [1]University Hospital of the RWTH Aachen, Clinic for Nuclear Medicine, Aachen, GERMANY, [2]Institute of Nuclear Techniques, Budapest University of Technology and Economics, Budapest, HUNGARY, [3]Department of Biophysics and Radiation Biology, Semmelweis University, Budapest, HUNGARY, [4]CROmed Translational Research Centers, Budapest, HUNGARY, [5]FH Aachen, University of Applied Sciences, Campus Jülich, Jülich, GERMANY, [6]Biological Nanochemistry Research Group, Institute of Materials and Environmental Chemistry, Research Centre for Natural Sciences, Budapest, HUNGARY.

Derivatized nucleosides have been used in basic cancer treatment since many years. This approach has highest therapeutical outcome if tumor cells exhibit a high proliferation associated with enhanced DNA related turnover. These therapies make higher serum levels mandatory which are paired with side effects especially in tissues with naturally elevated proliferation. In contrast, Auger electron emitter bearing nucleosides promise to reduce side effects since significantly lower concentrations of these radionucleosides already lead to an efficient therapeutic effect. The radionucleoside and thymidine analog [I-125]5-iodo-2'-deoxyuridine (IdUrd) has been reported already decades ago to efficiently drive proliferative cells into apoptosis. However, only a small fraction of that intravenously administered radionucleoside reaches the target cells due to both its extended metabolism and its rapid renal excretion. In order to reduce these two disadvantages, a targeted multimodal liposomal drug delivery platform has been developed for a theranostic approach. Self-assembled supramolecular structures like liposomes are suitable carriers for radionucleosides. They can be loaded with lipid-conjugated nucleosides simply by incorporation into the lipid bilayer. By this conjugation especially fast renal excretion is expected to be significantly reduced. In the present work we have used the lipid conjugate of [I-125]5-iodo-2'-deoxyuridine (IdUrd). Esterification was performed with both, hexanoic and oleic anhydride, and the conjugate was purified by reverse phase HPLC. Incorporation extent of the lipid-conjugated [I-125]IdUrd into the liposomes was monitored by size exclusion chromatography. Labeling of the liposomes with Ga-68/-67 for PET imaging was enabled by using a DTPA-conjugated phospholipid, while fluorescent labeling was achieved with a nitrobenzoxadiazole (NBD) fluorophore conjugated phospholipid with both building blocks being part of the liposomal construct. A specific targeting of the liposomal nanocarrier to cancer cells was enabled by covalent attachment of a prostate-specific membrane antigen (PSMA) ligand, basically comprising the peptide sequence Glu-urea-Lys. PSMA is highly overexpressed in prostate cancer, and therefore represents an excellent target for both, diagnostic and therapeutic treatments. The PSMA-ligand containing a primary amine-group was attached to the liposomes after having incorporated a N-hydroxy-succinimide activated polyethylene glycol - lipid conjugate (DSPE-PEG2000-NHS). In vitro binding with PSMA-targeted and fluorescently labelled liposomes in MDA-MB231 (PSMA positive) and PC-3 (PSMA negative) cell lines was evaluated by flow cytometric analysis, which verified a specific binding of the PSMA-targeted liposomes to the PSMA positive cells. This work was jointly supported by BMBF (Germany, grant 01DS14024) and NKFI (Hungary, grant TET_12_DE-I-2013-0013).

EP641

Labelling preparation of Rare-Sugar D-allose with ^{18}F for assessment of behavior in vivo

H. Yamamoto[1], N. Kudomi[1], K. Wada[2], Y. Yamamoto[3], Y. Nishiyama[3];

[1]Department of Medical Physics, Faculty of Medicine, Kagawa University, Kagawa, JAPAN, [2]Department of Chemistry for Medicine, Faculty of Medicine, Kagawa University, Kagawa, JAPAN, [3]Department of Radiology, Faculty of Medicine, Kagawa University, Kagawa, JAPAN.

Aim: Applicability of rare sugars, such as D-allose, for diagnostic and therapy purpose is focused on recently. It would be important to make reveal their behaviors *in vivo*. Fluorinated D-allose derivatives, namely [^{18}F]3-deoxy-3-fluoro-D-allose ([^{18}F]3FDAllo) and [^{18}F]6-deoxy-6-fluoro-D-allose ([^{18}F]6FDAllo), are epimers of corresponding D-glucose derivatives with respect to carbon atom 3, [^{18}F]3-deoxy-3-fluoro-D-glucose ([^{18}F]3FDG) and [^{18}F]6-deoxy-6-fluoro-D-glucose ([^{18}F]6FDG), respectively. Preparation of [^{18}F]3FDAllo and [^{18}F]6FDAllo is of great significance because of their potential utility as probe molecules to investigate metabolic dispositions of a rare sugar, D-allose. **Materials and Methods:** A precursor of [^{18}F]3FDAllo, 1,2,4,6-tetra-*O*-benzoyl-3-*O*-triflyl-β-D-glucopyranose, was prepared by 5-step reactions from 1,2:5,6-di-*O*-isopropylidene-α-D-glucofuranose, for the first time. On the other hand, a precursor of [^{18}F]6FDAllo, 1,2,3,4-tetra-*O*-benzoyl-6-*O*-triflyl-β-D-allopyranose, was prepared via a new route consisting of 4-step reactions from D-allose. Preparation procedure of [^{18}F]3FDAllo and [^{18}F]6FDAllo are as follows: 50-60 MBq of [^{18}F]fluoride was adsorbed on QMA and then extracted by K_2CO_3 (17 μmol)/K2.2.2 (53 μmol)/H_2O (0.2 mL)/CH_3CN (0.7 mL) mixture. After evaporation, another 1 mL of CH_3CN was added, and then it was evaporated again. 3 mL CH_3CN solution of a precursor (42 μmol) was added to it. The mixture was heated at 85 °C for 5 min, and concentrated. Deprotection reaction was carried in 0.3 M aq. NaOH/THF=1:1 at rt for 30 min. Then the reaction mixture was neutralized by 1 M aq. HCl and concentrated. [^{18}F]3FDAllo and [^{18}F]6FDAllo were purified by semi-preparative HPLC (column: Nakarai Sugar-D: ID10 x 20+250 mm, eluent: CH_3CN/H_2O=75:25, flow rate: 2 mL/min). The products were confirmed by HPLC and TLC. **Results:** [^{18}F]1,2,4,6-tetra-*O*-benzoyl-3-deoxy-3-fluoro-β-D-allopyranose and [^{18}F]1,2,3,4-tetra-*O*-benzoyl-6-deoxy-6-fluoro-β-D-allopyranose were obtained 85% and 70% radiochemical conversions (RCCs), respectively. [^{18}F]3FDAllo and [^{18}F]6FDAllo were obtained by 33% and 13% RCCs, respectively. RCCs were determined by radio-TLC. **Conclusion:** Basic synthetic procedures for [^{18}F]3FDAllo and [^{18}F]6FDAllo have been established and those would be applied to make reveal their behavior *in vivo*, though still some improvements of deprotection reaction process might be required.

EP642

Concentration of rhenium-188 for radiopharmaceutical synthesis

N. A. Konstantinov, A. Chagovets, A. Malysheva, G. Kodina; Burnasyan Federal Medical Biophysical Center FMBA Russia, Moscow, RUSSIAN FEDERATION.

In recent years more attention is attracted to rhenium-188 which can be obtained from generator directly in radiological departments. ^{188}Re is β-emitter, $E_{\beta max}$ = 2,1 MeV, Eγ = 155 keV, $T_{1/2}$ = 17 h, maximum run of β-particles in tissues - 11 mm. Such properties allow using it in the development of new radiopharmaceuticals for radionuclide therapy. Currently, the following commercial generators are available in the world: "GREN-1" (Russia), 3,7 - 37,0 GBq, eluate volume 5 ml; generator IDB Radiopharmacy (Netherlands), 3,7 - 18,5 GBq, eluate volume 8 ml; generator from Oak Ridge National Laboratory (USA), 9,25 - 111 GBq, eluate volume 10-20 ml; POLATOM (Poland), 3,7 - 18,5 GBq, eluate volume 8 ml. Synthesis of radiopharmaceuticals used for radiotherapy, requires high activity in a small eluate volume (1 - 3 ml). In connection with these requirements the application of different methods of eluate concentration before it use for radiopharmaceutical preparation is important. Aim: Investigation of concentration systems after generator elution. Materials and methods: $Na^{188}ReO_4$ was obtained from domestic generator "GREN-1" (Institute of Physics and Power Ingineering, Obninsk) and ^{188}W/^{188}Re generator with concentration module NEPTIS-TH (IRE ELiT, Belgium). Radiochemical purity (RCP) of concentrated eluate was determined by TLC in aceton and ITLC in saline. Results: The concentration system, which consists of two columns with sorbents, was used for the concentration of perrhenate solutions, obtained from generator "GREN-1". The cation-exchange resin DOWEX 50WX8 (100-200 mesh) in the Ag^+-form was used for the selective deposition of trace amounts of chloride-ions. Further recovery of perrhenate-ions was performed on a column with weak acidic alumina oxide (pH 4). ReO_4^- can be easily desorbed by 1 ml of 0,9 % NaCl. The yield of rhenium-188 was 70 - 85 %. The losses of rhenium-188 were calculated at each stage of concentration and were about 10 - 18 % on the cation-exchange column and about 5 - 6 % on the anion-exchange column. RCP of the concentrated perrhenate solution was more than 99 %. Elution volume from Belgium generator was 100 ml. Concentration module allows to obtain perrhenate solutions with high volume activity in 2 - 5 ml with ^{188}Re-yield 73.4 - 85.8 %. We observed relatively low RCP at concentration in volumes less than 2 ml. Conclusion: The application of concentration system allows obtaining $Na^{188}ReO_4$ solutions with high volume activity and radiochemical purity, which can be successfully used in the synthesis of radiopharmaceuticals for radiotherapy.

Tumor accumulation of 68Ga-DOTA-NAPamid is increased by HPLC purification of the tracer after labeling

J. L. Körner, S. Erdmann, L. Niederstadt, A. Wagener, S. Prasad, S. Exner, N. Beindorff, E. J. Koziolek, W. Brenner, C. Grötzinger; Charité - Universitätsmedizin Berlin, Berlin, GERMANY.

Aim Cutaneous malignant melanoma is one of the most lethal forms of cancer. Its incidence is increasing rapidly, making it a significant public health threat. Melanocortin receptor 1 (MC1R) is overexpressed in most melanomas making it a promising molecular target for diagnosis and peptide radioreceptor therapy. Because of their low molecular weight, low immunogenicity and excellent tumor penetration, radiopeptides have attracted steadily increasing interest in receptor-mediated tumor targeting. ^{68}Gallium labeling of DOTA-conjugated peptides is an established procedure in the clinic for use in PET imaging. In the radiochemical process, a large molar excess of peptide over radiometal is usually used to reach high ^{68}Ga complexation yields. Aim of this study was to compare a standard labeling protocol against the ^{68}Ga-DOTA-peptide purified from the excess of unlabeled peptide. **Materials and Methods** The well-known MC1R-binding DOTA-peptide NAPamide was labeled with ^{68}Gallium using a standard clinical protocol. Radioactive peptide was then separated from the excess cold NAPamide by HPLC: immediately after the incubation of peptide and ^{68}Gallium (95° C, 15 min), the reaction was loaded on a C18 column and separated by a water / acetonitrile gradient, allowing fractionation in less than 20 minutes. The radiolabeled products from the standard protocol and HPLC-purified peptide were compared in biodistribution studies and PET/MRI imaging using immunodeficient nu/nu mice, bearing MC1R-expressing B16-F1 xenograft tumors. **Results** In biodistribution studies, the unpurified ^{68}Ga-NAPamide was not found to accumulate in the tumor at 1 h post injection (around 1 %ID/g). With the additional HPLC step, the specific activity was raised around 10,000-fold by completely removing cold peptide. By using this rapid purification strategy, we were able to increase tumor uptake more than 8-fold without significant changes in the accumulation in any other tissue. The addition of unlabeled NAPamide to the purified product in various amounts led to a blocking effect and a decrease in specific tumor uptake, similar to the result seen with unpurified radiopeptide. In parallel, PET/MRI imaging was performed using the same tracers as in the biodistribution experiments. It was observed that purified ^{68}Ga-DOTA NAPamide shows superior tumor-to-background ratios.

Conclusion We showed that separation of radiolabeled and cold peptide via HPLC is technically feasible and beneficial, even for short-lived isotopes such as ^{68}Gallium. Unlabeled peptide molecules can strongly compete with receptor binding sites in the target tissue. Purification of the radiopeptide improved tumor uptake as well as signal-to-background ratios in PET/MRI scans.

EP644

Resolving false-positive bacterial endotoxin test results obtained with some radiopharmaceuticals and cold kits due to the presence of cations, colloidal particles or fatty acids

A. Mitra, S. Lad, S. Kulkarni, **M. G. R. Rajan**; Medical Cyclotrol Facility, Radiation Medicine Centre, BARC and BRIT, TMH Annexe, Parel, Mumbai, INDIA.

AIM: We have reported that certain ^{99m}Tc-radiopharmaceuticals (Tc-RPs) can give a false-negative BET due to the Ca^{++} in the lysate of the LAL reagent being trapped by the Tc-RPs (*JNMT,2014,42,278-282*). We now report instances where certain radiopharmaceuticals can give false-positive results due to the presence of cations, colloidal particles or fatty acids and how this effect can be overcome. MATERIALS: (a) Reagents: 9.6mM Ca^{++} and Mg^{++} free pH 7.1 PBS, LAL reagents (Sensitivity: 0.03EU/ml) used for BET including LAL-reagent water (LRW), Control Standard Endotoxin, Portable BET Test System (PTS) cartridges (Sensitivity:5-0.05EU/ml).(b) Radiopharmaceuticals studied: ^{99m}Tc-TRODAT, ^{99m}Tc-GHA, ^{99m}Tc-HSA-nanocolloid, ^{99m}Tc-Sulfur-colloid and their cold kits. ^{99m}Tc-carbonyl-DTPA-Rituximab, ^{99m}Tc-carbonyl-DTPA-Bevacizumab, ^{177}Lu-DTPA-Nimotuzumab, ^{177}Lu-DOTA-Nimotuzumab and their bi-functional chelated monoclonal antibody (BFCMA) cold kits, and ^{131}I-Lipiodol. METHODS: BET assays were performed for the RPs and cold kits using LRW or PBS as dilution agent by both gel-clot method (GCM) and kinetic chromogenic method (KCM) at various Maximum Valid Dilution (MVD) (400, 200,100 and 50) taking care of maximum injection volume and endotoxin limits (EL: 6 EU/ml- RPs, 1 EU/mg - BFCA-MoAb). RESULTS: ^{99m}Tc-TRODAT, ^{99m}Tc-GHA and their cold kits, ^{177}Lu-BFCA-MoAb and its cold kit exhibited false-positive result (elevated-BET) by GCM when using LRW as diluting agent, but this was resolved using PBS instead. Elevated-BET in ^{99m}Tc-HSA-nanocolloid, ^{99m}Tc-Sulfur-colloid and their cold kits were resolved by filtering with 0.22μm PES membrane filter before testing. Elevated-BET in ^{131}I-Lipidol, by GCM, was avoided by vigorous vortexing at 1:400 MVD in LRW. KCM did not exhibit any difference in BET values (Recovery Positive Product Control < 200%) on using either LRW or PBS. KCM could not be performed on colloid-RPs or their cold kits. CONCLUSIONS: Radiolabeled compounds and cold kits with high cation concentration can cause unusual aggregation resulting in a pseudo-coagulation reaction due to disruption of ionic bonds between divalent cations and PO_4^- moiety of lipo-polysaccharide (LPS). Hence, PBS prevents this in GCM assay. We were successful in overcoming the elevated-BET seen in GCM-BET assays for the above mentioned radiopharmaceuticals and cold kits having interfering cationic salt concentrations, using PBS for dilution. Elevated-BET observed with RPs having fatty acids and colloids was successfully taken care of after increasing the dilution and filtering the product respectively before the assay. Elevated-BET was not observed with KCM as the assay is based on absorbance of released chromophore. However, KCM is not recommended to replace GCM for pharmaceuticals (including RPs) where interference in the latter method is observed.

EP645

Simplified Automation of the GMP production for Ga-68 and Lu-177-labelled PSMA

S. Maus; University Medical Center of the Johannes Gutenberg University, Mainz, GERMANY.

Objectives Imaging of the prostate-specific membrane antigen (PSMA) for the detection of prostate cancer lesions and the therapy are more and more subject of intense research. With a view for the production of radiopharmaceuticals under GMP requirements the simplified automated processes for the GMP production of Ga-68-PSMA-11 and Lu-177-PSMA-617 using a cassette-based ModularLabPharmTracer® synthesizer (Eckert and Ziegler, Germany) in combination with the only recently pharmaceutically approved ^{68}Ge/^{68}Ga generator (GalliaPharm, Eckert & Ziegler Radiopharma GmbH, Germany) has been reported. **Methods** Ga-11-PSMA-11 labeling is conducted as follows: a Ge-68/Ga-68 generator (GalliaPharm, 50 mCi, Eckert & Ziegler Radiopharma GmbH, Germany) and cassettes (C4-Ga-68-PP) for [Ga-68]Ga-DOTA-peptides were used. 10 μg PSMA-11 precursor dissolved in 30 μl 0.25 M sodium acetate at pH of 4.5 was propounded in the reaction vessel and 2,2 ml generator eluat was transferred directly to the reaction vessel. After 5 minutes at 95° C the reaction mixture was diluted in 5 ml water and let passed a C18 cartridge. The product was eluted with 2 ml Ethanol:NaCl (50:50) and 8 ml 0.9 M NaCl and transferred to product vial via a 0.22μm sterile filter. Lu-177-PSMA-617 labeling usually starts with of 9.0 GBq Lu-177-Cl_3 (Lumark, IDB-Holland, Baarle Nassau,Netherlands) using a C4-Y90-00-standard synthesis cassette (Eckert & Ziegler Eurotope, Berlin, Germany). 100 μg PSMA-617 precursor dissolved in 500 μl 0.5 M sodium-acetate at pH of 4,85 were propounded in the buffer vial. The activity was transferred directly into the reaction vessel. After 20 minutes at 95° C the reaction mixture was diluted in 5 ml water and let passed a C18 cartridge. The product was eluted with 4 ml Ethanol:NaCl (50:50) and 16 ml 0.9 M NaCl and transferred into product vial via a 0.22μm sterile filter. **Results** Automated synthesis of ^{68}Ga-PSMA-11 resulted in radiochemical yields of 75 ± 10 %, purities of > 98 % and stabilities of ≥ 4 h. For Lu-177-PSMA-617 we obtained yields of (95 ± 2%), purities (>99 %) and stabilities up to 72 hours at room temperature without adding any additionally quencher like ascorbic or gentisic acid. **Conclusion** In this work we could show the simplified automated processes for the GMP production of Ga-68-PSMA-11 and Lu-177-PSMA-617 using the cassette-based ModularLabPharmTracer synthesizer with standard cassettes, which reduces the costs and makes the introduction of new cassette types or the acquisition of new software unnecessary.

EP646

Liposome carried radioiodine probes for the detection of orthotopic pancreatic tumor

J. Jung[1], W. Lee[1], R. Pal[1], G. I. An[2], J. Yoo[1]; [1]Kyungpook National University, Deagu, KOREA, REPUBLIC OF, [2]Korea Institute of Radiological & Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim: Pancreatic tumor is one of the most dreaded types of tumor, mainly because most of the cases are detected at advanced stage. So, an early diagnostic tool is extremely vital in order to provide proper treatment to patients with pancreatic tumor. Liposomes have been evolved as ideal drug delivery agents, but are rarely used to carry radiotracers for tumor imaging. This study focusses on the development of a liposome based radiotracer targeting orthotopic pancreatic tumor. Materials and methods: Hexadecyl-4-iodo benzoate was radiolabeled with 124/131I and consecutively loaded on liposome bearing DSPE-mPEG-2000-folate for active targeting of pancreatic tumor. The size of the liposome was measured using dynamic light scattering (DLS). The morphology of the liposomes was confirmed by transmission electron microscopy (TEM). Two different orthotopic pancreatic tumor models were prepared in BALB/c nu/nu mice using PANC-1 cells (folate receptor over-expressed cells, FR+) and MIA paca-2 (folate receptor deficient cells, FR-). Biodistribution studies were carried out in the tumor models. Results: The radiotracer was quantitatively radiolabeled with both isotopes of iodine, 124/131I. The TEM images clearly showed that the formed liposomes were of globular shape having a size of ~100 nm. The DLS measurements also showed good agreement with the TEM result having liposomes size distribution of mean diameter of 105 nm. Orthotopic pancreatic tumors

were well prepared by direct injection of the cells into the pancreas. In the biodistribution studies, at 24 h post injection, the pancreas uptake in the mice bearing PANC-1 cells (FR+) was about 2.7 times higher than that of the mice bearing MIA paca-2 cells (FR-). All other organs showed very similar uptake patterns between the two models. PET imaging study is going on. Conclusion: In this study, we developed a new radiotracer mediated active targeting of orthotopic pancreatic tumor in mice models.

EP647

Comparison of two radiopharmaceutical methods with ^{51}CrEDTA to calculate carboplatin dose

F. Alonso Zazo[1], C. Fernández García[1], B. Martínez de Miguel[1], D. Pérez Rodríguez[1], S. Rizkallal Monzón[1], A. Calviño Martínez[2]; [1]Hospital Universitario La Paz, Madrid, SPAIN, [2]Dpto Estadística e investigación operativa III. Facultad Estadística. Universidad Complutense de Madrid, Madrid, SPAIN.

PURPOSE Determine the best radiopharmaceutical technique to estimate the renal function using ^{51}CrEDTA and decide the appropriate dose of drugs in paediatric oncology. PATIENTS AND METHODS: Retrospective study of 24 patients with neuroblastoma aged between 8 months,16 years, and that will undergo treatment with Carboplatin. Carboplatin's pharmacokinetic depends on renal function, therefore it must be determined. To calculate the required dose of this drug we applied Newell´s formula that requires renal function and body weight and, achieving an ideal AUC (6,6mg/mL.min). To measure renal function we used two methods of ^{51}chromeethylenediaminetetraacetate (^{51}CrEDTA) clearance: Method 1: Glomerular Filtration Rate (GFR). One blood sample 120 minutes post-injection (Ham and Piepsz´s method) Method 2: half life ($t_{1/2}$). Three blood samples 120, 180, 240 minutes post-injection (Brochner Mortensen method) The results were compared using the Statistical test of Pearson's correlation. RESULTS Dose interval of Carboplatin obtained by the Ham and Piepsz´s method (GFR measurement) was [327,89 mg;1841,73 mg]. Dose interval of Carboplatin obtained by the Brochner-Mortensen´s method (Half time measurement) was [102,45 mg;791,27 mg]. The average of the absolute difference of dose between both methods was 640,24 mg. The average of the relative difference was 3.4217 (342,17 %) with a confidence interval of 95% (2.3531; 4.4903). CONCLUSIONS: The calculation of Carboplatin dose by the GFR Method measurement would imply a dose between 235,31% and 449.03% higher in comparison to the t1/2 measurement method, with a probability of 95 %, to obtain an AUC of 6,6 mg/ml.min. Therefore, in spite of the disadvantage of doing 3 extractions to the patient, it is preferable to use the half time measurement Method, since the ideal AUC will be achieved through the administration of less Carboplatin doses and, consequently, potential toxicity will be reduced.

EP648

A New And Facility Method To Preparation $^{188/186}$Re-EC (Ethylene Cysteine Dimer) As Radiopharmaceutical To Prevention Of Restenosis Vascular After Endovascular Brachytherapy

H. Kamali, M. Karamivand, A. Gravand, F. Farajbakhsh, M. Davarpanah, H. Abbasi; Pars Isotope company, Tehran, IRAN, ISLAMIC REPUBLIC OF.

After surgery angiography, it is possible rapidly re-clogging blood vessels. To avoid this complication, use of therapeutic radioisotopes, is one of the effective methods. The radioactive rhenium isotopes, ^{188}Re (half-life: 90.64h) and ^{186}Re (16.98h), have been suggested as radiopharmaceuticals for cancer therapy because of their energetic beta(β). Regarding the lack of hydrolysis of active ingredients radiopharmaceutical, EC(Ethylene cysteine dimer), within the liver and the possibility of survival within the vascular system and rapidly excretion of renal so for this purpose, $^{188/186}$Re-EC radiopharmaceutical was formulated with new and facility method. In this research, the preparation of [188/186Re] Re complex of EC with a new method was presented. 1 ml of an aqueous solution of EC, and 20 μl of $SnCl_2.H_2O$ in concentrated HCl were mixed together and ReO_4^-/saline (3700-7000MBq) was added and adjusted pH . In this method, the complex of 188/186Re-EC was formed at room temperature and the time of the labeling process was 15 minutes. Influencing various parameters for the preparation of radiopharmaceutical was investigated that include an amount of ligand and tin chloride, pH and the time of the labeling process. The best amount of parameters for this formulation method were 0.02 mmol of EC, 20μl(1×10-3 mmol.ml^{-1}) of $SnCl_2.H_2O$ were used for these research. The best radiochemical purity yield of $^{188/186}$Re-EC on optimum condition was achieved at 98%. The rate of clearance of $^{188/186}$Re-EC from blood was very adequate (1.5%), low persistence in vital organs. The advantage of this new method formulation is that no heating at 100 °C for 30 minutes and reaches the maximum efficiency of complex formation only at room temperature for 15 minutes.

EP649

Validation of Quality Control Method for 6-[^{18}F]fluoro-L-DOPA

J. G. Chan, K. Young, R. Mulligan, A. M. Scott, C. C. Rowe; Austin Health, HEIDELBERG VIC, AUSTRALIA.

Background: 6-[^{18}F]Fluoro-L-DOPA (FDOPA) has found increasing clinical demand for imaging CNS disorders and other malignant diseases such as neuroendocrine tumours and pancreatic adenocarcinoma. More recently development of improved nucleophilic syntheses methods giving higher specific activities, yields and purity are replacing more complex electrophilic fluorination with its inherent problems. Our department decided to utilise the nucleophilic method released on the NEPTIS® synthesizer from ORA™ providing a reliable one-pot nucleophilic production with high SA for routine production.Aims: To develop a suitable quality control method for the testing of FDOPA and to validate the automated synthesizer installation and production method. **Methods:** The quality control method was based on pharmacopoeial monographs and also a method provided by ABX. Radiochemical / chemical purity was determined by HPLC (Shimadzu Prominence) using the following conditions: Phenomenex Kinetex EVO, 5 μm, 250 x 4.6 mm, 100A, eluent: 0.08% TFA/ACN gradient, flow: 1 mL/min, UV: 283 nm, radio-HPLC detector (Flow-Ram, LabLogic). Analytical standards tested: 6-fluoro-L-DOPA, 6-hydroxy-D,L-DOPA and 6-nitro-formyl-DOPA. Free [^{18}F]fluoride content was tested via radio-TLC (Raytest Rita-Star). Enantiomeric purity was tested with Chirale HPLC (Shimadzu) using the following conditions: Diacel Crownpak CR(+) chirale column, 5 μm, 150 x 4.0 mm, 100A, eluent: 20 mM perchloric acid pH 2, flow: 1 mL/min, UV: 283 nm, radio-HPLC detector. Residual solvents were tested with gas chromatography (Shimadzu GC-2010 Plus) using a Restek Rtx-624 column, 30 m, 0.32 mm ID, FID. **Results:** The production validation runs (x3) successfully passed tests for sterility and endotoxins. Radiochemical purity was > 95% and impurities were well below set limits. Problems arose when developing a suitable TLC method for free [^{18}F]fluoride content and various methods are compared to determine the most suitable. A method utilising ITLC-SG glass microfiber strips (Varian) and acetonitrile:normal saline 50:50 was finally chosen. **Conclusion:** Routine production of FDOPA was successfully introduced. A quality control method was validated and final analysis demonstrated compliance with set specifications.

EP650

Transfer of a radiolabelling process with gallium-68 from a manual method to a remote controlled method for clinical applications: the example of NODAGA-RGDfK

M. Chomet[1], C. Provost[2], V. Vega[1], A. Prignon[2], J. Talbot[1], V. Nataf[1]; [1]APHP - Tenon Hospital, Paris, FRANCE, [2]UPMC - Tenon Hospital - LIMP, Paris, FRANCE.

Aim: Various peptides have been ^{68}Ga-radiolabelled in research laboratories and clinical units. However, each team uses different conditions and equipment which raises the issue of transferring production processes from one team to another. We adapted the method of Knetsch et al. (2011) for ^{68}Ga-radiolabelling of NODAGA-RGDfK, a ligand of integrins, to our module used for clinical routine, i.e. following GMP conditions. **Materials and methods:** Radiolabellings were performed using an Elusynth module (Iason). Knetsch et al. starting conditions were first tested. Adapted to our 50 µg GMP vial of RGDfK (PiChem), 180 µL of 0.8 M sodium acetate solution were added to the reaction vial. The ^{68}Ge/^{68}Ga generator (Obninsk) was eluted using the fractionated elution approach, 1.2 mL were collected and the reaction mixture at pH=3.5-4 was heated 300s at 40°C. The reaction mixture was transferred on a tC18 light Sep-Pack (Waters) for final purification. All parameters involved were checked, to improve either the radiolabelling yield or the solid phase extraction (SPE) efficiency. **Results:** Following published conditions, radiochemical yield (RCY) mean values were 60.1 ± 31.5 % (n=7). This method was not reproducible on our module. To improve the RCY we tested: • a higher temperature (95°C): the RCY increased to 98.5±0.5% (n=3) but the SPE efficiency was 19.5±11.7% (n=2). • an inversion in the order of introduction of reagents: the RCY increased to 98.9±0.4% (n=2) with a 100% SPE efficiency. However this method was not applicable in an automatic mode with our module as it requires an intervention of the user during radiolabelling. • a higher pH (4.5-5): the RCY was 98.41% (n=1) with a SPE efficiency of 96.4±4.4% (n=4). To improve the SPE efficiency at 95 °C: • the reaction mixture temperature was lowered with an extra vial containing water before transferring on the SPE: the efficiency was above 95% **Conclusion:** A transfer of process from a manual to a remote controlled method as well as between two modules for the same radiolabelling is achievable if all parameters, especially those influencing the kinetics of the reaction, are described. Furthermore, depending on the module, user interventions might be limited. We decided to increase the pH of the reaction as it proved to be a robust and easily applicable method. By determining thoroughly all parameters involved, we guaranteed a successful transfer of process for daily clinical use of [^{68}Ga]NODAGA-RGDfK which could be extended to ^{68}Ga-radiolabellings of other tracers.

EP651

Comparison of two alternative methods for RCP determination of (^{99m}Tc-EDDA-HYNIC-D-Phe(1), Tyr(3))-Octeotride

C. Beltrán Gracia[1], M. Hernández Fructuoso[2], B. Santos Montero[2], E. Miñana Olmo[2], J. Castell Conesa[3]; [1]Hospital Universitari Vall d'Hebron. Radiopharmacy Unit, Barcelona, SPAIN, [2]Hospital Universitari Vall d'Hebron - Institut de Diagnòstic per la Imatge. Radiopharmacy Unit, Barcelona, SPAIN, [3]Hospital Universitari Vall d'Hebron. Nuclear Medicine Department, Barcelona, SPAIN.

Aim: (^{99m}Tc-EDDA-HYNIC-D-Phe(1),Tyr(3))-Octeotride (^{99m}Tc-Tecktrotyd®) is a radioligand for somatostatin receptor used for neuroendocrine tumors diagnostic. During its preparation there are several potential impurities: ^{99m}Tc-pertechnetate, ^{99m}Tc-colloid and ^{99m}Tc-coligand. RCP (Radiochemical Purity) must be at least 90%, determined according to the Summary of product characteristics (SPC) through Instant Thin Layer Chromatography (ITLC); but it only separates ^{99m}Tc-pertechnetate and ^{99m}Tc- colloidal impurities. The aim of this study was to compare two methods to determine ^{99m}Tc-coligand impurity, and to obtain a faster and more accurate method of RCP testing compared with SPC procedure. **Materials and methods:** RCP was tested at different times: t=0 (n=10) and t>6 h (expiration time)(n=7). ITLC silica gel was performed using a two strip and solvent system: Methylethylketone was used to determine the amount of ^{99m}Tc-pertechnetate (Rf=1) and Acetonitrile/Water 1/1 for ^{99m}Tc- colloid (Rf=0). A third ITLC-SG strip with 0.1M sodium citrate pH5 as solvent was used to determine ^{99m}Tc-pertechnetate and ^{99m}Tc-coligand (Rf=1). The ITLC strips were measured in a dose calibrator and in a TLC Scanner (Mini Gita). Alternative method with Solid Phase Extraction (SPE) was evaluated: Sep-Pak C-18 was conditioned with 5ml 95% ethanol and 5ml saline. After the sample was loaded onto the cartridge, it was washed with 5ml saline to remove hydrophilic impurities (^{99m}Tc-pertechnetate and ^{99m}Tc-coligand). ^{99m}Tc-Tecktrotyd® was eluated with 5ml 95% ethanol followed by 5ml saline. The radioactivity of the eluates and the column were measured in a dose calibrator. **Results:** The RCP was calculated expressing the activity of ^{99m}Tc-Tecktrotyd® as percentage of the total activity measured. The results from SPC procedure were higher (t=0h; 97.9 ± 1.6/t>6h; 91.5 ± 4.2) than the other two methods. The results with citrate method (t=0h; 92.6 ± 3.4/t>6h; 85.9 ± 5.1) showed higher RCP compared to SPE, that showed the lowest values (t=0h; 89.3 ± 5.3/t>6h; 84.9 ± 4.7). The paired *t*-test showed statistical significant RCP differences between the three methods: SPC *vs* Citrate t=0h(p=0.00005), t>6h(p=0.00004); SPC *vs* SPE t=0h(p=0.00003), t>6h(p=0.00018) and Citrate *vs* SPE t=0h(p=0.00518), t>6h(p=0.04127). **Conclusion:** Using the method recommended by the manufacturer, we overestimate the RCP value, as it do not detect the amount of ^{99m}Tc-coligand. Using the alternative methods, we detect RCP values under specifications even in the shelf life of the labeled product. We recommend the use of SPE method in the clinical routine as it seems to determine all the impurities and it is faster and simpler than three strips TLC method.

EP652

Radiolabelling of DOTA^{MZOL} on an automated module System using NaCl post-processing

M. Meisenheimer, **E. Eppard**, S. Kürpig, M. Essler; University Hospital Bonn, Bonn, GERMANY.

Objectives: DOTA^{MZOL} is a bisphosphonate which can be used for diagnostic or therapeutic applications by radiolabelling it with ^{68}Ga or ^{177}Lu. It shows promising results in patients suffering from bone metastases. The aim of this study was to evaluate if it is possible to adapt the radiolabelling on an automated module utilizing NaCl-post processing, with regard to clinical application under additional radiation protection point of view. **Methodic:** ^{68}Ga was obtained from a 1 year old 1.85 GBq ^{68}Ge/^{68}Ga-generator (iThemba South Africa). Radiolabelling was performed on an automated cassette module (Gaia, Elysia-Raytest GmbH, Germany). DOTA^{MZOL} was obtained from (ITG, Garching, Germany). Modifications where made in comparison to standard labelling procedures in terms of cassette setup and eluents. Quality control was performed using radioTLC. Reactor screenning was necessary with different surfaces and coatings of glass and plastic vials. **Results:** The reactor screening showed DOTA^{MZOL} is sensitive to reaction vials and therefore in need of a specific preconditioned vial otherwise unplanned side products are obtained. Furthermore an automated method was obtained and tested. Radiochemical impurities could be separated by adding an anion exchanger before the sterile filtration of the final formulated radiopharmaceutical. **Conclusion:** A new syntheses route for DOTA^{MZOL} was developed with reduced handling of radioactive materials which reduces the radiation exposure of the operator. It was possible to reduce the effect of the used reactor to a minimum and to develop a purification method suitable for routine production. Also it was possible to adapt the synthesis on an automated module system. The whole process guarantees safe preparation of highly pure ^{68}Ga-DOTA^{MZOL} for clinical application. **Acknowledgement:** The bisphosphonate was made available from ITG, Garching, Germany.

Arteriovenous Fistula Influence on Glomerular Filtration Rate Results in Hemodialyzed Patients

J. GARCIA-REDONDO[1], E. MORILLO-MARTINEZ[1], L. SANZ-CEBALLOS[1], **A. RAMIREZ-NAVARRO**[1], J. LLAMAS-ELVIRA[2]; [1]Radiopharmacy Unit. Nuclear Medicine Department. COMPLEJO HOSPITALARIO UNIVERSITARIO DE GRANADA, GRANADA, SPAIN, [2]Nuclear Medicine Department. COMPLEJO HOSPITALARIO UNIVERSITARIO DE GRANADA, GRANADA, SPAIN.

Introduction: In our Department, glomerular filtration rate (GFR) with 51-Cr- EDTA by means of serial blood extractions is used to determine renal function in kidney transplant patients or potential donors, however, sometimes certain patients have higher plasma activity values in later times than in previous, contrary to expectations. **Aim:** Evaluate the possible relationship between patients presenting this device and the presence of arteriovenous fistula for having been subjected to hemodialysis. Patients and methods: Retrospective observational study of patients undergoing GFR test in our Nuclear Medicine Department from January 2012 until March 2016. Data if came from dialysis and what type of dialysis were collected. The procedure was to inject a dose of 51-Cr - EDTA along a via in one arm and the opposite arm drawing blood in time 0′, 5′, 10′, 20′, 120′, 180′ and 240′ from the injection of the radiopharmaceutical dose. In case of arteriovenous fistula by the hemodyalis, the injection of the radiopharmaceutical was in this same arm. For the bivariate analysis of qualitative variables Chi-square of Pearson test was used, considering statistical significance when $p < 0.05$. **Results:** 231 patients were studied, 174 came from hemodialysis and the remaining 57 came from a reference group consisting of patients undergoing peritoneal dialysis and patients not on dialysis. No cases with this device were observed in the control group, however, in the group of 174 from hemodialysis patients were observed 18 cases with this device. These results indicate that 10.3% of patients undergoing hemodialysis have this disorder, which represents a significant correlation ($p = 0.012$). **Discussion:** These results confirm the relationship between this disorder in plasma activity in the early stages of extraction and the presence of arteriovenous fistula because of having undergone hemodialysis, which makes suppose that in those cases in which vein injection fall into the fistula, this would act as a reservoir of the radiopharmaceutical, thus increasing the time of distribution of the same and causing this change.

EP654

Pharmaceutical development of albuminum microspheres labeled by rhenium-188 for hepatocellular carcinoma

A. Zverev[1], V. Petriev[2], V. Skvortsov[2]; [1]Federal center of nuclear medicine projects design and development, Moscow, RUSSIAN FEDERATION, [2]A. Tsyb Medical Radiological Research Centre, Obninsk, RUSSIAN FEDERATION.

Purpose. Pharmaceutical drug development based on radionuclide rhenium-188 and microspheres of human albumin (radiopharmaceutical) is for liver cancer therapy. The mechanism of action is as follows - after intra-arterial introduction of albumin microspheres 20-40 micrometers in diameter, rhenium-188 labeled particles deposit in the tumor and remain in the tumor area for a long time (up to a complete disintegration of the radionuclide rhenium-188); in addition to that tumor tissue receives a therapeutic dose of radiation due to internal beta-rhenium-188 with minimal damage to healthy liver tissue, which leads to growth inhibition and tumor regression. **Materials and methods.** A method for obtaining human blood albumin microspheres is based on the principle of an aqueous albumin solution emulsification in olive oil. During vigorous stirring, albumin solution droplets are formed in the oil with dimensions depending on the stirring rate. When heated, heat denaturation of albumin occurs with the formation of spherical particles, and the water evaporates. The formed microspheres are filtered, washed with acetone and dried. The microspheres are suspended in ethyl alcohol and fractionated using microsieve. Fraction is extracted in the range of 20 - 40 microns. It is dried out to constant weight. Rhenium-188 is obtained from the stationary centrifugal extractor. The extraction technique includes uploading irradiated tungsten oxide ($^{188}WO_3$) into the extractor dissolved in a mixture of hydroxide and alkali metal carbonate. Then, it is passed through an extractant (MEK). The received extract containing ^{188}Re, is evaporated to dryness and then it is dissolved by isotonic solution (0,9% NaCl solution), thereby obtaining a sodium perrhenate, ^{188}Re, required for the preparation of radiopharmaceuticals. **Results.** - microspheres size (20-40 microns); - the radiochemical purity of radiopharmaceutical - not less than 95%; - radiochemical impurities are not more than 5%; - stability of the labeled drug is not less than 5 hours from the time of production; - volume activity of radiopharmaceutical - 30-50 mCi /mL (1,11-1,85 GBq/ml); - safety - the forecast ratio of efficacy and toxicity will be positive. **Conclusion.** The composition and the form of the radiopharmaceutical preparation kit for the treatment of hepatocellular carcinoma and liver metastases is designed. Its main indicators of quality are offered. Theoretically and experimentally drug dosage form is developed. The prospects of development of the drug set conditions for the possibility of obtaining rhenium-188 from the sorption generator (^{188}W / ^{188}Re), allowing to apply the drug just before introducing it to the patient.

EP655

Evaluation of the accuracy and precision of a combine automatic system of FDG dose-dispensation and injection and its impact in operator radiation exposure.

I. Romero-Zayas[1], P. Saldaña-Gutierrez[2], C. Gámez-Cenzano[1], G. Reynés-Llompart[1], S. Rustarazo-Losada[1], D. Mateo-Navarro[1], I. Ferrero-Febrer[1], I. Liarte-Trías[1], M. Albadalejo-Castaño[1], A. Cebrián-Leiva[1], D. Coca-Castro[1], C. Picón-Olmos[2], M. Roca-Engronyat[1]; [1]Radiopharmacy and PET Units .Nuclear Medicine. IDI. Hospital U.de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Medical Physics.ICO.Hospital U.De Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.

AIM: The aim of this study was to evaluate the accuracy and precision of the dispensed FDG doses and the impact in operator radiation exposure using an automatic dose-dispensing and injector system. MATERIAL AND METHODS: KARl100 (Temasinergie) is an automatic motile dose-dispensing unit of FDG, which is used with a portable automatic injection pump, RAD-INJECT. The accuracy and precision was evaluated in 6561 dispensed doses (since September 2014 to December 2015), by using the difference between the requested activity dose and the dose dispensed automatically. The effective use of FDG supply was analysed measuring the residual dose in a sample of 150 after the loading procedure to the automatic system. The residual doses were also measured in a sample of 50 disposable syringes after patient infusion. The radiation exposure using a combined dose-dispensing and injection system was evaluated in 5 operators with the data from wrist, ring and badge dosimeters and it was compared with the manual dispensing and administration procedure. RESULTS: The mean accuracy (in absolute value) and precision of the dispensed doses was 0,15% (SD=3,59). The mean residual radioactivity in the manufacturer vial of FDG after the loading procedure was 174,6 MBq (SD= 191,5). It corresponds to the mean percentage of 3,10% (SD= 2,87). There was an inversely linear correlation with the amount of activity received ($r=-0,13$; $p<0,001$). The mean residual radioactivity in a sample of 50 syringes patient infusion was 0,67MBq (SD= 0,87). The mean effective dose received by the operators in 1 year using this system was: 1.63 mSv in ring dosimeter, 0.73 mSv in wrist dosimeter and 0.37 mSv in badge dosimeter. This corresponds to a decrease in 93.6%, 75.7%, 21.7% respectively when it is compared with a similar

period of time and clinical activity using a manual dispensing and injection technique. CONCLUSION: The combined automatic dose-dispensing and injection system has satisfactory accuracy and precision. An adequate effective use of the received FDG and dispensated/administrated FDG has been found (loss of FDG in the procedure loading and residual activity in the syringes are negligible). The radiation exposure of the operators is significantly reduced compared to manual protocol, especially in the extremities.

EP656

99m-Technetium radionuclide radiation measurements using a miniaturized gamma dosimeter

L. SANZ-CEBALLOS[1], **J. CESARI**[2], A. BARBANCHO[2], A. PINEDA[2], A. RAMIREZ-NAVARRO[3], J. LLAMAS-ELVIRA[4]; [1]Radiopharmacy Unit Nuclear Medicine Department. Complejo Hospitalario Universitario de Granada, Granada, SPAIN, [2]Integrated Circuits Malaga SL, Alaro, SPAIN, [3]Radiopharmacy Unit Nuclear Medicine Department. Complejo Hospitalario Universitario de Granada, Granada, Spain, Granada, SPAIN, [4]Nuclear Medicine Department Complejo Hospitalario Universitario de Granada, Granada, SPAIN.

Aim The aim of this work is to analyze the response of the miniaturized gamma dosimeter to see the sensitivity, linearity and other effects on the dosimeter to the ^{99m}Tc radionuclide. **Materials and methods** The materials used were two Floating gate (FG) gamma dosimeters integrated in one QFN32 package of 5x5 mm and mounted in a PCB and connected via USB to the computer. The computer was in charge via software to collect the data from both dosimeters with the rate of one sample every two seconds more or less. Samples of 5, 10 and 20 mCi of ^{99m}Tc were prepared in a five mililiter vial and measured with the reference activimeter (Atom Lab 400, Biodex). The measures were done during one, two or three hours depending on the dose. One run for each dose. This long time exposure was needed to see the Total Ionizing Dose (TID) accumulated by the dosimeter and also to have more relevant data as a first data measured from this kind of radionuclide with the dosimeter. The measures were carried out with the sensor attached to the external part of the vial. The measures from both dosimeters are compared and scaled versus the expected decay during the time from the ^{99m}Tc. All dosimeters were pre-characterized in temperature to remove the temperature effect from the measurements. The data collected from the dosimeters include the temperature for each sample and it permitted from the characterization curve in temperature to remove the temperature effect on the measures. **Results** The correlation with the data from the dosimeters and the expected decay curve from the radionuclide fits very well. The factor equivalency from mCi to TID is about 56,5 for the run one, 30.38 for the run two and 15 for the run three and the same equivalence factor for both dosimeters. From that values can be seen how the dosimeter has a lineal response for the different activities studied. **Conclusions** The dosimeters can measure linearly and with enough time the ^{99m}Tc radiation for activities ranges commonly used in a Radiopharmacy Unit. A coupling effect when the dosimeters are attached and unattached from the vial was observed and must be investigated. More investigation must be carried out to fix the sensitivity and limitations of the dosimeter for this radionuclide. Moreover other radionuclides should be studied.

EP657

On-chip gamma dosimeter measures comparison between ^{99m}Technetium and ^{60}Co radionuclides

L. SANZ-CEBALLOS[1], **J. CESARI**[2], A. BARBANCHO[2], A. PINEDA[2], A. RAMIREZ-NAVARRO[1], J. LLAMAS-ELVIRA[3]; [1]Radiopharmacy Unit Nuclear Medicine Department. Complejo Hospitalario Universitario de Granada, Granada, SPAIN, [2]Integrated Circuits Malaga SL, Alaro, SPAIN, [3]Nuclear Medicine Department. Complejo Hospitalario Universitario de Granada, Granada, SPAIN.

Aim To compare radiation measures on two different radionuclides (^{60}Co and ^{99m}Tc) using the same on-chip gamma dosimeter to the aim of finding future applications and upgrades on the dosimeter. **Materials and methods**The materials used were two Floating gate (FG) gamma dosimeters integrated in one QFN32 package of 5x5 mm and mounted in a PCB and connected via USB to the computer. The computer was in charge via software to collect the data from both dosimeters with the rate of one sample every two seconds more or less. Samples of 5, 10 and 20 mCi of ^{99m}Tc were prepared in a five mililiter vial and measured with the reference activimeter (Atom Lab 400, Biodex). The measures were done during one, two or three hours depending on the dose. One run for each dose. This long time exposure was needed to see the Total Ionizing Dose (TID) accumulated by the dosimeter and also to have more relevant data as a first data measured from this kind of radionuclide with the dosimeter. The measures were carried out with the sensor attached to the external part of the vial. The ^{60}Co radionuclide measures were done at different dose rates and time exposures using the same dosimeter. The dosimeter was at different distances from the gamma source depending on the dose rate desired. Three different dose rates were measured (20, 200 and 2000 rad/h). All dosimeters were pre-characterized in temperature to remove the temperature effect from the measurements. **Results** The measures from both radionuclides using the same dosimeter are discussed. The dosimeter shows a difference in terms of sensitivity response depending of the radionuclide. The output sensitivity for the ^{60}Co is around 300 Hz/rad and for the ^{99m}Tc 100 Hz/rad. The accuracy on the measure in terms of noise measured in the output is the same for both radionuclides. In addition when dosimeters are attached and unattached to the vial for the ^{99m}Tc measures an output coupling is observed. **Conclusions** The dosimeter behavior and performance measuring both radionuclides are the expected. The difference in terms of sensitivity between radionuclides measures must be because of the different energy emission for the gamma at each radionuclide (for ^{60}Co is about 1.1 MeV for the ^{99m}Tc is about 140 keV). More measures with similar dose rates and activites shall be performed. The coupling effect due to the measure attached to the ^{99m}Tc radionuclide must be investigated.

Image quality assessment of ALBIRA II PET system based on a range of positron-emitters

A. Attarwala[1], Y. Karanja[1], D. Hardiansyah[1], C. Romanó[1], M. Roscher[2], B. Wängler[2], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Molecular Imaging and Radiochemistry, Institute for Clinical Radiology and Nuclear Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY.

Aim: This study analyzes the performance characteristics of the Albira PET sub-system based on measuring the response of the system for the following positron-emitters: ^{18}F, ^{68}Ga, ^{64}Cu and ^{89}Zr in small animal imaging. **Materials and Methods:** The Albira tri-modal system (Bruker BioSpin MRI GmbH, Ettlingen, Germany) is a pre-clinical device with a PET, SPECT and CT. The PET sub-system is made up of single continuous crystal detectors of lutetium yttrium orthosilicate (LYSO) coupled to position-sensitive photomultipliers (PSPMTs). The detector assembly consists of three rings and eight detector modules. The trans-axial field of view (FOV) is 80 mm and the axial FOV is 148 mm. NEMA NU-4 image quality phantom (Data Spectrum Corporation, USA) having five rods (Ø 1-5 mm) and uniform central region was used

to analyse the system sensitivity and recovery coefficients. Measurements with ^{18}F, ^{68}Ga, ^{64}Cu and ^{89}Zr were performed with a starting activity concentration of 700 kBq/ml. Spatial resolution (NEMA NU-4 2008 method) was calculated based on an in-house phantom developed of polymethylmethacrylate (PMMA) with dimensions of (60x60x10) mm^3 containing cylindrical capillaries with a diameter of 1.2 mm, filled with a 1 μl point source solution of the respective radionuclide positioned at the geometric centre of the FOV. An energy window of 358-664 keV and a coincidence time window of 5 ns were selected. The data were reconstructed with a maximum likelihood expectation maximization (MLEM) algorithm; voxel size of 0.5 mm and iterations from 5 to 50 (step-size 5). All analyses were performed with PMOD software (PMOD Technologies Ltd., Switzerland) and MATLAB (R2015a, MathWorks, Natick, Massachusetts, USA). **Results:** The overall sensitivities for the entire FOV corrected for branching ratios were (3.78±0.05) %, (3.97±0.18) % and (3.79±0.37) % and (3.24±0.19) % for ^{18}F, ^{68}Ga, ^{64}Cu and ^{89}Zr, respectively. The spatial resolution in the x, y and z orientation was calculated and the median FWHM were 1.77 mm (^{18}F), 2.29 mm (^{68}Ga), 1.76 mm (^{64}Cu) and 1.74 mm (^{89}Zr). The image reconstruction algorithm converged after 25-30 iterations for all four radionuclides. The recovery coefficients for the 5 mm rod with an activity concentration of 400 kBq/ml were (0.77±0.13) ^{18}F, (0.51±0.08) ^{68}Ga, (0.89±0.20) ^{64}Cu and (0.58±0.11) ^{89}Zr, respectively. **Conclusion:** The Albira PET system has a comparable sensitivity range for the activity used for pre-clinical imaging for all the investigated radionuclides and the results indicate the system is a valuable tool for quantitative non-invasive small animal imaging studies.

EP659

Establishment of Hybrid Baculovirus-Sleeping Beauty 100× Vector-mediated Reporter Gene Imaging System

Y. Pan, J. Lv, Y. Zhang; Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.

Reporter gene imaging can be used to non-invasively and repetitively monitor various cellular and intercellular events *in vivo*, like gene delivery, endogenous gene expression and cell trafficking, most of them required stable or long-term monitoring. The commonly used stable transgenic viral vector in reporter gene imaging system is retrovirus or lentivirus, which have their own instinct limitations. Recent years, baculovirus as a novel attractive viral vector with many distinctive superiorities has been developed and broadly accepted, however the short-term transgene expression was its shortcoming. In this study, we introduced a *Sleeping Beauty* 100× transposon gene and neomycin resistance gene into baculoviral vector to achieve a hybrid vector (BV-SB100×). A high titer BV-SB100× vector (higher than 10^9 pfu/mL) was prepared according Bac-to-Bac system. The U87 cells and FTC-133 cells were infected by various types of BV-SB100× vector containing different reporter genes and selected by G418 for obtaining reporter gene stable-expressing cell lines. The results showed that these stable cells lines both maintained a long-term enhanced green fluorescent protein (eGFP) reporter gene expression for at least 180 days by the end of this study, with a stable expression level of more than 95% eGFP positive cells, compared with other constructed baculoviral vectors-mediated eGFP positive cells dropped to 10% in less than only 18 days. Reverse transcription PCR of different viral vector-infected cells in day1 or day 35 after infection also confirmed this result. CCK-8 cytotoxicity and proliferation assay indicated the biosafety of all different baculoviral vectors on two cell lines. BV-SB100× vector-mediated stable-expressed herpes simplex virus-1 thymine kinase could catalyze the ganciclovir, while the stable-expressed glucagon-like peptide-1 receptor (GLP-1R) could bind to its labelled ligand fluorescein-Trp^{25}-exendin-4. The eGFP fluorescent imaging showed a 35 days stable eGFP imaging *in vivo* after U87 cells transplantation, the further tumor frozen section analysis showed the high overlapping ratio of eGFP expression and DAPI nuclear staining in formed U87 tumors. At the end, GLP-1R radionuclide reporter gene imaging also confirmed the BV-SB100× vector-mediated long-term imaging in vivo for more than 50 days by nuclear medicine modality. In summary, the hybrid BV-SB100× vector could prolong the reporter gene expression as well as the reporter gene imaging, which would offset the drawback of transient transgene expression of baculovirus and broad the application of baculoviral vector.

EP660

Evaluation of Quantitative Accuracy of Tc-99m Small-Animal SPECT Imaging in Phantom Studies

S. Khorasani Gerdekoohi[1,2], N. Vosoughi[1], K. Tanha[3], M. Assadi[3], M. Ay[2,4]; [1]Department of Energy Engineering, Sharif University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Persian Gulf Nuclear Medicine Research Center, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: The purpose of single photon emission computed tomography (SPECT) imaging is to determine absolute amount of activity in body. The goal of this study is to investigate the feasibility of absolute quantification of a small-animal SPECT images in HiReSPECT scanner, the developed scanner in our department. *Materials and methods:* Image reconstruction code of system is based on maximum likelihood expectation maximization (MLEM) method including a resolution recovery algorithm during the iterative reconstruction. Decay compensation is done during data acquisition too. We also applied a post-processing uniform attenuation correction to compensate degradation of photon attenuation. To convert image matrix values to activity concentration (MBq/ml) we achieved a calibration factor (CF) by scanning a point source. Distance dependence of CF calculated to obtain it in all needed radius of rotations (ROR). For evaluating quantitative accuracy thirteen point sources which were almost attenuation free with known activities were scanned. Six cylindrical tubes with different volumes were scanned in same acquisition parameters too. Furthermore, we performed an experiment on the NEMA NU4-2008 image quality phantom to examine the relative error in estimation of activity concentration of its uniform region and hot rods. *Results:* In point sources, correlation between activities those were achieved by the dose calibrator and those estimated values using image matrix showed that difference between these two methods is not significant (p=0.98). Images of cylindrical phantoms results in RCs from 0.60 for 1ml tube to 1.02 for 30ml tube which means that by increasing the size of scanned object and decreasing the influence of partial volume effect, the quantitative accuracy has improved. In image quality phantom, RCs of hot rods in attenuation corrected images obtained 0.38, 0.65, 0.80, and 0.88 for hot rods with diameters of 2, 3, 4, and 5mm, respectively and it was improved 19% by applying correction for rod with diameter of 5mm. Finally, the relative error in estimation of activity concentration reduced from -15.5% to +5.1% in the uniform region of the phantom after applying attenuation correction. *Conclusion:* Our results show that reliable quantitative analysis in HiReSPECT scanner is feasible and also attenuation correction has a crucial role in improvement of quantitative accuracy.

γ-eye: Forward to small animal in-vivo imaging

M. Georgiou[1], P. Papadimitroulas[1], E. Fysikopoulos[1], K. Mikropoulos[1], G. Loudos[2]; [1]BioEmissionTechnology Solutions, ATHENS, GREECE, [2]Technological Educational Institute of Athens, ATHENS, GREECE.

Introduction-Purpose Small animal imaging has been well proven as a robust tool to non-invasively study the biodistribution of various biomolecules. A number of imaging systems are commercially available but with high purchase and maintenance costs. For this reason, we present the "γ-eye", a dedicated γ-camera suitable for in-vivo scintigraphic molecular imaging. The "γ-eye" is a unique benchtop system with 5x10cm^2 field-of-view for whole-body dynamic and static mouse imaging. **Materials & Methods** The "γ-eye" is based on two Position Sensitive Photomultiplier Tubes H8500 coupled to a CsINa pixelated scintillator and a general purpose parallel hexagonal hole collimator. The external dimensions of the entire system, including all required electronics, are 45x30x30cm^3. All studies can be stored as raw data and in DICOM format and are handled through a Database-Manager. The software supports a real-time viewer mode with selectable time frame and a post-processing mode, where various tools are adapted. **Results** The spatial resolution was measured 2mm @0mm, the energy resolution for the 140keV is 26% and the maximum sensitivity of the system is 200cps/MBq. The quantification ability was assessed using a phantom of 4 tubes filled with ^{99m}Tc solution with different activities. Our results demonstrate accurate quantitative information even for 10sec scans. The system was tested using a mouse injected with ^{99m}Tc-MDP for bone imaging, a mouse injected with ^{99m}Tc-DMSA for kidneys imaging and finally a mouse injected with ^{99m}Tc-MIBI for heart imaging. **Conclusion** A new low-cost system, suitable for scintigraphic mouse imaging has been developed and evaluated using phantoms and small animals. Its dimensions and cost make it a unique solution for groups activated in the field of small animal nuclear imaging.

Abscisic acid improves glucose tolerance in rats. A FDG-microPET study

A. Nieri[1], A. Buschiazzo[1], M. Magnone[2], F. Ticconi[1], L. Emionite[3], A. Democrito[1], C. Ghersi[1], A. Bozzano[1], G. Bottoni[1], A. Orengo[1], L. Sturla[2], C. Marini[4], E. Zocchi[2], G. Sambuceti[1]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa and IRCCS AOU San Martino-IST, Genova, ITALY, [2]Department of Experimental Medicine, University of Genoa, Genova, ITALY, [3]Animal facility, IRCCS AOU San Martino-IST, Genova, ITALY, [4]CNR Institute of Bioimages and Molecular Physiology, Milan, Section of Genoa, Genova, ITALY.

Aims Abscisic acid (ABA) is a plant hormone, present also in mammals. In vitro, nanomolar ABA concentrations stimulate GLUT4-mediated glucose uptake in myoblasts and adipocytes. In vivo, oral glucose load increases serum ABA concentration in healthy human subjects, but not in diabetic patients. In the present study, we aimed to verify the effect of single oral ABA microdose (1 μg/Kg) on glycemic response to oral glucose load in rats and the mechanisms underlying this action by a dynamic microPET approach. **Materials and Methods** All animal experiments were reviewed and approved by the Licensing and Ethical Committee of our Institute and by the Italian Ministry of Health. Eight male Wistar rats, fasted for 18 h, underwent glucose load without (control) or with ABA at 1 μg/Kg of body weight in a random sequence. Immediately after gavage, rats were anesthetized with intra-peritoneal administration of diazepam (4 mg/kg) followed by intramuscular administration of ketamine (33 mg/kg)/xylazine (5 mg/kg). Serum glucose level was tested and animals were positioned on the bed of a dedicated micro-PET system (Albira, Bruker, US) centering the scanner field of view on the chest. A dose of 30-45 MBq of FDG was then injected through a tail vein, soon after start of a list mode acquisition lasting 50 minutes. A volume of interest (VOI) was manually drawn over the left ventricle to identify the arterial input function that was used to obtain parametric maps of glucose consumption (MRGlu) by Patlak analysis using the routine of a dedicated software (PMOD, Zurich, CH). **Results** At tracer injection, serum glucose level was significantly lower after ABA with respect to control conditions (211±70 vs 263±75 mg/dL, respectively, p<0.01). In agreement with this observation, ABA administration markedly increased blood FDG clearance (from 0,005±0,002 to 0,011±0,004 ml/min/g of body weight, respectively, p<0.01) and thus overall whole-body glucose consumption (from 26,07±8,5 to 46,31±14,3 nMol/min/g of body weight, respectively, p<0.05). This finding closely agreed with the metabolic response of skeletal muscles and brown adipose tissue whose MRGLU doubled after treatment with respect to control condition (from 32±16 to 66±20 nMol/min/g of body weight and from 100 ±30 to 208±100 nMol/min/g, respectively, p<0,01). **Conclusion** Dynamic microPET studies indicate the capability of ABA in decreasing glycemia in response to an oral glucose load increasing the muscle and BAT glucose consumption.

EP663

Longitudinal SPECT studies on thyroid uptake in mice over a period of 24 months with respect to age, sex and circadian rhythm

N. Beindorff[1,2], A. Brönner[1], E. L. Huang[1], K. P. Huang[1], M. Lukas[1], C. Lange[1], I. G. Steffen[1], W. Brenner[1,2]; [1]Department of Nuclear Medicine, Charite - Universitaetsmedizin Berlin, Berlin, GERMANY, [2]Berlin Experimental Radionuclide Imaging Center, Berlin, GERMANY.

Aim: The aim of this longitudinal exploratory study was to establish normal values for the thyroid uptake of Tc-99m-pertechnetate as a function of age, sex and circadian rhythm in healthy mice. Materials and methods: In isoflurane anesthetized 11 female and 11 male C57BL/6 mice 9 consecutive multi-pinhole SPECT images of 10 min duration each were acquired as quasi-dynamic acquisition (nanoSPECT/CTplus, Bioscan/Mediso) starting at 5 min after intravenous injection of approx. 80 MBq Tc-99m-pertechnetate. Each mouse was imaged in follow-up studies up to 24 months (A: 1 month, puberty; B: 3 months, sexual mature, but not fully grown; C: 6 months, fully grown; D: 12 months; E: 24 months). In order to monitor circadian rhythm, animals were imaged during light (sleeping phase (SP)) as well as during night conditions (awake phase (AP)). Image viewing and quantification were performed using PMOD 3.4. The percentage tracer uptake of the injected activity is expressed as median [interquartile range; IQR]. Differences between groups were analysed using Mann-Whitney-U test and paired Wilcoxon test. Results: Maximum thyroid uptake in mice occurred between 10 and 45 min after injection of Tc-99m-pertechnetate. Female mice showed a significantly higher uptake than males (female 1.7 [1.5-1.8], male 1.2 [1.1-1.2] P<0.001). This effect could be observed up to an age of 12 months: A (female 1.6 [1.5-1.7], male 1.1 [1.1-1.3] P<0.001), B (female 1.7 [1.5-1.9], male 1.2 [1.0-1.2] P<0.001) C (female 1.8 [1.7-2.1], male 1.2 [1.1-1.3] P<0.001), D (female 1.6 [1.5-1.7], male 1.2 [1.1-1.2] P<0.001), E (female 1.1 [1.1-1.3], male 1.2 [1.1-1.2] P=0.79). A sex-related impact of age on thyroid uptake cannot be excluded in females (P=0.059) but in males (P=0.26). No relevant effect of circadian rhythm could be observed both in females (SP 1.6 [1.5-1.8], AP 1.7 [1.5-1.9]) and males (SP 1.2 [1.1-1.3], AP 1.1 [1.0-1.2]). Conclusion: This study showed a significant influence of sex on thyroid uptake of Tc-99m-pertechnetate in mice. Sex seems also relevant for age-related effects, which could be observed in females but not in males. In contrast to sex and age, circadian rhythm had no relevant impact on thyroid uptake. Therefore, the design of thyroid studies in mice using Tc-99m-pertechnetate should consider sex, and age in females as relevant factors, while circadian rhythm seems to be negligible.

EP664

BODIPY: a highly versatile platform for the design of MonoMolecular Multimodal Imaging Probes

C. Goze[1], M. Ipuy[1], N. Maindron[1], D. Lhenry[1], C. Bernhard[1], M. Moreau[1], P. Provent[2], A. Oudot[3], B. Collin[3], J. Vrigneaud[3], F. Brunotte[3], F. Denat[1]; [1]ICMUB-UMR CNRS 6302, Dijon, FRANCE, [2]Oncodesign, Dijon, FRANCE, [3]Centre G. F. Leclerc, Dijon, FRANCE.

Objectives. Due to their complementarity, combining fluorescence imaging with nuclear imaging techniques (PET or SPECT) can be advantageous both for preclinical and clinical use. The aim of our project is the elaboration of multimodal probes for optical/SPECT-PET imaging based on a BODIPY fluorophore. BODIPY derivatives appear as promising candidates for preclinical as well as clinical (surgery assistance) optical imaging applications owed to their excellent photochemical and photophysical properties, as well as a better stability when compared to the commonly used cyanines. **Methods.** Among the different approaches for the design of multimodal imaging agents, the MOMIP (MonomOlecular Multimodal Imaging Probes) systems present numerous advantages compared to the conventional "dual labelling" approach. We synthesized two MOMIP based on a distyryl-BODIPY using two different amino acid platforms, which was coupled to three DOTA macrocycles (TBK-686 and TBY-684). The photophysical properties of the different compounds and their "cold metallated"complexes were investigated, as well as their stability in serum. The most promising MOMIP, TBK-686, was activated and bioconjugated to trastuzumab via the lysine residues of the antibody. ^{111}In radiometallation of the resulting imaging agent was investigated. Additionally, the ability of TBK-686 trastuzumab to target HER2+ expressing tumor was studied *in vivo* in a model of BT474 tumor bearing mice. Whole-body fluorescence images were recorded at 24h and 48h post injection. *Ex-vivo* imaging was performed to provide semi-quantitative information about the tracer biodistribution, when the tissue absorption and autofluorescence were reduced at minimum. **Results.** The BODIPY core did not affect the radiolabeling efficiency of the antibody conjugate (specific activity = 490 MBq/mg). The ^{111}In-conjugate remains fluorescent after radiolabeling, and is stable even in the presence of 2000-fold molar excess of DTPA. *In vivo* biodistribution studies revealed that the NIR fluorescence signal emitted by the BODIPY core can be easily detected at the tumor site. *Ex-vivo* imaging confirmed that a higher fluorescence intensity was observed in the tumor rather than in other organs, which demonstrates that the dual labeled trastuzumab is able to accumulate in the HER2-positive tumor. **Conclusion.** The BODIPY-based MOMIP TBK-686 reported herein is a valuable tool for bimodal imaging. A dual imaging study (SPECT-optical imaging) is currently investigated.

EP665

Pre-targeting of the chemokine receptor 4 via activatable and de-activatable fluorescent constructs

T. Buckle, S. van der Wal, D. M. van Willigen, C. M. de Korne, F. W. B. van Leeuwen; LUMC, Leiden, NETHERLANDS.

Background Internalization of receptor targeting imaging agents is a key aspect of their function, but can be hard to assess. "Traditional" activatable dyes can be used to provide enhanced fluorescence upon internalization and subsequent enzymatic cleavage. This concept is, however, complex to apply for targeting tracers. Using a pre-targeting concept we developed a de-activatable chemokine receptor 4 (CXCR4)-targeted tracer wherein the fluorescence of the extracellular portion of the tracer could be turned off via a secondary click chemistry. The efficacy of this approach was tested against an activatable tracer targeted against CXCR4. **Methods** Ac-TZ14011, a CXCR4 specific peptide, was coupled to 1) an activatable FRET dye construct wherein a Cy3 dye was linked to a Cy5 dye through a reduction-cleavable disulfide bond and 2) a Cy5 dye that contained a chemo-selective azide handle suitable for pre-targeting applications with a FRET and stacking inducing DBCO-containing Cy7 quencher dye. Besides tracer assessment in solution, receptor-specific binding of the tracers (1uM) and subsequent visualization of cellular internalization was evaluated in CXCR4 over-expressing MDAMB231 X4 cells. **Results** The FRET efficiency of the disulfide-bridge containing activatable tracer (Kd > 500 nM) was 55% and a limited 2.3-fold increase in fluorescence was seen upon reduction in solution. Fluorescence imaging in viable cells revealed a similar effect; only a weak membranous staining and subsequent increase in the Cy3 signal in the cytoplasm of the cells was observed. In contrast, the de-activatable tracer set-up demonstrated that addition of the Cy7-quencher to the Cy5-azide labeled peptide (Kd = 177 ± 18.8 nM) resulted in a fast (2-5 minutes) and >90% reduction of the Cy5 signal in solution. Addition of the quencher resulted in an 80% decrease in the membranous staining within the first 10 minutes, while fluorescence of internalized tracer-component was preserved. **Conclusions** De-activatable fluorescence tracers were shown to provide a promising alternative for activatable tracers. Moreover, the click chemistry-based pre-targeting approach proved to be efficient and enabled clear assessment of the internalized fraction of the targeted tracer.

EP666

Pharmacokinetic of tumor FDG uptake in subcutaneous and orthotopic preclinical models of breast cancer - Influence of administration route

A. Oudot[1], J. M. Vrigneaud[1], O. Raguin[2], M. Guillemin[1], P. Provent[2], B. Collin[1,3], F. Brunotte[1,4]; [1]CGFL Preclinical imaging platform, Dijon, FRANCE, [2]Oncodesign, Dijon, FRANCE, [3]ICMUB - CNRS 6302, UBFC, Dijon, FRANCE, [4]Le2i - CNRS 6306, UBFC, Dijon, FRANCE.

Aim: Numerous studies evaluated FDG tumor uptake using microPET imaging in preclinical models. In parallel, many orthotopic tumors models were developed to better mimic human pathology. Our objective were i) to better characterize the kinetic of tumor uptake of FDG in subcutaneous and orthotopic models of breast cancer xenografts in mice, and ii) to evaluate alternative routes of administration of FDG injection that could be useful in preclinical studies involving repeated treatments with drugs via intravenous route. **Materials and methods:** NOD Scid mice were subcutaneously xenografted with BT-474 cells (HER2+ human breast cancer) and Balb/C mice were grafted in the mammary fat pad with 4T1 cells (triple negative mouse breast cancer). When tumors reached 200 mm^3, mice were randomized in subcutaneous (sc), intraperitoneal (ip) or intravenous (iv) FDG injection groups. The pharmacokinetic of FDG tumor uptake was evaluated in fasted mice by a 90-min dynamic list mode PET imaging after a single injection of FDG (4-6 MBq). Analyses were performed in reconstructed PET-CT images after delineation of a region of interest corresponding to the entire tumor. **Results:** In mice bearing subcutaneous BT-474 tumors, FDG tumor uptake plateaued within 15-20 min after iv injection, 30-35 min after ip injection and 50-60 min after sc administration. Tumor FDG contents at 90 min were similar in iv- (0.68±0.09 SUV units) or sc- (0.69±0.09 SUV units) injected mice but lower in ip-injected mice (0.55±0.04 SUV units). In orthotopic 4T1 tumors, FDG uptake appeared to be slowed down for both iv and sc groups. In ip group, tumor delineation was delicate due the vicinity of ip cavity. As for subcutaneous tumors, orthotopic 4T1 tumor FDG content was similar in iv- (0.87±0.11 SUV units) or sc- (0.86±0.07 SUV units) injected mice at 90 min post-administration. In both tumor models, i) similar FDG uptakes (SUVmean and SUVmax) were measured in iv groups after 20, 30 or 45 min uptake period, ii) FDG tumor uptake measured 60 min post-sc injection was similar to that measured 30 min post-iv injection. **Conclusion:** The present work showed that the kinetic of FDG tumor uptake was different in subcutaneous and orthotopic mice models of breast cancer and that ip FDG administration may not be a relevant option to replace iv FDG injection. Subcutaneous administration of FDG can however be considered as an alternative route of administration, provided that the uptake period is extended to ensure that the uptake plateau is reached.

EP667

Feasibility of [^{18}F]-FDG micro PET of resected, vital non-small cell lung cancer ex vivo

J. de Swart, T. G. Meijer, N. S. Verkaik, G. N. Doeswijk, J. F. Veenland, D. C. van Gent, A. P. W. M. Maat, J. H. von der Thüsen, R. Kanaar, M. de Jong, S. F. Petit; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: 2-deoxy-2-[^{18}F]fluoro-D-glucose ([^{18}F]FDG) is a well-known and often used radiopharmaceutical in PET imaging of, among others, tumour tissue *in vivo*. We investigated the feasibility of performing PET scans of small *ex vivo* non-small cell lung cancer (NSCLC) tissue slices as a prediction of tumour response to therapy. Method: After surgical resection, from three patients surplus material of the NSCLC tumour was cut in 300 μm thick slices. These slices were cultured using RMPI 1640 medium for 2 - 6 days at 37 degrees Celsius. Next, [^{18}F]FDG 11.4 ± 5.2 MBq was added to the medium and incubated on an orbital shaker (60 rpm) for 30 minutes at room temperature, washed in PBS on the orbital shaker for 30 minutes, washed again with PBS and placed in a micro PET scanner (Siemens Inveon, Knoxville, USA). A 30 minutes emission scan of a single bed position was made, followed by a transmission scan using two ^{57}Co sources. To a number of the slices 1, 10 or 30 μg/mL cis-diamminedichloridoplatinum(II) (cisplatin) was added to the medium from the onset of the culturing period to eradicate tumour cells enabling discrimination between specific and non-specific uptake of [^{18}F]FDG in the slices. The PET scans were reconstructed using the OSEM3D algorithm (2 iterations) and the Maximum A Posteriori (MAP) algorithm (18 iterations). The smoothing factor was set to 0.8 mm. Results: All slices showed a clearly heterogeneous [^{18}F]FDG uptake pattern. The slices that had not been treated with cisplatin or with 1 μg/mL had uptakes of 6.4 ± 1.4% (mean ± SD) and 5.8 ± 2.1%,respectively, of the added [^{18}F]FDG. In contrast, slices that had been treated with 10 or 30 μg/mL cisplatin showed a much lower uptake (0.68% and 0.44% respectively). Conclusion: It is feasible to image the specific uptake of [^{18}F]FDG in small slices of NSCLC ex vivo. This model may serve as a tool to monitor the effect of (radio)therapy on human tumour tissue.

EP668

Texture analysis of tumour heterogeneity in response to anti-angiogenic therapy in a preclinical colorectal cancer model

A. J. Weeks, J. Goda, M. Siddique, K. Shaw, S. Clarke, V. Goh, G. Cook; King's College London, London, UNITED KINGDOM.

Texture analysis refers to mathematical models that can be applied to an image to describe the relationship between voxel grey level intensities. Texture analysis may provide information about tumour heterogeneity that is not apparent from conventional image assessment. The purpose of this study was to assess multiparametric MR (mpMR) and ^{18}FDG PET/CT changes in tumour heterogeneity after treatment of mice bearing human colorectal cancer xenografts with the anti-angiogenic agent Bevacizumab. We hypothesised that Bevacizumab treatment would lead to normalisation of tumour vasculature and changes in tumour heterogeneity. CD1 athymic mice were injected with 5 x 10^6 LS174T cells (human colorectal carcinoma) and tumours were monitored until a mean diameter of 6-9mm was reached. Tumour bearing mice were assigned to one of two groups; untreated control or Bevacizumab treated (5mg/kg, IP, 3 times weekly, 2 weeks). Two days post treatment mice were subject to mpMR imaging (Bruker 9.4T, quantitative T1 +/- contrast 0.3mMol/kg Magnevist, T2, T2* and apparent diffusion coefficient, ADC) and FDG-PET/CT (Bioscan nanoPET/CT, 5MBq ^{18}F-FDG) the next day. Texture features were analysed by Matlab-based in house software. Bevacizumab treated mice showed no significant differences in global first order texture features compared to control mice with the exception of T1 images which demonstrated higher mean and median values (p=0.048 and p=0.027). The treatment group demonstrated statistically significant differences in high order loco-regional texture features in T2, ADC, CT and 18FDG PET images compared to the control group. T2 images showed differences in grey-level co-occurrence matrix autocorrelation and grey-level zone matrix (GLZM) short zone emphasis (p=0.021 and p=0.074). ADC showed higher values in 4 GLZM parameters in the treatment group (p=0.010, 0.043, 0.015 and 0.015). In CT images the treated group showed lower values in 5 grey-level run length (GLRL) parameters (p=0.026, 0.026, 0.026, 0.026, 0.026 and 0.018) and ^{18}FDG PET showed lower values in 4 GLRL parameters in the treated group (p=0.007, 0.006, 0.015 and 0.006). The difference in tumour growth between control and treated mice during the treatment period was not statistically significant (351 and 312 mm^3, respectively, p=0.70) indicating that standard size-related metrics of assessing treatment response are insensitive.Evaluation of image heterogeneity may provide additional novel parameters of response to anti vascular therapy with advantages over standard size-change.

EP669

High Throughput Rodent Imaging Using a Clinical Digital PET/CT System

M. V. Knopp, K. Briley, M. I. Menendez, M. Williams, A. Siva, K. Binzel, J. Zhang; The Ohio State University, Columbus, OH, UNITED STATES.

Preclinical imaging, especially of rodents, has been a key element of molecular imaging. Compared to genome sequencing which exploded with the introduction of high throughput technology, molecular imaging has been limited to single subject per device imaging with relatively long acquisition times. As these limitations are increasing obstacles to efficient and fast pre-clinical cohort studies, we initiated this project to develop the capability of multi-subject, simultaneous whole-body PET/CT imaging using a next generation, digital PET detector based, clinical PET system. A pre-commercial release, next generation, solid state, digital photon counting clinical PET/CT system (Vereos, Philips) was used to perform simultaneous, multi-rodent PET and CT imaging. Previously, a system comparison was performed using micro phantoms with a dedicated small animal imaging PET/CT system (Inveon, Siemens). The clinical PET/CT allows z-axis coverage of 164 mm and has an effective trans-axial imaging width of up to 676 mm. Enabling the pre-clinical imaging was the prior development of ultra-high definition (UHD) reconstruction that facilitates a 1 mm^3 voxel size leveraging the excellent time of flight timing resolution of 325 ps. CT imaging was also performed using a 1024 matrix size and reconstructed using 0.5 mm voxel length. In order to enable the simultaneous whole-body (WB) imaging of multiple mice, we developed a mouse hotel that can be variably configured to accommodate multiple animals. For the initial demonstration, we chose a 6 bed layout that was designed to consider also the TOF spatial resolution with only one bed within the resolution frame. Both CT and PET whole-body imaging was achievable within a single acquisition volume making even dynamic acquisitions readily feasible. The developed acquisition and reconstruction approaches led to surprisingly good image quality which was rated as fully acceptable for pre-clinical oncologic applications. No cross-interference from multiple beds was found. While the 6 bed layout appears practical, a higher number of beds is feasible without loss of spatial or quantitative quality. The multi to single bed comparison showed equivalent image and quantitative quality. Next generation digital detector, high performance time of flight clinical PET/CT systems can feasibly be used for high throughput, whole-body dynamic imaging of rodents in single bed to even more than 6 parallel bed configurations, with sufficient quality for oncologic molecular imaging. Special reconstruction and data handling approaches can be readily implemented making this a very effective approach for large rodent population imaging with effective radiotracer management especially for short half-life isotopes.

EP670

Genomic Profiling to Validate VPAC1 Expressing Liquid Biopsy Cells are Malignant

M. L. Thakur; Thomas Jefferson University, Philadelphia, PA, UNITED STATES.

Objectives: Detecting cancer by liquid biopsy remains the most active translational cancer research. We have developed a technique in which we target VPAC1 receptors expressed on shed prostate cancer (PCa) cells in voided urine and detect PCa with >98% sensitivity (n=160). This investigation was to ascertain by genomic profiling that these VPAC1 receptors expressing cells shed in urine are malignant. **Method:** Non-DRE urine was collected from 4 PCa patients and 3 normal volunteers. Urine was contrifuged (10 min., 450xg), cells were washed, incubated with 1μg TP4303, washed, resuspended, and were subjected to fluroescence activated cell sorter (FACS). Cells with TP4303 fluorscence were collected, centrifuged, washed and lysed in cell lysis buffer (Norgen Biotek). RNA was then extracted from the cells (Norgen Biotek), quantified (nanodrop ND-100 spectrophotometer), and RNA quality was determined. (Agilent Technologies). Affymetrix gene chips, Human Tanscriptome Array 2.0 (Affymetrix) were hybrizided with 5 μg fragmented and biotin-labeled cDNA in 200 μl hybrization cocktail. Target denaturation was performed at 99°C for 5 min., at 45°C for 5 min, and followed by hybridizaiton with rotation (60 rpm) for 16 hour at 45°C. Arrays were washed and stained (Gene Chip Fluidic Station 450). Chips were scanned (Affymetrix Gene Chip Scanner 3000) using Comman Console Software. Quality Control was performed by Expression Console Software. Experimental Group was compared with control group using Transcriptome array console software. Differentially expressed gene list was used for pathway analysis with IPA software. **Results:** Data showed that 5 coding PCa genes (AR, HSD17B, KLK3, KLK2 and ACTL6A were upregulated and 19 coding PCa genes (PTEN, MR01, BACH1, etc.) were down regulated (>1.5 fold, P=<0.05). **Conclusion:** These genomic PCa fingerprint data confirmed that VPAC1 expressing cells shed in voided urine of PCa patients are malignanat and validated our hypothesis that these malignanat cells can be correctly detected by TP4303. Research Supported in part by, NIH CA 157372-02, (MLT).

EP671

Biological mechanisms of FDG uptake in non-small cell lung cancer

S. B. Christlieb, B. B. Olsen, E. A. Segtnan, O. Gerke, K. E. Olsen, P. F. Høilund-Carlsen; Odense University Hospital, Odense C, DENMARK.

Aim: 18-fluorodeoxyglucose (FDG) positron emission tomography (PET) visualizes the glycolytic activity in tissue, and increased glycolytic activity is known to be a hallmark of malignant cells. The aim of this study was to explore the underlying biological mechanisms of FDG uptake by assessing markers of proliferation, glucose metabolism, and hypoxia in non-small cell lung cancer (NSCLC). **Materials and Methods:** Thirty-six patients with NSCLC (13 with squamous cell carcinomas and 23 with adenocarcinomas) aged 41 to 83 years (median 68 years), who had undergone PET/CT prior to surgery and from whom fresh frozen tissue was available, were included in the study. Expression of Ki67, glucose transporter-1 (GLUT-1), hexokinase-II (HK-II), and hypoxia-inducible factor-1alpha (HIF-1alpha) was assessed with immunohistochemistry and categorized into three groups (<10%, 10% to <50% and ≥50%). Activity of HK and glucose-6-phosphatase (G6Pase) was determined by a colorimetric and spectrophotometric assay, respectively. The FDG-avid lesions were segmented to yield standardized uptake values (SUV), i.e., SUVmax, SUVmean, and total lesion glycolysis (TLG). **Results:** Ki67 correlated positively with GLUT-1 (Spearman's rho= 0.41, p= 0.01) and HIF-1apha (rho=0.53, p<0.01), and GLUT-1 correlated positively with HIF-1alpha (rho=0.50, p<0.01). Furthermore, there was a positive correlation between the enzymatic activity of HK and G6Pase (rho=0.48, p<0.01). The variation in measurements of FDG uptake was minimal with a median of 0% (range 0-10%) for SUVmean and of 1% (range 0-16%) for TLG for both intra- and interobserver variation. There was no variation in measurements of SUVmax between observers. SUVmax and SUVmean were moderately correlated with GLUT-1 (rho=0.53, p<0.01 and rho=0.39, p=0.02, respectively). TLG was moderately correlated with Ki67 and GLUT-1 (rho=0.44, p<0.01 and rho=0.50, p<0.01, respectively). There was no significant correlation between the expression of HK-II and HIF-1alpha or the activity of HK and G6Pase with the FDG uptake. In multivariable linear regression including all parameters, only GLUT-1 contributed statistically significantly to the SUVmax (R^2 adjusted: 0.22). **Conclusion:** There was but a moderate correlation of GLUT-1 and Ki67 with the FDG uptake, whereas there was no correlation between any of the other parameters and FDG uptake. These results suggest that the underlying biological mechanisms of FDG uptake in NSCLC are complex and warrant further investigations, *i.e.,* in vitro studies of the interrelationship between the enzymatic pathways that governs the uptake of FDG in NSCLC.

EP672

Breast Cancer Inmunophenotipic Heterogeneity. Evaluation By Molecular Imaging

Q. G. Pitalúa Cortés, F. O. García Pérez; Instituto Nacional de Cancerología, Mexico City, MEXICO.

Background: Patients who develop distant metastases usually undergo systemic therapy with chemotherapy, hormonal therapy and/or human epidermal growth factor receptor 2 (HER2) targeted therapy. Choice of therapy is currently personalized on the basis of the inmunophenotype of the primary tumor, since distant metastases are often not biopsied. However, previous studies have indicated that receptor status may differ from the primary tumor, generally denoted "receptor conversion". An alternative for taking biopsies could be molecular imaging methods that are currently being developed to functionally assess inmunophenotype of breast cancer metastases. Published discordance rates between primary and recurrent disease are highly variable and range for example for the oestrogen receptors (ER) between 7.2 and 43.2% and for the HER2 between 0 and 64.3%. **Methods:** Ten patients with locally advanced or metastatic breast cancer were studied with ^{18}F-FDG PET-CT, ^{18}F-FES and ^{67}Ga-DTPA-Trastuzumab; tissue samples were collected post-imaging studies, and it was assessed ER and HER2 expression by IHC. We also correlated ^{18}F-FES uptake (SUVmax) with ER expression measured by H-SCORE (0-210). ^{67}Ga-DTPA-Trastuzumab uptake was measured by a visual analysis based on the hepatic and blood pool uptake (-, +, ++, +++) and was compared with HER2 expression measured by IHC (positive or negative, ordering FISH only if the IHC results don't clearly show whether the cells are HER2-positive or negative. The percentage of receptor change status in the metastases immunophenotype was also evaluated in order to correlate with the primary lesion. **Results:** We included 28 lesions in 10 patients. Histology of primary lesion was 9 invasive ductal carcinomas and 1 invasive lobular carcinomas, ER positive=7, PR positive=8, Her2 positive=3; histology of metastatic disease was 7 ductal carcinoma, 1 lobular carcinoma, 1 neuroendocrine carcinoma, 1 without neoplasm evidence, ER positive=12 PR positive=10 Her2 positive=7; we found receptor discordances in 8 lesions; RE + to -: 1, RE - to +: 1, HER2 + to -: 1, HER2 - to +: 5. Final results were 8 receptor discordances in 18 studied metastatic lesions. ^{18}F - FES SUVmax was correlated with ER H-Score (r: 0.7739, p: 0.0003); the uptake value of ^{67}Ga-DTPA-Trastuzumab was correlated with IHC (r: 0.8575, p: 0.0001). **Conclusion:** Molecular imaging in breast cancer is highly efficient to assess the receptor expression in metastatic lesions and any unsuspected change in this receptors, therefore leading change in the therapeutics.

EP673

Imaging neuroblastoma xenograft using [^{64}Cu]$CuCl_2$ for evaluation of novel treatment based on Dextran/Catechin conjugate

A. Parmar[1], O. Vittorio[2,3], A. Charil[1,4], M. Kavallaris[2,3], G. Pascali[1]; [1]ANSTO, Camperdown, AUSTRALIA, [2]Lowy Cancer Research Center, Randwick, AUSTRALIA, [3]ARC Centre of Excellence for Nanomedicine, UNSW, Randwick, AUSTRALIA, [4]Brain & Mind Center, University of Sydney, Sydney, AUSTRALIA.

Aim: Neuroblastoma is a very aggressive cancer with high mortality rate in children. Our group studies the effects of a novel treatment based on a Dextran-Catechin conjugate on animal models of neuroblastoma; survival and behavioural results have demonstrated the efficacy of this treatment. We have found evidence that the mechanism of action of this drug is linked to intracellular copper (Cu) trafficking and distribution. Our aim was therefore to employ [^{64}Cu]$CuCl_2$ to monitor Cu distribution *in-vivo* in neuroblastoma xenograft mouse models, both with and without treatment. **Materials and Methods:** A pilot study was carried out in normal healthy female BALB/c-Fox1nu/Ausb mice (n=4; 6-8 weeks of age) to understand the clearance of [^{64}Cu] over 2 days using 7-10MBq of [^{64}Cu]$CuCl_2$ in 100μL of PBS injected via the lateral tail vein. Scans were performed at the following time points: 0-2hrs, 5hrs, 24hrs and 48hrs, using a Siemens Inveon PET/CT scanner. We used the human neuroblastoma BE(2)-C xenograft mouse model in our study. On the day of imaging, 1hr prior to the PET scan, mice were intravenously treated either with saline (100μL) or Dextran-Catechin (300μg in 100μL of saline) and anaesthetised using 2% isoflurane. 7-10MBq of [^{64}Cu]$CuCl_2$ was injected via the lateral tail vein prior to PET/CT imaging at 0-2hrs and 5hrs post radiotracer injection. Following the imaging session, mice were sacrificed and tissues were collected for *in-vitro* analysis. Siemens Inveon IAW 2.0.0.1050 and IRW 4.2.0.8 software were used for image reconstruction and image analysis, as well as for obtaining kinetic curves for tumour and liver tissues. **Results:** The pilot study in normal mice demonstrated highest uptake of [^{64}Cu]$CuCl_2$ in the liver (20-30 %ID/g) followed by the kidneys and lungs. Interestingly there was high uptake in thyroid glands during the first 5hrs (4-7 %ID/g). The neuroblastoma tissues showed consistent uptake (2-4 %ID/g) in the saline group even after the 48hrs period, thus confirming high accumulation of Cu in the tumour mass. This [^{64}Cu] higher uptake was significantly reduced in Dextran-Catechin-treated animals. **Conclusion:** We have shown how Dextran-Catechin mediates its beneficial effects via copper metabolism, and this phenomenon could be highlighted by a relative lower uptake of [^{64}Cu]$CuCl_2$ in the tumour following the acute treatment of Dextran-Catechin in a neuroblastoma animal model. This opens the way to a deeper understanding of the molecular basis of Dextran-Catechin treatment and its potential applicability to other type of cancers.

EP674

Radiation-resistant cancer stem cells are sensitive to Auger-electron emission

B. B. Olsen, P. F. Høilund-Carlsen, H. Thisgaard; Odense University Hospital, Odense C, DENMARK.

Aim Cancer stem cells represent a clinical challenge, since they are involved in therapy resistance, recurrence and metastatic spread. Hence, successful treatment of cancer depends also on the elimination of cancer stem cells. The aim of this study was to investigate the radiation sensitivity of bulk cancer cells and cancer stem cells exposed to external ionizing radiation or Auger-electron emission. **Materials and Methods** Breast (MCF-7) and lung (NCI-H69) cancer cells were grown either as bulk cancer cells in 2D or as cancer stem cells in 3D. The cells were either irradiated with external irradiation (0, 2, 4, 6 and 8 Gy) or incubated with 0, 25, 100, 500, 1000, 2000 or 3000 Bq/ml of the Auger-electron emitting thymidine analogue [125I]5-Iodo-2'-deoxyuridine (125I-UdR). In all experiments, the viability was determined after 7 days using the Cell-Titer Blue assay. **Results** Both cancer cell lines formed spheres when grown in the absence of serum. The lung and breast cancer stem cells were significantly more resistant to external irradiation ($p<0.0001$ for 4, 6 and 8 Gy) than the bulk cancer cells. For the lung cancer cell line, the difference was also significant at 2 Gy ($p<0.005$). Approximately 50% of the cancer stem cells survived the highest dose tested (8 Gy), while the bulk cancer cells were effectively killed. In contrast, when cells were incubated with (125I-UdR), there was no difference in cell survival between cancer stem cells and bulk cancer cells. IC50 values were 183 Bq/ml (145-231 Bq/ml) and 183 Bq/ml (146-229 Bq/ml) for lung and breast bulk cancer cells, respectively. For the cancer stem cells IC50 values were 172 Bq/ml (145-203 Bq/ml) and 247 Bq/ml (182-337 Bq/ml) for lung and breast cancer stem cells, respectively. **Conclusion** The external radiation-resistant cancer stem cells were sensitive to Auger-electron emission by 125I. These results show that Auger-electron emitters have the ability to kill both bulk cancer cells and otherwise therapy-resistant cancer stem cells in different cancer types and that Auger-electron therapy should be further explored for the development of successful cancer treatment.

EP675

Blood flow and glucose metabolism relationship between normal liver and tumor in patients with breast cancer

U. Abdulrezzak[1], H. Akgun[2], M. Kula[1], A. Tutus[1]; [1]Erciyes University, School of Medicine, Department of Nuclear Medicine, Kayseri, TURKEY, [2]Erciyes University, School of Medicine, Department of Pathology, Kayseri, TURKEY.

Aim: The purpose of the study was to determine whether an interrelationship between tumor and normal liver in terms of blood flow kinetics and glucose metabolism with dynamic and static 18F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) in breast cancer patients. **Material and method:** Seventy six patients (75 female, 1 male; age: 50.89±12.89) with histological confirmed breast carcinoma were analyzed immunohistochemically for estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (cerb2), Ki67 index of proliferation. After the IV application of 296-444 MBq (8-12 mCi) of 18F- FDG, dynamic blood flow (*f*) study was performed over the breast region including the upper side of liver (L) for 10 minutes and a static acquisition 60-minute post injection were obtained for glucose metabolism imaging (*m*). The maximum standard uptake (SUVmax) values and mean activity concentration (AC) values (Bq/mL) of T (T-AC*f*, T-AC*m*) and L (L-AC*f*, L-AC*m*) were calculated on a spherical volume of interest (VOI) having a volume of ~1 cm3 in the hottest voxel from *f* and *m* images. The ratios of T to L (T/L-AC*f*, T/L-AC*m*) and the ratio of T-AC*m* to T-AC*f* (T-AC*m*/*f*) were calculated. **Results:** L-AC*f* was strongly negative correlated with the number of metastatic lymph nodes (r=-0.393, p=0.001). There were negative correlation between the L-AC*m* and mitotic grade and between the L-AC*m* and histologic grade (respectively r=-0.295, p=0.018 and r=-0,319, p=0,010). While T/L-AC*m* values were positive correlated with tumor volume, mitotic grade and histological grade (respectively r=0.499, p<0.001; r=0.298, p=0.017 and r=0.302, p=0.015). In triple negative patients, T/L-AC*m* and T-AC*m*/*f* values were significantly higher than those of non-negative patients (p=0.003 and p=0.010). T/L-AC*f* was positive correlated with cerb2 (r=0,246, p=0.036). ER positive patients showed significantly lower T/L-AC*f* and T/L-AC*m* values than those of negative patients (p=0.026 and p=0.007). In the PR positive patients, while L-AC*f* was significantly higher than those of negative (p=0.050); T/L-AC*f*, T/L-AC*m* and T-SUVmax values were significantly lower (respectively p=0.018, p=0.005 and p=0.032). **Conclusion:** In patients with breast cancer, we claim that there is an interconnection between the blood flow-glucose metabolisms of normal liver and breast tumor. While the

blood flow and glucose metabolism of the tumor showed increasing, those of the liver showed decreasing. Further investigations may be helpful in determining which one is triggering factor.

EP676

Angiotensin AT_2 receptors promote differentiation and induce apoptosis in human uterine leiomyosarcoma cells by a peroxisome proliferator-activated receptor gamma - dependent mechanism

Y. Zhao[1], K. Lucht[2], M. Marx[1], M. Zuhayra[1], J. Culman[2], U. Lüthen[1]; [1]Department of Nuclear Medicine, Molecular Imaging, Diagnostic and Therapy, UK-SH, Campus Kiel, Kiel, GERMANY, [2]Institute of Experimental and Clinical Pharmacology, UK-SH, Campus Kiel, Kiel, GERMANY.

Angiotensin AT_2 receptors promote differentiation and induce apoptosis in human uterine leiomyosarcoma cells by a peroxisome proliferator-activated receptor γ – dependent mechanismThe biology of the uterine leiomyosarcoma, the most malignant tumour occurring in the uterus, is poorly understood. The present study clarifies the role of the AT_2 receptor and the peroxisome proliferator-activated receptor γ (PPARγ) in proliferation, differentiation and apoptosis in the human leiomyosarcoma cell line, SK-UT-1 cells. Stimulation of AT_2 receptors was achieved by incubation of the cells with angiotensin II (Ang) II (10^{-7} M) in the presence of the selective AT_1 receptor antagonist, losartan. A 9 h stimulation of AT_2 receptors in SK-UT-1 cells increased the mRNA- and protein levels of smooth muscle differentiation markers, SM22α and calponin. Blockade of the PPARγ by the selective PPARγ antagonist, GW 9662 completely prevented the AT_2 receptor-induced differentiation of SK-UT-1 cells. Activation of AT_2 receptors for 24 h did not alter the proliferation of leiomyosarcoma cells, assessed by ^{3}H-thymidine incorporation and cell counting, but increased ^{99m}Tc-MIBI uptake. Stimulation of AT_2 receptors in SK-UT-1 cells for 48 h activated the intrinsic apoptotic pathway, as evidenced by increased levels of cleaved caspase-3 and Bax, down-regulation of the anti-apoptotic Bcl-2 protein and reduced ^{99m}Tc-MIBI uptake. Blockade of the PPARγ by the GW 9662 prevented the AT_2 receptor-induced caspase-3 activation and the induction of Bax level indicating that activation of the PPARγ is a prerequisite for the AT_2 receptor induced apoptosis in SK-UT-1 cells. These results demonstrate that Ang II acting at AT_2 receptors in leiomyosarcoma cells promotes differentiation at early stage of AT_2 receptor activation and apoptosis at later time points. Both processes are PPARγ – dependent, i.e they require activation of the PPARγ. Our findings provide the rationale for the use of AT_1 receptor antagonists and the PPARγ agonist, pioglitazone, for the treatment of human leiomyosarcomas.

EP677

Effect of cholesterol rich diet on tumor growth in tumor-bearing rat models

E. Galgóczi[1], **G. Trencsényi**[1,2], A. Farkas[3], G. Nagy[2], D. Szikra[1,2], M. Emri[1], I. Garai[1,2], P. Kertai[4]; [1]University of Debrecen, Department of Nuclear Medicine, Debrecen, HUNGARY, [2]Scanomed Ltd., Debrecen, HUNGARY, [3]University of Debrecen, Department of Urology, Debrecen, HUNGARY, [4]University of Debrecen, Department of Preventive Medicine, Debrecen, HUNGARY.

Aim: Cardiovascular diseases and malignant tumors are the major causes of morbidity and mortality in developed countries. Several studies reported that high cholesterol level increases the risk of cancer. The aim of this study was to investigate the effect of cholesterol-rich diet on tumor growth in hypercholesterinaemia-dyslipidemia rat model using ^{18}FDG. Methods: Fischer-344 (n=12) and Long-Evans (n=12) rats were used in this experiments. For the induction of hypercholesterinaemia-dyslipidemia rat model animals were fed with cholesterol-rich diet for two weeks. For the induction of syngenic tumor models My1/De (myelomonoblastic leukemia, $5x10^6$) or Ne/De (mesoblastic nephroma, $3x10^6$) cells were transplanted under the capsule of the left kidney using SRCA (subrenal capsule assay) technique. The tumor growth in control and dyslipidemic rats was followed with ^{18}FDG (11.2±0.2 MBq intravenously) imaging using the nanoScan PET/MRI (Mediso Ltd., Hungary). Two weeks after the tumor cell implantation animals were euthanized, the weights of the tumors were measured and blood samples were taken. Lipid profile (cholesterol, LDL, HDL, triglycerides) was determined from the blood. Results: By using cholesterol-rich diet the total cholesterol, LDL, HDL content of the serum significantly (p=0.001) increased in Ne/De and My1/De tumor-bearing animals. In tumor-bearing groups there were no significant differences in the weights and ^{18}FDG-SUV values of the tumors using different diets: standard diet-Ne/De tumor weight: 8.84±1.3g, SUVmean: 8.2±1.9; cholesterol-rich diet-Ne/De tumor: 9.21±1.4 g, SUVmean: 8.3±1.2). In case of My1/De leukemia animal model similar results were found. Conclusion: We have established a cancer-hypercholesterolemic animal model system in which large number of chemopreventive molecules can be tested quickly and relatively cheaply using small number of animals. In addition, cholesterol-rich diet had no effect on tumor growth in this model.

EP678

Up-regulation of key molecules for targeted imaging and therapy

P. Radojewski[1], V. Taelman[1], N. Marincek[1], A. Ben-Shlomo[2], A. Grotzky[1], C. I. Olariu[1], A. Perren[3], C. Stettler[1], T. Krause[1], L. P. Meier[1], R. Cescato[1], M. A. Walter[1]; [1]University Hospital Bern, Bern, SWITZERLAND, [2]Cedars Sinai Medical Center, Los Angeles, CA, UNITED STATES, [3]University Bern, Bern, SWITZERLAND.

Targeted diagnosis and therapy enable precise tumor detection and treatment. However, patients with tumors expressing low levels of the relevant molecular targets are deemed ineligible for targeted approaches. **Methods:** We performed a screen for drugs that up-regulate members of the somatostatin (sstr) and bombesin (bb) receptor families. Then, we characterized the effects of these drugs on transcriptional, translational and functional levels *in vitro* and *in vivo*. **Results:** We identified nine drugs that act as epigenetic modifiers, including the inhibitor of DNA methyltransferase (DNMT) decitabine as well as the inhibitors of histone deacetylase (HDAC) tacedinaline and romidepsin. *In vitro*, these drugs up-regulated $sstr_2$ and bb_2 on transcriptional, translational and functional level in a time- and dose-dependent manner. Thereby, their combinations revealed synergistic effects. *In vivo*, drug-based $sstr_2$ up-regulation improved the tumor-to-background and tumor-to-kidney ratios, which are the key determinants of successful $sstr_2$-targeted imaging and radiopeptide therapy. **Conclusion:** We present an approach that utilizes epigenetic modifiers to improve $sstr_2$-targeting *in vitro* and *in vivo*. Translation of this method into the clinic may potentially convert patients ineligible for targeted imaging and therapy to eligible candidates.

^{18}F-FDG PET and PET/CT findings in patients with polymyalgia rheumatica

Z. Rehak[1], P. Nemec[2], Z. Fojtik[3], J. Vasina[1], R. Koukalova[1], Z. Bortlicek[4]; [1]Masaryk Memorial Cancer Inst., Brno, CZECH REPUBLIC, [2]St. Anne´s University Hospital, Brno, CZECH REPUBLIC, [3]University Hospital, Brno, CZECH REPUBLIC, [4]Institute of Biostatistics and Analyses, Brno, CZECH REPUBLIC.

Aim: Polymyalgia rheumatica (PMR) is a disease presenting with pain and stiffness, mainly in shoulders, hip joints and neck. Laboratory markers of inflammation may bolster diagnosis. PMR afflicts patients over 50 years old, predominantly women, and may also accompany giant cell arteritis. *Patients and Methods:* 88 patients, who fullfiled Healey´s criteria for PMR in the period between 2004 and 2015 and had positive FDG PET (PET/CT) findings were retrospectively evaluated. FDG uptake was assessed in large arteries, proximal joints (shoulders, hips and sternoclavicular joints), in extraarticular synovial structures (interspinous, ischiogluteal and praepubic area). *Results*: Articular/periarticular involvement (A) was detected in 80/88 (90.9%) patients and extraarticular synovial involvement (E) in 70/88 (79.5%) patients either individually or in combinations. Vascular involvement (V) was detected in 36/88 (40.9%) patients only in combination with articular (A) and/or extraarticular synovial (E) involvement. These combinations were: A+E involvement in 62/88 (70.4%) patients, A+V involvement in 8/88 (9.1%) patients, E+V involvement in 6/88 (6.8%) patients and A+E+V in 22/88 (25%) patients. *Conclusions:* PMR presents by articular/periarticular synovitis, extraarticular synovitis and can be accompanied by giant cell arteritis. All types of involvement have their distinct FDG PET (PET/CT) finding, which can be seen either individually or in any of their 4 combinations. FDG PET (PET/CT) examination seems to be an advantageous one-step examination for detecting different variants of PMR, for assessing extent and severity and also for excluding occult malignancy.

EP680

Usefulness of F-18 FDG PET/CT for Detecting the Extent of Disease in Patients with Sarcoidosis

A. Georgakopoulos[1], N. Pianou[1], E. D. Manali[2], S. Papiris[2], S. N. Chatziioannou[1,3]; [1]Biomedical Research Foundation of the Academy of Athens, Clinical and Translational Research, Nuclear Medicine Division, PET/CT section, Athens, GREECE, [2]2nd Pulmonary Department, "Attikon" University Hospital, Athens Medical School, National and Kapodistrian University of Athens, Athens, GREECE, [3]2nd Radiology Department, "Attikon" University Hospital, Athens Medical School, National and Kapodistrian University of Athens, Athens, GREECE.

Aim:Sarcoidosis is a systematic granulomatous disease of unknown cause. Although lung is the most common site of disease, extrathoracic involvement occurs in 25%-50% of patients. Multi-organ involvement is often associated with a chronic and severe course,thus knowledge of the extent and severity of disease is crucial. The aim of this study is to determine the usefulness of F-18 FDG PET/CT for the detection of extrathoracic involvement in the sarcoidosis patients.Material and Method: Between 2013 and 2015, all biopsy proven sarcoidosis patients, from a tertiary referral center who then underwent F-18 FDG PET/CT were included in the study.18F-FDG was injected intravenously (5.5 MBq/kgr); and none of the patients had blood glucose levels >160 mg/dl. PET/CT images were obtained initially on the brain and then from the base of the skull to the feet. Positive findings were classified as thoracic and/or extrathoracic. Findings were described as positive-extrathoracic if there was increased 18F-FDG activity in one or more of the following: brain,peripheral lymph nodes, spleen, liver, bone/bone marrow, parotid glands, nasopharynx, skin, and muscle. Results: One hundred and ten patients, 66 % female, mean age (±SD) of 52±12.08 years were included. Mean disease duration was 5.9 years and 36.3% of patients were under steroid treatment.Findings consistent with active extrathoracic disease were identified in 58 patients (52.7%). Almost all these patients (96%) also demonstrated active thoracic disease. In 26 patients (23.6%) PET/CT was negative for active disease, while another 26 patients (23.6%) demonstrated only active thoracic disease. A significant percentage (34 patients, 31%) revealed active disease in the musculoskeletal system (muscular 17%, bone 15% and skin 9%). Other very common extrathoracic disease sites there were in peripheral lymph node stations, mainly in supraclavicular (25%), low cervical (17%), axillary (14,5%), retroperitoneal (17%), iliac (13%) and also in inguinal lymph nodes (32%). Active disease was also detected in organs such as the spleen (11%) and to a lesser percentage in the liver (5%) as well as in the parotid glands (3%). None of the patients revealed active brain disease. Conclusion: F-18 FDG PET/CT provides significant information in the assessment of extent and distribution of inflammatory activity in sarcoidosis, identifying in a large percentage of patients unsuspected and otherwise undetectable extrathoracic disease.

EP681

The Impact of 18F FDG PET/CT in Evaluating Thoracic Activity Disease in Patients with Sarcoidosis

N. Pianou[1], A. Georgakopoulos[1], E. Manali[2], S. Papiris[2], S. Chatziioannou[1,3]; [1]Biomedical Research Foundation, Academy of Athens, Nuclear Medicine Division, Athens, GREECE, [2]2nd Pulmonary Department, "Attikon" University Hospital, Athens Medical School, National and Kapodistrian University of Athens, Athens, GREECE, [3]2nd Radiology Department, "Attikon" University Hospital, Athens Medical School, National and Kapodistrian University of Athens, Nuclear Medicine Division, Athens, GREECE.

Aim: Sarcoidosis is a systemic disease of unknown cause, characterized by the presence of granulomas in one or more organs, most commonly in the lungs. The ability to reveil unsuspected and persisting inflammatory activity may add in patient evaluation. The aim of the study is to investigate the role of 18F-Fluoro-deoxyglucose Positron Emission Tomography/Computerized Tomography (18F-FDG PET/CT) in the evaluation of disease activity in the thorax. Material & Methods: We evaluated patients with biopsy proven sarcoidosis with a whole body 18F-FDG PET/CT scan from the base of the skull to the feet, by intravenously injecting 18F-FDG (5.5 MBq/kgr). In order to evaluate the myocardial involvement, we also performed a prolonged fasting and appropriate modification of low carbohydrate diet for 18 hours to suppress the 18F-FDG uptake from normal myocardial cells. Results: During 2014-2016 we studied 90 patients with known sarcoidosis, 53 women and 37 men (mean age 52y, range 31-81y). The average glucose values before the scan was 98 mg/dl (range 67-189 mg/dl). The thoracic involvement includes lung parenchyma, mediastinal and hilar lymph nodes, phrenic and axillary lymph nodes, as well as pleural, pericardial and left ventricle myocardial involvement. Findings consistent with active thoracic disease were identified in 27 patients (30%), in 20 patients (22.2%) PET/CT was negative for active disease, 23 patients (25.5%) demonstrated thoracic and also extrathoracic disease, while 3 patients (3.3%) had only extrathoracic disease. Based on 18F-FDG/PET/CT findings, 28 patients had lung active disease (31.1%). A significant percentage (49 patients, 54.4 %) revealed bilateral lymphadenopathy consistent with active disease, while other very common sites of lymph node involvement included upper/anterior mediastinum (17 patients, 18.8%), upper and lower paratracheal area (73 patients, 81.1%), pretracheal area (19 patients, 21.1%), prevascular area (38 patients, 42.2%), subcarinal area (42 patients, 46.6%), aortopulmonary window (27 patients, 30%), paraoesophageal area (15 patients, 16.6%), phrenic area (9 patients, 10%), paracardial area (2 patients, 2.2%), internal mammary chain (7 patients, 7.7%) and axillae (18 patients, 20%). Other sites of involvement were pleura (3 patients, 3.3%), pericardium (2 patients, 2.2%) and left ventricle myocardium (6 patients, 6.6%). The SUVmax values of the hypermetabolic lesions of the lung parenchyma, the mediastinal and hilar lymph nodes showed a range of 1.4-10.0, 1.7-20.5 and 1.8-17.3 respectively. Conclusion: 18F-FDG PET/CT contributes significantly in the evaluation of thoracic disease activity in patients with sarcoidosis and could guide therapeutic decisions.

EP682

Assessment of the role of 18F-FDG PET/CT in the diagnosis of cardiac sarcoidosis

M. GODOY BRAVO, L. FRUTOS ESTEBAN, J. GIMENO BLANES, M. IBAÑEZ IBAÑEZ, R. REYES MARLES, I. SIME LOAYZA, L. MOHAMED SALEM, J. NAVARRO FERNANDEZ, M. CASTELLON SANCHEZ, F. NICOLAS RUIZ, M. CLAVER VALDERAS; HOSPITAL CLINICO UNIVERSITARIO VIRGEN DE LA ARRIXACA, MURCIA, SPAIN.

AIM: Cardiac sarcoidosis (CS) is due to granulomatous infiltration of the myocardium, causing restrictive cardiomyopathy or heart failure, and it should be diagnosed by a combination of clinical, analytical, electrocardiographic, morphological, metabolic and histological findings.We evaluate the usefulness of the metabolic diagnosis of CS by 18F-FDG PET/CT (PET/CT). MATERIALS AND METHODS: We studied prospectively a number of 30 PET/CT carried out since January 2014 to March 2016, 27 of them at initial diagnosis and the other 3 for response assessment. All of them received a standard dose of 370 MBq 18F-FDG, in most of them preceded by heparin 50 UI/kg iv 15 minutes before. They followed the protocol of 12-18h of overnight fasting before study preceded by a low carbohydrate diet the day before. We performed acquisition of whole-body images at 60 minutes and delayed cardiac images 180 minutes respectively after 18F-FDG injection. RESULTS: 16 of the 30 PET/CT were negative, 10 were positive (classified according either patchy or focal pattern) and 4 could not be interpreted (deficient patient preparation or difficult assessment because of cardiac physiological uptake).8 of the10 positive PET/CT had patchy pattern (5 at initial diagnosis and 3 for response assessment) and 2 had focal pattern. All patients with patchy pattern PET/CT at initial diagnosis (5) were confirmed for CS: 4 were consistent with the endocardial biopsy and 1 with clinical evaluation. The 2 patients with focal pattern PET/CT were inconclusive for CS (1 patient with inespecific biopsy and 1 patient still under study).All patients with negative PET/CT (16) had favorable clinical course with no specific therapy for CS.In all patients with positive PET/CT that were confirmed for CS, delayed cardiac images showed a greater increase in FDG uptake than in early whole-body images. CONCLUSION: PET/CT is a powerful tool both for the diagnosis of CS and follow up in order to evaluate therapy response. PET/CT is useful for diagnosing CS with an adequate pre-treatment such as overnight fasting > 12h preceded by a low carbohydrate diet. According to our study: -A negative PET/CT allows excluding the diagnosis of CS and thus, it could avoid implementing an invasive procedure like endocardial biopsy. -A positive PET/CT strongly supports the diagnosis of CS.

EP683

Pulmonary mycobacterial solitary masses evaluated by FDG PET/CT

K. Hayasaka, T. Saitoh, M. Fukasawa, H. Inoue, Y. Shiraishi, F. Kikuchi, T. Yoshiyama, A. Kurashima, H. Gotou; Fukujuji Hospital, Japan Anti-tuberculosis Association, Tokyo, JAPAN.

PurposeTo define the features of pulmonary mycobacterial solitary masses on F-18 FDG PET/CT images. **Materials and Methods** This retrospective study reviewed the medical records, F-18 FDG PET findings and other data of 56 mycobacterial masses in 53 patients (male, n = 27; female, n= 26; age, 70.2 y; SD, 12.0 y) with pulmonary mycobacteriosis (Mycobacterium tuberculosis [TB], n = 16; Mycobacterium avium-intracellulare complex [MAC], n = 40). Mycobacteriosis was confirmed by biopsy (n = 27), surgery (n = 17) and bacterial culture (all) according to ATS/IDSA statement 2007. Maximum standardized uptake values (SUVmax) and ratios of changes in the SUVmax (%CR-SUVmax) were compared between F-18 FDG PET images of 56 and 39 lesions acquired at one (E-SUVmax) and two (D-SUVmax) hours, respectively, after FDG injection. All data were statistically analyzed using SPSS Version 11.0 software (SPSS Inc., Chicago, IL, USA). Statistical significance was set at $p < 0.05$. **Results** The mean (SD) sizes of the TB and MAC masses were 24.7 (14.8) and 20.7 (8.0) mm, respectively. Differences in nodule size did not significantly differ ($p = 0.380$) between the two. The means (SD) of the E-SUVmax, D-SUVmax and the %CR-SUVmax in TB and MAC disease were 3.8 (2.2), 5.0 (2.8) and 28.4(16.9), and 4.8 (3.1), 5.2 (3.8) and 17.5 (19.0), respectively. The E-SUVmax ($p = 0.721$), D-SUVmax ($p = 0.744$) and %CR-SUVmax ($p = 0.064$) did not significantly differ between TB and MAC disease. Pearson correlations between mass size and E-SUVmax, D-SUVmax and %CR-SUVmax were $r = 0.717$ ($p = 0.002$), $r = 0.576$ ($p = 0.010$) and $r = -0.268$ ($p = 0.377$) for TB, and $r = 0.478$ ($p = 0.002$), $r = 0.193$ ($p = 0.344$) and $r = -0.214$ ($p = 0.294$) for MAC disease, respectively. Differences were statistically significant between mass and E-SUVmax and D-SUVmax for TB, and between mass and E-SUVmax for MAC disease. **Conclusion** F-18 FDG PET/CT can help to evaluate the disease activity of TB and MAC disease, and might be useful for selecting appropriate anti-mycobacterial chemotherapy and assessing its effects on TB and MAC disease. However, this should be confirmed in further prospective studies.

EP684

Clinical Impact of 18F-FDG-PET/CT in Patients with Suspected Cardiac Device Infection

B. Rodriguez-Alfonso, J. Mucientes-Rasilla, V. Castro, I. Zegri, A. Ramos-Martinez, A. Prieto Soriano, M. Mitjavila-Casanovas; Hospital Universitario Puerta de Hierro, Majadahonda (Madrid), SPAIN.

AIM: Infections related to cardiac implantable electronic devices (CIED) are increasing in incidence. CIEDs have intravascular and extravascular components. Infection can involve generator pocket, leads and/or native cardiac structures. It is mandatory to accurate diagnose the presence and extent of the infection as it affects the decision to complete or partially remove CIED or to manage it with antimicrobial therapy. The aim of this study was to analyse the diagnostic performance of ^{18}F-FDG-PET/CT in suspected CIED infection and to assess its clinical impact on patient management. MATERIALS AND METHODS: All patients suspected of having CIED infection referred to our PET/CT department from 08/2011 to 02/2016 were retrospectively analysed. Patients were classified according to modified Duke criteria to determine the pre-PET probability of having CIED-related infective endocarditis (CIED-IE) and by clinical exam to determine superficial skin or pocket infection. ^{18}F-FDG-PET/CT studies were visually analysed and interpreted as positive or negative for superficial infection, pocket infection or CIED-IE based upon the presence and location of ^{18}F-FDG hotspots. Definite diagnosis was established by material cultures from the CIED in case of removal or by clinical follow-up and committee agreement in case of only antimicrobial treatment. Pre-test probability and PET/CT results were compared with final diagnosis to calculate sensitivity and specificity. Clinical impact of PET/CT on treatment decisions was also assessed.RESULTS: Twenty-nine patients were included (15 pacemakers and 14 cardioverter defibrillators). Definite diagnosis was obtained after CIED removal in 14 patients and by follow-up in 15. CIED-IE was established in 11 patients, pocket infection in 3 and infection was ruled-out or limited to the skin in 15. Sensitivity and specificity of PET/CT for the detection of CIED-IE were 81% and 94.7% respectively (pre-PET assessment according to modified Duke Criteria showed a sensitivity 63.6% and specificity 38.9%). Additionally PET/CT correctly detected an unsuspected aortic graft infection, a septic arthritis of hip and septic emboli to the lungs (2 patients). Also an unknown papillary thyroid carcinoma and low-grade colonic neoplasm were depicted. PET/CT information was essential to determine complete removal of 3 CIED. The overall impact on patient management was 17.2%. CONCLUSION ^{18}F-FDG-PET/CT can accurately diagnose

IE and performs better than modified Duke criteria in patients suspected of having CIED infection. ^{18}F-FDG-PET/CT leads to changes on patient management, being sometimes the most robust evidence for the need of CIED removal. ^{18}F-FGD-PET/CT enables the detection of unsuspected secondary or concomitant relevant process, allowing early interventions.

EP685
Renal Kinetics of ^{11}C-Metformin

S. Jakobsen, O. L. Munk, A. K. O. Alstrup, J. Frøkiær; Aarhus University Hospital, Aarhus, DENMARK.

INTRODUCTION In the search for a PET tracer suitable for kidney studies, we recently synthesized ^{11}C-metformin and evaluated the tracer in healthy animals[1-2] and humans[3], as well as in a mouse model of chronic kidney disease[4]. Consistently, ^{11}C-metformin showed rapid renal kinetics, which could not be described by standard compartment models. Thus, our aim is to develop a physiologically based modeling of renal ^{11}C-metformin PET data, that gives information on renal plasma flow and mean parenchymal transit time. The ensuing model should also be able to handle the kinetics of other tracers, such as ^{15}O-H_2O and ^{15}O-CO. METHODS Anesthesized pigs with catheters placed in the femoral artery, left renal vein and both ureters allowed detailed analysis of renal tracer handling. A flow probe placed around the left renal artery allowed constant monitoring of renal blood flow. Dynamic PET scans with ^{15}O-H_2O, ^{15}O-CO and ^{11}C-metformin were performed with simultaneous blood and urine sampling. In parallel, constant infusion renal clearance of ^{131}I-hippurate was performed. Regions of interest (ROIs) of renal cortex and medulla were drawn on a contrast enhanced CT image which allowed us to generate time-activity curves (TACs) on the coregistered PET images. Furthermore, data from the initial human study with 5 volunteers consisted of plasma, whole blood and renal parenchymal TACs. RESULTS In its current form, our new model encompasses the renal cortex uptake processes (filtration plus secretion) and the urine flow which serve to remove activity from the ROI. In the single pig analyzed so far, cortical uptake of ^{11}C-metformin was fast (K_1=2.2 ml/ml/min), the renal extraction fraction of ^{11}C-metformin was 0.9-0.95 and that of ^{131}I-hippurate was 0.65-0.75. Blood flow from ^{15}O-H_2O PET scans (2.2 ml/ml/min) in agreement with flow probe measurements (220-245 ml/min/whole kidney) and the blood volume (^{15}O-CO PET) was determined to 16% (cortex) and 14% (medulla). Kinetic analysis also indicated that information on cortical urine outflow is necessary to model medulla ^{11}C-metformin TAC. CONCLUSION ^{11}C-metformin shows very attractive properties for renal PET application (no metabolism, < 0.5% plasma protein binding, very high extraction fraction) and with some adjustments we believe that the model can adequately describe the human kidney ^{11}C-metformin PET data. This will allow simultaneous determination of renal plasma flow and mean parenchymal transit time. [1] Jakobsen S *et al*. J_Nucl_Med_2016_57:615-621 [2] Jensen JB *et al*. EP686
Effect of Reduced CT-Tube Current on Quantitative PET Values in Hybrid PET/CT

P. Ritt[1], T. Kuwert[1], M. Kramer[2]; [1]Clinic of Nuclear Medicine - University Hospital Erlangen, Erlangen, GERMANY, [2]Institute of Radiology - University Hospital Erlangen, Erlangen, GERMANY.

Aim: It is known from phantom experiments, that the current of the CT's X-ray tube not only affects the CT image quality but also, to a small extent, the quantitative PET values of hybrid PET/CT. Unfortunately, studies using real patient data are still lacking. The aim of this work was to determine the influence of reduced CT tube currents onto attenuation correction and quantitative PET values for patient acquisitions. *Methods:* 20 patients underwent a standard FDG-PET/CT examination. CTs were acquired at diagnostic quality with an average effective tube current time product of 168 mAs (100% = 7.3 mGy CTDIvol) at 100 kV tube voltage. Using a method which we validated on phantom scans, the patients' CT raw data were computationally modified in order to simulate scans with reduced tube current, without the actual need for additional scans. By this, CT images with 75% (126 mAs), 50% (84 mAs), 25% (42 mAs), and 5% (8.4 mAs) of the initial tube current were generated and applied for AC of the PET data. The differences between PET images based on attenuation correction with 100% tube current and the reduced currents were evaluated by determining liver SUVmean, SUVmax in FDG-positive lesions, and ratio SUVmean liver to SUVmax lesion. *Results:* Liver SUVmean, lesion SUVmax, and their ratio were marginally - but statistically significantly ($p<0.05$) - increased for reconstructions based on reduced CT currents. The average increase from 100% to 5% tube current was 1.3±0.6%, 0.6±0.4%, and 0.8±0.7% for SUVmean, SUVmax, and ratio, respectively. The maximal occurring changes for any patient were 2.2%, 1.4%, and 2.1% for SUVmean, SUVmax, and ratio, respectively. The deviations increased with decreasing tube current. *Conclusion:* We validated a method for computationally simulating datasets with reduced CT current. We applied that method on patient CTs and evaluated the influence on attenuation corrected PET images. We found that a reduced CT current and increase in image noise caused slight increase in PET SUVs. Although statistically significant, the effect is of such small extent that it'll most likely have no consequences for clinical routine.

EP687
Potential impact of different reconstruction algorithms on FDG PET-CT semiquantitative measurement: a correlation study between SUVmax and lesions volume

I. Rambaldi, I. Santi, S. Panareo, S. Taralli, V. Schincaglia, L. Lodi, L. Uccelli, C. Cittanti; Nuclear Medicine Unit, Ferrara, ITALY.

Aim: in oncological imaging the ^{18}F-FDG tissues accumulation evaluated with PET-CT is proportional to the amount of increased glucose metabolism. Its semi-quantitative measure (SUV) has quickly become the most common parameter used for detection, staging, restaging and therapy response evaluation in clinical oncology. The aim of this study was to compare PET-CT image reconstruction with standard iterative (IR) vs new True-X-TOF (Siemens Medical Solutions, Erlangen, Germany) method in order to assess their potential impact on quantification. Methods: we retrospectively analyzed 189 PET-CT lesions in lung cancer (92 pulmonary nodules, 67 metastatic lymph nodes) and lymphoma patients (30 Hodgkin or Non-Hodgkin pathologic lymph nodes). SUVmax and volume were calculated with IR and True-X-TOF. The distribution of SUVmax, in relation to the reconstruction method used, was statistically studied by linear regression (frequency distribution curves and scatter plots). The relationship between volume and ratio between SUVmax True-X-TOF and IR was evaluated and studied with box-plots. Results: True-X-TOF over iterative SUV ratios "x" were divided into three groups, I $1.0\leq x\leq 1.5$, II $1.5<x\leq 2.0$, III $x>2.0$, inside which regression correlation stays excellent (R=0.996, 0.996 and 0.993 respectively). Among the three groups a statistically significant stratification of ratios between lesion volumes and SUV ratio values was observed ($p<0.001$): smaller volumes are associated to greater SUV ratios while larger volumes (>2cm^3) are associated to SUV ratios closer to 1. Pulmonary lesions and lymph nodes represented 70% and 30% respectively of findings in group I, and 45% and 55% in group II and III combined. Conclusions: FDG PET-CT SUV is determined by a lot of parameters, among which acquisition and reconstruction techniques can play a pivotal role. Our preliminary data, obtained from a daily clinical setting, demonstrated that True-X+TOF shows greater SUV values in comparison to IR method. However, greater differential SUVmax values were identified in small lesions compared to larger ones, probably meaning that IR underestimates SUV in smaller

lesions. Therefore, True-X+TOF reconstruction algorithm seems to allow more sensitive metabolic characterization of small lesions in comparison to iterative methods making the impact of that feature more relevant in staging and prognostic stratification of lymph nodes than of generally larger pulmonary lesions. Moreover our study highlights the risk to compare PET-CT scans obtained with different reconstruction methods during clinical follow-up and so the importance of standardization in PET-CT imaging. Larger clinical prospective trials are mandatory to confirm these preliminary findings and to assess their potential impact in clinical practice.

EP688

Clinical Utility Of F-18 FDG PET/CT In Initial Evaluation And Response Assessment Of Langerhans Cell Histiocytosis

K. Shilpa, M. Indirani, S. Shelley, A. Jaykanth, J. Avani, K. Abhishek; Apollo hospital, Chennai, INDIA.

AIM/ OBJECTIVE: Langerhans cell histiocytosis (LCH) is a rare multisystem disorder caused by idiopathic proliferation of histiocytes. It represents a wide spectrum of disorders which varies from asymptomatic to severe, life-threatening complications. Frequently used indications for F-18 FDG PET/CT are in evaluation for malignancy and infection. Aim of this study is to evaluate the findings of F-18 FDG PET/CT and its utility role in this cancer like disease LCH. **METHODS:** Fourteen patients (9 children, 5 adults; 8 males, 6 females) who were diagnosed histopathologically as LCH were evaluated. After conventional imaging (MRI/CT/X-rays) all 14 patients had undergone F-18 FDG PET/CT scan before commencement of treatment with 3 patients also underwent post therapy follow-up F-18 FDG PET/CT scans. **RESULTS:** Out of the 14 patients in the study, 12 had skeletal lesions and 2 had extra-skeletal lesions- one each in choroid plexus and in parotid gland. All the lesions showed increased FDG uptake. In the 12 cases with skeletal involvement 5 were unifocal and 7 were multifocal. In the 5 unifocal cases, 3 showed additional metabolically active lesions on F-18 FDG PET/CT scan. In patients with multifocal skeletal involvement, F-18 FDG PET/CT scans showed numerous additional lesions compared to MRI/CT. In addition 4 out of these 12 patients had evidence of extra-skeletal involvement also, 2 in the lymph nodes and one each in liver and lung. In the patient with left parotid gland lesion, additional active lesions were noted in the thymus, submandibular glands whereas in the patient with choroid plexus involvement no other lesion was detected. In the 3 patients with post treatment follow-up F-18 FDG PET/CT scan, complete resolution was noted in 2 patients while 1 showed metabolically inactive residual lytic lesion. Overall F-18 FDG PET/CT was more sensitive and superior in lesion identification as compared to conventional imaging. **CONCLUSIONS:** F-18 FDG PET/CT is a sensitive tool for early identification of multiple skeletal as well as extra-skeletal active lesions helping in stratification and treatment of disease. F-18 FDG PET/CT acts as a single "one-stop" modality of imaging which demonstrates the dissemination of disease in the whole body and provides a clear picture of soft tissue involvement. It has an important role in monitoring response to treatment and detection of recurrence as well.

EP689

Do clinical and laboratory variables have any impact in the diagnostic performance of 18F-FDG PET/CT in patients with long-term fever?

M. TELLO GALÁN[1], A. GARCÍA VICENTE[1], J. ROS IZQUIERDO[2], M. AMO-SALAS[3], B. LA ROSA SALAS[2], G. SERRANO PRADAS[2], G. JIMÉNEZ LONDOÑO[1], N. DISOTUAR RUIZ[1], J. CORDERO GARCÍA[1], A. PALOMAR MUÑOZ[1], Á. SORIANO CASTREJÓN[1]; [1]NUCLEAR MEDICINE DEPARTMENT HGUCR, Ciudad Real, SPAIN, [2]INTERNAL MEDICINE DEPARTMENT HGUCR, Ciudad Real, SPAIN, [3]MATHEMATICS DEPARTMENT UCLM, Ciudad Real, SPAIN.

Objective: To assess the influence of clinical features and laboratory test results in the origin determination of the fever by means of 18F-FDG PET/CT. *Methods:* Retrospective and longitudinal analysis, including all the PET/CT studies requested for long term fever without a diagnosis performed in our department (2007-2015). Clinical pictures were classified as fever of unknown origin (FUO), inflammation of unknown origin or others. The existence of fever, 7 days before or after PET/CT, immunosuppressant risk factors, previous or active neoplasm and surgery or invasive procedures 3 months previous to PET/CT, among others, were extracted. Patients with a final diagnosis or a follow-up time greater than 12 months were included. Reference standard was established by serology, cultures or biopsy with other laboratory tests or clinical follow-up when necessary. Inflammation markers, protein analysis, serology and culture results, close to the PET scan were obtained. The final diagnosis was classified in 3 groups: group 1: focal aetiology (infection or neoplasm), group 2: diffuse aetiology (vasculitis, autoimmune disease or non infectious inflammatory disease) and group 3: others (auto-limited fever or fever persists without diagnosis). PET/CT scans were classified as positive (conclusive or unspecific findings) or negative and moreover in helpful or not in the diagnosis of the fever origin. The effect of clinical features and laboratory test variables in the PET/CT results was analysed. *Results* Sixty-seven patients met the inclusion criteria. The final diagnosis was: Group 1 (25), Group 2 (20) and Group 3 (22, 13 auto-limited). 64.2% of the patients was classified as FUO. 90.9% had positive inflammatory markers (79% of them ≥3), 31.7% protein alterations and 21.2% positive cultures. PET/CT was positive in 54/67 patients (44.8% conclusive and 35.8% unspecific findings). PET/CT helped in the establishment of the fever origin in 52.2% of the cases and was especially helpful in groups 1 and 2 (p=0.035). Sensitivity, specificity and accuracy of PET/CT were: 84%, 31% and 61%. PET results shown relations with the final diagnosis (p=0.035), cultures (p=0.055), inflammation markers (p=0.029) and protein analysis (p=0.064). No significant relations were observed with the rest of clinical or laboratory variables. *Conclusions:* 18F-FDG PET/CT had a high sensitivity although a low specificity in the diagnosis of the fever origin, probably due to the high rate of diffuse and auto-limited aetiologies. Patients most likely to benefit from the PET/CT study would be those with several positive inflammation markers reflecting a higher pre-test probability of active disease.

EP690

Intrapatient Comparison of 18F-Fluodeoxyglucose Positron Emission Tomography/Computed Tomography (PET/CT) in Patients with a Driveline Infection after Left Ventricular Assist Device (LVAD) implantation

P. Kanapinn, R. Preuß, W. Burchert, J. Körfer; Heart and Diabetes Center North Rhine-Westphalia, Bad Oeynhausen, GERMANY.

Aim. Driveline infection (DI) after left ventricular assist device (LVAD) implantation is a challenging condition in longterm support of patients with chronic heart failure. While some studies evaluated the role of 18F-Fluodeoxyglucose (FDG) Positron Emission Tomography/Computed Tomography (PET/CT), little is known about the intrapatient changes in PET/CT after DI. *Material and Methods.* Fourteen patients underwent a whole body FDG PET/CT at first in the context of a heart transplantation listing or because of fever of unknown origin - with no clinical signs of a DI. At a later date, these patients received a second PET/CT because of a clinically suspected DI. PET/CT findings were analysed qualitatively and quantitatively. The results of the two PET/CTs were compared. Clinical and microbiological data were obtained. *Results.* Qualitative comparison of the two PET/CTs revealed a superficial DI (above the transverse fascia) in five cases and a deep DI (below the transverse fascia, with additional signs of an infection of either the outflow cannula or the device) in nine cases. The mean time to infection was 521 days. Quantitative analysis of the SUV_{max} around the driveline showed an increase by the factor of 3.26

(mean SUV_{max} before infection 4.96; mean SUV_{max} after infection 16.18). However, the other sites of the LVAD showed no significant difference. *Conclusion.* FDG PET/CT is a frequently used diagnostic tool in the setting of a suspected DI. This study illustrates the intrapatient changes in uptake pattern of a DI after LVAD implantation. It is implied that PET/CT can differentiate qualitatively between superficial and deep DI, but the quantitative analysis is only reliable for the area around the driveline.

EP691

Our experience of the clinical utility of F18-FDG PET/CT in the therapeutic response of cardiac sarcoidosis

K. L. Wallitt, S. R. Khan, S. Yusuf, N. Soneji, D. Gopalan, W. Svensson; Imperial NHS Trust, London, UNITED KINGDOM.

Aim:Review cases where F18-FDG PET/CT was utilized in the assessment of therapy for cardiac sarcoidosis (CS), and their outcomes. Materials & Methods:57 cardiac F18-FDG PET/CTs (resting gated cardiac and whole body PET/CT following an 18 hour fast) have so far been performed at Imperial NHS Trust, UK in suspected/established CS. Of these, 4 patients with serial PET/CTs following a course of therapy for CS were selected. Individual cases were reviewed noting clinical manifestations of their cardiac disease, treatments received at baseline and follow-up imaging, and their PET/CT findings. The distribution of FDG uptake (focal, in-homogenous or diffuse, homogenous), maximum standardized uptake values (SUVs) and myocardial to blood pool ratios were recorded. Results:4 patients had serial imaging to monitor disease response to therapy. All patients had active disease in a focal, in-homogenous distribution. One had concurrent pulmonary sarcoidosis. 2 patients had a permanent pacemaker (PPM), which precluded assessment with MRI. 2 patients had left ventricular dysfunction (LVD), of which one had severe heart failure; MRI could not be performed in this patient due to breathing difficulties. 1 patient had AV block, and 1 patient had both arrhythmogenic disease and LVD. All patients at baseline were receiving steroids, with or without immunotherapy. In 3 patients, there was a good response to therapy. In one of these patients, there was initially some disease response, but echocardiogram demonstrated worsening left ventricular function leading to a change in therapy. A subsequent PET/CT demonstrated complete metabolic response but the patient developed cryptococcal meningitis and reactive nodes from immunosuppression. Concurrent pulmonary disease responded in-line with cardiac disease in this patient. In the fourth patient there was disease progression, which led to a change in therapy. Conclusion:The role of F18-FDG PET/CT for disease response in CS has not yet been fully established, however we have found that in all 4 of our cases, F18-FDG PET/CT has had a positive role in optimizing therapy, with the aim of preventing end stage heart failure. Our experience also highlighted its use in patients with a PPM or breathing difficulties from severe LVD precluding assessment with MRI, and in assessing non-sarcoid

EP692

Usefulness of 18F-FDG-PET/CT in IgG4-Related Disease

B. Rodriguez-Alfonso, C. Field-Galan, J. Mucientes-Rasilla, J. Mulero Mendoza, R. Jimeno Pernett, J. Cardona-Arboniés, M. Mitjavila Casanovas; Hospital Universitario Puerta de Hierro, Majadahonda (Madrid), SPAIN.

AIM: To describe the most usual findings in IgG4-related disease in 18F-FDG-PET/CT and their correlation with the serum concentration levels of IgG4 as well as the use of PET/TC in monitoring treatment response. MATERIAL AND METHODS: We have retrospectively analysed all the PET/CT studies performed at baseline when IgG4-related disease was suspected or performed as response to treatment. We included all patients with histological confirmation or high serum concentration levels of IgG4 and those with high suspicion although no histological or serum confirmation when no other entity could be assumed. Images were visually analysed. A positive PET/CT was considered when hot spots outside physiological uptake areas were detected. SUVmax of the most representative lesions were collected. The results were correlated with the clinical data and IgG4 levels. RESULTS: 13 patients have been referred for PET/CT since 2010 for IgG4-related disease suspicion. 4 have been excluded as the final diagnoses were others (sarcoidosis, lymphoma, amyloidosis and malignancy). The histological diagnosis was obtained in 6 patients, 2 of which had also high IgG4 serum concentration levels. One patient was exclusively diagnosed by elevated serum levels of IgG4 and 2 by high clinical suspicion. Nine patients underwent baseline PET/CT of which 5 had also PET/CT study for monitoring response. 6 PET/CT baseline studies showed positive findings. The most affected areas in accordance with the PET/CT images were retroperitoneum (4), lung (3), hilum/mediastinum(2), retro-orbital space (2) salivary glands(2). Higher levels of IgG4 were correlated with higher SUVmax at baseline. Negative PET /CT (3) were correlated with no increase in IGg4 levels. When monitoring response to treatment a negative PET/CT correlated with a normalization of the serum levels of IgG4 and in patients with no serum elevation of IgG4 at baseline, PET/CT was useful to asses disease progression (1 patient) and good treatment response (1patient), determining in both cases further treatment (impact on patient management 22%). CONCLUSION: Our results suggest PET/CT is a useful tool in the diagnosis and extension assessment of IGg4-related disease and in monitoring treatment response, specially in patients with no elevated serum levels of IgG4.

EP693

Optimization and evaluation of low dose CT protocol for attenuation correction of PET data

Z. Mojabi[1,2], P. Ghafarian[3,4], H. Ghadiri[1,2], M. Bakhshayeshkaram[3,4], H. Jamaati[3], **M. Ay**[1,2]; [1]Department of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Chronic Respiratory Diseases Research Centre, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]PET/CT and Cyclotron Centre, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Purpose: It is obvious that among all imaging modalities, X-ray computed tomography (CT) has the highest patient adsorbed dose. The critical point of interest is the growth usage of CT lonely for diagnostic and also as attenuation correction (AC) for quantification and localization in PET/CT images. In this study, we aim to analyze and evaluate the possibility of using low dose CT for attenuation correction while keeping optimal image quality. **Materials and Methods:** Quality assurance (QA) and cylindrical phantom were scanned with Discovery 690 GE PET/CT scanner that equipped with 64-slice CT. Smart mA with various noise index(NI) and fixed mA method at various tube voltage (80,100 and 120kVp), tube current(20-100mA), 1s rotation time and various pitch number was utilized. We also use the CT Dosimetry software which works based on Monte Carlo simulation to estimate organ absorbed dose. Optimization of low dose CT protocol was designed based on both quantitative factors such as modulation transfer function (MTF), contrast to noise ratio (CNR) and image noise and qualitative. **Results:** at 100kVp, 3.75 mm slice thickness and NI of 19 the CNR and image noise was 29.86 and 3.22HU when smart mA was applied, while fixed mA method (10mAs) can lead to 14.75 and 6.44 for CNR and noise respectively. With decreasing slice thickness from 3.75 to 2.5 mm and using smart mA method with

NI of 19 and 100 kVp tube voltage, CNR decline 53 %. MTF illustrated 97.6%, 93.06%, 72.96%, 49.86%, 34.19%, and 31.99% ,when resolution were 1.6, 1.3, 1, 0.8, 0.6, 0.5mm respectively (100 kVp, smart mA, 3.75mm slice thickness). However when using 10 mAs, the value of 78.78%, 49.21%, 51.11%, 30.88% reported for MTF and the resolution bar of 0.6, 0.5mm disappeared. By decreasing tube voltage form 120 to 80, Dose length product (DLP) was declined 59%, meanwhile MTF, at 0.5 mm resolution increased 42%. **Conclusion:** This study demonstrates a possibility of reducing the dose of patients while maintaining image quality that meets diagnostic radiology goals. MTF increased by decreasing kVp from 120 to 80 when smart mA method was used while DLP was diminished. It should be noted that, utilizing low fixed mA in comparison with smart mA method can lead to miss smaller lesion. However combination of proper tube current and NI must apply when using smart mA method.

EP694

Role of FDG PET-CT in Distinction of benign thrombus and tumor thrombus in Oncologic Patients and Additional Contribution to Other Radiological Imaging Methods

P. Ozcan Kara[1], E. Yaman Sezer[2], Z. Koc[1], E. Yilmaz[3]; [1]Mersin University Faculty of Medicine Department of Nuclear Medicine, Mersin, TURKEY, [2]Mersin University Faculty of Medicine Department of Oncology, Mersin, TURKEY, [3]Mersin University Faculty of Medicine Department of Radiation Oncology, Mersin, TURKEY.

Aim: Accurate diagnosis of tumor thrombus and distinguishing benign thrombus from tumor thrombus avoid unnecessary anticoagulant treatment of oncological patients and it is important for the patient management. In this prospective study, we aimed to demonstrate the role of Fluorodeoxyglucose (FDG) PET-CT imaging for the distinction of benign thrombus from tumor thrombus and to compare it with other radiological methods. **Materials and Methods:** FDG-PET/CT imaging performed for staging, restaging and treatment response in oncological patients patients with thrombus were evaluated for accurate diagnosis of tumor thrombus and distinguishing benign thrombus from tumor thrombus by the examination of maximum standard uptake value (SUVmax). PET-CT imaging were evaluated both with visual assessment and increased metabolic activity. PET-CT findings were confirmed by clinical follow-up and biopsy in some cases. **Results:** PET-CT imaging findings of a total of 13 patients with suspected tumor thrombus (11 men, 2 women, mean age: 51-range: 22-82) were evaluated. Tumor thrombus in 5 segments in 5 patients (3 linear, 2 focal) and benign thrombus in 17 regions in the other 8 patients were reported in the evaluation of a total of 22 thrombi region in 13 patients on visual analysis and according to the increased metabolic activity. The most common region of thrombosis was defined as vena cava inferior. SUVmax values ranged from 9.27 to 19.45 in 5 tumor thrombus patients. Compared to mediastinal region increased metabolic activity was not detected in none of the 8 patients with benign thrombus and these patients were treated with anticoagulant agents. **Discussion:** In a similar study in the literature for distinguishing benign and malignant tumor thrombus reported 71.4% sensitivity and specificity values of % 90 with SUVmax cut-off value of 3.63, while in another study cut-off value has been reported as 2.25 (1-2). In this study, despite the limited number of patients, FDG PET-CT examinations were found useful in distinction of tumor thrombus & benign thrombus. As a conclusion, FDG PET-CT imaging may be useful in oncological patients when radiological imaging findings are suspicious for tumor thrombus. **Key Words:** FDG; PET-CT; Tumor thrombus **References** 1. Detection of pleural and muscle involvement in Erdheim-Chester disease using FDG PET/CT

B. Seven[1], M. Turkeli[2], A. K. Ayan[3], K. Cayir[4], E. Orsal[5]; [1]Department of Nuclear Medicine, Amasya University Sabuncuoglu Serefeddin Training and Research Hospital, Amasya, TURKEY, [2]Department of Internal Medicine, Division of Medical Oncology, Medical Faculty, Ataturk University, Erzurum, TURKEY, [3]Department of Nuclear Medicine, Medical Faculty, Ataturk University, Erzurum, TURKEY, [4]Department of Internal Medicine, Division of Medical Oncology, Numune State Hospital, Konya, TURKEY, [5]Department of Nuclear Medicine, İstanbul Medeniyet University Göztepe Training and Research Hospital, İstanbul, TURKEY.

Erdheim-Chester disease, a rare form of non-Langerhan's cell histiocytosis with unknown specific etiology and pathogenesis, may present with focal or diffuse manifestation. While bone pain is the most common presenting symptom of the disease, extraskeletal manifestations are present in half of patients and are the main determinants of survival. The authors report the case of a 30-year-old man who was referred for evaluation of the extent of disease by F-18 fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT). The patient was received a treatment for diabetes insipidus for 8 years and was asymptomatic. Sagittal CT, FDG PET and fusion images from a PET/CT scanning demonstrate extensive pleural thickening and uptake in the pleura and muscles. Axial CT, FDG PET and fusion images also demonstrate skeletal involvement and uptake in the ribs, thoracic spine, and at muscles level. FDG PET/CT scan may be useful in assessing the extention of ECD and may detect extraskeletal involvement of ECD such as pleura and muscle.

Simultaneous Positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) with MRI enterography for monitoring activity of inflammation in patients with Crohns disease - a pilot study

B. Gomez[1], K. Beiderwellen[2], S. Lütje[1], A. Bockisch[1], T. Lauenstein[2], G. Gerken[3], P. Heusch[4], M. Ruenzi[5], J. Langhorst[6]; [1]Clinic for Nuclear Medicine, University Duisburg-Essen, Essen, Germany, Essen, GERMANY, [2]Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, University Duisburg-Essen, Essen, Germany., Essen, GERMANY, [3]Clinic of Gastroenterology and Hepatology, University Hospital Essen, University of Duisburg-Essen, Essen, Germany., Essen, GERMANY, [4]Department of Diagnostic and Interventional Radiology, University of Duesseldorf, Duesseldorf, Germany., Duesseldorf, GERMANY, [5]Department of Gastroenterology, Kliniken Essen-Sued, University Duisburg-Essen, Essen, Germany, Essen, GERMANY, [6]Integrative Gastroenterology, Kliniken Essen-Mitte, University Duisburg-Essen, Essen, Germany, Essen, Germany, Essen, GERMANY.

Background: To assess the performance of combined PET/MR enterography in the non-invasive assessment of inflammatory bowel lesions in patients with Crohns disease (CD). **Materials and Methods:** The first 20 patients with confirmed CD (female: n=11; mean age: 46 ± 11 years; n=7 reported previous surgery; n=7 with current stenosis) underwent PET/MR enterography using an integrated PET/MR scanner

(Biograph mMR, Siemens Healthcare, Erlangen, Germany) with [18F]Fluorodeoxyglucose (FDG) in this ongoing study. For small bowel distension an oral contrast solution was ingested. The following sequences were acquired: a) TrueFISP coronar; b) T2w HASTE with fat saturation coronar; c) T1w VIBE coronar post gadolinium; d) T1w FLASH 2D coronar and axial post gadolinium. PET was acquired simultaneously in list mode with 8 min per bed. All datasets were reviewed by two readers in consensus with regard to the presence of active inflammation. For each segment SUVmax as well as SULmax (SUVmax/SUVmaxLiver) was determined. For a segment-based analysis the lower gastrointestinal tract was divided into 7 segments (rectum, sigmoid, descending, transverse and ascending colon, caecum, terminal ileum). A colonoscopy with a segment based analysis served as standard of reference. ROC analysis for diagnostic accuracy as area under the curve for SUVmax and SULmax was performed to determine an optimal cutoff value. Furthermore diagnostic accuracy, sensitivity and specificity for PET, MRI and PET/MRI were calculated. **Results:** A total of 122 ileocolonic segments were evaluated. According to the reference standard, active inflammation was present in 15 segments. A cutoff value for SULmax of > 1 was associated with the highest accuracy (SULmax > 1: 0.77; SULmax>1.5 : 0.69; SULmax > 2: 0.75; SULmax > 3: 0.62) for the detection of inflammation. Using a cutoff value of SULmax < 1 sensitivity for PET was 87%, specificity 78%. MRI alone was associated with a higher specificity (sensitivity: 73%, specificity: 97%). Compared to MRI alone the combination of PET and MRI lead to an increase in sensitivity as well as decrease in specificity (sensitivity: 86%, specificity: 88%). **Conclusion:** 18F-FDG PET as well as MR enterography provide complementary approaches for the non-invasive assessment of inflammatory bowel lesions. The combination lead to an increase in sensitivity at a decrease of specificity in this ongoing study. Further studies investigating the integration of the different MR sequences as part of the PET/MR enterography protocol as well as the performance in the different segments should be performed.

EP697

Glucose uptake in visceral adipose tissue is decreased in obese type 2 diabetic subjects compared to healthy obese subjects, as measured by ^{18}F-FDG PET/CT

M. Boss, H. M. M. Rooijackers, M. Buitinga, M. Janssen, A. Arens, L. de Geus-Oei, L. Salm, B. E. de Galan, M. Gotthardt; Radboud University Medical Center, Nijmegen, NETHERLANDS.

Background and aims: The amount and distribution of adipose tissue are important risk factors for type 2 diabetes. Studies have shown decreased uptake of glucose in adipose tissue of non-diabetic obese-, compared to lean subjects, but no differences between healthy obese and type 2 diabetic obese subjects. This study was aimed to examine glucose uptake by ^{18}F-FDG PET/CT in adipose tissue of healthy obese and type 2 diabetic obese subjects under insulin-induced hypoglycemia. We hypothesize that hypoglycemic stress could elucidate differences not seen under physiological conditions. **Materials and methods:** 5 non-diabetic obese subjects and 5 BMI-matched (±2 kg.m^{-2}, mean BMI: 29.8 ± 3.2 kg.m^{-2}) type 2 diabetic subjects underwent a hyperinsulinemic hypoglycemic clamp (120 U.m^{2}.min^{-1}). As a control, 5 BMI matched non-diabetic obese subjects underwent a hyperinsulinemic euglycemic clamp. When stable blood glucose levels were reached (3.0 ± 0,16 mmol/L for hypoglycemia and 5.0 ± 0.27 mmol/L for euglycemia), 1,6 MBq/kg ^{18}F-FDG was infused. After 60 minutes all subjects underwent a static whole body PET scan (4min/bp) (Siemens Healthcare). Uptake of ^{18}F-FDG in total adipose tissue, visceral-, subcutaneous- and gluteofemoral adipose tissue and skeletal muscle was quantified using Inveon Research Workplace software. **Results:** Uptake of glucose in all adipose tissue depots of healthy obese subjects was raised during hypoglycemia compared to euglycemia (visceral: 631.1 ± 51.5 versus 927.2 ± 106.4 Bq/ml resp. (p=0.03), subcutaneous: 284.6 ± 78.0 versus 513.0 ± 114.1 Bq/ml resp. (p=0.007), gluteofemoral: 415.0 ± 47.0 versus 634.0 ± 71.4 Bq/ml resp. (p=0.04). Under hypoglycemia, mean glucose uptake in visceral adipose tissue was lower in obese type 2 diabetic individuals than in healthy obese individuals (566.5 ± 36.4 versus 927.2 ± 106.4 Bq/ml resp., p=0.011). There was no difference in uptake in subcutaneous and gluteofemoral adipose tissue (subcutaneous: 324.1 ± 70.9 versus 513.0 ± 114.1 Bq/ml resp., gluteofemoral: 462.8 ± 116.3 versus 310.2 ± 7.9 Bq/ml resp., p>0.05 for all).Uptake in skeletal muscle was similar in all groups (euglycemia: 414.7 ± 47.0, hypoglycemia: 634.3 ± 71.4 for healthy obese and 400.3 ± 33.1 for obese diabetic subjects, p>0.05 for all). **Conclusion:** Conditions of hypoglycemic stress, resulting in stimulated adipose tissue metabolism, elucidate a specific impairment of visceral adipose tissue glucose metabolism in type 2 diabetes. BMI matching ensures this impairment to be related to type 2 diabetes rather than obesity. This could indicate an important role of visceral adipose tissue in development of type 2 diabetes.

EP-39 – Sunday, October 16, 2016, during Exhibition hours, e-Poster Area

Molecular & Multimodality Imaging: SPECT & SPECT/CT

EP698

Quantification of Facet Joint Activity with Tc-99m MDP SPECT-CT

S. Razavi[1], R. Klein[1], D. Vu[2], L. Zuckier[1], **W. Zeng**[1]; [1]The Ottawa Hospital, Ottawa, ON, CANADA, [2]University of Sherbrooke, Sherbrooke, QC, CANADA.

Introduction Bone scintigraphy is commonly performed to identify active facet joint for cortisone injection in patients with back pain. SPECT-CT has the advantage of anatomical localization and soft tissue attenuation correction compared to planar images. The standard method of evaluating these patients has been visual inspection of the planar and SPECT-CT images. Recent availability of quantitative SUV SPECT enables absolute quantification of facet joint activity. The purpose of this study was to assess quantitative measurement of facet joint uptake and its correlation with visual subjective interpretations. **Methods** 48 consecutive patients who had undergone Tc-99m-MDP SPECT-CT for localization of facet arthropathy over 3 years were retrospectively reviewed. Patients were divided into having normal, mild, and moderate/severe facet uptake based on prior interpretation. Data were reconstructed using newly available quantitative SUV SPECT software (HERMES HybridRecon) including CT-based attenuation, scatter, and resolution recovery. For each facet joint with increased activity in the lumbar spine, a volume of interest (VOI) based on the measured maximum SUV was drawn and validated by a nuclear medicine physician. The VOI was then copied onto the contralateral or higher or lower ipsilateral level normal facet joint. Absolute mean SUV [g/mL] and VOI volumes [mL] were measured. Abnormal-to-normal facet ratios for each patient were also calculated. **Results** Of the 48 patients evaluated, 29 patients were visually diagnosed with facet arthropathy based on bone scan (19 female; mean age: 61±11 years): 19 were interpreted as having mild disease (34 facets in total) and 10 (16 facets) as moderate/severe. Abnormal-to-normal facet uptake ratios were 2.43±0.96 for the mild and significantly higher (4.75±2.65, p=0.003) for moderate/severe. Reference-normal facet mean SUV was 3.2±1.2, compared to mild abnormal (7.9±3.6, p<0.001) and to moderate/severe (11.6 ±4.2, p<0.001 vs. normal and p=0.006 vs. mild). Receiver-operating-characteristics (ROC) derived cutoff points (SUV=3.7 for mild and 9.2 for moderate) were used to classify facets into normal, mild and moderate/severe based on Mean SUV and had good concordance (Cohen's Kappa= 0.60) with visual classification. **Conclusion** Abnormal-to-normal facet uptake ratio can well differentiate abnormal

and normal facet as well as quantitatively characterize the severity of facet arthropathy. The value of the ratio may be useful to guide trainees in interpretation. Prior visual methods of facet assessment correlate well with new absolute measures of bone uptake. Furthermore, absolute mean SUV may be able to objectively classify severity of inflammatory arthropathy, but further validation would be required.

EP699

Quantitative assessment of femoral head ischemia using two-phase bone SPECT/CT in patients with proximal femoral fracture

K. Iwata[1], Y. Fukushima[1], S. Kumita[1], T. Hamana[1], H. Hashimoto[2], Y. Sugihara[1]; [1]Nippon Medical School Hospital, Tokyo, JAPAN, [2]Toho University Omori Medical Center, Tokyo, JAPAN.

Introduction: Proximal femoral fractures may cause femoral head ischemia associated with vascular injuries. Although femoral head necrosis caused by these fractures can be diagnosed using MRI, diagnostic procedures for the detection of femoral head ischemia remain unestablished. Furthermore, surgical indications are determined by the fracture site and the degree of fracture segment dislocation. Since the severity of femoral head ischemia is not allowed for the decision criteria, the criteria still remain some room to be improved. The aims of this study were to estimate the degree of femoral head ischemia and to assess the relationship between the proximal-femoral-fracture classifications and the degree of femoral-head ischemia in patients with proximal femoral fracture. ***Materials and methods:*** A total of 20 consecutive patients (6 men and 14 women, 78 ± 6 years) between January 2013 and March 2016, who were diagnosed with proximal femoral fracture and underwent bone SPECT/CT before the treatment, were included in this study. In the procedure of bone SPECT/CT, perfusion and bone-metabolism images were acquired respectively 10 min and 2 hours after the administration of ^{99m}Tc-HMDP 740 MBq. The percentage of femoral-head perfusion-defect (%FHPD) was calculated by dividing femoral-head perfusion-defect volume derived from bone-perfusion SPECT images by femoral-head volume derived from CT images. All patients were divided into low- and high-classification groups based on surgical indications [Garden I-II or Evans Type 1 (group 1-2) and Garden III-IV or Evans Type 1 (group 3-4)-Type 2]. The relationship between the proximal-femoral-fracture classifications and %FHPD was analyzed. ***Results:*** Low and high proximal-femoral-fracture classification groups consisted of 14 and 6 patients, respectively. %FHPD was 67 (59-73) in the low group and 92 (84-99) in the high group ($p = 0.009$). The incidence of high %FHPD was higher in the high classification group than in the low group [odds ratio: 18.33 (1.51-222.89), $p = 0.022$]. ***Conclusions:*** The degree of femoral head ischemia was estimated by calculating %FHPD via two-phase bone SPECT/CT. In patients with proximal femoral fracture, the high classification can result in high %FHPD.

EP700

The Added Value of Hybrid SPECT/CT in Evaluation of Painful Orthopedic Implants and Fracture Healing Complications

B. Gunalp, S. Ince, A. Ayan, K. Okuyucu, N. Arslan; Gulhane Military Medical Academy and Medical Faculty, ANKARA, TURKEY.

PURPOSE: The aim of this study to investigate the added value of single photon emission computed tomography (SPECT)/computed tomography (CT) to three phase Tc-99m methylene diphosphonate (MDP) bone scan, Tc-99m hexamethylpropylene amine oxime (HMPAO) labeled leukocyte and Tc-99m nano-colloid (NC) bone marrow planar imaging in patients who complain pain after insertion of orthopedic implants (joint prostheses and internal fixation devices) and delayed fracture healing. MATERIAL AND METHOD: We retrospectively evaluated Tc-99m MDP bone and Tc-99m HMPAO labeled leukocyte and in 7 cases Tc-99m NC bone marrow planar and SPECT/CT scans in 74 patients with orthopedic implants (24 knee, 16 hip and 34 internal fixation devices). The final diagnosis was made using bacteriologic data or clinical follow-up. Increased activity in all three phases of bone scan and increased activity bone-prosthesis interface and medulla in SPECT/CT, increased HMPAO leukocyte activity and decreased or absence of activity in NC bone marrow scan in similar areas defined as bone or orthopedic implant infection. RESULTS: Of the 74 patients, 14 patients (4 with knee prostheses, 2 with hip prostheses and 5 with fixation devices) had a diagnosis of prosthetic implant infections In two suspicious cases Tc-99m NC SPECT/ CT had an added value to bone and leukocyte SPECT/CT for identifying and excluding bone infection and further increased diagnostic accuracy. Diagnostic performances of planar, SPECT and combined tests (sensitivity, specificity and accuracy, respectively) have been found as follows: Three phase planar bone scan 81%, 37%, 44%; Bone SPECT/CT 90%, 45%, 52%; Leukocyte planar 72%,35%, 41; Leukocyte SPECT/CT 91%, 60%, 63%, Bone + Leukocyte + Bone Marrow SPECT/CT 100%, 100%, 100%. CONCLUSION: Correct diagnosis of orthopedic implant infections and other complications is very important in patient management. SPECT/CT offers additional information by providing not only precise localization of radiopharmaceutical accumulation but also anatomical information that can be critical for patient management. It is concluded that bone SPECT/CT should be the first line screening test for the investigation of causes of orthopedic implant failure and combine leukocyte and bone marrow SPECT/CT is the most accurate test for differential diagnosis of orthopedic implant infections.

EP701

The utility of 99mTc-Pyrophosphate SPECT in combination with left atrium 64-MDCT in diagnosis of latent myocarditis in patients with atrial fibrillation: a pilot study

Y. Ilyushenkova[1,2], S. Sazonova[1,2], R. Batalov[1], S. Popov[1]; [1]Research institute of cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim: to compare results of 99mTc-Pyrophosphate myocardium SPECT in combination with left atrium 64-MDCT with histology data in patients with isolated persistent atrial fibrillation (AF). Materials& methods: We examined 15 patients (pts) (12 males and 3 females, mean age 44±7.5) with isolated persistent AF. After complete clinical and instrumental examination, all patients underwent SPECT with 99mTc-Pyrophosphate (99mTc-PYP) 18 hours post injection (delayed SPECT), following by left atrium 64-MDCT. Both images were then combined using 2 marks (radionuclide and radiopaque) to define more exactly the localization of 99mTc- PYP uptake in the heart and to exclude ventricles blood pool and bone elements. Endomyocardial biopsy (EMB) samples were taken during catheter ablation of AF. SPECT-CT results were compared with the EMB and immunohistochemical findings. Results: According to clinical and instrumental data only 11 pts repine of the arrhythmia , 7 pts- inspiratory dyspnea and in 6 pts was the relationship of AF and previously infectious disease. Any changes in the blood indicating inflammation have been identified in any pts. Moreover, in all patients LVEF was normal. According to histological data active lymphocytic myocarditis was verified in 13 pts (86%), in addition all pts had signs of cardiosclerosis different grading and staging. Immunohistochemical study detected the presence of viral antigens (gerpes simplex of 1, 2 and 6 types, Epstein-Barr virus, enterovirus VP1) in myocardium samples of every patient with histologically confirmed myocarditis. The pathological uptake of 99mTc-PYP was found in 11 patients. The number of true-positive results was 11, true negative 2, false-positive - 0, false negative 2. The sensitivity was 84%, specificity 100%, accuracy 86%. Conclusion: The results of our study have shown that in 86% of patients with isolated

AF had latent myocarditis. Cardiac SPECT with 99mTc-PYP combined with left atrium 64-MDCT has a potential as an effective noninvasive tool of diagnoses of latent myocarditis in pts with isolated AF. Acknowledgment: This study was funded by Russian Science Foundation "The role of autonomic nervous system in pathogenesis and progression of ventricular and supraventricular arrhythmias" (grant number 15-15-10016)

EP702

A single region SPECT-CT along with a whole body bone scan provides a conclusive answer in solitary bone metastasis - an analysis of 140 bone scans with equivocal solitary bone lesions

J. DAS, Jr.; TATA MEDICAL CENTER, KOLKATA, INDIA.

Aim 99mTc-MDP whole body bone scan is the standard imaging method to detect bone metastases. Though radionuclide imaging is having an excellent sensivity , the specificity is relatively low especially for solitary bone metastases. In this retrospective study we analyzed the incremental value of a single region SPECT-CT performed along with the whole body bone scan in 140 cases with equivocal solitary bone lesions. **Materials and methods** Data of the 140 patients was retrospectively analysed.The patients were administered 20 to 25 mCi of 99mTc-MDP approximately. In all of them a solitary lesion was identified which was indeterminate in nature . Immediately after the bone scan ,a SPECT-CT of the same region was performed (360 degree,step and shoot,GE Infinia Hawkeye 4). In approximately 20 % of the patients a single bed position diagnostic CT was obtained instead of SPECT-CT. Prior consent was obtained in all of them. **Results** In more than 90 % cases SPECT-CT provided incremental additional information about the character of the solitary bone lesion which influenced the management . It helped to localize the lesion either in the bone or in the extraosseous soft tissue . The CT component could characterize the lesion by either identifying it as a physiological variant like bone island or by identifying structures and features like osteophytes, fractures ,cortical destruction or associated soft tissue component which could classify the lesion as more likely to be benign or malignant. The study also informed whether image guided biopsy was possible or not. **Conclusion** Inclusion of SPECT-CT as a part of 99mTc-MDP whole body bone scan protocol could provide incremental information which had positive impact on the management and influenced decision making in approximately 90% cases with solitary bone lesions therefore negating the requirement of an additional imaging like 18F -NaF bone PET, MRI or 18 FDG PET-CT. This could enable resource optimised use of imaging equipment and minimize number of visits to the hospital . The cost of the investigation is also significantly less in comparison with other imaging modalities which could be utilized as a problem solving tool in solitary indeterminate bone lesions.

EP703

The effect of partial volume in quantitative pre-clinical imaging of ^{111}In-labelled antibodies

A. M. Denis-Bacelar[1], S. E. Cronin[1], C. Da Pieve[1], R. Paul[1], S. A. Eccles[1], T. Spinks[1], C. Box[1], A. Hall[2], J. K. Sosabowski[3], G. Kramer-Marek[1], G. D. Flux[2]; [1]The Institute of Cancer Research, London, UNITED KINGDOM, [2]The Royal Marsden Hospital NHS Foundation Trust, London, UNITED KINGDOM, [3]Barts Cancer Institite, London, UNITED KINGDOM.

Aim: Standard pre-clinical imaging systems do not usually provide correction for partial volume effects. This can be of particular importance if results are compared with measurements from other methods, including *ex-vivo* gamma counting. The aim of this study was to explore the potential role of quantitative pre-clinical SPECT imaging as a substitute for biodistribution studies. **Materials and Methods:** Six female CD-1 nude mice were injected with SK-OV-3 cells and 6-9.8 MBq of ^{111}In-labelled antibodies diluted in saline were administered via the tail vein. The mice were scanned using the Albira SPECT/PET/CT system (Bruker), with a 20% energy window width at 171 keV, default OSEM reconstruction and without attenuation, scatter or partial volume corrections. The mice were imaged at 4, 24, 48, 72 and 96 hours post-injection (pi) and two were additionally imaged at 168 and 197 hours pi. A CT and a 15 minute SPECT scan were performed at each time-point. Dead-time measurements were performed. Partial volume effects were investigated using four spherical phantoms with diameters of 3.8, 6, 13, and 20.2 mm, with a cold background and sphere to background ratios (SBR) of 3:1 and 4:1. The activity, mass and %IA/g of the tumour calculated from the last SPECT scan were compared with those obtained from the biodistribution study (gold standard). **Results:** A decrease in counts of 14% was observed for 13.5 MBq due to dead time. No differences in the calibration factors were observed between the different SBR when the data were corrected for dead time. A difference in calibration factors of 118% was obtained for the range of tumour masses measured (0.041-0.232 g). The measured SBR for the largest sphere was underestimated by 22-23%, highlighting that partial volume effects are still significant in large volumes. The median relative difference between the tumour mass determined from imaging and biodistribution was 17% (-31% - 52%). The tumour activity from the SPECT scan was underestimated in all mice, with a median relative difference of -16% (-27% - -6%). When the differences in activity and mass are compounded into the %IA/g calculation, no relationship between imaging and biodistribution uptake values was observed. **Conclusion:** Accurate tumour volumes are essential for image quantification and therefore dosimetry calculations. Partial volume effects were still significant for a sphere with radius of 10 mm and therefore should also be considered in studies with larger-size rodents.

EP704

Value of attenuation corrected SPECT in bone scanning of the spine - Comparison of SPECT vs SPECT/CT

L. Louw, M. H. W. Vangu; University of the Witwatersrand, SA, Johannesburg, SOUTH AFRICA.

Aim: A retrospective study undertaken to evaluate the additional diagnostic value of SPECT/CT imaging of the spine with ^{99m}Tc-MDP compared to CT attenuation corrected SPECT imaging, in patients with solid tumour malignancies. **Materials and methods:** A total of 192 adult patients (131 males, 61 females), aged 19-89 years, referred for bone scan from January 2013 - May 2015 were included. SPECT/CT reconstructed images of the spine were acquired for either better localization of abnormal foci on planar, or in the presence of back pain but unremarkable planar images. Attenuation correction for the SPECT images was done with the use of CT. CT attenuation corrected SPECT (M1) and fused SPECT/CT images (M2) were visually analyzed. Focal uptake in the posterior aspect of the vertebral body or pedicle, or diffuse uptake in the vertebral body was considered as likely malignant. **Results:** In the thoracic spine a total of 606 lesions were identified in M1 and 600 in M2. In M1, a total of 79 lesions were identified as potentially malignant in the thoracic spine and 68 in M2. Neither the difference in numbers (p=0.223) nor the increment (p=1.0) was significant from M1 to M2. Similar results were noted for the lesions that were seen in lumbar spine (580 lesions in M1 and 581 in M2). Furthermore, a total of 53 lesions were identified as potentially malignant in M1, and 46 in M2 in the lumbar spine. Once again neither the difference in these numbers between M1 and M2 (p=0.414), nor the increment of lesions from M1 to M2 (p=1.0) was significant. Using the CT component of the SPECT/CT images as reference, only 0.8% of affected vertebrae changed location from M1 to M2. The greatest impact in patients with probable metastatic disease (29 patients) was noted by down staging of 20 of them to “no metastatic

disease" from M1 to M2. **Conclusion:** Our study didn't find an overwhelming benefit of SPECT/CT as opposed to attenuation corrected SPECT imaging of the spine. However, the additional value of SPECT/CT was primarily found in down-staging a small number of patients. The use of this expensive modality in resource-limited settings has to be weighed carefully against added benefits, especially when diagnostic staging CT is often done as part of patients' investigations. A prospective study comparing SPECT/CT with non-CT based attenuation corrected SPECT is required.

EP705

Added value of ^{67}Ga SPECT-CT in the monitoring of antibiotic treatment in necrotizing external otitis

D. BEN SELLEM, L. ZAABAR, B. DHAOUADI, B. LETAIEF, M. F. BEN SLIMENE; University of Tunis El Manar, Faculty of Medicine of Tunis, Salah Azaiez Institute, Department of Nuclear Medicine, Tunis, TUNISIA.

Aim: Necrotizing external otitis (NEO) is an uncommon but severe and evolutive infection affecting mainly old diabetic. This osteitis spreads to the skull base at the temporal bone. Prognostic vital can be affected, treatment must be energic, rapid and well adapted. Gallium 67 Citrate (Ga ^{67}) scintigraphy is an early valuable tool to monitor the efficiency of antibiotic treatment. The aim of this study is to evaluate the additional diagnostic value of fused single photon emission computed tomographic (SPECT) and computed tomographic (CT) images (SPECT-CT), compared to planar ones. **Materials and Methods:** Forty diabetics with trailing otitis resistant to different treatments have benefited of 45 SPECT-CT, in order to monitor the efficiency of antibiotic treatment. These patients (22 men, 18 women) aged 66,2±13,8 years (20 to 87 years, median 67 years) underwent, 72 h after intravenous injection of a mean activity of 185 MBq (5 mCi) Ga ^{67}, static planar scintigraphy and SPECT/CT scan focused on skull, and whole body scan. Planar images and fused SPECT-CT ones were retrospectively and separately interpreted. **Results:** The qualitative analysis of the planar acquisition had shown an increased temporal uptake in 5 patients. The exam was negative in 40 cases. The qualitative analysis of the SPECT/CT has objectified a radiotracer uptake of the mastoid in 20 cases, indicating the continuation of antibiotic therapy. Also, the fused images allowed determining the extension of the osteitis: to the ipsilateral temporomandibular joint in 5 cases and to the deep spaces of the face, the skull base and the temporomandibular joint in another case. In 3 others cases, the temporal osteitis was inactive, but the SPECT/CT has diagnosed contra-lateral osteitis in one case and a persistent inflammation of the soft tissue in 2 cases. In the 22 last cases, the fused images were negative, showing a scintigraphic remission and allowing so stopping the antibiotic treatment. After analyzing the fused images, the final report was changed in 40 % of cases. **Conclusion:** The necrotizing otitis externa is a serious infection that can affect the vital prognostic. The monitoring of antibiotic treatment is crucial. Ga ^{67} scintigraphy is an early valuable tool to monitor the efficiency of this treatment. The fused SPECT/CT images provided additional information in 40 % of cases, by detecting active infection imposing the prolongation of antibiotic therapy. It allowed also a better defining of the location and the extent of infection.

EP706

An Investigation into Metal Artefact Reduction Approaches in CT Attenuation Correction for SPECT/CT and PET/CT

J. A. Johnson; Cambridge University Hospitals NHS Foundation Trust, HERTFORDSHIRE, UNITED KINGDOM.

Background. Metal implants, and the artefacts which result from their CT imaging, pose an issue when acquiring attenuation correction data. The high density and atomic number of the implant materials cause streaking, especially when FBP reconstruction is performed. This leads to erroneous attenuation correction and potentially mis-diagnosis. The aim was to quantitatively assess the severity of artefacts, assess existing MAR methods, and optimise the parameters used at acquisition to gain the most diagnostically useful CTAC images. ***Methods.*** A customised phantom was used to investigate the impact of different CT acquisition parameters and reconstruction techniques. The severity of the artefact was quantified both across the image FOV, and axially throughout the imaged volume for various acquisition parameters and CT reconstruction approaches. By positioning activity-filled syringes adjacent to the metal and at the phantom edge, the effect of the metal upon the visibility of a small feature was highlighted. ***Results***. The data highlighted that no optimal technique exists for MAR. However, the artefact was shown to extend both across the field of view within a slice, and axially through the imaged volume. Iterative techniques appeared to marginally extend the artefact axially and decrease spatial resolution from the 1.4mm determined for FBP-reconstructed CT data. The visibility of lesions was affected by their proximity to the metal. The maximum counts/pixel was 18% lower adjacent to the hip in comparison to at the phantom edge. The use of a high kV CT scan for CTAC was shown to be beneficial for image quality. Therefore a new CT protocol was devised for imaging patients with metal hip implants, which is to be put into clinical practice for CTAC. Discussion. Evidently metal implants significantly affect image quality and the ability to make accurate diagnoses, with no existing CT reconstruction technique offered by GE providing an optimal solution. Acquisition parameters allow the artefact to be minimised, whilst quantifying the error provides awareness of the extent and impact of the artefact and highlights the shortcomings in the MAR techniques provided by manufacturers. ***Conclusion.*** It's clear that further work is needed to provide improved MAR approaches for CTAC. Further attempts to access CT reconstruction algorithm information from the scanners would allow novel approaches to be sought. Further investigation of the artefact's impact upon clinical images would also be valuable. It is clear, however, that regardless of the reconstruction technique used presently, the artefact has a noticeable impact upon the CTAC.

EP707

The Use of SPECT-CT with Besilesomab-99mTechnetium in Diagnosis of Actinic Enteritis: A Case Report

I. C. Palazzo, N. L. Correa, M. F. Veras, G. M. N. Sadeck, A. C. Y. Cotrado, w. K. d. Aguiar, M. M. M. Sabra, W. d. Ker, F. S. Costa, J. d. Azevedo, C. T. Mesquita; Hospital Pró-Cardíaco, rio de janeiro, BRAZIL.

A 67 years old male with hypertension, type 2 diabetes, diagnosed with rectal adenocarcinoma, which was surgically resected. The patient was receiving oral chemotherapy (Capecitabine associated with Docetaxel) and radiotherapy. After 20 sessions of external radiotherapy the patient developed fever, weight loss and diarrhea and was sent to the emergency room. The contrasted computed tomography (CT) demonstrated two thrombi in the infrarenal aorta, the largest measuring about 2 centimeters. In order to investigate a possible infection of the thrombi, scintigraphy with labeled leukocytes was requested. The scintigraphy was performed after the human anti-mouse antibody (HAMA) test to exclude the possibility of immune reaction to the radiotracer (besilesomab-99mTechnetium). The images were acquired in a hybrid gamma camera (Single-photon emission computed tomography), with low-dose computed tomography which allows attenuation corretion and anatomic correlation. In addition to the low dose CT, the scintigraphic images were fused with the previous contrasted CT. The analysis of the images did not show radiotracer accumulation in the thrombi, however revealed reduced uptake in bone marrow lumbar vertebrae (post-radiotherapy effect) and high intensity uptake in the small intestine. A revision of the contrasted CT

demonstrated signs of distal small bowel inflammation. The radiotracer accumulation in the intestine was present in both early and late images, and confirmed the sugested clinical diagnosis of actinic enteritis. Inflamatory process of the bowel after radiation is not uncomon, up to 90% of patients undergoing radiotherapy for pelvic tumors develop altered bowel habits and 50% report reduction in quality of life. Despite being common, there are few publications that show this pathology through scintigraphy with labeled leukocytes. The scintigraphy with labeled leukocytes allowed the oncologists to rule out other causes of fever, directly impacting the care of the patient.

SPECT/CT Improves Inter-Observer Agreement of Equivocal Osseous Lesions Detected on Planar Bone Scan

Y. G. A. Abdelhafez[1], N. Bashank[2], L. Eloteify[2], M. Mekkawy[2]; [1]South Egypt Cancer Institute, Assiut University, Assiut, EGYPT, [2]Faculty of Medicine, Assiut University, Assiut, EGYPT.

Aim To compare inter-reader agreement for planar and SPECT/CT interpretation of equivocal osseous lesions detected on bone scintigraphy in cancer patients. **Materials & Methods** This prospective study recruited patients known to have primary tumor referred for bone scintigraphy with their planar images showing solitary or few equivocal osseous lesions. Every patient underwent planar whole body scan followed by SPECT/CT for the concerned region(s). The gold standard was based on clinical/imaging follow-up for at least 6-12 months. Two experienced readers (reader 1 has 8-year experience & reader 2 has 12-year experience) scored each lesion on a subjective 5-point score for the possibility of being malignant (1=benign, 2= probably benign, 3 = equivocal, 4=probably malignant & 5 = malignant). True & false results were identified were identified in relation to the gold standard. Kappa measure of agreement was measured for both modalities. **Results** A total of 150 patients were included in this study (110 females ,40 males) with median age 54 years (range:7-84). On planar imaging, both readers successfully identified 48 true positive (TP) & 19 true negative (TN) patients. Both readers were false positive (FP) in 31 & false negative (FN) in 3 patients. They disagree in 2 patients. Moderate agreement was noted (kappa = 0.55). While on SPECT/CT imaging, both readers successfully identified 58 TP & 62 TN patients. Both readers reported FP results in 11 & FN in 2 patients. They disagree in a total of 9 patients. Perfect agreement was noted (kappa = 0.82). **Conclusion** SPECT/CT significantly improved inter-observer agreement among readers for equivocal osseous lesions detected on planar bone scintigraphy.

EP709

The role of gamma scintigraphy in the diagnosis of latent myocarditis in patients with atrial fibrillation

Y. Ilyushenkova[1,2], S. Sazonova[1,2]; [1]Research institute of cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim: To evaluate the role of labeled ^{99m}Tc-HMPAO leucocytes (^{99m}Tc-HMPAO-L) myocardium SPECT in the diagnosis of latent myocarditis in patients with atrial fibrillation (AF).Materials & methods: We examined 70 patients (pts) (49 males and 21 females, mean age 48.72±6) with isolated persistent AF. After complete clinical and instrumental examination, all patients underwent SPECT with ^{99m}Tc-HMPAO-L 18 hours post injection (delayed SPECT), following by SPECT with ^{99m}Tc-MIBI at the rest condition. Both images were then combined to define more exactly the localization of ^{99m}Tc-HMPAO-L uptake in the heart and to exclude ventricles blood pool. In 50 pts Cardiac Magnetic Resonance (CMR) with gadolinium and immunobiochemical analysis of blood serum to determine the concentration of proinflammatory cytokines were performed. Endomyocardial biopsy (EMB) samples were taken during catheter ablation of AF. All results were compared with the EMB findings. According to the results of statistical analysis of clinical and instrumental data, we have identified a number of clinical and radiological signs, with the highest informative value in the diagnosis of latent myocarditis in patients with AF. To determine the importance of gamma scintigraphy in the diagnosis of latent myocarditis have been developed 2 models of multinomial logistic regression, the diagnostic performance was calculated using ROC analysis. Model 1 included the diagnostic signs such as inspiratory dyspnea, low-grade fever, cardialgia, the link between the appearance of AF with infectious disease, late gadolinium enhancement at CMR and local contractility dysfunction of left ventricle. Model 2 included the full range of characteristics of model 1 and myocardial scintigraphy 99mTc-HMPAO-L. Results: According to the results of ROC analysis the sensitivity and specificity of model 1 in the diagnosis of latent myocarditis is 50% and 70% respectively, AUC= 0.662. The sensitivity and specificity of model 2 in the diagnosis of latent myocarditis was 70% and 96%, respectively, and the area under the ROC curve to 0,866. Conclusion: The results of our study have shown that adding to the diagnostic algorithm ^{99m}Tc-HMPAO-L myocardium SPECT increase the efficacy of diagnostics of latent myocarditis in patients with atrial fibrillation by 20%. Acknowledgement: This study was funded by Russian Science Foundation "The role of autonomic nervous system in pathogenesis and progression of ventricular and supraventricular arrhythmias" (grant number 15-15-10016).

Quantification of normal Sacroiliac joint to Sacrum Ratio with Tc-99m MDP SPECT/CT in Women

S. Bazarjani, S. Razavi, R. Klein, L. Zuckier, W. Zeng; The Ottawa Hospital, Ottawa, ON, CANADA.

Introduction Bone scintigraphy is commonly performed to identify sacroiliitis. Sacroiliac joint to sacrum (SIS) uptake ratio based on planar images has been used as a diagnostic aid. The SIS ratio quantification based on planar images may produce significantly variable values in even normal individuals due to body habitus such as the degree of soft tissue attenuation and variation of sacral curvature. SPECT/CT imaging may resolve these issues by providing soft tissue attenuation correction and precise anatomical delineation of sacral and SI joint components. The goal of this study was to quantify the SIS ratio with SPECT/CT in patients with normal sacroiliac joints and sacrum. **Methods** 18 patients referred to our department for ^{99m}Tc-MDP SPECT/CT bone scintigraphy were reviewed by 2 board certified nuclear medicine physicians. Patients with normal SI joint and sacrum on CT and no lumbar or hip symptoms to have significant effect on these joints were selected for the study. Male patients were excluded in this study due to limited numbers with normal SI joints. SPECT images were reconstructed using attenuation, scatter, and resolution recovery corrections with CT and quanitified in SUV units using Hermes software. For each sacroiilac joint or sacrum, a volume of interest (VOI) based on the measured maximum SUV and the CT anatomy was drawn by experienced nuclear medicine physicians. Various parameters were evaluated including the mean SUV [g/mL], the integral SUV [g] within the VOI, and the SIS ratio. **Results** 18 female patients (mean age: 44.5 ± 12.3, range: 21-64) were evaluated in this study with the majority having breast cancer. Volumes (mL) of the right and the left SI joints and proximal sacrum were 67.8±18.4, 69.9±19.5, and 41.1 ±11.7, respectively. Mean SUVs were 4.44±0.88 for the right SI joints, 4.38±1.08 for the left SI joints and 3.49±0.82 for the sacra. Considerable size variation of the SI joint volumes was noted (SE=27%). However, SIS ratios remain relatively constant as expected, measuring 1.29 ± 0.16 (SE=13%) on the right and 1.26 ± 0.14 (SE=11%) on the left. There is no statistic difference between the right and the left SIS ratios (p=0.22) by paired t-test.

Conclusion The current study demonstrated the feasibility of quantifying the SI joints and sacral activity. The SIS ratios obtained in this study from subjects with normal SI joints and sacra are helpful as a reference in evaluating patients with suspected sacroiliitis.

EP711

SPECT/CT Characterization of Equivocal Osseous Lesions Detected on Tc-99m-MDP Planar Bone Scintigraphy

N. Bashank[1], **Y. G. A. Abdelhafez**[2], L. Eloteify[1], M. Mekkawy[1]; [1]Faculty of Medicine, Assiut University, Assiut, EGYPT, [2]South Egypt Cancer Institute, Assiut University, Assiut, EGYPT.

Aim: To compare diagnostic performance of SPECT/CT versus planar imaging in characterization of equivocal osseous lesions in cancer patients detected on bone scintigraphy. Materials & Methods: This prospective study recruited patients known to have primary tumor referred for bone scintigraphy with their planar images showing solitary or few equivocal osseous lesions. Every patient underwent planar whole body scan followed by SPECT/CT for the concerned region(s). The gold standard was based on clinical/imaging follow-up for at least 6-12 months. The findings from both modalities were compared for diagnostic performance indices. Results: A total of 150 patients were included in this study (110 females ,40 males) with median age 54 years (range:7-84). The sensitivity, specificity and accuracy for planar scintigraphy versus SPECT/CT were (72% vs. 85%, 61% vs. 83% & 66% vs. 84%; respectively. The differences in sensitivity & specificity were statistically significant (P = 0.04 & 0.001); respectively. Conclusion: SPECT/CT significantly improved the diagnostic performance of planar bone scintigraphy in characterization of equivocal osseous lesions.

EP712

Validation of attenuation correction using SPECT/CT in MPI

L. Ali[1], S. Panchadar[2], Y. Al-Sayed[2], G. Biswas[2], M. Al-Garashi[2]; [1]Faculty of Allied Health, Kuwait University, KUWAIT, [2]Chest Diseases Hospital, Ministry of Health, KUWAIT.

Gated SPECT (G-SPECT) myocardial perfusion imaging (MPI) using 99mTc-Tetrofosmin is used to evaluate coronary artery disease (CAD). Soft tissue attenuation in the anterior wall from breasts in female and inferior wall from diaphragm, leads to false positive studies. Computed tomography (CT) has recently been introduced for localization of lesions and correction for attenuation in hybrid SPECT/CT. The aim of this work was to use CT in a half dose-half acquisition protocol to correct for attenuation and investigate whether it imposes a great impact on the presence and severity of perfusion defects. **Methods:** Two hundred G-SPECT/CT MPI 2 days stress/rest studies were retrospectively selected. The acquisition was performed on hybrid (True Point Symbia SPECT/CT) equipped with SMATZOOM collimator. Uncorrected (NC) and attenuation corrected (AC) SPECT images were analyzed using 17 segments polar maps to obtain summed stress score (SSS), summed rest score (SRS) and summed difference score (SDS). Percentage perfusion defect and associated perfusion count was also evaluated. Two experienced NM physicians have assessed the abnormalities using visual scoring of 3-point scale (1 no difference in perfusion between AC and NC, 2 small difference in one or more segment, 3 marked difference in perfusion). **Results:** Out of 200 patients, 173 (86.6%), including 118 male (68.2%) and 55 female (31.7%) has shown significant improvement in perfusion by AC. 88 out of 131 male have defects in RCA territory in which 90.7 % have been modified whereas 57 out of 69 female have LAD defect in which 56.6 % have been modified after AC. The SDS for attenuation corrected stress and rest (3.12±2.9) was significantly decreased compared to SDS for uncorrected data (6.72±4.10), p value=0.0003. The severity of lesions were shifted to normal from either mild, moderate, severe or absent in 44% (n=68), 16% (n=25), 5% (n=8) and 1% (n=2) respectively and were shifted from moderate to mild and severe to moderate in 22% (n=34) and 12% (n=18) respectively. McNemar test showed that visual improvement in perfusion with AC was seen in 122 out of 155 patients (79%) in which marked differences were seen in 45 patients (29%), p value=0.0001. Good agreement between observers with Kappa 0.73. **Conclusion:** Our results show that AC with CT is efficient in reducing the number of false-positive studies.

EP713

SPECT/CT lung perfusion study in Swyer-James-MacLeod syndrome: a case report

Z. Jurasinovic[1], A. Tabain[2], I. Bračić[1], G. Horvatic-Herceg[1]; [1]University Hospital Centre Zagreb, ZAGREB, CROATIA, [2]Outpatient Clinic Medikol, ZAGREB, CROATIA.

Swyer-James-MacLeod syndrome (SJMS), otherwise known as unilateral hyperlucent lung syndrome, is a rare disease occurring in childhood that is believed to be caused by bronchiolitis obliterans. Hypoplastic pulmonary arteries remain after such an event, leading to decreased vascularity and ultimately in reduced lung size. Nevertheless, this syndrome can remain unrecognized well beyond childhood due to an indolent course and than sometimes discovered in an adult. We scheduled a 42-year-old female patient for the lung perfusion study after she was treated for upper right lobe pneumonia, but the infiltrative lesion seen on her X-ray hasn't cleared after the treatment. Lung MSCT was performed before our study and showed localized emphysema in the upper and middle right lung, which raised the suspicion of SJMS. Six standard planar images were made after the administration of 148 MBq Tc-99m labelled macroaggregated albumin (MAA) and perfusion defects were noted in the right upper apical and anterior segments as well as a large defect in the middle lobe. SPECT study was additionaly performed, combined with low-dose CT scan and hybrid images were generated so that it was possible to match perfusion defects with hyperlucent areas in the afore mantioned areas. We decided that lung ventilation study isn't warrented and concluded that MSCT angiography can also be omitted.

EP714

Abdominal SPECT/CT using Tc-99m-labelled aulotogous heath-denatured red blood cells after blunt abdominal trauma and splenectomy: a case report

Z. Jurasinovic; University Hospital Centre Zagreb, ZAGREB, CROATIA.

Twenty-nine years old female patient went to urgent splenectomy after blunt abdominal trauma and rupture of the spleen. On follow-up MSCT discovered a node measuring 0.8 cm in diameter located near the empty spleen bed, but also multiple nodes up to 4 cm in diameter throughout the left side of the abdomen, reaching front abdominal wall at the level of supravesical region. The patient was scheduled for abdominal scan with Tc-99m-labelled autologous heath-denatured red blood cells to confirm traumatic splenosis.We labelled red blood cells with Tc-99m and denatured the cells with heath using standard procedure and then performed SPECT/low-dose CT scanning of the abdominal and pelvic region. Hybrid images revealed multiple areas of splenosis not only in the upper left abdominal region and peritoneal surfaces of the entire left abdominal and pelvic region, but also one small focal lesion located in the upper right abdomen, between liver and diaphragm, not seen on CT slices.

Estimation of administered fluorodeoxyglucose activity in patients on the basis of dose equivalent rate on head by multiple regression analysis

M. Hosono, K. Sakaguchi, T. Imamura, N. Takahara, M. Hayashi, C. Hosokawa, M. Yamada, K. Ishii; Kindai University, Faculty of Medicine, Osaka-Sayama, JAPAN.

Aim: The aim of this study was to establish a method for estimation of administered dose of Fluorodeoxyglucose (FDG) of patients on the basis of variables including dose equivalent rate (DER) on the right temporal region of the head, sex, body weight (weight), blood sugar, elapsed time after administration, by using multiple regression analysis. Such estimation would be useful because intravenous injection is sometimes accidentally discontinued due to extravasation of FDG, complaint of pain, or trouble of injection devices during administration, and in such cases, estimation of already-injected FDG doses may help to know whether you should make another venipuncture and inject additional FDG or to estimate an eventual influence of underdose to standardized uptake values and image quality. Methods: Five hundred twenty patients (234 females, 286 males) undergoing PET examination with a single administration of FDG were prospectively enrolled in this study. FDG was prescribed as 3 MBq/kg, and administered into patients using an automated injector. The actual administered doses (ADs) were recorded as well as patients' characteristics. The correlation of AD with independent variables of DER on the right temporal region of the head, sex, weight, blood sugar, elapsed time after administration was analyzed using multiple regression analysis to obtain linear, quadratic, and cubic regression equations. In this process, DER was converted to corrected DER (CDER) by a plotting of DER/AD and weight, which was unaffected by the influence of weight. Results: Using CDER, regression equations were acquired as, Linear: AD=L(1)xCDER, Quadratic: AD=Q(1)xCDER^2+Q(2)xCDER, Cubic: C(1)xCDER^3+C(2)xCDER^2+C(3)xCDER, where L(1), Q(1), Q(2), C(1), C(2), and C(3) were regression coefficients. When these estimated ADs were compared with actual ADs, within an accuracy of ±10% using linear, quadratic, and cubic regression equations were included 60.77%, 61.92%, and 61.92% of all patients, and within an accuracy of ±20% were included 87.12%, 89.99%, and 90.20%, respectively. Conclusions: This method proved to be accurate for estimation of AD on the basis of DER and independent variables of sex, weight, blood sugar, and elapsed time after administration by adopting the cubic regression equation. We propose this method to know already-injected FDG dose in various clinical circumstances.

EP716

Does SUV normalization based on individual CT-based LBM calculation provide better SUVs?

J. Devriese[1], L. Beels[2], A. Maes[2], C. Van de Wiele[2], H. Pottel[1]; [1]KU Leuven campus Kulak, Kortrijk, BELGIUM, [2]AZ Groeninge, Kortrijk, BELGIUM.

Aim In positron emission tomography/computed tomography (PET/CT) semi-quantitative evaluation of tumour metabolic activity is possible though the standardized uptake value (SUV), which is usually normalized for body weight (BW). Other proposed normalizations include lean body mass (LBM) and body surface area (BSA). The purpose of this study was to determine patients' LBM and lean tissue (LT) mass using a CT-based method, and to compare SUV normalized by these parameters to conventionally normalized SUVs. **Materials and methods** PET/CT examinations covering head to toe were retrospectively retrieved. LBM was determined using CT image segmentation (LBM_{CT}) based on tissue-specific Hounsfield unit (HU) thresholds, and again using the predictive formulas of James (LBM_{James}) and Janmahasatian (LBM_{Janma}). BSA was determined using the DuBois formula. LBM_{CT} was compared to formula-based estimates using the Bland-Altman method. SUVs in two healthy reference tissues, liver and mediastinum, were normalized for the aforementioned parameters and compared to each other in terms of variability and dependence on normalization factors and BW, and within-patient SUV variation was assessed in an independent dataset. **Results** LBM_{James} estimates are significantly higher than LBM_{Janma} with biases of 4.7kg (95%CI: 3.1 to 6.3) for females and 1.0kg (95%CI: 0.4 to 1.6) for male patients. Formula-based LBM estimates do not significantly differ from LBM_{CT}, neither for men nor for women. Variance of SUV normalized for LBM_{James} ($SUV_{LBM\text{-}James}$) was significantly reduced in liver compared to SUV_{BW}. All SUV variances in mediastinum were reduced, except SUV_{BSA}. Only SUV_{BW} and $SUV_{LBM\text{-}James}$ show independence from normalization factors. **Conclusion** No advantage of alternative SUV normalization over BW could be demonstrated.

EP717

Quantification of perfusion heterogeneity in patients with hypertrophic cardiomyopathy: evaluated by fractal analysis

K. Kiso[1], Y. Nishimura[2], Y. Takahasi[3]; [1]National Cerebral and Cardiovascular Center, Suita, JAPAN, [2]Teikyo University, Ohmuta, JAPAN, [3]FUJIFILM RI Pharma, Tokyo, JAPAN.

Backgrounds: Although patients with hypertrophic cardiomyopathy (HCM) showed heterogeneous perfusion distribution, there is no useful tool for quantitative assessment of such perfusion heterogeneity. "Fractal analysis" is known as one of the methods to evaluate the geometric self-similarity, which is applied for the assessment of heterogeneity of geometry or density. In this study, we investigated usefulness of "fractal analysis" for quantification of perfusion heterogeneity in HCM patients, and compared to that in normal subjects. Moreover, we also investigated the factors which influenced the perfusion heterogeneity in patient with HCM. **Methods**: Ten patients with HCM and 7 normal subjects (Normal) underwent ECG-gated myocardial perfusion SPECT at rest with ^{99m}Tc-MIBI. Polar map, which was generated from 3D-SPECT imaging, was analyzed with "box counting (BC)" and "pixel counting (PC)" methods, which were the procedures of fractal analysis to evaluate the degree of heterogeneity of geometry (BC) and density (PC). Then, we calculated and compared "fractal dimensions (FD)" of each method between HCM and Normal groups. Moreover, we investigated the relationship between FD and left ventricular (LV) functions (end diastolic volume: EDV, ejection fraction: EF), summed rest score (SRS), maximum wall thickness (MWT). **Results**: FD of both BC and PC methods, did not show significant differences between HCM and Normal groups. However, FD ratio of BC/PC was significantly higher in HCM than in Normal group (P=0.01). From further comparison of myocardial perfusion count profile between HCM and Normal, this significant difference of FD ratio between two groups might be derived from the difference of lower count distribution. In ROC analysis, AUC of detecting HCM by using this FD ratio was 0.9. In HCM patients, FD of BC and PC showed significant negative correlation with MWT (r=-0.65, P<0.05), and showed significant positive correlation with LVEDV (r=0.78, P<0.01). However, there were no significant correlation with LVEF and SRS. **Conclusions:** Fractal analysis might be useful for quantitative assessment of perfusion heterogeneity in HCM patients. Furthermore, this perfusion heterogeneity is influenced by MWT and LV volume.

EP718

Partial volume correction for improved PET quantification in 18F-NaF imaging of atherosclerotic plaques

J. Cal-Gonzalez[1], X. Li[1], D. Heber[1], I. Rausch[1], S. C. Moore[2], K. Schäfers[3], M. Hacker[1], T. Beyer[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]Harvard Medical School and Brigham and Women's Hospital, Boston, MA, UNITED STATES, [3]University of Münster, Münster, GERMANY.

Aim. ^{18}F-NaF PET uptake has been described as a marker of early calcium deposition in atherosclerotic plaques in the carotid arteries. However, due to the small size of these plaques, partial-volume effects (PVE) will compromise the quantification accuracy of the PET data. Therefore, our aim was to increase the accuracy of ^{18}F-NaF PET uptake in carotid plaques following partial-volume correction (PVC). **Materials** and methods. The local projection (LP) method was implemented for PVC in clinical PET imaging. The performance and accuracy of the method was evaluated by using static acquisitions of a thorax phantom with three "plaque-type" lesions of 36mL, 31mL and 18 mL inserted, and lesion-to-background ratio (LBR) of 70:1. After the validation of the method with phantom data, LP-PVC was applied retrospectively to a cohort of 17 patients (12 m, 5 f. mean age: (64±9) y), each with at least one positive plaque in the carotid or ascending aortic arteries. In total, 51 calcified (HU>110 within the plaque) and 16 non-calcified plaque lesions (HU<110) were analyzed. For all calcified lesions, the tissue-segmentation required for the PVC was obtained from CT. In non-calcified plaque lesions and the thorax phantom data, a threshold-based segmentation of the PET image was performed by using the 3D isocontour halfway between the background and maximum lesion voxel values. The maximum HU value and the volume of the plaque were obtained from the CT images. The lesion-to-background ratio LBR (using the mean activity within the lesion) and the activity recovery within the lesions after PVC were measured on PET images. **Results**. For the phantom acquisitions we observed a significant increase in the LBR ratio when PVC was applied (42% to 109% for the three plaque lesions). In patient images, PVC led to a significant increase of the LBR in both calcified (mean = 38% [4%-116%]) and non-calcified plaques (mean = 43%, [9%-77%]). The inverse correlation of ^{18}F-NaF uptake and HU values improved for the calcified plaques when PVC was applied. **Conclusions**. An LP-PVC method was evaluated in clinical NaF-PET/CT imaging of patients with carotid artery plaques. The PVC performance using the two proposed segmentation algorithms was evaluated in phantom experiments providing similar results in all cases. The PVC method performed well in phantom and patient data and led to improved quantification of atherosclerotic plaques in the carotids. Footnotes J. Cal-Gonzalez et al, Phys Med Biol. 2015; 60: 7127-49.

Comparison of an automatic method for the placement of a blood pool reference region compared to manual placement

A. Nelson, S. Chung; MIM Software Inc., Cleveland, OH, UNITED STATES.

Purpose: To compare the mean SUV values of a manually placed blood pool reference region to a reference region placed using a completely automated method. Methods: 45 subjects with FDG-PET/CTs were chosen for this study. The upper portion of the descending aorta (DA) was manually segmented on the CT scan for each subject in the study. These subjects were combined into an atlas to automatically generate DA contours on each subject using a leave-one-out analysis. For the atlas-segmentation, the 5 most closely matched subjects are automatically found and then deformably registered to the test subject. The 5 DA are then combined using STAPLE into a final atlas contour. An automatic method was used to search for the lowest coefficient of variation within a 1 cm sphere for the atlas-generated DA. The mean SUV value was then recorded and compared to PERCIST-based blood pool reference regions which had previously been manually placed in the DA. Results: The manually placed blood pool reference regions had an average mean SUV value of 1.91 with a standard deviation of 0.35, while the automatically generated blood pool reference regions had an average mean SUV value of 1.95 with a standard deviation of 0.38. The correlation between the two methods was 0.93, with an average difference of 0.11 (6.26%). The largest absolute deviation between automatic and manual was 0.40 SUV (20.62%). Conclusions: The automated method for blood pool reference region placement was found to agree well with manually placed reference regions and thus has the potential to save time when using criteria, such as PERCIST, that recommend reference to blood pool values.

EP720

Intra- and Interobserver Agreement with Quantitative PET Measures: Deriving Repeatability Coefficients from Variance Component Analysis

O. Gerke[1], M. H. Vilstrup[1], E. A. Segtnan[1], U. Halekoh[2], P. Høilund-Carlsen[1]; [1]Odense University Hospital, Odense C, DENMARK, [2]University of Southern Denmark, Odense C, DENMARK.

Aim: Quantitative measurement procedures must be accurate and precise to be of clinical use. Accuracy refers to deviation of a measurement from the true value of the quantity being measured. Precision reflects deviation of groups of measurement from another. Closeness of comparable measurement sets is often expressed as proportions of agreement, standard errors of measurement, coefficients of variation, or the Bland-Altman (BA) plot. Applying the concept of variance component analysis (VCA), we estimated the variances due to errors caused by separate elements of a PET scan (scanner, time point, observer, etc.) to express the composite uncertainty of repeated measurements and obtain relevant repeatability coefficients (RC) for comparison with BA plots in a test-retest setting. The RC is the limit below which 95% of differences will lie. Material and Methods: For analysis we used data sets obtained in two different studies at our institution. In study 1, 30 patients with ovarian cancer were scanned pre-operatively, and SUVmax values were obtained twice by the same observer two months apart. In study 2, 14 patients with glioma were scanned up to 5 times before and during treatment, and resulting 49 images were assessed by three observers, who calculated total hemispheric glycolysis, i.e., the segmented metabolic volume times SUVmean. Thus, the two studies served as examples of intra- and interobserver variability assessment, respectively. In study 1, we treated 'reading' (1st vs 2nd) as fixed factor and 'patient' as random factor. In study 2, both 'observer' and 'time point' were considered fixed, whereas 'patient' and 'scanner' were treated as random effects. Results: In study 1, the within-subject standard deviation times 2.77 ($\sqrt{2}$x1.96) yielded a RC of 2.46 equalling half of the width of the BA band. In Study 2, the RC for identical conditions (same patient, same observer, same time point, same scanner) was 2392; allowing for different scanners resulted in a RC of 2543. The differences between observers were negligible compared to the other factors: estimated difference between observer 1 and 2: -10, 95% CI: -352 to 332; observer 1 vs 3: 28, 95% CI: -313 to 370. Conclusion: VCA appears to be a more informative and comprehensive approach to agreement studies that are conventionally tackled with simple measures only. VCA is built on various model assumptions; however, this has not been an obstacle to the extensive use of intraclass correlation coefficients in reliability analyses.

EP721

Evaluation of the clustering based image segmentation algorithms for nuclear medicine imaging

D. Borys[1], M. Niezgoda[1], K. Szczucka-Borys[2], I. Gorczewska[2], M. Frackiewicz[1]; [1]Silesian University of Technology, Gliwice, POLAND, [2]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, POLAND.

Aim: A segmentation is a nontrivial and important step in an image analysis in every aspect of usage of imaging techniques. Especially in medical imaging, when tumour delineation is concerned, this task becomes a crucial challenge. In this work, with many segmentation algorithms, we used those, based on clustering. Standard k-means clustering technique was compared with neural gas clustering algorithm. The aim was to validate segmentation quality of those algorithms in PET segmentation imaging. Materials and methods: Data has been obtained with Philips Gemini hybrid PET/CT device at the Department of PET Diagnostics at Institute of Oncology in Gliwice. First phantom was a standard cylinder with five spheres of different radius and volume (diameter from 1.3 cm up to 4 cm). The second phantom was the Pro-NM SPECT performance phantom containing many internal structures for evaluating: pixel size, spatial resolution, etc. Spheres, in the first phantom, and the cylinder in the second one, have been filled with F-18 with constant concentration. For segmentation purpose, two clustering algorithms were tested. The first is a standard k-means clustering and the second is a neural gas algorithm. In both algorithms, the number of clusters was fixed to 2 as we are interested in discovering the borders between the lesion and the background. The Euclidean distance was used as a distance measure. For the neural gas algorithm, two parameters have to be set up: an adaptation step size A and neighbourhood size L. The number of iterations had to be determined as well and was set to 50. By maximising a Jaccard index values of parameters have been calculated and were A=0.3, L=0.96. We applied described methods to segment intensity images and to compare the results with other frequently used method based on the absolute SUV 2.5 level threshold. Results were compared to CT image based reference mask by using a Jaccard index ([0,1] where 1 corresponds to the full similarity of sets). Results: The mean values of the Jaccard index were: for the first phantom 0.65 (k-means), 0.7 (SUV 2.5) and 0.98 (neural gas), for the second phantom 0.79 (k-means), 0.22 (SUV 2.5) and 0.79 (neural gas). Conclusion: Neural gas method results with the highest Jaccard index in both phantoms. However, both methods obtained a reasonable result in the second case where standard SUV 2.5 threshold misclassified a lot of structures.

EP722

A Resolution and Noise Level Matching-Based Simulated SPECT Image Generation using PET

H. Moon[1,2], J. S. Oh[1], J. Park[1], M. Oh[1], S. Oh[1], J. Kim[1]; [1]Department of Nuclear Medicine, Asan Medical Center, University of Ulsan College Medicine, Seoul, KOREA, REPUBLIC OF, [2]Department of Medical Science, University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim Brain amyloid PET is a representative imaging biomarker in Alzheimer disease. We performed spatial resolution matching (SRM)- and noise level matching (NLM)-based generation of simulated SPECT images using phantom/clinical PET images, to explore the feasibility of Tc-99m-based amyloid SPECT. **Materials and methods** To match PET resolution/noise onto those of SPECT, we acquired PET and SPECT images of Hoffman 3D Brain Phantom (HBP) using 18MBq fluorine-18 (F-18) and 185MBq Tc-99m, where both were reconstructed using iterative methods with clinically-used iteration/subset parameters for PET and SPECT in our institution. However, we did not apply post-smooth filter to better explore the resolution/noise level differences. For the SRM of PET/SPECT, we used CT-based tissue label map (CTM), i.e., SPM8-based segmentation of a couple of best quality CT images of HBP. After morphologic image processing, we generated a label map valued four for Gray matter (GM) and one for White matter (WM) that correspond to the ideal uptake ratio in HBP PET. The CTMs were registered to individual PET and SPECT images of HBP using the transformations that project CTM onto CT images corresponding to PET and SPECT, respectively. After smoothing registered CTMs using Gaussian kernel with one-to-twenty mm FWHM (0.5mm interval), we found the resolution difference of PET and SPECT using best-fit kernels with the highest correlation coefficient for PET and SPECT. For the NLM of PET/SPECT, we added variable amplitudes (i.e., SD) of Gaussian noise before PET smoothing to find the additive noise level matching the coefficient of variation of smoothed PET in predefined GM VOI with that of SPECT. Using these matching parameters, we generated simulated patient brain SPECT using representative F-18 florbetaben (FBB) PET of patients with positive/negative/moderate amyloid deposition, followed by visual inspection of board-certified Nuclear Medicine Physicians (MO and JSK). **Results** According to the estimated SRM/NML factors (70% of mean PET GM count and 7.5mm FWHM), we could match resolution and noise level of PET onto those of SPECT by adding 70% noise and 7.5mm smoothing. Expert visual inspection-based diagnosis of positive/negative/moderate amyloid burden by F-18 FBB PET was not changed by SPECT-matched PET images. **Conclusion** By conducting SRM and NLM, we could generate the simulated amyloid SPECT image on the basis of clinically-used amyloid PET image. The simulated SPECT images of patients using the clinical F-18 FBB PET images exhibited the feasibility of a new Tc-99m-based SPECT imaging in terms of consistent clinical diagnosis.

EP723

The Value of the 3hr SeHCAT Scan - Could we Estimate a Baseline Instead?

A. Smout[1], A. Fullbrook[2], J. Ward[2], L. Wright[2], J. R. W. Hall[2], P. Hinton[1]; [1]Royal Surrey County Hospital, Guildford, UNITED KINGDOM, [2]Frimley Park Hospital, Frimley, UNITED KINGDOM.

The aim of this prospective audit was to see if an estimate of the 3 hour counts could be made instead of acquiring a baseline image. This would simplify the patient experience and avoids the use of an assumption that there is no clearance in the first 3 hours. A secondary aim of this audit was to investigate whether an episode of diarrhoea between administration and baseline imaging reduced the counts in the image. Patients are given a 0.37MBq Se-75 Tauroselcholic (SeHCAT) capsule and return 3 hours later for a 5 minute intrinsic acquisition using a gamma camera. The patients are asked if they have opened their bowels and if they are currently on anti-diarrhoeal medication - this information is noted in the clinical report. The decay and background corrected geometric mean counts from day 7 are compared to those of the baseline to calculate the percentage retained at 7 days and compared to published normal ranges. The counts in the baseline image are, in theory, a function of the activity in the patient, camera geometry and patient body habitus. For this audit of 67 patients the camera geometry was standardised, the capsule reference information was recorded to calculate the administered activity, and the patient height and weight were also recorded. A relationship between counts and the patient size was derived from the simple assumption that patients are homogenous cylinders of density 1 g/cm3. The effective radius was calculated and used within an exponential attenuation equation with attenuation coefficient for soft tissue of 0.1175 per cm. This simplistic approximation, which did not rely on any empirical factors, showed reasonable correlation (correlation coefficient 0.82) with the measured counts from imaging. A comparison between the measured counts and body mass index and again with body surface area gave correlation

coefficients of 0.78 and 0.60 respectively but gave increasing errors for more attenuating patients. The mean difference between the estimated and measured counts for patients that had opened their bowels (8 of 67) was -0.6%, suggesting that there had been no Se-75 excreted in the first 3 hours. The standard deviation of the difference between measured and estimated baseline counts was 8.0%, corresponding to a final standard deviation in the retained SeHCAT percentage of +/- 0.8% on a test result of 10%. This suggests that it may be viable to replace the 3 hour image with an estimate of the baseline counts.

EP724

Impact of the geometric mean calculation on the assessment of liver clearance with dynamic scintigraphy

Y. D'Asseler, R. Troisi, B. Lambert; Ghent University, Gent, BELGIUM.

Patients with liver tumors undergo a resection of the affected part of the liver as part of their treatment. In order to avoid complications, it is important to assess whether the liver function of the remaining part will be sufficient. This is done by dynamically scanning the patient with a gamma camera after injection of Tc-99m labeled Mebrofenin. Clearance from the blood by the liver is calculated according to the method proposed by Ekman et al. [Nuc Med Comm 1996, 17, 235-242]. In order to compensate for photon attenuation, the geometric mean of the anterior and posterior image was taken for construction of the time activity curves. In this paper, we investigate the sensitivity of the clearance calculation to the way this geometric mean is taken into account. 13 patients scheduled for liver surgery received a dose of approximately 180 MBq of Tc-99m-labeled Mebrofenin and were subsequently dynamically scanned for 10 min with 10 second time frames. For the first method, regions of interest (ROI's) of the liver and heart were drawn manually on the anterior image, and copied onto the posterior image. Time-activity curves (TACs) were constructed by taking the geometric mean of the anterior and posterior total counts in the ROI. These TAC's were then used as an input to calculate liver clearance using the method described in [1]. The second method consisted in calculating the geometric mean image pixel by pixel for each frame, and then drawing ROI's on these images to obtain the TAC's and calculate the liver clearance.For method 1, with geometric mean calculated on the total counts for each ROI, the average liver clearance was (12,0 ± 3) %/min, for method 2, using a pixelwise geometric mean, liver clearance was (14,5 ± 4) %/min. Calculating the relative difference in liver clearance for each patient, we obtained a mean difference between both methods of (17,4±2,6) %, with a maximum observed difference of 22%. We observe a significant and large difference between calculated liver clearances if the pixel by pixel geometric mean calculation is performed instead of calculating the geometric mean on a ROI basis. Mathematically, a pixel by pixel calculation is the more correct method, however, not all clinical Nuclear Medicine processing packages allow this operation. Moreover, care should be taken in low count regions where pixels with zero counts in the posterior or anterior image may lead to a bias.

EP725

Quantitative Estimation of Acivities in a Tc-99m/In-111 Small Animal SPECT Study

K. Ogawa[1], S. Endo[1], I. O. Umeda[2], H. Fujii[2]; [1]Hosei University, Tokyo, JAPAN, [2]National Cancer Center, Kashiwa, JAPAN.

Aim: This study is aimed to develop a method to measure the distribution of two activities (^{99m}Tc and ^{111}In) simultaneously in a small animal SPECT study with multi-pinhole collimator. **Materials and Methods**: In the estimation of activities we applied an artificial neural network (ANN) with three layers: one input layer with three or four units, one hidden layer with twice the number of units in the input layer, and one output layer with three units. For values input into the units in the input layer, we used a predefined number of ratios of counts calculated with several energy windows, which are the ratios of the count C_k acquired with the k-th window to the sum of the above counts C_s. That is, the value input into the k-th unit was the ratio R_k to C_s. The outputs were three count ratios defined as follows: R_{Tc} was the count ratio of primary photons for ^{99m}Tc (141keV), R_{In1} was that for ^{111}In (171keV), and R_{In2} was that for ^{111}In(245keV). With these ratios, each of the primary counts was estimated by multiplying R_{Tc}, R_{In1}, and R_{In2} with C_s. The ANN was trained with a back-propagation algorithm using the above data obtained with a Monte Carlo method. The data acquisition geometry was the same as that of the nano-SPECT/CT with four cameras each with a nine-pinhole collimator. To make training data, we used a cylinder (radius 20mm) filled with water, in which we located two small cylinders (radius 3mm) and emitted photons of ^{99m}Tc and ^{111}In. The number of emitted photons was 10Giga. The pixel size was 1.035x1.035mm^2. The evaluated target was a cylinder (radius 15mm, length 10cm), inside which we located two small cylinders with a radius of 4mm. After separating the two radionuclides in the projection data, images were reconstructed with the ML-EM method. The accuracy of the estimation was evaluated by the root mean square error in the reconstructed images. **Results**: The results showed that the three-inputs ANN with three photopeak windows (^{99m}Tc: 1 and ^{111}In: 2) was suitable for the estimation of ^{111}In activities. And the four-inputs ANN including an extra energy window to measure scattered photons was suitable for the estimation of ^{99m}Tc activities. **Conclusions**: We applied the ANN method to quantitatively measure the distribution of activities with the ^{99m}Tc/^{111}In simultaneous data acquisition in a small animal SPECT study and determined the structure of the ANN.

EP726

Optimisation of time of flight FDG PET/CT for whole body imaging

E. Kalogianni, D. Ruiz, G. Havariyoun, C. Benjamin, G. Vivian; King's College Hospital, LONDON, UNITED KINGDOM.

Aim: The motivation of this project was to assess and optimise the relationship between FDG administered activity and accurate quantification as well as image quality in PET/CT whole-body (WB) imaging. Method: WB time-of-flight (TOF) PET/CT was performed in 32 patients, 64 ±6 min after the injection of 336±53 MBq (range 226-423 MBq) ^{18}F-FDG, using a linear relationship between administered activity (A) and body mass (W) (A(MBq)=4.5×W(kg)). Median body mass was 73±14 kg (47-105kg) and height was 1.7±0.1 m (1.3 -1.8m). TOF reconstructions were created from simulated 1.5-min, 2-min and 2.5-min data taken from the 3-min per bed position (reference) acquired list mode data in order to create reduced count statistics. SUVmax from 93 FDG avid foci, from 24 patients was analysed using a 3-mm diameter VOI, autopositioned on all the reconstructed images. Bland-Altman plots were produced to assess the reproducibility of SUV measurements. Liver signal-to-noise-ratio (SNR_{liver}) that was determined from nine 3-mm diameter VOI placed in the uniform liver region and noise equivalent counts per axial length ($NEC_{patient}$) were used to assess the image quality. Results: SUV measurements showed high correlation between the reference acquisition and the 1.5-min, 2-min and 2.5-min acquisitions (r>0.99). Reproducibility slightly worsened as acquisition time decreased; 95% confidence limits were ±8% (or ± 0.1 SUV) for the 1.5-min per bed position. SNR_{liver} showed moderate correlation (r>-0.5) with body mass index (BMI) for all acquisitions. Median SNR_{liver} was reduced by 27% for the 1.5-min per bed position from 11, as measured for the reference acquisition. 90% percentile of SNR_{liver} of patients with BMI<25kg/m^2 scanned with at least 2.5-min acquisition was greater than 10, at 95% confidence. $NEC_{patient}$ was strongly correlated with body mass (r>-0.7). Median $NEC_{patient}$ decreased by 52% for the 1.5-min per bed position from 26 Mcounts/m, as measured for the reference acquisition. All median

$NEC_{patient}$ values and median SNR_{liver} for the 3-min and 2.5-min acquisitions satisfied the Fukukita et al [1] image quality criteria. Conclusions: Reduced time acquisitions resulted in images with higher level of noise, but without significant bias in the SUV measurements. BMI was a better predictor of image noise. This study shows that time reduction up to 20% will not have significant impact to image quality, especially to patients with BMI<25kg/m^2. Visual assessment is needed to evaluate the findings. Reference: [1] Fukukita H, et al. Ann Nucl Med (2014) 28:693-705.

EP727

Quantification accuracy of PET images as a function of emission scan time in PET/CT and PET/MR

S. Wampl[1], I. Rausch[1], T. Traub-Weidinger[1], T. Beyer[1], M. Gröschl[2], J. Cal-González[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]Vienna University of Technology, Vienna, AUSTRIA.

Aim. To evaluate the effect of reduced emission times on the PET quantification accuracy in PET/CT and PET/MR. Materials and methods. Measurements were performed on a Biograph TruePoint-TrueView (TPTV) PET/CT and Biograph mMR PET/MR. Full acquisitions were split into time frames of (10, 5, 3, 2 and 1) min and reconstructed using iterative methods (OSEM, 4i21s, 5x5mm Gaussian post filtering) with and without resolution recovery (PSF, no post filtering). Phantom evaluation: A 20 min list mode acquisition of the NEMA NU-2 IQ phantom containing six spheres (10mm-37mm) was acquired. Quantification accuracy was evaluated by means of Signal-to-Noise-Ratios (SNR) and Recovery Coefficients (RC) for the maximum- (RC_{max}), and mean activity in a volume-of-interest defined by a background-corrected threshold at 50% of the maximum voxel (RC_{A50}). Time-dependent variations of segmented volumes were analyzed for the VOI used for RC_{A50} (V_{50}). Patients: 10-min dynamic data of ^{18}F-FET brain scans (7 PET/CT, 4 PET/MR, 1 both) were processed similar to the phantom data. Quantification accuracy was evaluated using image noise, SNR and Standardized Uptake Values (SUV) for the maximum (SUV_{max}) and mean (SUV_{A50}) activity in V_{50} VOI. Results. In phantom images, noise increases by up to 200% when reducing acquisition time (AcqT) from 20min to 1min, independent of the reconstruction method and PET system used. In PET/MR, reduction of AcqT introduced an increase of the RC_{max} in the biggest sphere for OSEM (+9%) and PSF (+60%). RC_{A50} demonstrated only half of these increases. The segmented volumes for the bigger spheres were reduced by up to 70% when shortening the AcqT. SNR decreased by 80% when reducing AcqT, independent of the sphere-size or reconstruction method. Reducing frame duration in patient studies (OSEM) using PET/CT and PET/MR increased image noise by 80% and 50%, thus, resulting in 15% and 9% higher SUV_{max}, respectively. PSF reconstructions revealed higher dependencies of SUV on the frame duration in PET/CT and PET/MR: 95% and 140% noise; 35% and 50% SUV_{max}, respectively. SUV_{A50} was less affected by reduction of AcqT. Conclusions and outlook. RC_{max} and SUV_{max} values are strongly affected by reduced emission scan times, thus, affecting quantification accuracy of PET images while RC_{50} and SUV_{A50} show a more stable behavior.

EP728

Optimization of ^{201}Tl-SPECT Imaging in Brain Tumors Utilizing Simple Three 360° Rotational Acquisition and SPECT/MRI Hybrid Imaging

A. Abe[1], S. Abe[2], S. Oya[1], T. Matsui[1]; [1]Saitama Medical University, Kawagoe, JAPAN, [2]Shizuoka Medical Center, Shizuoka, JAPAN.

Background: ^{201}Tl-SPECT is useful in diagnosing brain tumors. The minimum radiopharmaceutical dosage of ^{201}Tl-chloride and the appropriate length of scan time for diagnosing brain tumors are, however, difficult to determine and have not been precisely investigated. Aim: Validating the possibility of shortening the length of ^{201}Tl-SPECT scan time in patients with brain tumors is the primary purpose of this study. Materials and Methods: Ten cases of preoperative brain tumors: 5 intraaxial and 5 extraaxial, were included in this study. The early-phase imaging and delayed-phase imaging were started at 15 min and 3 hours 15 min after the injection of 111MBq of ^{201}Tl-chloride in a pre-filled syringe, respectively. One ^{201}Tl imaging took 27 min and consisted of three 360° rotational acquisition: one 360° rotation took 9min. The short length (9 min) scan data were acquired from the first 360° rotational scanning. The middle (18 min) and long (27 min) length scan data were acquired from the first and second and from the first to third 360° rotational scanning, respectively. The region of interest (ROI) was precisely placed on the uptake of the tumor (T) and its contralateral area as background uptake (N) on the ^{201}Tl-SPECT/MRI hybrid images obtained utilizing the NEUROSTAT-based multimodality fusion software. Thallium uptake indices of the early-phase imaging (ER) and delayed-phase imaging (DR) were defined as follows: thallium uptake index = mean counts per voxel in T / mean counts per voxel in N. The group of 9 min ERs, 18 min ERs and 27 min ERs were statistically compared with Friedman's χ^2r-test and the same comparison was also applied for 9 min DRs, 18 min DRs and 27 min DRs. Results: No statistically significant difference was observed among the groups of 9 min ERs, 18 min ERs and 27 min ERs (P =1.34) and also among the groups of 9 min DRs, 18 min DRs and 27 min DRs (P =1.48). Conclusion: ER and DR were invariable regardless of scan length: 9 min, 18 min and 27 min. The short length scan taking 9 min is, therefore, sufficient to calculate thallium uptake indices, i.e. ER and DR, which are essential to evaluate the degree of uptake of ^{201}Tl to brain tumors. These results also suggest the radiopharmaceutical dosage of ^{201}Tl-chloride can be reduced to a minimum of 37 MBq, one third of current 111 MBq, with the long length scan taking 27 min.

EP729

Fusion and Analysis of PET And CT Images of Patients with Non-Small Cell Lung Cancer

O. Ayyıldız[1], B. Yilmaz[1], S. Karacavus[2,3], O. Kayaalti[4], K. Eset[3], C. Gazeloglu[1], S. Icer[3], E. Kaya[5]; [1]Abdullah Gul University, Department of Electrical and Electronics Engineering, Kayseri, TURKEY, [2]Bozok University, Department of Nuclear Medicine, Yozgat, TURKEY, [3]Erciyes University, Department of Biomedical Engineering, Kayseri, TURKEY, [4]Erciyes University, Department of Computer Technologies, Kayseri, TURKEY, [5]Acibadem University, Department of Nuclear Medicine, Kayseri, TURKEY.

Background: Non-small cell lung carcinoma (NSCLC) accounts for 85% of all cases of lung cancer. Use of positron emission tomography - computed tomography (PET-CT) imaging systems permits the acquisition of functional and morphological data within a single session. Recently, texture features obtained from PET/CT images that reflect the heterogeneity of the tumor are shown to be complementary to the quantitative assessment of the tumor. The texture analysis is mainly performed on only PET images. The number of studies that deal with fused images are very few. **Material and Methods**: In this work, we used PET/CT images of 67 NSCLC patients. We worked on PET slices with the maximum standard uptake value and the corresponding CT slices. The first step was to define the object boundaries and perform intensity based image registration to align the images. We applied principal component analysis (PCA) and discrete wavelet transform (DWT) to fuse registered PET and CT images. We compared fused images based on objective fusion metrics such as spatial frequency (SF), mutual information (MI), and fusion symmetry (FS). An experienced nuclear medicine expert also visually assessed the fusion performances. Then, we applied active contour segmentation method to segment the tumors in PET and CT images

separately and in images fused with PCA and DWT. Next, we extracted features using the gray level co-occurrence matrix (GLCM) and compared the texture features obtained from only PET images and images fused with DWT. **Results**: We found that the DWT was better than the PCA in terms of visual and objective metrics. We also found that there is no significant difference between textures features obtained from only PET and fused images ($p<0.05$). **Conclusion**: Texture features determined from only 18F-FDG PET images can use to evaluate the heterogeneity of the tumor in non-small cell lung cancer.

EP730

Assessment the Performance of Adding Risk Factors to Quantitative Analysis of Myocardial Perfusion Imaging

M. bordbar[1], S. Ghasempoor[2]; [1]Department of Communication Engineering, Shiraz University of Technology, Shiraz, IRAN, ISLAMIC REPUBLIC OF, [2]Alzahra Charity Hospital, Shiraz, IRAN, ISLAMIC REPUBLIC OF.

Although the regional and global quantitative analysis may improve the reproducibility and certainty of interpretation of SPECT myocardial perfusion imaging (MPI), but still there is not enough association between the quantitative values and physician's visual interpretations. In this study we assess if adding the risk factors as the complementary values to quantitative analysis, can improve the association to visual interpretations. In a retrospective study, all the patients (age: 51 ± 23, 155 male, 306 female) with likelihood of coronary disease who underwent rest/stress 99mTc-sestamibi gated SPECT in our hospital during a month were selected. An expert interpreted the images visually while the quantitative data and risk factors were shown to him. The quantitative analysis results compared with the expert's decision about the patient's ischemia. According to our results, the sensitivity and specificity and area under curve of sum rest (SRS) and sum stress score (SSS) are 0.53 and 0.79, 0.74 and 0.63, 0.63 and 0.76 respectively. Adding the adequate risk factors to SRS and SSS analysis the total accuracy changes from 0.63 to 0.65 and from 0.71 to 0.63, and the precision growths dramatically from 0.67 to 0.87 and 0.68 to 0.78 for SRS and SSS respectively. The results of this study show that adding adequate risk factors as the complementary values to quantitative analysis can improve the diagnostic value of SRS and SSS. These findings suggest that computer aided diagnostic systems can effectively improve their performance by using quantitative parameters of MPI along with risk factors as the complementary values.

EP731

How much reduction in time can we go in myocardial perfusion SPCT Imaging? role of resolution recovery and correction of image degrading factors

M. M. Khalil[1], T. Ahmed[2,3], W. Elshemey[4], A. ELfiky[4]; [1]Faculty of Science Helwan University, Physics Department, Cairo, EGYPT, [2]Nuclear Medicine and Cyclotron department King Hamad University Hospital, Busaiteen, BAHRAIN, [3]Faculty of science, Biophysics department, Cairo University, Cairo, EGYPT, [4]Faculty of Science Cairo University, Biophysics Department, Cairo, EGYPT.

Objective:The aim of the present study was to evaluate the effect of reducing the acquisition time on the performance of Iterative Reconstruction (IR) algorithms accompanied with attenuation, scatter and resolution recovery corrections (IRACSCRR) on the quality of myocardial perfusion SPECT imaging.Methods:A standard cardiac phantom with solid inserts was used to simulate a routine myocardial perfusion SPECT/CT imaging. Two solid inserts were used; one placed in the mid anterior portion of the myocardium while the other was inserted in the basal inferior wall.The phantom was placed inside a uniform cylindrical phantom. A clinically relevant count rate and acquisition time was used to avoid discordance with real data acquisition.Four SPECT scans were acquired using vendor standard cardiac protocol for resolution recovery applying different acquisition times (5, 10, 15 and 20 sec per frame).The CT attenuation map was acquired using 50 mA and 100 kV. Figures of merit used to evaluate the performance of the reconstruction algorithms were count uniformity, coefficient of variation (CoV) and Contrast to Noise ratio (CNR) calculated for normally perfused myocardium while percentage defect contrast was used to assess hypo-perfused segments represented by solid inserts. The slice uniformity and CoV were calculated using maximum count of 60 radial rays of circumferential profiles drawn over normal slices. Image reconstruction was carried out using FBP and IR (OSEM;IRACSCRR). Results: The image quality of (IRACSCRR) showed an improvement in terms of CNR and defect contrast resolution as we move towards longer acquisition time. CNR was improved in the direction of basal to apical slices while, there was significant improvement in defect contrast resolution for both defects at longer acquisition time. No large difference was found in the defect contrast of non-transmural relative to transmural defect for the same acquisition time. However, this was associated with slight increase in image noise as shown from image uniformity and CoV analysis. There was also improvement in CNR when using longer acquisition time but still not significant.Conclusion: The results showed that the image uniformity, CoV, defect contrast and CNR were improved by applying the higher acquisition time with slight differences appeared on apical versus basal slices and transmural versus non-transmural perfusion defects. In Comparison, the reduction in imaging time (down to one-third) was found non-significantly affecting the image quality. However, individualizing the acquisition parameters due to variable patient habitus could stabilize image quality among different subjects and/or scans. This is to be addressed in future studies.

EP732

Comparison of QGS, 4DM-SPECT, and MIMcardiac Left Ventricular Volumes for Tc99m SPECT to Cardiac Computed Tomography Angiography (CCTA) Volumes

A. Nelson, S. Pirozzi, A. Pilla, D. Nelson; MIM Software Inc., Cleveland, OH, UNITED STATES.

Purpose: To compare the left ventricular volumes generated by three commercially available software packages with reference to CCTA volumes for cardiac Tc99m sestamibi gated SPECT.Methods: CCTA images were collected for 15 patients with corresponding gated (8 frame) stress Tc99m sestamibi SPECT studies. The LV endocardial cavities were manually segmented on the CCTA's. The CCTA images were fused to the corresponding gated SPECT study and the most closely matched frame was identified prior to generating the SPECT contours. The gated SPECT scans were then processed using MIMcardiac, QGS, and 4DM to generate time volume curves. The volume from the frame that was previously determined to most closely match the CCTA was recorded. All processing was done completely automatically without any operator intervention. **Results:** MIMcardiac had correlation of 0.94 with an average volume difference of 31 mL (23% diff) compared to CCTA. 4DM had the next highest correlation of 0.90 and an average volume difference of 92 mL (63% diff). QGS had a correlation of 0.88 and an average volume difference of 64 mL (59% diff). Three of the fifteen QGS segmentations needed adjusted and after adjustment the results improved to a correlation of 0.93 and average volume difference of 48 mL (39%). All MIMcardiac and 4DM results were completely automatic. **Conclusions:** All three methods showed good correlation with CCTA volumes with MIMcardiac showing the highest correlation and least difference in volume. Additional studies are planned with comparison to gated cardiac MRI.

Usefulness of 18F-FDG PET/CT for the Diagnosis of Tuberculous Pericarditis

T. Li, Z. Jiang; The First Affiliated Hospital of Nanjing Medical University, nanjing, CHINA.

The diagnosis of tuberculosis as the aetiological cause is important. However, in a significant number of patients, a definite diagnosis cannot be established. Positron emission tomography (PET) can be a useful supplement to computed tomography (CT) because its depiction of metabolic activity in the pericardium or in pericardial fluid. When combined together, PET/CT may help with early diagnosis of tuberculous percarditis. By far, only a few case reports have discussed the usefulness of ^{18}F-FDG PET/CT for tuberculous pericarditis. It's value is not well determined. Therefore, we present the result with six cases of tuberculous pericarditis to analyze the clinical value of ^{18}F-FDG PET/CT in diagnosis of tuberculous pericarditis and review the literature. CONCLUSION: 18F-FDG PET/CT features like pericardial thickening, pericardial enhancement of FDG uptake, mediastinal lymph nodes enlargement, mediastinal lymph nodes enhancement of FDG uptake may help to differentiate with idiopathic pericarditis. Mediastinal lymph nodes without hilar node involved may help to differentiate with malignant pericardial disease.

Collimator-Detector Response Compensation in Preclinical SPECT using STIR Framework

H. Mahani[1,2], G. Raisali[2], A. Kamali-Asl[3], **M. Ay**[4,1]; [1]Research Center for Molecular and Cellular Imaging (RCMCI), Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Radiation Application Research School, Nuclear Science and Technology Research Institute (NSTRI), Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiation Medicine Engineering Department, Shahid Beheshti University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Ever growing need for high spatial resolution in quantitative molecular imaging of small-animals mandates to compensate the SPECT images for resolution degrading processes. The collimator-detector response (CDR) is well known as a primary function determining SPECT images resolution. Therefore, the principal objective of this study was to recover the lost resolution in molecular SPECT using STIR framework. **Materials and Methods:** To derive distance-dependent CDR functions, a set of point-source measurements at various distances from the collimator were conducted using HiReSPECT scanner, a dedicated small-animal SPECT camera developed in our department. Micro Derenzo as well as NEMA image quality (IQ) phantoms were analytically simulated (64 views over 360 degrees) with the STIR in order to acquire CDR-degraded projection data. The data were then corrupted by a Poisson noise to mimic a realistic data acquisition. Subsequently, the CDR-blurred sinograms were iteratively reconstructed with and without resolution modeling using an OSEM algorithm (4 subsets and 32 subiterations). Activity recovery coefficient for hot-rods part of the phantom, noise behaviors for its uniform part, and spill-over ratios for two cold cylinders inserted in the phantom were assessed in order to study how well the STIR compensates SPECT images for the CDR. The STIR study was validated by means of comparison with experimental measurements. **Results:** As a results of the CDR compensation, a substantial gain in spatial resolution is yielded, and the rods with 1.6 mm diameter become resolvable in the micro Derenzo phantom reconstruction. The CDR compensation results in a significant increase in recovery coefficient up to a factor of 1.24 for the largest diameter rod. Spill-over ratio falls off from 0.24 to 0.16 (averaged for the two cold cylinders) as consequence of CDR modeling. A subtle reduction in coefficient of variation, as a metric indicating noise performance, from 8.4% to 6.7% was also observed. The CDR compensation mechanism outcomes a correlated blobby noise-texture compared with original Poisson one. In addition, a 15.5% overshoot at the edge of the uniform part, known as Gibbs ringing artifact, occurs as an unavoidable side-effect. The uncompensated recovery coefficients obtained using the STIR agree with those experimentally calculated, a maximum 11% difference for the 5-mm diameter cylinder. **Conclusion:** The STIR-provided results showed the importance of CDR modeling in preclinical SPECT. This modeling considerably corrects partial volume effect, but at the expense of Gibbs artifact as well as altering image noise-pattern.

EP735

The evaluation of the spatial dependence of noise correlation structure in SPECT images with and without resolution modelling

I. S. Armstrong, M. J. Memmott; Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

Aims. Lung SPECT has been shown to be superior to planar scintigraphy and a continued shift towards SPECT is anticipated. Resolution modelling (RM) has been shown to provide superior quality. Initial evaluations with Lung SPECT have shown promise but streak artefacts, primarily in sagittal and coronal planes, have prohibited its implementation. We believe these artefacts are due to spatial dependence of the noise correlation structure with RM. This work aims to quantify the degree of spatial dependence of noise structure in a uniform phantom. Methods. Gated SPECT data, generating 24 replicate images, of a 30cm diameter cylindrical phantom were acquired on a GE Optima with LEHR and ELEGP collimators. Attenuation-corrected images were reconstructed with and without RM; with 2, 5 and 10 iterations; 10 subsets and no post-filtering. Nine 17x17x17 voxel regions were extracted (8 radially offset and one central). For each region, Image Roughness (IR) was measured and a voxel correlation kernel was produced. A 2-dimensional Gaussian was fit to each kernel. The Coefficient of Kernel Elongation (CoKE) was expressed as the ratio of the FWHM of the Gaussian in orthogonal directions. A CoKE of 1 indicated a radially symmetric kernel and hence no directional noise structure. Results. With RM, average IR reduction relative to non-RM was 64%, 62% and 54% at 2i, 5i and 10i with LEHR collimators and 74% 75 and 71% with ELEGP collimators. Correlation kernels from non-RM images showed very little elongation for all regions indicating no spatially dependent noise structure. Mean CoKE at 2i, 5i and 10i were: LEHR non-RM: 1.07, 1.04, 1.03; ELEGP non-RM: 1.08, 1.04, 1.03. Substantial radial kernel elongation was observed for both sets of RM data in the offset regions. This was less pronounced with LEHR collimators and was seen to decrease with increasing iteration for LEHR only. Mean CoKE at 2i, 5i and 10i were: LEHR RM: 1.49, 1.47, 1.45; ELEGP RM: 1.62, 1.63, 1.64. Conclusion. Voxel variance reduction due to RM is greater with ELEGP collimators than LEHR collimators. However, the broader point spread function of ELEGP collimators produces notably greater spatially dependent radial correlation structure when RM is used, compared with LEHR collimators. This study demonstrates RM, particularly with ELEGP collimators, is unlikely to be useful in lung SPECT and alternative methods of variance reduction such as isotropic post-filtering may be more appropriate than RM for either collimator.

EP736

Accuracy of Attenuation Correction in PET/MRI with Special Focus on Large Arteries

A. Mota-Cobian[1], J. Alonso Farto[1,2], L. Fernández-Friera[1,3], J. Sánchez-González[4], B. López Melgar[1,3], L. Jiménez-Borreguero[1,5], V. Fuster[1,6], J. Ruiz-Cabello[1,7], S. España[1,7]; [1]CNIC (Spanish National Cardiovascular Research Centre), Madrid, SPAIN, [2]Hospital General Universitario Gregorio Marañón, Madrid, SPAIN, [3]Hospital Universitario Montepríncipe, Madrid, SPAIN, [4]Philips Healthcare, Iberia, Madrid, SPAIN, [5]Hospital Universitario La Princesa, Madrid, SPAIN, [6]Mount Sinai School of Medicine, New York, NY, UNITED STATES, [7]Ciber de Enfermedades Respiratorias (CIBERES), Madrid, SPAIN.

Introduction PET/MRI combines the capabilities of PET to provide functional information, with the anatomical information provided by MRI. Accuracy on quantitative PET image analysis, relies on the correct application of attenuation correction among others factors. In PET/CT scanners, reliable attenuation maps are obtained from CT images. However, obtaining an attenuation map from a MRI scan is one of the major challenges for PET/MRI that remains to be solved. The purpose of this study was to evaluate the effect of MRI-based attenuation maps and the use of flexible coils on the quantitative accuracy of PET images. We paid special attention to the use of FDG-PET for the assessment of vascular inflammation in atherosclerotic plaques. ***Methods*** PET/CT data from eight oncologic patients was used. PET data was reconstructed using attenuation maps with different level of detail emulating several approaches available on current PET/MRI scanners. PET images obtained with CT-based (CTAC) and MRI-based (MRAC) attenuation maps were compared to evaluate the quantitative accuracy obtained in different tissue types, and for the quantification on several arteries (carotid, iliac, femoral, aortic arch and abdominal aorta). In addition, the quantitative effect produced by the presence or absence of flexible MRI receiver coils in the attenuation maps was studied. ***Results*** Mean bias between CTAC and MRAC increased, as the attenuation map simplifies, in fat (-1.5 %, -1.2 %, 22.0 %), non-fat soft-tissues (-4.6 %, -5.2 %, 1.5 %) and bone (-5.5 %, -37.9 %, -36.5 %). Despite lung tissue is included in all MR-based attenuation maps, large deviations (18 % bias and 42 % RMSE) were obtained due to the high heterogeneity and inter-patient variability of the lung. The quantification of vascular inflammation using FDG-PET acquired with PET/MRI scanners had small deviations (*SUV* bias below 10%) except for the case when the flexible coil was added (up to 20%). On the other hand, *TBR* compensate quantitative errors produced by attenuation map simplification leading to lower biases than *SUV*. ***Conclusions*** In this study the effect of using simplified attenuation maps as provided by PET/MRI scanners on the quantitative accuracy of PET images has been studied. The quantitative accuracy of reconstructed PET images was gradually diminished as the attenuation map simplify. This degradation was especially significant for the quantification of lung and bones. However, the assessment of vascular inflammation using FDG-PET on PET/MRI scanners produce acceptable results, particularly when the TBR is considered.

EP737

Should the PET Reconstruction be Optimized in a Different Way for ^{18}F-FLT?

P. Subramanian, K. Binzel, **P. Bhatia**, B. Ramaswamy, J. Zhang, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

^{18}F-fluorothymidine (FLT), is a promising marker to assess proliferation in tissue and the reticuloendothelial system, and is being explored as an alternative to FDG in PET imaging of advanced disease and response monitoring. In order to improve lesion characterization, we have previously validated and optimized the use of smaller voxel volume, high definition reconstruction for FDG acquisitions performed in parallel as part of a dual tracer imaging trial. Our aim is to also advance the image quality of FLT acquisitions and the use of high definition reconstruction to further improve lesion conspicuity and quantitative accuracy. List mode raw data acquired previously for a FDG/FLT PET/CT breast cancer clinical trial for 10 patients were reconstructed using the default, standard definition (SD, 4 mm^3 voxel volume, 3 iteration, 33 subset) protocol and an investigational high definition (HD, 2 mm^3 voxel) protocol with varying numbers of subsets per iteration, 33, 29, 21, 15, 11, 9, and 7 subsets. The resulting images were visually assessed by 3 independent blinded reviewers and ranked in regard to clinical image quality. Quantitative assessment was performed by placing 3D ROI over lesions as well as liver and bone marrow, to compare default and HD quantification. ROC analysis was used to assess image quality performance in relationship to the modified reconstruction approaches. High definition FLT images revealed that using the standard 33 subsets improved visual detail, however increased image noise. Similar to the prior assessment of FDG parameters, we observed a substantial reduction in noise by lowering the number of subsets. The ROC analysis indicated that the optimization of the reconstruction parameters converged differently than seen in the same patient population for the FDG acquisitions. Images with higher subsets appear sharper, however are rated noisier. For FLT, the use of 9 subsets was rated most preferable with substantially more detail-containing images and markedly improved visualization of lesion heterogeneity. Quantification of the optimized images showed a signification increase in SUV_{max} while SUV_{mean} remained comparable in background. HD reconstruction greatly improves image quality, aiding in lesion detection and assessment of heterogeneity. Due to the different biodistribution of FLT, the optimization of image reconstruction revealed different characteristics, thus indicating that tracer specific reconstruction optimization is beneficial. It also appears to be preferential for quantitative robustness to assess clinical response.

EP738

A Software Motion-Correcting PET Reconstruction Reduces Nodule Size

N. C. D. Morley[1], D. R. McGowan[1,2], K. M. Bradley[1], F. V. Gleeson[1,2]; [1]Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM, [2]Oxford University, Oxford, UNITED KINGDOM.

BACKGROUND: Periodic respiratory motion can obscure focal activity in PET scans. Data Driven Gating (DDG) is used to detect this motion in the PET list data, without additional hardware. The technique has been further developed by gating the PET data into 5 respiratory phases. These phases can be individually corrected and then recombined, allowing data from all parts of the respiratory cycle to be used. Conventional DDG considers data only in the static part of the respiratory cycle. **AIM**: To compare a novel motion-correcting DDG reconstruction to our current clinical technique, using scans with FDG avid nodules affected by respiratory motion. **METHODS**: List mode data was retained for oncology FDG PET/CT scans (free-breathing studies, 90 mins after 4 MBq/kg FDG IV, with attenuation correction CT). After clinical reporting and identification of artefacts, the data was submitted to an additional retrospective DDG reconstruction using principal component analysis to detect motion. The data was divided into 5 respiratory phases which were then registered to a reference phase. The new reconstruction is compared to our current clinical standard using lesion measurements of the cranio-caudal diameter (manual, SUV window 0-6) and SUV_{max} (measured automatically within applied VOI). Both reconstructions use a Bayesian penalised likelihood algorithm with a beta of 400. Corrected data were normalised to the standard data to give relative values, and averaged to mean with 95% confidence interval (CI). 20 nodules have been assessed in 14 cases (max. 2 per case): 8 pulmonary, 11 hepatic, and 1 splenic. RESULTS: In most cases the nodules showed an increase in conspicuity, a decrease in lesion diameter and an increase in SUV_{max}. Mean lesion diameter decreased by

30% (CI 21 to 39%) and SUV_{max} increased by 7% (CI -4% to +17%). **CONCLUSION**: Software detection of periodic respiratory motion in clinical PET data can be used to divide the data into phases, allowing subsequent motion correction with minimal data loss. This has improved conspicuity and quantitative assessment of nodules affected by respiratory motion. Improved lesion detection could increase the accuracy of staging and patient care. Better quantification could facilitate better assessment of therapeutic response.

EP739

Effect of Monte Carlo Collimator Modelling on ^{90}Y Bremsstrahlung SPECT Images

C. A. Porter[1], M. D. Walker[1], K. M. Bradley[1], D. R. McGowan[1,2]; [1]Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM, [2]University of Oxford, Oxford, UNITED KINGDOM.

Aim: To investigate the effect of Monte Carlo collimator modelling (HybridRecon, Hermes Medical Solutions AB, Stockholm) on ^{90}Y Bremsstrahlung SPECT studies, with particular focus on the post-therapy imaging of ^{90}Y selective internal radiation therapy (SIRT) patients, and to compare the quality of such images with those acquired according to current local protocol. **Method**: A NEMA IQ phantom and the Abdo-Man™ phantom (a 3D-printed liver phantom with fillable inserts) [1] were imaged using a GE Discovery 670 SPECT/CT scanner with a number of different hot sphere to background ratios. Datasets were reconstructed twice using HybridRecon (Hermes Medical Solutions AB): using standard OSEM (5 iterations, 15 subsets) and using OSEM (5 iterations, 15 subsets) combined with Monte Carlo modelling of the GE MEGP collimators used in the acquisition. No filters were applied to any of the images. Regions were drawn in each of the hot spheres, with corresponding regions in the warm background. These were used to calculate contrast recovery (CR), background variability (BV) and contrast to noise ratio (CNR = CR/BV). Phantom images and ten patient images were also blind scored for image quality by a consultant radiologist. **Results**: With a sphere to background ratio of 4:1 in the Abdo-Man™ phantom, the CR for the 30mm diameter and 40mm diameter spheres was higher when Monte Carlo collimator modelling was used (by 14% and 11% respectively). No effect was observed on the CR for the 20mm diameter sphere. For the 20mm, 30mm and 40mm diameter spheres there was a decrease in BV of 2% when Monte Carlo collimator modelling was used. CNRs of the 20mm, 30mm and 40mm diameter spheres were increased when Monte Carlo collimator modelling was used (by 29%, 95% and 77%, respectively). **Conclusion**: In this study, it was shown that Monte Carlo collimator modelling improves CR, BV and CNR in ^{90}Y Bremsstrahlung SPECT images. **Reference**: [1] J.Gear et al EJNMMI,42(S1):Abs.P872

EP740

Computationally efficient method for fully 4-D voxel based direct estimation of time activity curve in dynamic myocardial SPECT

S. Entezarmahdi[1], A. Banani[2], A. Kamali-asl[1], R. Faghihi[3], M. Haghighatafshar[4]; [1]Department of Medical Radiation, Shahid Beheshti University, GC, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Engineering, Isfahan University, Isfahan, IRAN, ISLAMIC REPUBLIC OF, [3]Ray Medical Engineering Department, Shiraz University, Shiraz, IRAN, ISLAMIC REPUBLIC OF, [4]Nuclear Medicine and Molecular Imaging Research Center, Shiraz University of Medical Sciences, Shiraz, IRAN, ISLAMIC REPUBLIC OF.

It has been shown that direct approach to estimating the dynamic parameters from inconsistent, as well as insufficient and truncated, image sequence of slow rotation SPECT projection data can reduce the bias and variance. But the model assumption of blood pool and other segments should be appropriate to follow the dynamic behavior of different segments. On the other side, while the system matrix and dynamic model became more complicated the final dynamic parameters estimation may be impossible or at least the bias can rise up. In this study we suggest a computationally efficient model to represent the voxel-based dynamic behavior which is easy to be resolved by iterative optimization methods. We assumed that in a dynamic myocardial SPECT all the voxels can be modeled by a two terms exponential equation. Three different dynamic curves was extracted from published papers for each segment (blood pool, normal myocardium, and background) and tested to evaluate the suggested models. Five different generic optimization algorithms were used to solve the nonlinear equation and estimate the exponential equation coefficients. The proposed method was tested on a 32*32 matrix size image, simulated in MATLAB. Each voxel of simulated map belonged to known segment and had the dynamic behavior while projection data was acquired. The simulated dynamic SPECT acquisition consisted of just one rotation in 12 minutes with 90 views, each 6 seconds. Results show that the Levenberg-Marquardt algorithm was the superlative one to estimate each of the three input dynamic data for all of the segments (mean of three input data, blood pool: $R2=0.935 \pm 8\%$, $p<0.01$ - Myocardium: $R2=0.963 \pm 9\%$, $p<0.01$ - background: $R2=0.948 \pm 8\%$, $p<0.01$). We have implemented computationally efficient method for fully 4-D voxel based direct estimation of spatiotemporal distributions from dynamic myocardial SPECT projection data. Two terms exponential equation was used to model the time-activity curves for the blood pool and tissue volumes in a simulated cardiac data acquisition. Iterative Levenberg-Marquardt algorithm estimates of time-activity curves quickly and accurately. From these curves, kinetic parameters can be estimated accurately.

EP741

Data Driven Gating of Clinical List-Mode PET can Improve Lesion Detection and Quantification

N. C. D. Morley[1], D. R. McGowan[1,2], K. M. Bradley[1], F. V. Gleeson[1,2]; [1]Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM, [2]Oxford University, Oxford, UNITED KINGDOM.

BACKGROUND: In oncology FDG PET/CT, respiratory motion can obscure focal uptake in the thorax and upper abdomen. This includes the liver and lung bases which are common sites of metastatic disease. Improved lesion detection could increase accuracy of staging and patient care. Better quantification could facilitate better therapeutic-response assessment. Data Driven Gating (DDG) is a deviceless technique to detect and gate respiratory motion from the list-mode data. **AIM**: Initial evaluation of a prototype DDG PET reconstruction, using FDG avid nodules affected by respiratory motion artefacts in clinical scans. **METHODS**: Standard oncology FDG PET/CT scans, 4 mins per bed-position, free-breathing, 90 mins after 4 MBq/kg FDG IV, with attenuation correction CT. After clinical reporting and identification of artefacts, the list-mode data was submitted to an additional retrospective DDG reconstruction, using principal component analysis (PCA). The new reconstruction is compared to our current clinical standard using lesion measurements of SUV_{max} (automatic within applied VOI) and craniocaudal diameter (manual, SUV window 0-6). Both reconstructions use a Bayesian penalised likelihood algorithm with a beta of 400. The gated data was normalised to the standard data for percentage and statistical analysis by mean with 95% Confidence Interval (CI). 18 nodules have been assessed in 12 cases (max 2 per case): 6 pulmonary, 11 hepatic, and 1 splenic. **RESULTS:** All 18 nodules examined showed a subjective increase in conspicuity, increase in SUV_{max}, and decrease in lesion diameter. In one case, a pulmonary nodule (6mm on CT) had identifiable uptake only after DDG. On average, SUV_{max} increased by 39% (CI 31-60%) of that in the standard reconstruction, and lesion diameter decreased by 34% (CI 25-42%). **CONCLUSION:** DDG using PCA can retrospectively identify and gate respiratory motion in clinical PET data without additional hardware or calibration. This can

improve image quality and quantitative assessment of lesions. We have observed an example of improved lesion detection.

EP742

Comparison of Quantitative Iodine-124 PET Imaging Accuracy between PET Systems

R. Gregory[1,2], I. Murray[1,2], M. Aldridge[3,4], S. Chua[1], G. Flux[1,2]; [1]Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM, [2]Institute of Cancer Research, Sutton, UNITED KINGDOM, [3]UCL Institute of Nuclear Medicine, London, UNITED KINGDOM, [4]UCL Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Aim: Several methods have been implemented to correct for PET noise introduced by 602 keV γ-photons emitted in cascade with over half the positrons of ^{124}I. These γ-photons can be detected in coincidence with one-another and/or annihilation photons. Prompt gamma compensation (PGC) on the Siemens Biograph systems corrects these events by fitting the estimated random and scatter distributions to the sinogram tails prior to subtraction. The other newer systems, for example GE Discovery 710, remove a uniform background fit to the sinogram tails. Older systems, such as the GE Discovery ST and VCT, can image in 2D mode with septa that discard γ-photons. The aim of this study was to compare the quantitative accuracy of ^{124}Iimaging attained using each method. Materials and Methods: Measurements were made on 2 Siemens Biograph mCT systems and the GE Discovery ST, VCT and 710 PET/CT systems. A 20 cm long, 20 cm diameter cylindrical phantom was filled uniformly with 50 MBq ^{124}I. One 20 million true event PET scan was acquired to assess uniformity and the phantom was scanned repeatedly as its activity decayed. The NEMA image quality phantom was filled with ^{124}I to give a sphere-to-background ratio (SBR) of 21 and 6.5 MBq total activity. A 20-minute PET/CT scan was acquired at 1 bed position. The activity concentration accuracy was assessed along with recovery coefficients. Results: PGC consistently underestimated the activity concentrations in the uniform cylinder and background of the image quality phantom by 10%. The average recovery coefficient of the two largest spheres based on SUV peak was 0.90±0.04. Without γ-photon correction the cylinder and background of the image quality were non-uniform in 3D PET images giving an average 60% underestimation in activity concentration. These values were underestimated by 3% in the 2D images. However these images were noisier due to the low sensitivity of 2D PET. The SUV of the uniformly filled cylinder was within 1% with uniform background subtraction although the SUV in the background of the image quality phantom was overestimated by 17%. The largest sphere's SUV peak recovery coefficient was 0.97±0.05. Conclusion: The consistent 10% underestimation in ^{124}I activity concentration with PGC may be corrected by the same factor (1.11) for any activity distribution. Uniform background subtraction provides the correct SUV for the uniform SUV validation phantom and SUV peak of the larger spheres but under-corrects the counts in the background of the image quality phantom.

EP743

Performance evaluation of the step and shoot acquisition modality of the IRIS PET scanner

n. camarlinghi[1], C. Luongo[1], N. Belcari[1], D. Panetta[2], P. Iozzo[2], S. Burchielli[3], P. Salvadori[2], G. Sportelli[1], A. Del Guerra[1]; [1]Dipartimento di Fisica dell'universita' di Pisa & INFN sezione Pisa, 56127, ITALY, [2]Institute of Clinical Physiology (IFC) CNR, Pisa, Italy, 56127, ITALY, [3]CNR/Tuscany Foundation "G. Monasterio" (FTGM), 56127, ITALY.

AimThe IRIS PET/CT scanner (now distributed by Inviscan s.a.s., France) is a novel multimodal preclinical tomograph for high resolution PET/CT imaging of small animals. The PET component of the scanner features the unique possibility of performing both static and "step and shoot" rotational acquisitions. This latter modality allows the user to obtain quantitative high quality images. However, in case of rotational scans, the image reconstruction becomes a very time-consuming task, thus hindering the use of this modality in clinical practice. To overcome this limit, we implemented a dedicated GPU CUDA-based 3D iterative reconstruction algorithm. In this work we present an assessment of the quantitative performance of both the static and rotational modalities obtained with the GPU algorithm.**Materials and methods** ThePET component of the scanner consists of 16 modular detectors arranged in two octagonal rings. Each detector module comprises a matrix of 702 LYSO:Ce crystals of 1.6 mm×1.6 mm×12 mm with a pitch of about 1.7mm. The scanner features a total of 24 million of Lines Of Responses (LOR). The standard 3D quantitative image reconstruction of the IRIS/PET is implemented with a dedicated multi-core Maximum Likelihood Estimation Maximization (MLEM) iterative algorithm. The system response matrix is pre-calculated using a multi-ray "Siddon" algorithm and stored on file. The size of the system matrix is reduced using symmetries.As image reconstruction exhibits a high degree of parallelism, to improve the performance of the standard reconstruction software we ported it on a Graphics Processing Unit (GPU) using the NVIDIA CUDA programming model. The GPU reconstruction implements an "on-the-fly" calculation of the system model.In order to perform a quantitative evaluation of the different modalities, four NEMA quality phantoms were acquired: one was acquired with a stationary scan, while the others were acquired in "step and shoot" mode using 2,4,8 views spanning over 45 degrees. All the acquisitions lasted 20 minutes. The image quality of 18F-FDG imaging on mice and rats was also evaluated.**Results and Conclusions**We compared the results obtained with the GPU algorithm to those obtained with the reconstruction software included with the IRIS PET, obtaining no significant difference. Moreover, we achieved speedups in the reconstruction times up to 5x with respect to the original implementation.

EP744

Benefit of scatter limitation correction for cold artifacts caused by arm motion in whole-body PET/CT: physical phantom study

H. ONISHI[1], A. Furuta[2], Y. Kangai[1], N. Yada[1], T. Saho[1], H. Amijima[3]; [1]Program in Biological System Sciences, Graduate School of Comprehensive Scientific Research, Prefectural University of Hiroshima, MIHARA, HIROSHIMA, JAPAN, [2]Program in Health and Welfare Sciences, Graduate School of Comprehensive Scientific Research, Prefectural University of Hiroshima, MIHARA, HIROSHIMA, JAPAN, [3]Graduate school of nursing,Hyogo University of Health Sciences, Kobe, Hyogo, JAPAN.

Aims: Algorithms for scatter limitation correction in whole-body PET/CT systems have potential for mis-registration. The present study used physical phantoms to validate scatter limitation correction of mis-registered of CT and PET images caused by arm motion. *Methods:* We used a NEMA-IEC body phantom (simulated tumor targets comprised 10 and 37 mm spheres) and two peripheral bottles (7 cmφ) positioned laterally on either side of body phantom to represent arms. The ratios of the sphere to background and the two bottles containing 18-F solution were setting 4:1. We acquired PET/CT images in the 3D mode for 20 min with arms movement. To validate the performance of no-scatter (nonSC), scatter (SC), and scatter limitation correction (SLC) algorithms, the standardized uptake value (SUV) and scatter fraction factor (SFF) were measured in ROI on the 10 and 37 mm spheres in the PET images at the center and at 1 - 5 cm offset from the center with arm motion in 1 cm increments (inside, outside and topside). We compared SUV and SFF with nonSC, SC and SLC corrections for arms motion. *Results:* A cold artifact moved < 2 cm to inside, and < 5 cm to the topside of the arm in the PET images. Significant outside and topside (1 - 4 cm) cold artifacts did not occur. The cold artifact was improved by adapting itself in the SLC. The SUV of each target was increased by 5.13% (nonSC), 2.8% (SC), and 2.78% (SLC) by outside arm motion.

The SUV of nonSC was increased by 1.2%, whereas SC and SLC were decreased by 28.6% and 9.0% respectively by inside arm motion. The SUV of nonSC, SC, and SLC were increased with top-side arm motion. Outside SFF in SC and SLC was minimally affected by arm position. Inside SFF increased 2.5-fold (0.78) in SC and remained at 30% (0.45) of increment in SLC. The SFF of SLC did not exceed 0.45 under all conditions. *Conclusion:* The cold artifact caused by inside arm movement was improved in the SC algorithm using SLC. The finding results indicated that the optimal SFF setting in PET/CT systems should be 0.45.

EP745

Whole Body Dynamic FDG Acquisition : Validation of Static reconstruction Methods

P. M. Koulibaly; Centre Antoine Lacassagne, Nice, FRANCE.

Aim Whole Body Dynamic (WBD) acquisition has the promise of capturing variation of FDG uptake during conventional acquisition duration. This approach could replace dual point imaging in the future. This preliminary study investigates summation strategies of WBD reconstructions to show whether they can replace standard static reconstruction (STD) for conventional diagnosis and quantification. **Materials and methods** 20 oncology patients underwent WBD acquisition after (G1, 10 cases) or before (G2, 10 cases) conventional whole body static (WBS) FDG acquisition on a Siemens Biograph mCT camera. The WBD consisted in 3 1min/bed passes and WBS in one 2.5min/bed acquisition. Two static reconstructions were generated from each WBD acquisition: sum of 3 reconstructed dynamic frames (SRDF) and reconstruction from the summed sinograms (SSINO). The summed and STD images were assessed blindly and compared qualitatively and quantitatively. Two physicians rated image quality (equivalent or better) and assessed acceptance for clinical read and diagnostic interpretation. SUV max and peak of up to 3 lesions per case (51 in total) were compared, together with mean and standard deviation (SD) of ROIs in an area of uniform uptake in the liver. Correlation analyses were performed for quantitative parameters. **Results** The quality of all images was rated good for clinical read and diagnostic interpretation. Both SRDF and SSINO images had slightly better rating overall than WBS STD images, likely due to the 30s (20%) longer acquisition. The SSINO images had slightly better ratings than the SRDF, likely due to better noise modelling. The correlations of quantification parameters obtained from SRDF/SSINO vs static reconstruction were analyzed into two separated groups. SUVmax and SUVpeak were highly correlated in both groups. In G1, SUVs are higher due to increase of tracer uptake over time which would result in a slope >1 (G1_SUVmax (SRDF/SSINO): slope 1.23/1.19, R^2 0.99/1.00) (G1_SUVpeak: slope 1.19/1.14, R^2 1.00/1.00). In G2, the effect was reversed (G2_SUVmax: slope 0.75/0.76, R^2 0.99/0.94) (G2_SUVpeak: slope 0.77/0.75, R^2 0.96/0.95). Liver mean and SD values were also highly correlated except SD of G2 due to more counts in WBD (G1_SUVmean: slope 0.98/0.88, R^2 0.94/0.94) (G1_SUVstd_dev: slope 1.29/1.15, R^2 0.85/0.91) (G2 SUVmean: slope 1.06/0.99, R^2 0.99/0.94) (G2_SUVstd_dev: slope 0.92/0.46, R^2 0.29/0.60). Similar correlations were observed between SRDF and SSINO (results not shown). **Conclusion** WBD acquisition is feasible and the resulting summed images give identical image quality than conventional acquisition. This opens the way to collecting dynamic information during a single acquisition of standard duration.

EP746

Impact of non-specific normal databases on perfusion quantification of low-time myocardial SPECT studies in overweight or obese patients

C. Scabbio[1,2], **M. Lecchi**[1], A. Del Sole[1], G. Lucignani[1]; [1]Department of Health Sciences, University of Milan and Nuclear Medicine Unit, ASST Santi Paolo e Carlo, Milan, ITALY, [2]Medical Physics Postgraduate School, University of Milan, Milan, ITALY.

Aim. We have previously reported that stress myocardial perfusion quantification in overweight patients is negatively influenced when the acquisition time is reduced to a quarter of the reference while using standard-time databases of normality. This study was aimed at evaluating the impact of non-specific databases of normality on the estimates of the percent summed stress score (SS%) in overweight or obese patients. **Patients and Methods**. The study population comprehended 40 overweight/obese patients (mean BMI ± standard error = 29.4±0.6 kg/m^2) undergoing myocardial stress gated SPECT (BrightView^{TM}, general-purpose gamma-camera, standard acquisition time=16 min, 8 MBq/kg). Three simultaneous scans, started at the same time after tracer injection ([^{99m}Tc]Tetrofosmin^{TM} activity = 659±12 MBq), were acquired with three different acquisition-time/projections (30, 15 and 8 sec/step, i.e. full-time, half-time and quarter-time acquisitions, respectively). The three sets of projections were reconstructed using the Astonish^{TM} iterative reconstruction algorithm with resolution recovery (default parameters: 4 iterations, 8 subsets and cut-off frequency = 1 cycles/pixel). Then, three different normality databases were used to estimate the SS% perfusion parameter: 1) full-time Astonish^{TM} (full-time-A); 2) full-time iterative reconstruction algorithm provided by the manufacturer with 12 iterations and Butterworth filter (0.66 cycles/pixel and order=5) (full-time NOT-A) and, 3) half-time Astonish^{TM} (half-time-A). The impact of database of normality on the SS% and acquisition-time/projections on the SS% was assessed by two-way ANOVA analysis and post-hoc test (Tukey pairwise for multiple contrasts). **Results**. Both the database of normality and the acquisition-time/projections influenced the SS% perfusion parameter in overweight or obese patients (F=42.3 and F=8.3, respectively). Whereas no significantly differences were found between the SS% assessed with the two Astonish^{TM} databases applied to the scans with different acquisition-time (SS%=3.88±0.98 for full-time-A and SS%=3.92±0.98 for half-time-A), significantly higher SS% values were observed with the full-time-NOT-A database (SS%=6.83±1.06). Significantly higher SS% values were also confirmed for quarter-time scans compared to half-time scans, even though a little reduction of the SS% overestimation was found by using half-time-A database compared to full-time-A database (mean SS% difference = +0.68% and +0.75%, respectively). **Conclusions**. Different reconstruction algorithms require the adoption of the specific database of normality developed for each reconstruction method. It is important to underline that a summed score for the stress exam higher than the real one could lead to wrong risk-stratification with regard to cardiac event-free survival.

EP747

Investigating the Operating Characteristics of Q.Clear Reconstruction

A. Hughes; Royal Preston Hospital, PRESTON, UNITED KINGDOM.

Aim To investigate the operating characteristics of Q.Clear (a fully convergent, noise constrained iterative reconstruction package) following the recent installation of a GE Discovery 710 PET/CT system. Reconstructed image quality was investigated as a function of the β value (a noise regularisation parameter) and bed overlap. **Method** Experiments were conducted using a NEMA PET (NU2) phantom filled with a uniform concentration of 5kBq/ml F18 and scanned over two bed positions using standard imaging parameters (192x192 matrix, ToF, scatter, randoms & attenuation corrections applied). The overlapping bed sections were positioned over the centre of the phantom. Reconstructed image noise was measured for a range of slice overlaps and different values of β. A NEMA Image Quality (IQ) phantom was filled with solutions of F18 at concentrations of 17.3kBq/ml and 4.8kBq/ml for the spheres and background respectively. This was scanned over two bed positions with the spheres (a) at the centre of the overlap and (b) at 3cm offset from the centre of the overlap. SUVmax and SUVmean were calculated for spheres ranging in diameter from 10 to 22mm at differing values of β. **Results**

Reconstructions of the NU2 phantom demonstrated a marked variation in image noise along the axis of the phantom in the vicinity of the overlapping sections. For an 11 slice overlap the noise increased from 6.9% on the central slice to 10.5% for slices at approximately 3cm either side of this position (β=400). The difference in noise values became more exaggerated at lower β values (8.8% on the central slice increasing to 12.8% 3cm to either side, β=300). Increasing the slice overlap reduced this axial variation in noise, with 15 slices being optimum. Q.Clear reconstructions of the IQ phantom demonstrated an increase in both the SUVmax & SUVmean at all sphere sizes over standard iterative techniques. However, SUVmax for the 10 and 17mm diameter spheres varied from 2.1 to 2.8 and 3.1 to 5.5 respectively (β=300, 11 slice overlap) depending on whether the spheres were positioned over the central slice of the bed overlap or offset from it axially by 3cm. Increasing the slice overlap to 15 slices reduced this variation in SUVmax with axial position. **Conclusion** Reconstructions using Q.Clear have the potential to improve image quality and increase the visibility of small lesions. However, slice overlap and β values must be carefully chosen to optimise its function. SUVmax should be used with caution, especially for small lesions.

EP748

Optimization of 90Y PET/CT imaging using an antropomorphic torso phantom with a gel suspension of glass microspheres in the liver

A. Zorz[1], A. Scaggion[1], L. Riccardi[1], A. R. Cervino[2], P. Reccia[2], G. Saladini[2], M. Paiusco[1]; [1]Medical Physics Department, Veneto Institute of Oncology IOV-IRCCS, Padova, ITALY, [2]Division of Nuclear Medicine, Veneto Institute of Oncology IOV-IRCCS, Padova, ITALY.

Because of its superior image resolution and quantitative capability, 90-yttrium PET/CT imaging is becoming part of the routine protocol to confirm the accurate delivery of radionuclide after radioembolization.The aim of this study was to optimize 90Y-PET/CT image quality in terms of absolute quantification and noise, comparing different reconstruction algorithms and parameters in images of an antropomorphic torso phantom.An antropomorphic torso phantom with lung, liver and spine inserts was filled with cold water. A plastic bottle with a mix of gel and 90Y glass microspheres was positioned inside the liver cavity in order to simulate a post-radioembolization small tumor activity concentration. The activity of the microsphere was measured with a dose calibrator before the phantom preparation. PET images were acquired with a Siemens Biograph mCT PET/CT scanner equipped with LSO crystals in 3D mode. Phantom scan was performed in two 40 minutes bed positions. All scan parameters were identical to a clinical scan protocol. Images were reconstructed with the standard 3D OSEM iterative algorithm with scatter, random, attenuation correction, resolution recovery (TrueX), 3 iterations, 21 subset, 168x168 matrix size and 4 mm gaussian filter. Different reconstructions were performed by varying the reconstruction algorithm (FBP) and OSEM parameters as the matrix size and the iteration number. For absolute quantification, a volume of interest (VOI) encompassing the entire microspheres sediment was generated by selecting a fixed volumetric isocontour threshold of 1%. All the data were corrected for the branching ratio of yttrium. The calculated activity in the VOI was compared to the actual value. To evaluate the background effects due to the random counts, a set of planar ROIswere positioned in different phantom areas outside the liver (3 in the lung, 6 in the body). Data were collected and compared for all the reconstructions.It was observed that the microspheres, even if mixed with gel, sedimented as an effect of their higher density. As a consequence, the microsphere sedimentcould be visible in the CT images with a mean HU number significantly higher than water (about 240 HU). Absolute quantification and background counts change according to different reconstructions. Minimal variations of the estimated activity were found with different matrix sizes, while the iteration numbers had a more appreciable effect.The study shows the feasibility of the 90Y-PET/CT absolute quantification provided that the optimal algorithm and reconstruction paremeters are chosen.

EP749

Effect of kV changes in CT for Attenuation Correction on relative and absolute SPECT Quantification

N. A. Bebbington; Siemens Healthcare A/S, Aarhus, DENMARK.

AIMS: It is well known that lower kV reduces dose, but can alter CT HUs which could impact on attenuation maps for attenuation correction (AC). The aim was to assess how kV changes on AC CT affect relative and absolute quantification in SPECT. MATERIALS AND METHODS: Absolute quantification: Five spheres (13mm-37mm) in the NEMA-IEC image quality phantom were filled with Tc-99m, with water background. SPECT and 18 CT exposures with different kV (130, 110, 80) and mAs (100, 50, 30, 20, 12, 8) combinations were undertaken on a Siemens Symbia system. A second SPECT with 18 CTs was undertaken with greater attenuation (two sandbags (300-400 HU) under the phantom). Flash3D SPECT reconstructions were made with dual-energy-window scatter correction and AC with each CT. Total and maximum voxel counts for SPECT reconstructions made with 110kV and 80kV CTAC were compared with those using 130kV. Relative quantification: SPECT was undertaken with a Data Spectrum cardiac insert and phantom (inferolateral and septal defects) in two different attenuating conditions, each with 18 CT datasets as above, and reconstructed with Flash3D and CTAC. Scores used clinically in Cedars-Sinai QPS (SRS, extent (%) and TPD (%)) and defect contrast relative to the anterior wall were assessed. RESULTS: Absolute quantification: In the standard phantom, at 110kV CTAC sphere VOI and maximum voxel counts were underestimated by up to 0.17% and 0.12%, across the range of sphere sizes and mAs. At 80kV CTAC, sphere VOI and maximum voxel counts were overestimated by up to 0.64% and 0.59%. With additional attenuation, at 110kV sphere VOI and maximum voxel counts were overestimated by up to 0.60% and 0.43%. At 80kV, sphere VOI and maximum voxel counts were overestimated by up to 4.01% and 3.79%. Relative quantification: There were no differences in SRS (15), extent (26%), TPD (19%) or defect contrast (0.68) between 130kV, 110kV or 80kV CTAC reconstructions. CONCLUSIONS: Absolute quantification differences for SPECT reconstructed with 130kV and 110kV CTAC were minimal, but differences increased considerably for reconstructions using 80kV CTAC. Increasing differences were observed with increasing attenuation. kV reduction may therefore have significant implications for absolute SPECT quantification and further assessments should assess effects with materials of higher HU, and the advanced OSCG reconstruction which is recommended for absolute quantification. No differences in relative cardiac quantification measures were observed with reduced kV under the conditions in this study.

EP750

Stochastic origin ensemble image reconstruction algorithm for time-of-flight dual photons emission computed tomography system

C. C. Chiang[1], K. S. Chuang[1], H. H. Lin[1], Y. C. Ni[2]; [1]National Tsing Hua University, Hsin-Chu, TAIWAN, [2]Health Physics Division, Institute of Nuclear Energy Research, Atomic Energy Council, Taoyuan, TAIWAN.

Aim: Stochastic origin ensemble (SOE) approach based on Markov chains theory is an iterative image reconstruction useful in photon-limited emission tomography. In this study, we apply SOE to a new time-of-flight dual photons emission computed tomography (TOF-DuPECT) system. Specifically, the main goal is to investigate its performance at different coincidence resolving time (CRT) of detectors by Monte Carlo simulation. **Method:** DuPECT is a system to image distribution of isotope that emits cascade photons simultaneously. In theory, the possible location of decay could be determined by TOF information and coordinates of detectors in spatial domain. When the coincidence

photons arriving detectors, the hyperbolic response curve can be directly described on the reconstructed space. During the process of proposed SOE reconstruction, the origins of each event are randomly assigned to locations on hyperbolic response curve. After a sufficient number of iterations, the possible origins can converge to actual position of emitters and then reaches a quasi-stationarity state. To validate and evaluate the proposed SOE algorithm, an in-house developed GATE/MPHG Monte Carlo software were used. The geometry of Siemens Biograph 6 PET scanner was considered and built in the simulation. The contrast phantom and the 19-rods phantom filled with selenium-75 were used to test the performance of proposed algorithm. **Results**: Results show that SOE method can be successfully employed for TOF-DuPECT system. The spatial resolution in the central field-of-view can achieve about 20 mm when CRT is under 100 ps. The results indicate that there is a strongly relationship between spatial resolution and CRT. Regarding to the reconstruction results of phantom studies, the SOE method seems practical for proposed system and can obtain well image quality. **Conclusion**: The conclusion is drawn that TOF-DuPECT system is feasible and potential technique and SOE method has been proved to be useful for the system. Furthermore, this technique would extend its usefulness to non-positron gamma-gamma coincidence imaging. Future works will include more phantom studies and correction techniques development for the TOF-DuPECT system (e.g., scatter correction and attenuation correction).

EP751

Improvement of PET/CT reconstructions by implementation of metal artifact reduction in CT

C. S. van der Vos[1,2], A. I. J. Arens[1], J. J. Hamill[3], A. P. W. Meeuwis[1], L. de Geus - Oei[1,2,4], **E. P. Visser**[1]; [1]Radboud university medical center, Nijmegen, NETHERLANDS, [2]University of Twente, Enschede, NETHERLANDS, [3]Siemens Healthcare, Knoxville, TN, UNITED STATES, [4]Leiden University Medical Center, Leiden, NETHERLANDS.

In recent years different metal artifact reduction (MAR) methods have been developed for CT. MAR could be beneficial for interpretation and quantification of the PET/CT scan, however these methods have only very recently been implemented in PET/CT. In this study both phantom and patient data were used to analyze visually and quantitatively the effect of MAR CT data on PET scans. *Materials and Methods:* The phantom consisted of two types of hip prostheses in a solution of ^{18}F-FDG and water, and was scanned in an mCT PET/CT scanner (Siemens). To analyze clinical relevance of MAR, ^{18}F-FDG PET/CT scans of 14 patients with metal implants (either dental implants, hip or metal implants elsewhere) were scored by an experienced nuclear medicine physician. In all patients a lesion was located near the metal implant. For these scans the standard low-dose CTs were processed with the MAR algorithm. The PET data were reconstructed using the attenuation correction provided by both the standard CT and the MAR-processed CT. In addition to the 14 ^{18}F-FDG PET scans a ^{68}Ga-PSMA scan was included to analyze the benefit of MAR for patients with metastasized prostate cancer (and who also have one or two hip prostheses). *Preliminary Results:* For the phantom scans, cold artifacts (where FDG concentrations are lower than expected, caused by metal) were visible in the FDG solution. There was a 30% deficit in FDG concentration which was restored by MAR processing, indicating that metal artifacts on the CT image influence the quantification of the PET data. So far, 10 (out of 15) patient scans were reviewed. In 9 out of 10 patients the MAR algorithm was helpful and increased the confidence. On average the confidence in interpretation improved by 29±30% (scored on a scale of 0 - 100% confidence) if MAR was used. The mean difference in SUVmean of the lesions was 9.0±8.2%. SUV increase or decrease was dependent on the type of metal artifact. *Conclusion:* So far, the metal artifact reduction algorithm increases the confidence of the interpretation of the PET/CT scan. The added value depends on the indication for the PET/CT scan, location of the prosthesis and extent of the disease. For radiotherapy planning and therapy response monitoring, metal artifact reduction could be of relevance in specific cases where the implant has influence on tumor delineation and quantitative parameters.

EP752

MR-based attenuation correction in PET/MRI of the lungs: Clinical effect of truncation artifacts and ignoring bone

S. K. Øen[1], I. Rausch[2], M. L. Lassen[2], M. Fenchel[3], T. Beyer[2], L. Eikenes[1]; [1]Norwegian University of Science and Technology, Trondheim, NORWAY, [2]Center for Medical Physics and Biomedical Engineering, Wien, AUSTRIA, [3]Siemens Healthcare GmbH, Magnetic Resonance, Erlangen, GERMANY.

Aim: To evaluate the influence of different MR-based attenuation correction (MR-AC) methods used in PET/MRI and their effect on clinical lung cancer patient examinations. **Materials and methods**: 15 lung cancer patients were examined in a PET/MRI system (Siemens Biograph mMR) using two consecutive bed positions covering the thorax. PET emission data were reconstructed with four different AC maps: (A) Standard Dixon-based AC segmenting the body into four tissue classes; (B) Standard Dixon-based AC in combination with the implemented MLAA (maximum likelihood reconstruction of attenuation and activity) option to correct for truncation artifacts; (C) Prototype atlas based bone segmentation approach incorporating main cortical bone structures into the standard Dixon based AC and (D) CT based AC from a prior PET/CT scan from the same day. For the latter, the arms and shoulders from (A) were kept, as the arm position is different in PET/CT than in PET/MR. Reconstructions were performed in vendor-based non-product research software (e7tools, Siemens HC) with standard settings (ordered subsets expectation-maximization (OSEM), 21 subsets and 3 iterations). Mean standardized uptake values (SUV_{mean}) were derived from volumes-of-interest (VOIs) placed in a lung lesion (42% threshold) and two background regions (liver (14cm^3) and mediastinum (3cm^3)). Further, differences in the projected linear attenuation coefficients (pLACs) of the AC maps were calculated for (C) and (D) in the lung region. **Results**: Average differences in SUV_{mean} of lung lesions relative to (A) were 5.8±4.7% ($p<0.01$) (B), 0.2±0.2% ($p<0.01$) (C), and -1.5±6.2% ($p=0.30$) (D). Differences in background tissues were measured to be 11.2%±7.4 ($p<0.01$) (B), -0.1±0.2% ($p=0.12$) (C) and 2.9±5.3% ($p=0.30$) (D) for liver and 31.1±41.1% ($p<0.01$) (B), 0.4±1.5% ($p=0.61$) (C) and 3.6 ±8.5% ($p=0.12$) (D) for mediastinal VOIs. Average pLAC differences relative to (A) were 0.2±0.1% ($p<0.01$) and 1.2±0.8% ($p=0.30$) for (C) and (D), respectively, while the maximum relative difference was found to be 0.6% for (C) and 11.4% for (D). **ConclusionTruncation** cause a significant impact on SUV, which may have a clinical impact, while ignoring bone and segmentation of the AC maps in different tissue classes only cause minor changes in SUV for lung cancer patients.

EP753

Impact of PSF and Gaussian Filtering on SUV Assessment - A Clinical Study Using Digital PET

K. Binzel, A. Siva, T. Saif, C. Lehn, J. Zhang, M. V. Knopp; The Ohio State University, Columbus, OH, UNITED STATES.

Aim: Next generation digital PET/CT imaging systems provide a platform which allows for highly sensitive and precise molecular imaging. Advanced reconstruction options, such as point spread function (PSF) correction and Gaussian filtering, enable further improvements in the visual quality and quantitative accuracy of such imaging. We assessed the impact of these reconstruction options on images reconstructed using next generation digital PET. **Materials and Methods**: PET/CT images

for 35 patients were acquired on a pre-commercial release, next generation digital PET/CT system (Vereos, Philips). Patients were imaged for 90 seconds per bed position following a targeted 480 MBq dose of ^{18}F-FDG. Images were reconstructed with the default protocol, a 4 mm^3 voxel volume, using 3 iterations and 29 subsets. The images were further reconstructed using the same settings, with the addition of a system PSF correction, Gaussian filter, or both. The resulting image sets were quantitatively assessed, placing regions of interest over target lesions as well as in background areas. Taking the SUV_{max} and SUV_{mean} from the default reconstruction, the percent change in SUV was calculated for the three additional reconstructed image sets. Blinded image quality review was conducted as well. **Results**: The addition of the Gaussian filter decreased the SUV in all measured tissues, including target tumor lesions. The average change in SUV_{mean} of physiologic uptake in background areas was less than 10%. In target lesions, the SUV_{max} decreased between 6% and 22%, as compared to default readouts. The use of PSF correction had an opposite impact, leading to an increase measured SUVs in all tissues. For target lesions, the SUV_{max} increased between 12% and 33% with the use of the PSF correction. A combination of the PSF and Gaussian filter had a more balanced impact, in general leading to a minimal increase in SUVs. Image quality reviews revealed that PSF only images exhibited undesirable noise levels, while Gaussian only images appeared blurred, potentially impacting lesion detectability and characterization. In general, the combination PSF and Gaussian images were deemed most preferable. **Conclusion**: Phantom tests have shown that the use of PSF correction in image reconstruction leads to more accurate SUV measurements, however leads to noise. While the use of a Gaussian filter decreases quantitative values, it reduces visual noise. We conclude that a balanced optimization utilizing both methodologies appears to be the most robust and preferred approach for clinical FDG PET procedures.

EP754

Effect of TOF and PSF in detection of lymph node metastases in head and neck of PET/CT images

p. Ghafarian[1,2], A. Ketabi[3,4], A. Doroudinia[1,2], M. Bakhshayesh Karam[5,2], M. R. Ay[3,4]; [1]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, Iran., Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, Iran., Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Pediatric Respiratory Diseases Research Centre,National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Accurate staging in related to patients with head and neck cancer is essential for using proper therapy assessment. As reconstruction technique can affect contrast resolution, spatial resolution and noise level on the PET image, the aim of this work was to investigate the impact of time-of-flight (TOF) and point spread-function (PSF) along with various filter size and iteration number on lesion detectability and the standardized uptake value (SUV) of lymph node metastasis.**Materials and methods**:20 patients with lymph node Metastases, uptake time 62 ±3 min and injection of 310MBq (range 255-375MBq)^{18}F-FDG were scanned with Discovery 690 GE PET/CT scanner,equipped with 64-slice CT. All PET images were retrospectively reconstructed with OSEM+PSF (3 iterations, 18 subsets) and OSEM+PSF+ TOF (2 iterations, 18 subsets) with various Gaussian filter size (1,3,4,5 and 6.4mm) and 3min for each bed position.It should be emphasized that conventional method was OSEM+PSF (3 iterations, 18 subsets,6.4 mm post filter). For comprehensive evaluation, we used NEMA image quality phantom with target to background ratio 4:1. A semi-quantitative analysis was performed with SUV_{max} and also coefficient of variance (COV), lesion to background ratio and signal-to-noise ratio (SNR) were considered for each lesion. The PET/CT images reviewed by two expert physicians blinded to the reconstructed methods. **Results**: In OSEM+PSF+TOF algorithm,with decreasing of Gaussian filter size, the relative difference of the SNR in lymph nodes were 11.57±1.81, 14.62±8.60,15.77 ±15.05,15.75±20.11and 15.83±23.48when compared with conventional reconstruction algorithm. In OSEM+PSF+TOF with 3 and 4mm post filter, the SUV_{max} were 31.73±7.86 and 21.32±5.65 in related to conventional reconstructed method respectively.The relative difference of lesion to background ratio increased with decreasing post filter from 6.4 to 3 mm in OSEM+PSF+TOF versus to conventional algorithms(2.63±1.27 to 32.89±6.25).According to balance among the lesion detectability, contrast, noise and visual assessment, the optimal images were observed with OSEM+PSF+TOF method along with post filter size between 3 to 5 mm. **Conclusion**:The presented results clarify that the conventional reconstruction method may not be convenient in the head and neck region. Major improvements can be achieved in lymph node metastases detectability and contrast to background ratio in OSEM+PSF+TOF in comparison with OSEM+PSF method with regard to decrease Gaussian filter size. It should be noted that this improvement can achievable by increasing image noise and SUV values. **Key Words**: Time-of-Flight, Point-Spread Function, lymph node metastasis, Gaussian filter, Standardized Uptake Value, FDG-PET

EP755

Comparison of ten reconstruction algorithms in myocardial perfusion SPECT imaging: relative role of different degrading factors

T. Ahmed[1,2], M. M. Khalil[3], W. Elshemey[4], A. ELfiky[4]; [1]King Hamad University Hospital, Busaiteen, BAHRAIN, [2]Faculty of Science, Biophysics department, Cairo University, Cairo, EGYPT, [3]Faculty of Science Helwan University, Physics Department, Cairo, EGYPT, [4]Faculty of Science Cairo University, Biophysics Department, Cairo, EGYPT.

Objective: The aim of the present study was to assess the relative performance of Iterative Reconstruction algorithms accompanied with different combinations of attenuation, scatter and resolution recovery corrections versus filtered back projection on the quality of myocardial perfusion SPECT imaging. Methods: The study was performed using standard cardiac phantom with two cold defects one anterior transmural and non-transmural positioned in the inferior wall. The phantom was placed inside the Jaczack cylindrical phantom. To simulate clinical count rate, an activity of 1.2 mCi was injected into myocardial walls whereas 11.8 mCi was used for background. SPECT/CT scan was acquired using vendor standard cardiac protocol for resolution recovery. The CT attenuation map was acquired using 50 mA and of 80 kV covering the whole length of the cylindrical phantom. Ten different algorithms were applied in image reconstruction namely FBP, FBPSC, IRNC, IRSC, IRAC, IRACSC, IRNCRR, IRSCRR, IRACRR, IRACSCRR; where SC, AC, and RR refer to scatter, attenuation correction and resolution recovery respectively. NC denotes no correction was applied. Figures of merit used to evaluate the performance of the reconstruction algorithms were slice count uniformity, Coefficient of Variation (CoV) and CNR calculated for normally perfused myocardium while percentage defect contrast was used to assess hypo-perfused segments represented by cold inserts. Results: When compared to analytical techniques, IR showed better performance in terms of CNR and defect contrast resolution especially with gradual correction of SPECT degrading factors.

However, this was associated with slight increase in image noise as demonstrated by uniformity and CoV analysis. There was also a trend towards an improvement of defect contrast in transmural compared to non-transmural defect. On the other hand, CNR was not significantly different as applying different combinations of image degrading corrections (i.e IRACSCRR, IRSCRR, and IRACRR) while there was noticeable improvement in defect contrast for both defects as we move towards the scheme (i.e. IRACSCRR) that considered all corrections in image reconstruction .Conclusion: The results showed more insights on how iterative (with different corrections) and analytical techniques handle image noise, defect contrast, CNR with remarkable differences appeared on apical versus basal slices and transmural versus non-transmural perfusion defects. This will have significant implications on quantitative perfusion parameters derived from the chosen reconstruction algorithm. Further investigations are underway to exploit the full potential of iterative based image correction techniques in myocardial perfusion imaging.

Validation of atlas-based head attenuation correction in the GE SIGNA PET/MR - initial results

G. Schramm[1,2], A. Rezaei[1,2], S. Willekens[1,2], R. Peeters[1,3], **M. Koole**[1,2], J. Nuyts[1,2], K. van Laere[1,2]; [1]Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM, [2]Division of Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM, [3]Division of Radiology, University Hospitals Leuven, Leuven, BELGIUM.

Aim Accurate attenuation correction (AC) of the head is crucial for absolute quantification of PET images. Due to the lack of signal from bone in MR images, AC is challenging in PET/MR brain examinations. In the GE SIGNA PET/MR, an atlas-based approach (GEAC) is used to generate attenuation images including a skull compartment with fixed bone attenuation values. In this study, we aimed to validate the accuracy of GEAC compared to CT-based attenuation correction (CTAC) in [^{18}F]FDG brain examinations of healthy volunteers. **Methods** PET/MR raw data sets of 10 healthy subjects were reconstructed using GEAC (PET_{GEAC}) and CTAC (PET_{CTAC}) in the GE PET reconstruction toolbox v.1.22 (static TOF-OSEM reconstruction, 40 - 60 min p.i., 2 iterations, 28 subsets). The CTAC attenuation image including templates for the bed and MR-coils was derived from AC-CTs of PET/CT acquisitions performed immediately after the PET/MRI scan, using a Siemens HIREZ PET/CT. The AC-CT was rigidly co-registered and bilinearly scaled to PET attenuation coefficients. The alignment of the attenuation images was visually verified. Subsequently, relative differences in the mean [^{18}F]FDG uptake of 86 anatomical regions of the Hammers atlas were calculated in PMOD v3.4 (PMOD, Zurich, Switzerland) and analyzed in R v.3.0.2 (R Foundation, Vienna, Austria). **Results** The bias (mean ± standard deviation) in the uptake of PET_{GEAC} compared to PET_{CTAC} was: 4.6 ± 2.6 % averaged over all regions, 4.6 ± 3.2% in grey matter, 5.5 ± 2.4% in white matter, 2.2 ± 1.6 % in the cerebellum, and 4.4 ± 1.3% in the striatum. In all regions the difference was significant ($p < 0.05$ using a Wilcoxon signed-rank test). The intra-regional variability was largest in the grey matter regions (-4.9% to 13.4%), and overestimation occurred especially in cranial regions (high frontal and parietal cortex). The highest intra-subject variability was found to be -1.2% to 13.3%. In 8 cases, the difference in the bias in the cerebellum compared to the bias in the superior gyri was larger than 5%. **Conclusion** GEAC leads to a small but significant region-dependent overestimation of the reconstructed [^{18}F]FDG uptake in healthy volunteers, especially in cranial grey matter regions. Further patient studies are needed to verify if [^{18}F]FDG uptake pattern interpretation is affected by the observed regional and intra-subject variability.

EP757

The impact of extending the acquisition time for quality of PET-CT examinations with 18F -FDG in obese patients on the LYSO TOF scanner

M. Koza[1], K. Buraczewska[1,2], A. Budzyńska[1,2], M. Dziuk[1,2]; [1]Affidea, Warsaw, POLAND, [2]Military Institute of Medicine, Warsaw, POLAND.

Background: The aim of the study was a quantitatively analyze the effect of extending the acquisition time by 25% in the PET-CT examinations in patients with the BMI above 30 (BMImean = 36.97, SD = 2.47). Methods: We evaluated 29 lesions in PET-CT exams with 18F-FDG in 15 patients. The average administrated activity was 4MBq/kg, and the acquisition time was 2.5 min per bed position. The raw data were recorded in the List Mode, and then reconstructed retrospectively with the time of acquisition 2 min per bed position. In both cases the use of AC reconstruction with the Time of flight function and the PSF reconstruction (without TOF).The tumor to liver ratio (TLR) and tumor to background ratio (TBR) were calculated for SUVmax. The same measurements were performed for the SUVmean. The statistics were made for the following pairs of dependent samples ($SUV2{,}5_{min/bed}$ position and $SUV2_{min/bed}$) in a quantitative scale. None of the groups was characterized by a normal distribution, therefore Wilcoxon test as a test of significance was used in all cases. Results: There was significant improvement of TBR and TLR ($p>0.05$) in all cases for the PSF reconstruction for both SUVs. The value of TBR for AC reconstruction was statistically significant. The mean difference of TLR for AC and PSF reconstructions were -0,65 (SD=2,1) and 0,12 (SD=0,19) respectively. The TLR for SUV mean was 0,83 (SD=2,51) for AC reconstruction and -0.061 (DS=0,12) for PSF reconstruction. Conclusions: The prolonged acquisition time by 25 % is statistically significant in all cases TBR and TLR in TPR reconstruction. There is no statistical difference in TLR value in AC reconstruction.

EP758

Q.Clear - the new reconstruction algorithm of PET images in the analysis of lung tumours.

B. Grebieniow[1], S. Antczak[1], A. Wyszomirska[2], R. Giersz[3], R. **Czepczyński**[2,1], W. Cholewiński[2,4], M. Ruchała[2]; [1]Affidea, Poznań, POLAND, [2]Poznan University of Medical Sciences, Poznań, POLAND, [3]Greater Poland Centre of Pulmonology and Thoraci Surgery, Poznań, POLAND, [4]Greter Poland Centre of Oncology, Poznan, POLAND.

Q.Clear reconstruction algorithm based on the Bayesian penalized-likelihood and image noise control dependant on the activity level was introduced in order to improve quality of the images and parameters of the quantitative image analysis. The aim of this study was to evaluate the impact of this algorithm on the PET diagnosis of lung tumours. Material and methods. Patients with untreated lung tumours were qualified to the study. The patients were subjected to PET-CT 60 min after injection of 4 MBq/kg of 18F-FDG. The scans were registered by the Discovery IQ PET-CT scanner (GE Healthcare) using standard parameters. The images were analysed visually by two experienced observers. SUVmax values of the lung tumours were registered for both: Q.Clear reconstruction algorithm with the b parameter related to the noise level of the image equal to 350 and for the standard VPHD iterative 3D reconstrunction algorithm. Patients with malignant tumours were operated. In case of negative PET scan, patients were followed-up with CT. Results. Sixty-seven patients aged 30-85 years (mean 64 yrs.), 52 men (60%) and 34 women were qualified to the study. In 37 patients with increased 18F-FDG uptake, the histopathology confirmed malignancy. Remaining 30 patients with slight or no 18F-FDG uptake were classified as benign and the follow-up did not show any progression. SUVmax measured using VPHD and Q.Clear was respectively: adenocarcinoma (n=19) 6.4±4.2 and 8.4±5.4,

squamous cell carcinoma (n=13) 8.8±2.9 and 10.6±3.7, macrocellular carcinoma (n=5) 8.5±1.5 and 10.7±1.4, benign lesions (n=30) 1.4±0.7 and 1.7±0.9. In case of malignant tumours a positive correlation between tumour size and SUVmax was found in both reconstruction methods. The correlation was stronger for VPHD than for Q.Clear reconstruction algorithm (r=0.5 vs. 0.4). In case of benign disease this correlation was found only for Q.Clear algorithm. Conclusion. For both, benign and malignant tumours, Q.Clear shows higher SUVmax values than with VPHD method. The Q.Clear reconstruction algorithm improves the quality of the images and quantitative image analysis.

EP759

The influence of TOF and PSF techniques along with scan duration on respiratory artefact reduction in PET/CT images

p. Ghafarian[1,2], R. Sharif Pour[3,4], A. Doroudinia[5,2], M. Bakhshayesh Karam[6,2], M. R. Ay[7,4]; [1]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Pediatric Respiratory Diseases Research Centre,National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, IRAN, ISLAMIC REPUBLIC OF, [7]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, Iran., Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: The introduction of new techniques such as time of flight (TOF) and PSF modeling in reconstruction of PET images can alter respiratory artifact in diaphragmatic region. The aim of this study was to evaluate the influence of TOF+PSF reconstruction on decreasing of acquisition time per bed position while the white band respiratory artefact can be improved. **Materials and methods**:29 patients with uptake time 61±2min and injection of 327.5MBq (range 261-350MBq)^{18}F-FDG were scanned with Discovery 690 GE PET/CT scanner,equipped with 64-slice CT.All of the lesions were in the diaphragmatic region and were in patients with extended white band artefact.For comprehensive evaluation we used NEMA image quality phantom with target to background 4:1.The PET images were retrospectively reconstructed using OSEM+ PSF(3itrations,18subsets) and OSEM+TOF+ PSF(2itrations,18subsets) with 4.4,5.4 and 6.4Gaussian filter size and 2,2:30 and 3min acquisition time per bed. A semi-quantitative analysis was utilized by SUV_{max} and $SUV_{mean}$with 45% threshold. For quantitative purpose, coefficient of variance, signal-to-noise ratio (SNR) and contrast to background evaluation were also considered. The PET/CT images reviewed by two expert physicians.**Results**: In the phantom study, the relative difference of FWHM in transverse view between OSEM+TOF+ PSF(2itrations,18 subets,6.4mm filter size,3min) and conventional algorithm(OSEM+ PSF with 3itrations,18subsets,6.4 mm post filter and 3min scan time) varied from -30.08% to -1.39% when the diameter sphere size increased from 13mm to 37mm, while the contrast ratio was still illustrated higher value in OSEM+TOF+PSF versus to OSEM+PSF in all sphere sizes. In clinical study, the combination of OSEM+TOF+PSF even in 2min acquisition time showed more SNR in related to OSEM+PSF with 3min scan time and 6.4mm post filter (23.14%±14.62%) and the relative difference of SUVmax and SUV45% were 24.48 and 22.49 respectively. ICC correlation for SNR value in all OSEM+TOF+PSF algorithm with 6.4 and 5.4mm post filter and 2 to 2:30 min per bed position demonstrated excellent behavior with Cronbach's α values between 0.949 to 0.995.**Conclusions**:A significant lesion delectability and reduction of white band respiratory artifact was observed with combination of TOF and PSF versus to only PSF modeling. It is valuable that decreasing scan time from 3min to 2min still retained image quality and altered lesion size in PET images in the artifact region. It is suggested that decreasing of scan time is strongly depend on utilizing appropriate filter size along with convenient iteration number and subset in OSEM+TOF+PSF algorithm.

Impact of advanced image reconstruction algorithm on qualitative and quantitative oncological 18F-FDG PET/CT

I. Shiri[1], P. Ghafarian[2,3], A. Bitarafan[1,4], M. BakhshaieshKaram[2,3], M. AY[5,6]; [1]Department of Medical Physics, School of Medicine, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Cardiovascular Intervention Research Center, Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim New technology such as Time-of-Flight (TOF) and Point Spread Function (PSF) theoretically have led to higher signal to noise ratio (SNR) and improve spatial resolution. The aim of the current study was to investigate the effects of PSF and TOF reconstruction parameters on qualitative and quantitative oncological 18F-FDG PET/CT images. **Materials and Methods** A complete set of measurements were performed with GE Discovery 690 PET/CT scanner using NEMA IEC body phantom containing 6 spheres (diameter10 to 37mm) filled by F18-FDG with two sphere to background ratio (SBR) (2:1,4:1). Phantom image were reconstructed into 3D-OSEM + PSF and 3D-OSEM+ PSF + TOF and post-smoothing filters with FWHM 1 to 6.4 mm was applied to image. We evaluated lesion by qualitative parameters such as visual assessment, contrast and SNR. Each lesion, also was quantified with different parameters as follows: SUVmax, SUVmean, SUV41%, SUV50% and SUV75% (mean within a 41%, 50%, 75% isocontour). **Results** For phantom spheres ≥13 mm, we found higher SNR (15-20%) using OSEM+PSF+TOF mode rather than OSEM+PSF. Also, in terms of post smoothing filter FWHM (1-6.4 mm), the highest value was obtained with increasing filter FWHM (increasing 26-40%) at all SBRs with the highest differences for SBR 4:1 decreasing to the lowest for SBR 2:1(from 30% in difference to 10%). Both OSEM+PSF and OSEM+PSF+TOF reconstruction resulted in a substantial alteration (≥35%) of SUVmax in phantom spheres ≥17 mm and SUV50 was more accurate when activity measurements is performed. **Conclusion** The implementation of PSF and TOF within the OSEM reconstruction algorithm clearly improves image quality. In quantitative analysis, advanced reconstruction techniques overestimate SUVmax while provide more accurate in quantification of SUV50. SUV50 has been shown as the best alternative in large lesion (≥13 mm) when using 3D-OSEM + PSF and 3D-OSEM+ PSF + TOF reconstruction algorithm.

Implementation of Correlated Signal Enhancement (CSE) Technique for Accurate Positioning in Gamma Camera

B. Teimourian Fard[1,2], **M. Ay**[1,3], S. Sajedi[1,3], A. Akbarzadeh[1], S. Kaviani[1], M. Farahani[1]; [1]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Energy Engineering and Physics, Amir Kabir University of Technology (Tehran Polytechnic), Tehan, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: The most of modern gamma cameras are rectangular because of matching the FOV required for tomographic imaging. Despite the fact that square PMTs are completely compatible with the rectangular geometry and so they can minimize the dead zone in the camera, the use of them is limited due to the difficulty in implementation of conventional anger logic to estimate the position of interaction in the crystal. Because the main hypothesis in the anger logic is that the distances between the centers of neighboring PMTs is the same in all directions and this assumption is violated in square PMTs, therefore the uniformity of the images is destroyed. Different correction methods were applied to modify the uniformity of the distorted images. Since the correction methods in highly dependent to even small changes in PMT characteristics (such as gain), the correction methods are not useful enough. Therefore the need of existence of a positioning technique that can deliver an image with good uniformity characteristics is necessary. In this work, we applied the Correlated Signal Enhancement (CSE) to improve image quality in presence of square PMTs. **Materials and Methods**: CSE is a new positioning algorithm that could overcome the problem with the simple summation of signals of every row or column and the identical 1D center of mass (COM) calculation determines the position of photon in separate direction x or y. A gamma camera with the NaI(Tl) crystal, that has 40x25 mm^2 area and 9.5mm thickness, coupled with an array 24 square PMTs in 4x6 designed and developed to evaluate the performance of CSE algorithm. There are 6 values for rows and 4 values for columns that used to estimate the x and position of the interaction respectively. Results: The CSE method optimized for the proposed camera and intrinsic **spatial** resolution and the energy resolution were obtained 3.7mm and 8.5% respectively. The differential and absolute uniformity of the acquired flood field image (a point source of Tc-99 is located far from of camera face) were measured 0.99% and 1.56% in UFOV. Also a LEHR (Low Energy High Resolution) parallel-hole collimator was located over the camera face and the extrinsic spatial resolutions were calculated 7.6mm. **Conclusion**: The presented results that show the developed positioning method significantly improve the accuracy of photon detection in our developed detector.

A drop-in gamma probe for radioguided surgery in an -robot-assisted- laparoscopic setting

N. S. van den Berg[1], M. N. van Oosterom[1], H. Simon[2], L. Mengus[2], M. M. Welling[1], H. G. van der Poel[3], F. W. B. van Leeuwen[1]; [1]LUMC, Leiden, NETHERLANDS, [2]Eurorad S.A., Strassbourg, FRANCE, [3]NKI-AVL, Amsterdam, NETHERLANDS.

Introduction Other than in open surgery, during laparoscopic radioguided surgery procedures, the limited maneuverability of a traditional laparoscopic gamma probe can hinder identification of (low-activity) lesions that are located near a high-activity background. To increase the maneuverability during laparoscopic procedures, a 'drop-in' gamma probe technology was developed. Such a drop-in gamma probe can be manipulated using the available and often flexible (robotic) laparascopic surgical tools. **Methods** Taking general engineering restrictions such as detector surface, shielding, trocar-diameter, cable thickness, and patient safety into consideration, drop-in designs with 0°, 45°, 90°, and 135°-grip orientations were designed and 3D printed. Gripping was evaluated using both a laparoscopic and robotic forceps. In human-like phantoms, the maneuverability- and scanning direction of the different prototypes were evaluated and compared to a conventional laparoscopic gamma probe. Lastly the most potent grip designs were ex vivo evaluated in a clinical set-up. **Results** Phantom experiments showed that distinguishing a low objective from a high-activity background source (1:100 ratio) was only possible with the detector faced away >90° from the high background source. The best maneuverability- and resulting scanning range was obtained with the 90°-grip design (0-180° versus 0-111°, 0-140°, and 37-180° for 0°, 45° and 135°-grip designs, respectively). In the ex vivo clinical setup, during sentinel node biopsy for prostate cancer, the drop-in technology allowed accurate discrimination of the low-activity sentinel node from the nearby high-activity prostate. **Conclusion** The drop-in gamma probe technology provides and increases rotational freedom when using (robotic) laparoscopic surgical tools. This in turn improves probe-placement and increases the detectability of low-activity lesions.

EP763

Designing 14C-Urea Breath Test System for Detecting Helicobacter Pylori

A. Radnia[1], M. Farahani[1], M. Ay[1,2]; [1]1.Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences,, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]2.Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences,, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: UBT is a painless, non-invasive and easy to use test method which detects the metabolically active bacteria, which makes the test suitable for pretreatment detection as well as for monitoring results after eradication treatment against Helicobacter pylorus (HP). In 14C-UBT method HP infection detection has 96.6% sensitivity and 100% specificity and has the best diagnostic performance compared with other methods like RUT, PCR, and HP-HE. In this work we designed, developed and evaluated a UBT system called HeliGuide based on 14C-UBT. **Materials and Methods:** In developed system the traditionally used liquid scintillator has been replaced with a detector containing two built-in Geiger-Muller counters operating in parallel mode. HeliGuide UBT consisting of two components, a breath-card and an analyzer. The patient exhales into the breath-card and the analyzer counts the activity of 14C in the breath-card. The absorbed 14C in the two pads mounted in Breath-Card emits low energy ß-radiation. Two Geiger-Muller counters mounted in the Analyzer will detect and sum up all type of radioactive activity (α, ß, and γ) reaching the sensors, so a shielding is designed to prevent penetration of background radiation. An optical sensor is designed in the shielding to detect insertion of breath-card. A DC high voltage is applied to detectors and the signals from them is amplified and then processed and counted. The microprocessor- controlled electronics in the analyzer steer the measurement cycle. Due to the short range of ß-radiation, All activity registered by both sensors simultaneously, must originate from background activity, and thus all these activities are disregarded in the counting process in microprocessor. Finally the result is illustrated in LCD display. **Results:** The background error is omitted successfully; beta activity of breath-cards is measured properly and Maximum true count rate measuring of system is 20K count per second. 221 reference breath-cards have been analyzed with system and all results are matched with the reference.

Conclusion: The designed UBT system (HeliGuide) is a high accuracy UBT system which is adequate for detecting helicobacter pylori.

EP764

A Crosstalk Compensation for Simultaneous ^{99m}Tc/^{123}I Dual-isotope SPECT Imaging by Filtering Technique and Artificial Neural Network

K. S. Chuang[1], H. H. Lin[1], C. C. Chiang[1], Y. F. Wang[1], Z. J. Wei[1], Y. C. Ni[2], T. Y. Luo[3]; [1]National Tsing-Hua University, Hsin-Chu, TAIWAN, [2]Health Physics Division, Institute of Nuclear Energy Research Atomic Energy Council, Long-Tan, TAIWAN, [3]Isotope Division, Institute of Nuclear Energy Research Atomic Energy Council, Long-Tan, TAIWAN.

Aim Dual isotope simultaneous acquisition (DISA) can be used to visualize two radiotracer distributions at the same time to reduce scan time and avoid mis-registration artifact. However, DISA is marred by the crosstalk when the two photopeaks are close, e.g. ^{99m}Tc (140 keV) and ^{123}I (159 keV). Artificial neural network (ANN) is mostly employed to tackle the crosstalk. Conventional ANN techniques require more than 20 energy windows which are not supported by current SPECT. In this study, we incorporated ANN with attenuation information of a filter using only three energy windows to decontaminate the crosstalk. **Materials and methods** A metal filter is placed over the collimator to attenuate photons of different energy by various degrees. Based on the attenuation difference of the gamma from each isotope, we can separate the two isotopes. The constructed ANN consisted of three layers: input (6 nodes), hidden (9 nodes), and output (4 nodes). Photon counts in three energy windows from scans with and w/o filter are fed into ANN. The outputs are primary gamma of the two isotopes, w/ and w/o filter. The outputs of the ANN are then combined to form two primary data with crosstalk and scatter corrected each for the ^{99m}Tc and ^{123}I. A GATE Monte Carlo code is used for the DISA SPECT simulation. **Results** A gold filter with 0.2 mm thickness is attached to one of the collimator of a dual-heads E.CAM (Siemens, German) for the DISA simulation study. Preliminary results show that the crosstalk is successfully resolved by the proposed method. The results show that quantitative recovery from mixed ^{99m}Tc and ^{123}I sources is comparable to that from matched single-isotope sources. **Conclusion** In this study, a DISA SPECT technique to tackle the crosstalk using filter is proposed. Projection data with and without filter are inputted to an ANN to separate the energy spectrum of the two isotopes. Due to the extra information provided by the filtering, only 3 energy windows are needed. This method is simple to perform and yet generates promising results.

EP765

Channel Reduction in SiPM Array Using Fast Output for a PET Block Detector

S. Sajedi Toighoun[1], M. Taheri[1], N. Zeraatkar[1], S. Kaviani[1], M. Ay[2]; [1]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aims: By introducing PET/MR imaging in the early 2000s, Avalanche Photo-Diode (APD) and afterward SiPM based systems grew rapidly. By development and cost reduction in SiPM technology, more imaging detector configurations have been using this technology. In the imaging application, SiPM detectors are usually arranged in array form and because of high density of pixels in a detection area, the readout electronics is a challenging issue and efforts have been made to reduce number of readout channels with less performance degradation. The new developed SiPM series by SensL (Cork, Ireland) are equipped with 'fast output' as an extra output to improve timing resolution of detector. In this work, we tried to reduce readout channels by implementing Scrambled Crosswire Readout (SCR) using 'fast output' signals. **Methods**: The utilized array is ArrayB-30035-144P-PCB having 12×12 pixels, each having 3×3 mm^2 active area with 4.2 mm pixel pitch. The SCR method, recommended by SensL, reduces 144 channels to 25 (9 tiles+16pixels) channels, where the array area is divided to 9 tiles each containing 16 pixels. This method multiplexes all anodes of similar pixels in different tiles, producing 16 Analog-to-Digital Convertor (ADC) channels for positioning of the incident photon inside the tile. In addition, it multiplexes all cathodes of pixels in the same tile, producing 9 comparator circuits to allocate the fired tile. The fast output can be replaced for cathode in SCR method. In this arrangement, all fast outputs of the pixels inside a tile are multiplexed to one output which can be detected by the level threshold. Also, the fast output multiplexing is further required for time-pickoff discrimination. The arrangement was evaluated in a detector block using an array of LYSO crystal pixels with the size of 2×2×10 mm^3 and 2.1 mm pixel pitch. **Results**: The flood-field image has been taken to obtain enough counts per crystal pixel. The image showed admissible pixel resolution and the peak-to-valley ratio in different pixels varied between 10 to 17. The energy resolution of detector block was measured about 25% at 511 keV. **Conclusion:** The proposed readout method reduces 144 SiPM channels to 16 ADC channels, derived from 'standard output' signals, and 9 level threshold channels, derived from 'fast output' signals. Since in a PET detector block there is another effort to reduce 144 of 'fast output' channels to perform time-pickoff discrimination, we tried in this work to combine two channel reduction methods by one implementation.

Initial Evaluation of a New High Resolution Non-human Primate (NHP) PET System (LFER 150)

Z. Sarnyai[1], K. Nagy[2], G. Rosenqvist[1], A. Takano[1], R. Maior[1], M. Tóth[1], B. Gulyás[1], C. Halldin[1], A. Varrone[1]; [1]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, SWEDEN, [2]Mediso Ltd, Budapest, HUNGARY.

Aim The LFER 150 PET/CT by Mediso was developed for high-resolution imaging of the brain of non-human primates. The PET system uses LYSO crystals of 1.51x1.51x10 mm, and has a field of view of 20 cm and 15 cm in the radial and axial direction, respectively. Gantry bore diameter is 26 cm. The objective of this study was initial performance evaluation of the system using the NEMA NU 4 standard protocol and *in-vivo* non-human primate (NHP) PET measurements. Materials and **Methods** Data were acquired and evaluated using the methodology of the NEMA NU4 standard for resolution, sensitivity, image quality and noise equivalent count rate (NEC). An additional Derenzo phantom scan was performed to test resolution using 3D OSEM reconstruction. Practical usability of the system was evaluated by NHP (cynomolgus monkey, weight: 4.5 kg) examination with a D2/D3 receptor radioligand, [^{11}C]raclopride (94 MBq). The NHP was anesthetized using I.V. administration of ketamine and Xylazine. List mode PET data were acquired for 65 min and reconstructed into 34 frames with the Tera-Tomo 3D engine using OSEM algorithm. **Results** Radial FWHM resolution was better than 2.2 mm and 3.2 mm in the central 60 mm and 160 mm diameter region, respectively. Maximum sensitivity in 400-600 keV and 250-750 keV energy window was 30.03 cps/kBq (absolute value 3.3 %) and 49.11 cps/kBq (5.4 %) respectively. Using the image quality phantom, the uniformity standard deviation was 6.2 % and the spill-over ratio for air and water was 0.06. Using the rat like phantom the NEC curve peaked at 399 kcps and 149 MBq. Using the Derenzo phantom, rods with 1.1 mm diameter could be visualised. In the NHP, the reconstructed 3D images of [^{11}C]raclopride were consistent with the known distribution of D2/D3 receptors and with the kinetic behavior of this radioligand. **Conclusion** The LFER 150 is a high-resolution PET-CT system suitable for molecular imaging studies of the brain in NHPs.

Optimal SPECT Detector Configuration for Myocardial Perfusion Scintigraphy in Patients with Small Body Habitus

N. A. Bebbington; Siemens Healthcare A/S, Aarhus, DENMARK.

AIMS: In patients with very small body habitus, the standard 90° detector configuration used in Myocardial Perfusion Scintigraphy (MPS) can allow truncation of the heart, where part of the heart is outside of the field of view in some projections, creating artefactual perfusion defects. Siemens Symbia systems offer '90° NCO Prescan' and '76° NC' detector configuration/orbits to eliminate this effect. The aim was to assess which configuration is optimal for patients with small body habitus, considering truncation effects and image quality in a phantom. MATERIALS AND METHODS: The Data Spectrum cardiac insert was filled with Tc99m and underwent SPECT on a Symbia Intevo 6 with the standard 90°NC, 90°NCO Prescan, and 76°NC configurations, in two conditions: scan 1) unrealistic patient geometry with minimal adjacent tissue (with anteroseptal and inferolateral defects), to demonstrate worst case scenario truncation; scan 2) in cyclindrical body phantom (with septal defect) to represent a patient with small body habitus. Number of projections with cardiac truncation and mean detector radius were recorded for each acquisition. SRS, Extent (%) and TPD (%) were measured in Cedars-Sinai QPS, and image quality determined by line profiles for septal and inferior walls. RESULTS: Scan 1 (unrealistic patient geometry): cardiac truncation was present in 28/64 projections for standard 90°, and was borderline in 10/64 for 90°NCO Prescan, but not present in 76°. True SRS in the truncated region was 4 (determined by 76° configuration without truncation), but increased to 10 for 90°NCO Prescan (possible truncation artefact), and to 31 for standard 90°. 76° gave smaller mean detector radius (225mm) than 90°Prescan (250mm). Minimum/maximum intensity on the line profiles demonstrated comparable defect contrast between 76° (0.58) and 90°Prescan (0.57). Scan 2 (realistic small body habitus geometry): cardiac truncation was present in 8/64 projections for standard 90° and was not present in 76° or 90° Prescan configurations. Defect scores were comparable between all configurations. 76° gave smaller mean detector radius (230mm) than Prescan 90° (259mm). Defect contrast was more favourable in the 76° configuration (0.60) compared with the Prescan 90° (0.67). CONCLUSIONS: 76°NC acquisitions guarantee no cardiac truncation in patients with small body habitus, and provided smaller rotation radii compared with 90° Prescan mode, which resulted in improved defect contrast in the phantom geometry representing a patient with small body habitus used in this study.

Monte Carlo Modeling of a Gamma Probe for Sentinel Lymph Node Biopsy

A. Nikoogoftar[1,2], N. Zeraatkar[2], M. Shamsaie[1], **M. Ay**[2,3]; [1]Faculty of Nuclear Engineering and Physics , Amirkabir University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Centre for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Gamma probe is a small gamma detector with output of radiation count rate detected in addition to audio signal proportional to the count rate. The main application of gamma probe is in sentinel lymph node biopsy (SLNB). Radioactive colloid (mostly Tc-99m) is injected near the tumor .Then after a specific time passes, surgeon with the help of guidelines and protocols can find the location of Sentinel Lymph Node. Various gamma probe systems are available with different detector materials, detector sizes, and collimation for different type of application. The gamma probe performance is described by some quantitative parameters e.g., sensitivity, spatial resolution, and shielding. The purpose of this study is to develop a Monte Carlo (MC) model for a gamma probe system (SUEGEOGUIDE II). Different quantitative parameters were measured using experimental and MC simulation according to NEMA NU3 protocol. Materials and methods: "The SUEGEOGUIDE II" is composed of two main parts: probe and control unit The probe includes tungsten collimator, cesium iodide (thallium-activated) [CsI(Tl)] scintillator crystal, silicon photomultiplier(SiPM), and electronic boards. Sensitivity profiles were obtained using a point source placed on the long probe axis at distance of 10, 30, and 50 mm. The spatial resolution was determined by increasing lateral distance from a 30mm-far point source. Full-width at half-maximum (FWHM) was calculated after Gaussian fitting. -For shielding calculation the source was moved all around the probe head in contact with, and the largest count rate was considered. We used Monte Carlo simulation MCNP4C code to model the system and them measurement of the abovementioned parameters with the same methods. Result: Sensitivity at distance of 10, 30, and 50 mm was calculated respectively as 7,120 cps/MBq, 1,830 cps/MBq, and 790 cps/MBq by practical measurements. The MC simulation result revealed sensitivity of 8540 cps/MBq , 2054 cps/MBq , and 890 cps/MBq for the same distances. Spatial resolution at distance of 30 mm with experimental and MC simulation was measured as 40 mm and 42 mm, respectively. Also, shielding was about 98% for both MC and practical methods. Conclusion: We developed an MC model for a gamma probe system .Then using practical experimental and the MC simulation, some performance parameters of the system such as sensitivity, spatial resolution, and shielding were measured .The result showed that the MC model is valid and can be used for other. We aim to optimize the crystal size and shielding thickness using the developed model.

Performance characteristics of NeuroPET system using GATE Monte Carlo simulation

P. Sheikhzadeh[1,2], H. Sabet[3], H. Ghadiri[1,2], P. Geramifar[4], H. Mahani[2,5], P. Ghafarian[6,7], **M. Ay**[1,2]; [1]Department of Medical Physics and Biomedical Engineering,Tehran university of medical science, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Massachusetts General Hospital, Harvard Medical School, Charlestown, MA, UNITED STATES, [4]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [7]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: The aim of this study is to model the NeuroPET system using GATE simulation toolkit and compare the simulation result with reported data. **Materials and methods**: The NeuroPET scanner composed of 7 modules, 84 block detector and two LYSO scintillator detector layers in that the two layers are placed with half scintillator pixel offset with respect to each other. Crystal array including 2222 for outer and 21×21 for inner layer. Thickness of each layer is 10 mm and crystals dimension is 2.3 ×2.3 mm^2. We modeled NeuroPET geometry in GATE environment. An energy threshold of 400-650 keV and a 7 ns coincidence window was selected for the simulations to follow the published experimental results. The energy and timing resolution and dead time was set to real scanner electronic response to obtain accurate results. For absolute sensitivity assessment, a 700 mm line source uniformly Filled with 2.7 MBq 18F

and five concentric Aluminum sleeves around the line source was modeled according to the NEMA NU2-2012. The rate was normalized to the 70 cm line source. Final results were obtained by extrapolating the data to zero thickness using linear regression. To determine NECR, a 700 mm long, polyethylene scatter phantom was simulated. The phantom was centered in the FOV, and the 700 mm line source of F-18 being 45 mm below the transverse center was modeled. The NECR was calculated for different range of activities. In-house C++ code was developed to analyze the Root output from the simulated data. **Results**: Simulation results show that the sensitivity, 7.8 kcps/MBq (versus 7.5 kcps/MBq from experimental results) at center of FOV increases to 9.1 kcps/MBq (versus 8.8 kcps/MBq from experimental results) at a 10 cm center of FOV. The difference of the published experimental results and simulation sensitivities is reproduced to 3.8 and 3.2%, respectively. Also NECR curve was plotted against different activities and maximum NECR of 18.1 kcps was obtained for an activity of 3.1 kBq/ml (versus 19.5 kcps for an activity of 2.9 kBq/ml from experimental results). **Conclusion**: Our results show a good agreement between simulations and published experimental measurements with the NeuroPET scanner. The simulated system also provides insight for our ongoing research to develop brain-dedicated PET scanner with depth of interaction information using similar dual layer detector geometry.

Contrast Recovery Dependence on Activity Volume for a 1mm^3 Resolution Clinical PET System

D. F. C. Hsu, D. L. Freese, D. R. Innes, **C. S. Levin**; Stanford University, Stanford, CA, UNITED STATES.

We are constructing the world's first 1 mm^3 resolution clinical PET system dedicated to locoregional imaging (e.g. breast, head/neck, etc). The edge-on layout of densely-packed 8x8 arrays of 0.9x0.9x0.9 mm^3 LYSO crystal elements provides high sensitivity and the capability to position the 3-D coordinates of one or more 511 keV photon interactions per event. In order to understand the ability of this system to visualize and quantify smaller lesions, contrast recovery (CR) performance, which provides a measure of how accurately regions of focal tracer accumulation in the field-of-view (FOV) are reconstructed, must be evaluated before quantitative clinical studies can be performed. Each panel of the built dual-panel system prototype has a sensitive area of 160mm by 33mm by 64mm. A micro-Derenzo phantom, having rods of 1.2/1.8/2.4/3.2/4.0/4.8 mm diameter, with 200 μCi of 18F-FDG, is placed inside an acrylic scattering medium covering the FOV and scanned for 30 minutes. A trimmed dataset of 5 minutes was derived from the original dataset, and 80 iterations of MLEM reconstruction was performed on both datasets with a reconstructed voxel size of 0.5mm. We define cylindrical regions-of-interests (ROIs) with a height of 33 mm and the same diameter as each of the rod sizes. The CR coefficient and normalized standard deviation are calculated as the mean and standard deviation of the voxel intensity in each ROI divided by the mean voxel intensity in the ROI of the 4.8 mm rod. Results show reconstructed CR of greater than 0.5 for 1 mm diameter rods, with the standard deviation in CR decreasing with increasing scan time.

Triple Head Multi Pinhole Brain SPECT System for striatal imaging

A. Forgács[1], A. Wirth[2], T. Bükki[2], J. Pechan[3], S. Barna[1], L. Nagy[2], J. Hopin[3], I. Garai[1], A. Verma[4]; [1]ScanoMed Ltd, Debrecen, HUNGARY, [2]Mediso Ltd, Budapest, HUNGARY, [3]InviCRO, Boston, MA, UNITED STATES, [4]Biogen, Cambridge, MA, UNITED STATES.

OBJECTIVES: to present the optimization of the scan and reconstruction parameters based on phantom data, and to share the initial clinical experiences of a newly designed and developed triple head multi-pinhole brain SPECT system optimized for striatal imaging. **METHODS**: helical brain SPECT and Low Dose CT scans were performed for both human and phantom studies. Quantitative image reconstruction was applied, including CT based attenuation correction and Monte-Carlo based scatter correction. Optimization was carried out using an anthropomorphic striatal head phantom filled with 123I solution. Patient preparation was performed following the procedure detailed in European DaTSCAN guideline. For comparison, each patient was also examined on a conventional SPECT system equipped with parallel hole collimators, using the routine clinical protocol. The reconstructed human brain images were registered with additional dedicated brain MR images for improved visual reporting and segmentation. The measurements were quantitatively evaluated using dedicated medical imaging software, with additional visual evaluation of the patient data performed by two experienced medical doctors. **RESULTS**: The acquisition and reconstruction parameters are optimized. The error of activity concentration in the reconstructed image is under 10% in the clinically relevant range of activity concentration of 123I. Qualitatively, the reconstructed human brain images measured by the multi-pinhole brain SPECT system show significant improvement in image quality compared to the images provided by a conventional SPECT system equipped with parallel hole collimators. **CONCLUSION:** The advanced multi-pinhole imaging technology may support higher accuracy for the clinician in the differential diagnosis of movement disorders related to parkinsonian syndromes and essential tremor. The improved image quality also lends itself to the development of a new normal database in the future.

Novel Cadmium Zinc Telluride (CZT) - based General Purpose Gamma Camera: Clinical Assessment and Comparison with a Standard Camera

Z. Keidar, R. Lugassi, I. Raysberg, A. Frenkel, O. Israel; Rambam Healthcare Campus, HAIFA, ISRAEL.

Objective: To prospectively compare the clinical performance of a newly designed Cadmium Zinc Telluride (CZT) based general purpose gamma camera (CZT-camera), with a standard Sodium Iodide (NaI) based device (NaI-camera). **Methods:** Fifty-five patients (25 men, age range 18 - 86y) referred for Nuclear Medicine procedures were prospectively recruited. The studies included Tc99m-MDP bone scintigraphy (23), one day, gated, rest-stress, single -(Tc99m-MIBI) or dual- (Tc99m-MIBI & Thallium 201) isotope myocardial perfusion imaging (10), Tc99m thyroid (5), Tc99m-MAA lung (4), Tc99m-DMSA renal (6), Tc99m-MIBI parathyroid (4) and Tc99m-HMPAO brain perfusion (3) scintigraphy. All patients underwent the standard scintigraphic procedure according to the specific routine protocol using both the dual head NaI-camera and the CZT-camera with the same acquisition protocols. The studies were performed sequentially at an average of 30 minutes time interval between the acquisitions on both devices. Forty-three patients were scanned on the NaI-camera first and rescanned with the CZT-camera while in 12 patients acquisition was completed first on the CZT-camera followed by imaging on the NaI-camera. Two readers scored all studies in consensus using a 5-point scale (1=non-diagnostic to 5=excellent) for perceived image quality and spatial resolution. The scores obtained for the two devices were compared using the Mann-Whitney test with $p<0.05$ considered as statistically significant difference. In addition a comparison of the above parameters was performed separately in the subgroup of patients in whom the acquisition was firstly performed on the NaI-camera and in those who were scanned initially on the CZT-camera. **Results**: Overall, 130 studies performed on each device in 55 patients were compared including 85 planar and 45 SPECT studies. The average image quality and spatial resolution scores in the CZT-camera studies were 4.63 and 4.74 respectively. These values were statistically significantly higher than the scores obtained with the NaI-camera (4.40 and 4.25 respectively, $p<0.05$). The

same statistically significant difference in image quality and spatial resolution scores was found when the CZT-camera images were obtained both after or before the scans on the NaI-camera. **Conclusions:** These initial results suggest that the CZT-based general purpose gamma camera has a higher diagnostic performance as compared to the standard NaI-based camera when using the same acquisition parameters. Future studies will assess whether time reduction and/or a decrease in the injected dose can be implemented for the CZT-camera acquisition protocols without any compromise in image quality and subsequent diagnostic accuracy.
